Animals of the Rainforest

Rainforests are dense forests with a high rainfall. They are a great place to live for many animals because there is lots of water, shelter and food, and it is always warm. Rainforests are very important because their plants make much of the Earth's oxygen, which we need to breathe. Rainforests are being destroyed every day by humans.

Anaconda

WORD SEARCH

Words may be horizontal, vertical, backwards, or diagonal

Spider Monkey

Tapir

Parrot

Toucan

Sloth

Crow

House Sparrow

Duck

Color the Possum

Coyote

Animals of the Mountains

Animals must be tough to survive the rugged terrain of the mountains. Many animals migrate—which means travel to another area—during the harsh winters to search for food and warmer weather.

Sea Turtle

Endangered Species

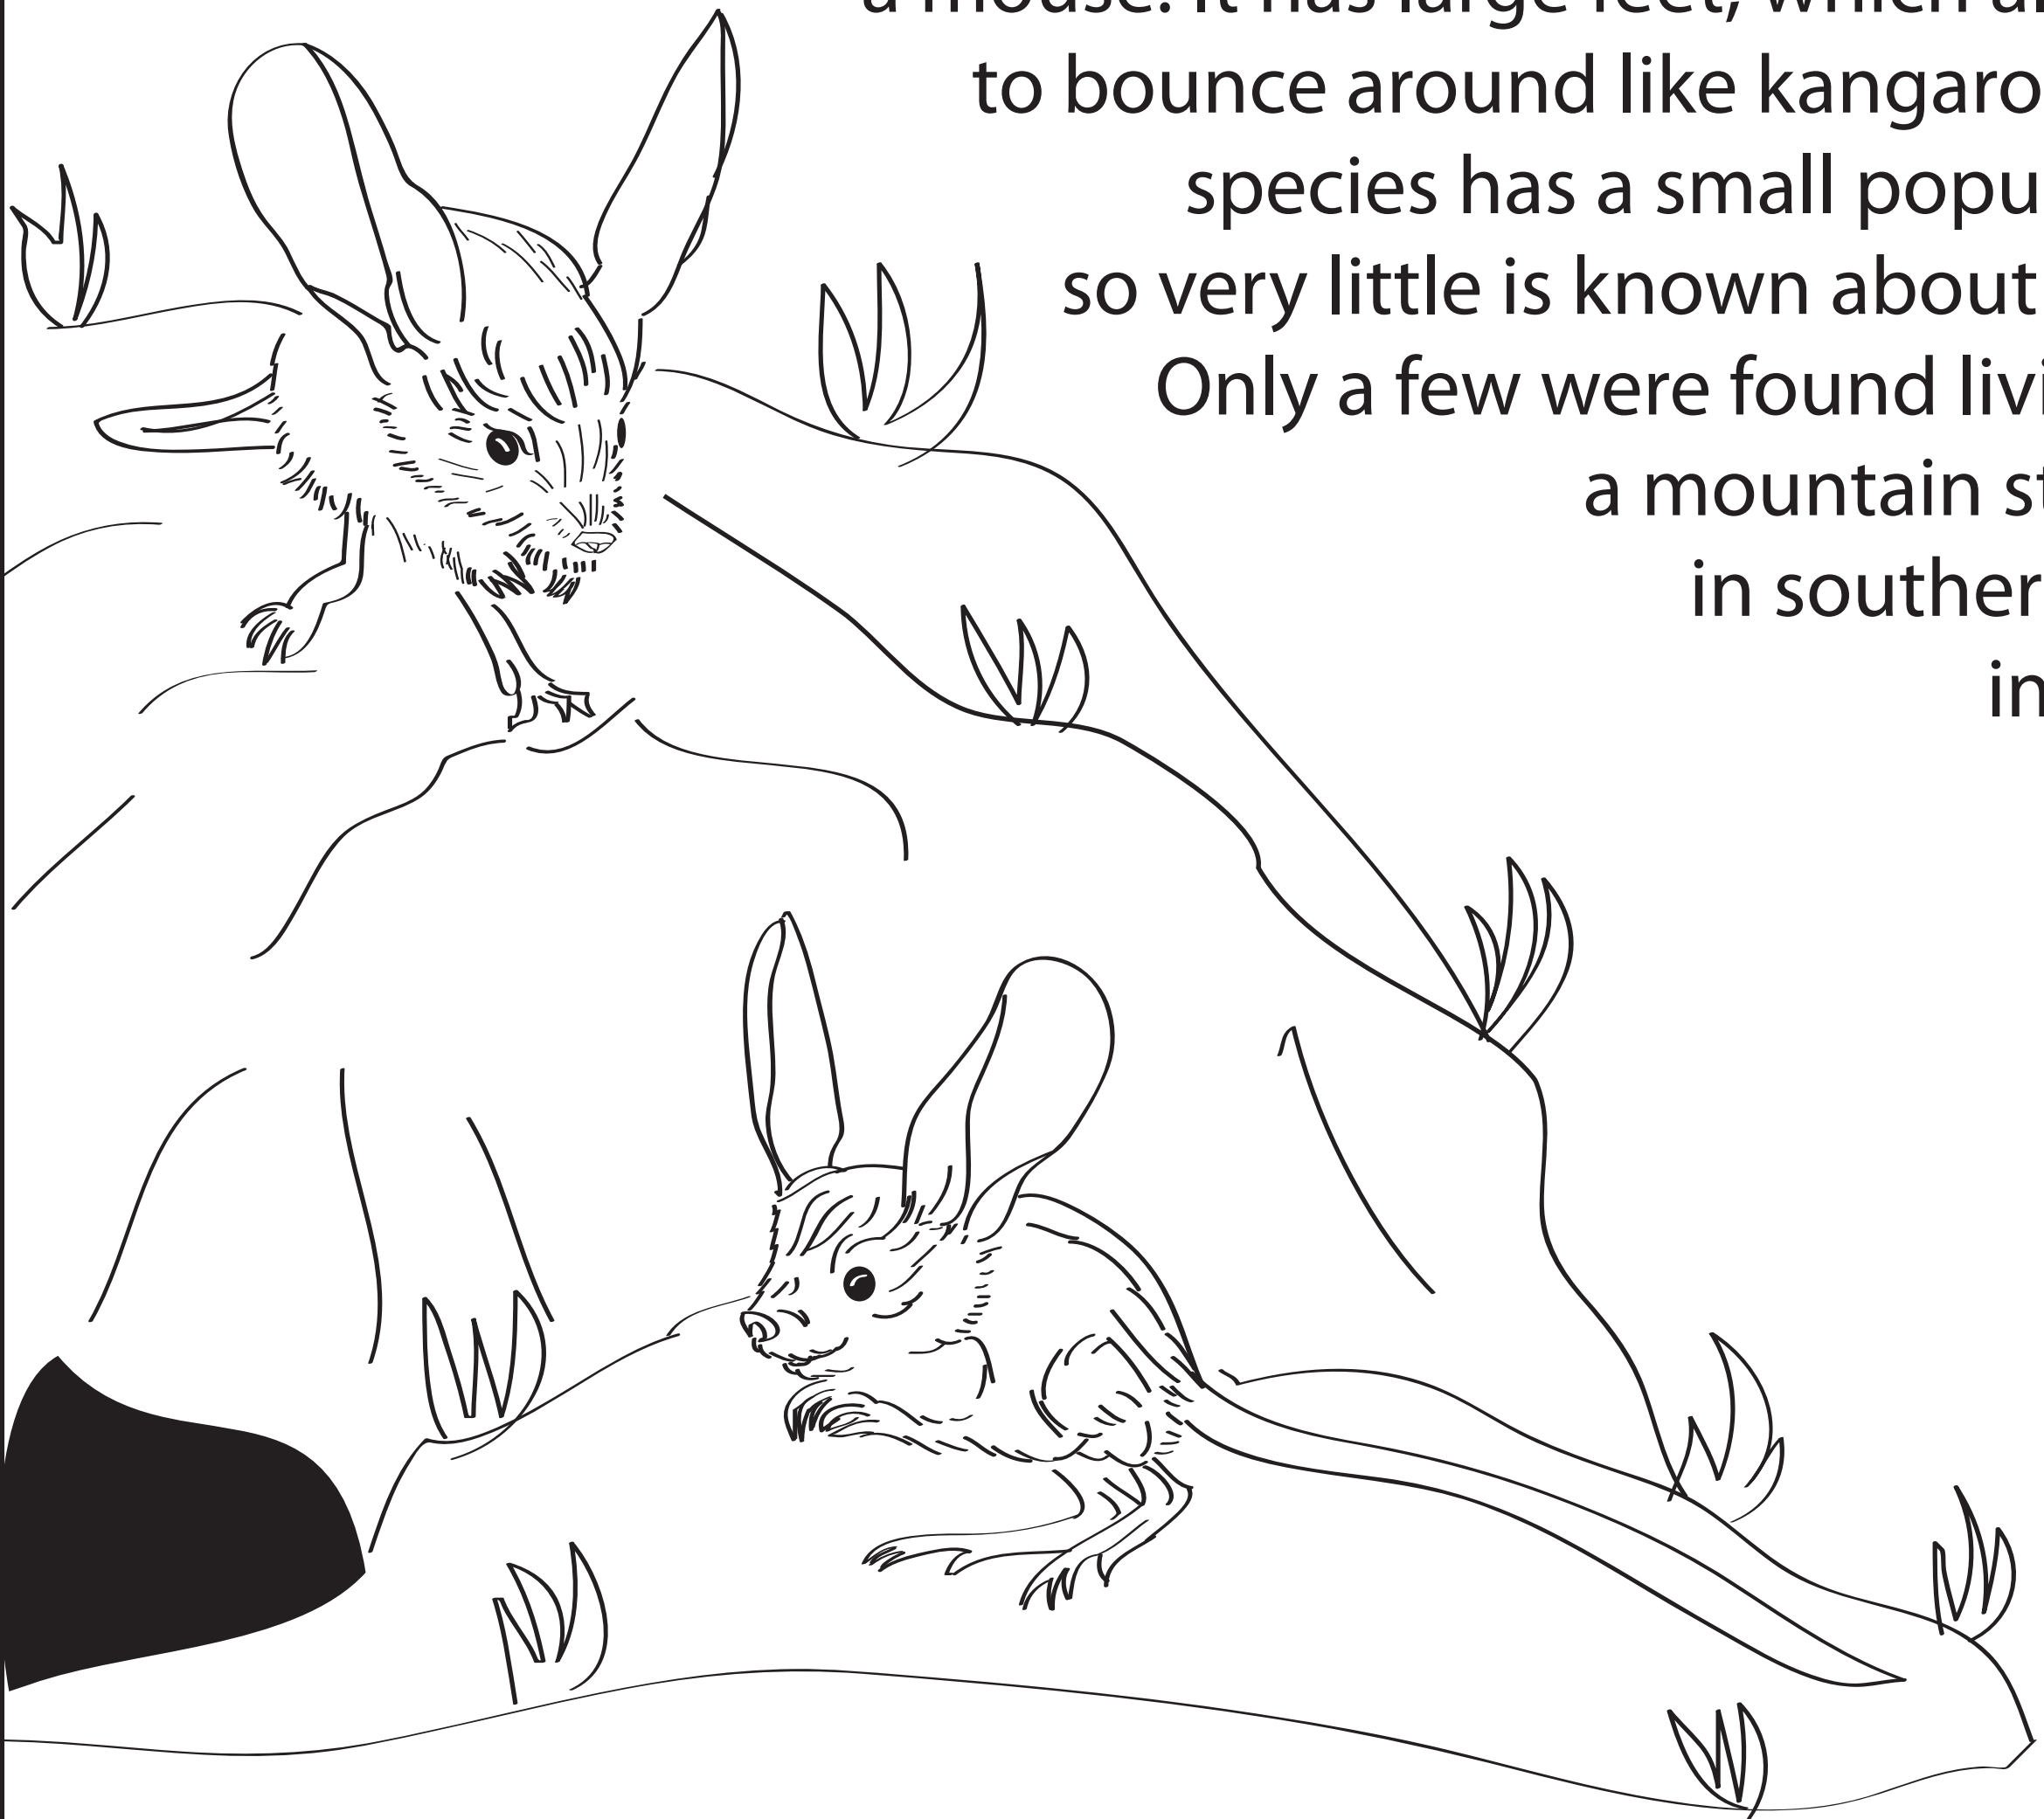

Iranian Jerboa

Allactaga firouzi

Southern Iran

The jerboa is a very small rodent that resembles a mouse. It has large feet, which allow it to bounce around like kangaroo. This species has a small population, so very little is known about them. Only a few were found living on a mountain steppe in southern Iran in 2005.

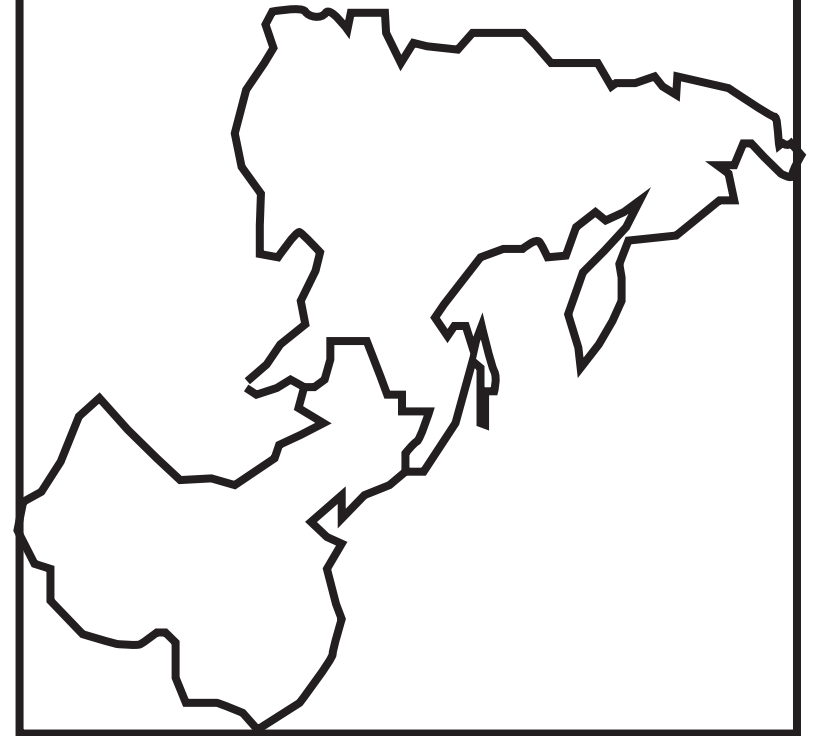

Endangered Species

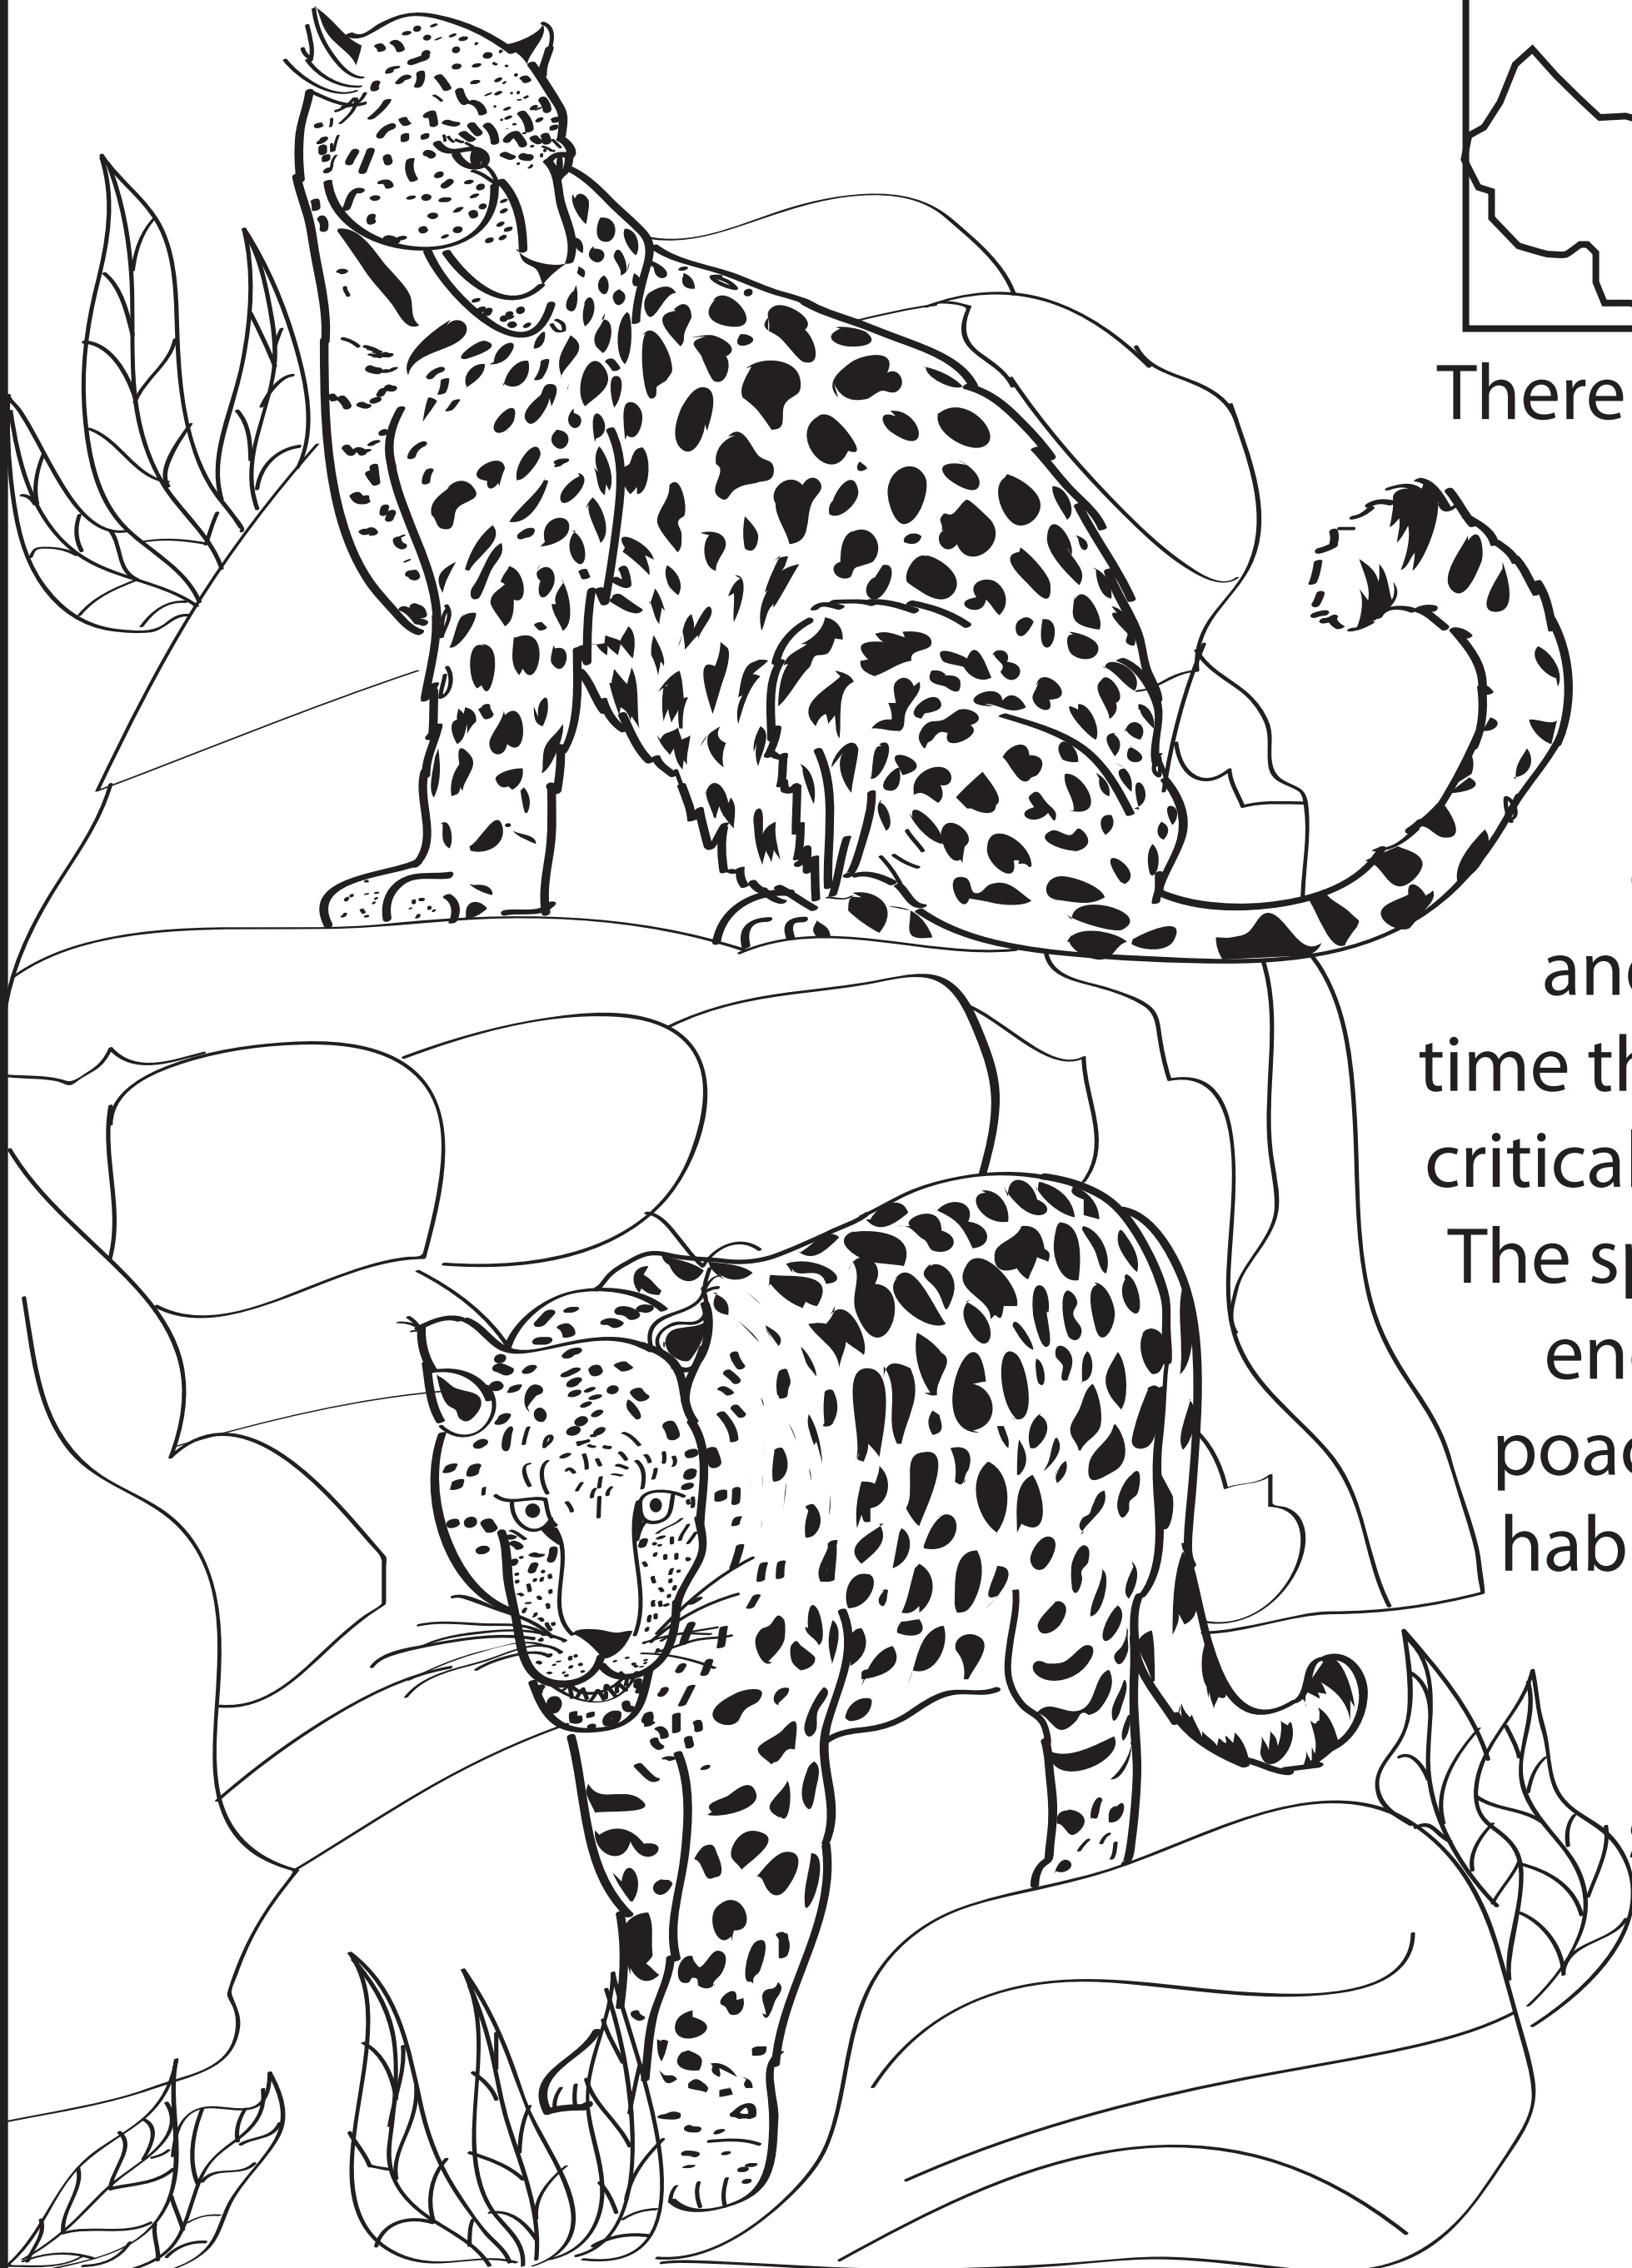

Amur Leopard

Panthera pardus orientalis

Russia Far East
&
Northern China

There are only about 20-30 Amur leopards left in the wild, in a tiny area that connects China and Russia. At this time they are listed as critically endangered. The species is threatened by excessive poaching, and their habitat is in danger due to high levels of construction. Their numbers are increasing in captivity.

Manatee

Manatees are also known as sea cows. They are mammals that live under the water. They rise to the surface to breathe oxygen. They live in shallow water, usually less than 7 feet deep. They eat plants, such as grass and algae.

There are three different species of manatees. One species, called the West African manatee lives in Africa. A second species, called the Amazonian manatee, lives in South America. The West Indian manatee lives mostly in the Caribbean and the coast of the Gulf of Mexico but may move north during the spring and summer.

A manatee mother with her calf

It is hard for scientists to know how many West Indian manatees there are. They estimate between 2,000 to 5,000. The West Indian manatee has been listed as an endangered species. This means that the population is so low that the West Indian manatee may become extinct. Many die because of accidents with ships or other human causes, such as pollution. Federal and state laws protect the manatee. Scientists are working to find ways to help the manatee survive.

Fill in the Blank

How many species of manatees are there?

Where does the West Indian manatee mostly live?

What does "endangered species" mean?

What do manatees eat?

Manatee Facts

- The manatee's closest relative in the animal world is the elephant and hyrax.
- Manatees average over 9 feet in length and weigh between 800 to 1200 pounds.
- Manatees may live 60 years or more.

Buffalo

The buffalo is also known as the American bison. It is the largest land mammal in North America.

Buffalo live in herds, or groups, and travel from place to place looking for grass to eat. The buffalo was a major source of food for the Native Americans who lived on the Great Plains.

Millions of these animals once lived across most of North America. The buffalo was almost extinct after human hunting in the 1800s.

Conservation methods by ranchers and the government beginning in 1899 have saved the buffalo from extinction. Today, there are around 400,000 buffalo on public lands, private ranches and zoos.

Buffalo Facts

The average buffalo is about 5-6 feet tall at the shoulder and can weigh up to 2,200 pounds.

A buffalo can run 35-40 miles an hour.

Buffalo like to roll on the ground, often in the same spot as other buffaloes. This creates a hole in the ground, called a buffalo wallow.

Tell a Story

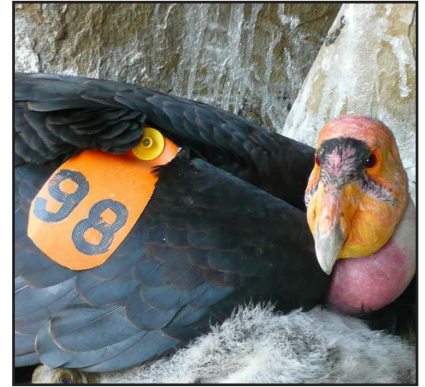

This picture shows a wolf pack which has surrounded a buffalo. Write a story about what happens next. Write the story either as one of the wolves or as the buffalo.

California Condor

The California condor is a type of vulture, which means it eats the meat of dead animals. The condor lives in the U.S. states of California, Utah and Arizona. There are also condors in the Mexican state of Baja California. It is the largest land bird in North America.

The population of condors dropped very low in the 20th century. In 1987 there were just 22 birds left living in the wild. As a way to help the condor survive, the California Condor Recovery Plan captured all the wild birds and placed them in zoos. There the condors were protected and could have baby chicks. When the chicks were grown, they would be returned to the wild. The program was successful and today there are almost 400 California condors. Over 180 of these live in the wild.

A mother condor lays on a baby chick. She wears a tag so scientists can follow her.

About the California Condor

- The condor has a wingspan, or length of the wings from tip to tip, of over 9 feet.
- Condors can fly fast, sometimes up to 55 miles per hour.
- Condors may live up to 60 years.

Tell a Story

Imagine you are this condor, flying in the sky. Write a story about where you are going and what you see as you fly.

Grizzly Bear

The grizzly bear is a type of brown bear found in North America. Grizzly bears once lived over much of the continent, from the Arctic to Mexico. Today the grizzly lives only in Canada, and the U.S. states of Alaska, Idaho, Washington, Wyoming and Montana.

The word “grizzly” comes from the description of the gray hair in the bear’s fur. Except for mother grizzly bears with cubs, the grizzly lives its life alone.

Grizzly bears eat a wide variety of food. They eat meat and will kill animals such as deer or elk. They like fish, particularly salmon. They also eat nuts, berries and insects.

There are about 55,000 grizzly bears in North American today. Because the grizzly bear population has dropped to a low level, the governments of the United States and Canada have started programs to increase the number of the bears.

Grizzly Bear Facts

- An adult grizzly weighs between 290 to 790 pounds. A grizzly cub weighs less than 1 pound when it’s born.
- The average adult grizzly bear is over 8 feet tall.
- Unlike black bears, grizzly bears have a hump on their back.

Tell a Story

Imagine you are one of these grizzly bear cubs. Your mother has told you and your brother to stay in one place while she hunts. She is late coming back and both of you are hungry. Write a story about what you and your brother do next.

The Silverback Gorilla

The silverback gorilla is an adult male gorilla. He is called silverback because of the silver hair that grows on his back after he has become an adult.

Family

Gorillas live in a family group called a troop. Each troop is lead by one silverback gorilla. There are also adult female gorillas and their babies in the troop.

About Gorillas

There are two types, or species of gorillas:

- The eastern gorilla lives in east central Africa
- The western gorilla lives in west central Africa.

Both species are classified as endangered.

Gorilla Food

Gorillas eat mostly leaves, tree shoots and some fruit. The Eastern Gorilla also eats insects, such as ants.

Silverback Size

A silverback gorilla may be as tall as 5 feet 9 inches and weigh over 400 pounds.

Tell a Story

Imagine you are a silverback gorilla who lives in a zoo. Write a story about what you would do when the zoo visitors come to see you.

Great job!
