

ELECTROSTATICS

1. INTRODUCTION

The branch of physics which deals with electric effect of static charge is called electrostatics.

2. ELECTRIC CHARGE

Charge of a material body or particle is the property (acquired or natural) due to which it produces and experiences electrical and magnetic effects. Some of naturally charged particles are electron, proton, α -particle etc.

Charge is a derived physical quantity. Charge is measured in coulomb in S.I. unit. In practice we use mC (10^{-3}C), μC (10^{-6}C), nC (10^{-9}C) etc.

C.G.S. unit of charge = electrostatic unit = esu.

1 coulomb = 3×10^9 esu of charge

Dimensional formula of charge = $[M^0L^0T^1I^1]$

2.1 Properties of Charge

- (i) **Charge is a scalar quantity** : It adds algebraically and represents excess, or deficiency of electrons.
 - (ii) **Charge is of two types : (i) Positive charge and (ii) Negative charge** Charging a body implies transfer of charge (electrons) from one body to another. Positively charged body means loss of electrons, i.e., deficiency of electrons. Negatively charged body means excess of electrons. This also shows that **mass of a negatively charged body > mass of a positively charged identical body**.
 - (iii) **Charge is conserved** : In an isolated system, total charge (sum of positive and negative) remains constant whatever change takes place in that system.
 - (iv) **Charge is quantized** : Charge on any body always exists in integral multiples of a fundamental unit of electric charge. This unit is equal to the magnitude of charge on electron ($1e = 1.6 \times 10^{-19}$ coulomb). So charge on anybody $Q = \pm ne$, where n is an integer and e is the charge of the electron. **Millikan's oil drop** experiment proved the quantization of charge or atomicity of charge
- $\frac{1}{3}e$ $\frac{2}{3}e$
- Note** : Recently, the existence of particles of charge $\pm \frac{1}{3}e$ and $\pm \frac{2}{3}e$ has been postulated. These particles are called quarks but still this is not considered as the quantum of charge because these are unstable (They have very short span of life).
- (v) Like point charges repel each other while unlike point charges attract each other.
 - (vi) Charge is always associated with mass, i.e., charge can not exist without mass though mass can exist without charge. The particle such as photon or neutrino which have no (rest) mass can never have a charge.
 - (vii) **Charge is relativistically invariant**: This means that charge is independent of frame of reference, i.e., charge on a body does not change whatever be its speed. This property is worth mentioning as in contrast to charge, the mass of a body depends on its speed and increases with increase in speed.
 - (viii) A charge at rest produces only electric field around itself; a charge having uniform motion produces electric as well as magnetic field around itself while a charge having accelerated motion emits electromagnetic radiation.

2.2 Charging of a body

A body can be charged by means of (a) friction, (b) conduction, (c) induction, (d) thermionic ionization or thermionic emission (e) photoelectric effect and (f) field emission.

(a) Charging by Friction :

When a neutral body is rubbed against other neutral body then some electrons are transferred from one body to other. The body which can hold electrons tightly, draws some electrons and the body which can not hold electrons tightly, loses some electrons. The body which draws electrons becomes negatively charged and the body which loses electrons becomes positively charged.

For example : Suppose a glass rod is rubbed with a silk cloth. As the silk can hold electrons more tightly and a glass rod can hold electrons less tightly (due to their chemical properties), some electrons will leave the glass rod and gets transferred to the silk. So in the glass rod there will be deficiency of electrons, therefore it will become positively charged. And in the silk there will be some extra electrons, so it will become negatively charged

(b) **Charging by conduction (flow):** There are three types of material in nature

(i) **Conductor** : Conductors are the material in which the outer most electrons are very loosely bounded, so they are free to move (flow). So in a conductors, there are large number of free electrons.

Ex. Metals like Cu, Ag, Fe, Al.....

(ii) **Insulator or Dielectric or Nonconductor** : Non-conductors are the materials in which outer most electrons are very tightly bounded, so they cannot move (flow). Hence in a non-conductor there is no free electrons. Ex. plastic, rubber, wood etc.

(iii) **Semi conductor** : Semiconductor are the materials which have free electrons but very less in number.

Now lets see how the charging is done by conduction. In this method we take a charged conductor 'A' and an uncharged conductor 'B'. When both are connected some charge will flow from the charged body to the uncharged body. If both the conductors are identical & kept at large distance, if connected to each other, then charge will be divided equally in both the conductors otherwise they will flow till their electric potential becomes same. Its detailed study will be done in last section of this chapter.

(c) **Charging by Induction** : To understand this, lets have introduction to induction.

We have studied that there are lot of free electrons in the conductors. When a charge particle $+Q$ is brought near a neutral conductor. Due to attraction of $+Q$ charge, many electrons ($-ve$ charges) come closer and accumulate on the closer surface.

On the other hand a positive charge (deficiency of electrons) appears on the other surface. The flow of charge continues till there is resultant force on free electrons of the conductor becomes zero. This phenomena is called induction, and charges produced are called induced charges.

A body can be charged by induction in the following two ways :

Method I :

Step 1. Take an isolated neutral conductor..

Step 2. Bring a charged rod near to it. Due to the charged rod, charges will induce on the conductor.

Step 3. Connect another neutral conductor with it. Due to attraction of the rod, some free electrons will move from the right conductor to the left conductor and due to deficiency of electrons positive charges will appear on right conductor and on the left conductor there will be excess of electrons due to transfer from right conductor..

Step 4. Now disconnect the connecting wire and remove the rod.

The first conductor will be negatively charged and the second conductor will be positively charged.

Method II

Step 1. Take an isolated neutral conductor..

Step 2. Bring a charged rod near to it. Due to the charged rod, charges will induce on the conductor.

Step 3. Connect the conductor to the earth (this process is called grounding or earthing). Due to attraction of the rod, some free electrons will move from earth to the conductor, so in the conductor there will be excess of electrons due to transfer from the earth, so net charge on conductor will be negative.

Step 4. Now disconnect the connecting wire. Conductor becomes negatively charge.

- (d) **Thermionic emission** : When the metal is heated at a high temperature then some electrons of metals are ejected and the metal becomes positively charged.

- (e) **Photoelectric effect** : When light of sufficiently high frequency is incident on metal surface then some electrons gain energy from light and come out of the metal surface and remaining metal becomes positively charged.

- (f) **Field emission** : When electric field of large magnitude is applied near the metal surface then some electrons come out from the metal surface and hence the metal gets positively charged.

Solved Examples

Example 1. If a charged body is placed near a neutral conductor, will it attract the conductor or repel it?
Solution.

If a charged body (+ve) is placed leftside near a neutral conductor, (–ve) charge will induce at left surface and (+ve) charge will induce at right surface. Due to positively charged body –ve induced charge will feel attraction and the +ve induced charge will feel repulsion. But as the –ve induced charge is nearer, so the attractive force will be greater than the repulsive force. So the net force on the conductor due to positively charged body will be attractive. Similarly we can prove for negatively charged body also.

From the above example we can conclude that. "A charged body can attract a neutral body."

If there is attraction between two bodies then one of them may be neutral. But if there is repulsion between two bodies, both must be charged (similarly charged).

So **"repulsion is the sure test of electrification".**

Example 2. A positively charged body 'A' attracts a body 'B' then charge on body 'B' may be:
(A) positive (B) negative (C) zero (D) can't say

Answer. B, C

Example 3. Five styrofoam balls A, B, C, D and E are used in an experiment. Several experiments are performed on the balls and the following observations are made

- (i) Ball A repels C and attracts B.
- (ii) Ball D attracts B and has no effect on E.
- (iii) A negatively charged rod attracts both A and E.

For your information, an electrically neutral styrofoam ball is very sensitive to charge induction, and gets attracted considerably, if placed nearby a charged body. What are the charges, if any, on each ball ?

	A	B	C	D	E
(A)	+	–	+	0	+
(B)	+	–	+	+	0
(C)	+	–	+	0	0
(D)	–	+	–	0	0

Answer. C

Solution. From (i), As A repels C, so both A and C must be charged similarly. Either both are +ve or both are –ve. As A also attract B, so charge on B should be opposite of A or B may be uncharged conductor.

From (ii) As D has no effect on E, so both D and E should be uncharged, and as B attracts uncharged D, so B must be charged and D must be on uncharged conductor.

From (iii) a –ve charged rod attract the charged ball A, so A must be +ve, and from exp. (i) C must also be +ve and B must be –ve.

Example 4. Charge conservation is always valid. Is it also true for mass?

Solution. No, mass conservation is not always. In some nuclear reactions, some mass is lost and it is converted into energy.

Example 5. What are the differences between charging by induction and charging by conduction ?

Solution. Major differences between two methods of charging are as follows :

- (i) In induction, two bodies are close to each other but do not touch each other while in conduction they touch each other. (or they are connected by a metallic wire)
- (ii) In induction, total charge of a body remains unchanged while in conduction it changes.
- (iii) In induction, induced charge is always opposite in nature to that of source charge while in conduction charge on two bodies finally is of same nature.

Example 6. If a glass rod is rubbed with silk it acquires a positive charge because :

- (A) protons are added to it
- (B) protons are removed from it
- (C) electrons are added to it
- (D) electrons are removed from it.

Answer. D

3. COULOMB'S LAW (INVERSE SQUARE LAW)

On the basis of experiments Coulomb established the following law known as Coulomb's law.

The magnitude of electrostatic force between two point charges is directly proportional to the product of charges and inversely proportional to the square of the distance between them.

$$\text{i.e. } F \propto q_1 q_2 \quad \text{and} \quad F \propto \frac{1}{r^2} \quad \Rightarrow \quad F \propto \frac{q_1 q_2}{r^2} \quad \Rightarrow \quad F = \frac{K q_1 q_2}{r^2}$$

Important points regarding Coulomb's law :

- (i) It is applicable only for point charges.

- (ii) The constant of proportionality K in SI units in vacuum is expressed as $\frac{1}{4\pi\epsilon_0}$ and in any other medium expressed as $\frac{1}{4\pi\epsilon}$. If charges are dipped in a medium then electrostatic force on one charge is $\frac{1}{4\pi\epsilon_0\epsilon_r} \frac{q_1q_2}{r^2}$. ϵ_0 and ϵ are called permittivity of vacuum and absolute permittivity of the medium respectively. The ratio $\epsilon/\epsilon_0 = \epsilon_r$ is called relative permittivity of the medium, which is a dimensionless quantity.
- (iii) The value of relative permittivity ϵ_r is constant for medium and can have values between 1 to ∞ . For vacuum, by definition it is equal to 1. For air it is nearly equal to 1 and may be taken to be equal to 1 for calculations. For metals the value of ϵ_r is ∞ and for water is 81. The material in which more charge can induce ϵ_r will be higher.
- (iv) The value of $\frac{1}{4\pi\epsilon_0} = 9 \times 10^9 \text{ Nm}^2 \text{ C}^{-2} \Rightarrow \epsilon_0 = 8.855 \times 10^{-12} \text{ C}^2/\text{Nm}^2$.
Dimensional formula of ϵ is $\text{M}^{-1} \text{L}^{-3} \text{T}^4 \text{A}^2$
- (v) The force acting on one point charge due to the other point charge is always along the line joining these two charges. It is equal in magnitude and opposite in direction on two charges, irrespective of the medium, in which they lie.
- (vi) The force is conservative in nature i.e., work done by electrostatic force in moving a point charge along a close loop of any shape is zero.
- (vii) Since the force is a central force, in the absence of any other external force, angular momentum of one particle w.r.t. the other particle (in two particle system) is conserved,
- (viii) In vector form formula can be given as below.
- $$\vec{F} = \frac{1}{4\pi\epsilon_0\epsilon_r} \frac{q_1q_2}{|\vec{r}|^3} \vec{r} = \frac{1}{4\pi\epsilon_0\epsilon_r} \frac{q_1q_2}{|\vec{r}|^2} \hat{r} \quad (q_1 \text{ \& } q_2 \text{ are to be substituted with sign.})$$
- here \vec{r} is position vector of the test charge (on which force is to be calculated) with respect to the source charge (due to which force is to be calculated).

Solved Examples

Example 7. Find out the electrostatics force between two point charges placed in air (each of + 1C) if they are separated by 1m.

Sol.
$$F_e = \frac{kq_1q_2}{r^2} = \frac{9 \times 10^9 \times 1 \times 1}{1^2} = 9 \times 10^9 \text{ N}$$

From the above result we can say that 1 C charge is too large to realize. In nature, charge is usually of the order of μC

Example 8. Two particles having charges q_1 and q_2 when kept at a certain distance, exert a force F on each other. If the distance between the two particles is reduced to half and the charge on each particle is doubled then what will be the force between the particles:

Answer. 16 F

Solution.
$$F = \frac{kq_1q_2}{r^2}$$

If $q'_1 = 2q_1$, $q'_2 = 2q_2$ $r' = \frac{r}{2}$,

$$k(2q_1)(2q_2)$$

then
$$F' = \frac{kq'_1q'_2}{r'^2} = \frac{k(2q_1)(2q_2)}{\left(\frac{r}{2}\right)^2}$$

$$F' = \frac{16kq_1q_2}{r^2}$$

$$F' = 16F$$

Example 9. A particle of mass m carrying charge q_1 is revolving around a fixed charge $-q_2$ in a circular path of radius r . Calculate the period of revolution and its speed also.

Solution.

$$\frac{1}{4\pi\epsilon_0} \frac{q_1q_2}{r^2} = mr\omega^2 = \frac{4\pi^2mr}{T^2}$$

$$T^2 = \frac{(4\pi\epsilon_0)r^2(4\pi^2mr)}{q_1q_2} \quad \text{or} \quad T = 4\pi r \sqrt{\frac{\pi\epsilon_0 mr}{q_1q_2}}$$

and also we can say that

$$\frac{q_1q_2}{4\pi\epsilon_0 r^2} = \frac{mv^2}{r} \Rightarrow v = \sqrt{\frac{q_1q_2}{4\pi\epsilon_0 mr}}$$

Example 10. A point charge $q_A = +100 \mu\text{C}$ is placed at point A (1, 0, 2) m and another point charge $q_B = +200 \mu\text{C}$ is placed at point B (4, 4, 2) m. Find :

- (i) Magnitude of Electrostatic interaction force acting between them
- (ii) Find \vec{F}_A (force on A due to B) and \vec{F}_B (force on B due to A) in vector form
- Solution.**

Value of F : $|F| = \frac{kq_Aq_B}{r^2} = \frac{(9 \times 10^9)(100 \times 10^{-6})(200 \times 10^{-6})}{\sqrt{(4-1)^2 + (4-0)^2 + (2-2)^2}} = 7.2 \text{ N}$

(ii) Force on B $\vec{F}_B = \frac{kq_Aq_B}{r^3} \vec{r} = \frac{(9 \times 10^9)(100 \times 10^{-6})(200 \times 10^{-6})}{\sqrt{(4-1)^2 + (4-0)^2 + (2-2)^2}} [(4-1)\hat{i} + (4-0)\hat{j} + (2-2)\hat{k}]$

$$= 7.2 \left(\frac{3}{5}\hat{i} + \frac{4}{5}\hat{j} \right) \text{ N}$$

Similarly $\vec{F}_A = 7.2 \left(-\frac{3}{5}\hat{i} - \frac{4}{5}\hat{j} \right) \text{ N}$

Action (\vec{F}_A) and Reaction (\vec{F}_B) are equal but in opposite direction.

4. PRINCIPLE OF SUPERPOSITION

The electrostatic force is a two body interaction, i.e., electrical force

between two point charges is independent of presence or absence of other charges and so the principle of superposition is valid, i.e., force on charged particle due to number of point charges is the resultant of

forces due to individual point charges, therefore, force on a point test charge due to many charges is given by $\vec{F} = \vec{F}_1 + \vec{F}_2 + \vec{F}_3 + \dots$

Solved Examples

Example 11. Three equal point charges of charge $+q$ are moving along a circle of radius R and a point charge $-2q$ is also placed at the centre of circle as (shown in figure), if charges are revolving with constant and same speed then calculate speed

Solution.

$$F_2 - 2F_1 \cos 30^\circ = \frac{mv^2}{R} \Rightarrow \frac{K(q)(2q)}{R^2} - \frac{2(Kq^2)}{(\sqrt{3}R)^2} \cos 30^\circ = \frac{mv^2}{R}$$

$$\Rightarrow v = \sqrt{\frac{kq^2}{Rm} \left[2 - \frac{1}{\sqrt{3}} \right]}$$

Example 12 Two equally charged identical small metallic spheres A and B repel each other with a force $2 \times 10^{-5} \text{ N}$ when placed in air (neglect gravitation attraction). Another identical uncharged sphere C is touched to B and then placed at the mid point of line joining A and B. What is the net electrostatic force on C?

Solution.

Let initially the charge on each sphere be q and separation between their centres be r ; then according to given problem.

$$F = \frac{1}{4\pi\epsilon_0} \frac{q \times q}{r^2} = 2 \times 10^{-5} \text{ N}$$

When sphere C touches B, the charge of B, q will distribute equally on B and C as sphere are identical conductors, i.e., now charges on spheres;

$$q_B = q_C = (q/2)$$

So sphere C will experience a force

$$F_{CA} = \frac{1}{4\pi\epsilon_0} \frac{q(q/2)}{(r/2)^2} = 2F \text{ along } \overrightarrow{AB} \text{ due to charge on A}$$

$$\text{and } F_{CB} = \frac{1}{4\pi\epsilon_0} \frac{(q/2)(q/2)}{(r/2)^2} = F \text{ along } \overrightarrow{BA} \text{ due to charge on B}$$

So the net force F_C on C due to charges on A and B,
 $F_C = F_{CA} - F_{CB} = 2F - F = 2 \times 10^{-5} \text{ N along } \overrightarrow{AB}$.

Example 13 Five point charges, each of value q are placed on five vertices of a regular hexagon of side L . What is the magnitude of the force on a point charge of value $-q$ coulomb placed at the centre of the hexagon?

Solution. **Method-I :** If there had been a sixth charge $+q$ at the remaining vertex of hexagon force due to all the six charges on $-q$ at O would be zero (as the forces due to individual charges will balance each other), i.e. $\vec{F}_R = 0$

Now if \vec{f} is the force due to sixth charge and \vec{F} due to remaining five charges.

$$\vec{F} + \vec{f} = 0 \quad \text{i.e.} \quad \vec{F} = -\vec{f}$$

$$\text{or } |\vec{F}| = |\vec{f}| = \frac{1}{4\pi\epsilon_0} \frac{q \times q}{L^2} = \frac{1}{4\pi\epsilon_0} \frac{q^2}{L^2}$$

$$\vec{F}_{\text{Net}} = \vec{F}_{CO} = \frac{1}{4\pi\epsilon_0} \frac{q^2}{L^2} \text{ along OD}$$

Method : II

In the diagram we can see that force due to charge A and D are opposite to each other

$$\vec{F}_{DO} + \vec{F}_{AO} = 0 \quad \dots(i)$$

$$\text{Similarly } \vec{F}_{BO} + \vec{F}_{EO} = 0 \quad \dots(ii)$$

$$\text{So } \vec{F}_{AO} + \vec{F}_{BO} + \vec{F}_{CO} + \vec{F}_{DO} + \vec{F}_{EO} = \vec{F}_{\text{Net}}$$

$$\text{Using (i) and (ii) } \vec{F}_{\text{Net}} = \vec{F}_{CO} = \frac{1}{4\pi\epsilon_0} \frac{q^2}{L^2} \text{ along OD}$$

Example 14. A thin straight rod of length l carrying a uniformly distributed charge q is located in vacuum. Find the magnitude of the electric force on a point charge 'Q' kept as shown in the figure.

Solution. As the charge on the rod is not point charge, therefore, first we have to find force on charge Q due to charge over a very small part on the length of the rod. This part called element of length dy can be considered as point charge.

$$\text{Charge on element } dq = \lambda dy = \frac{q}{l} dy$$

$$\text{Electric force on 'Q' due to element} = \frac{K \cdot dq \cdot Q}{y^2} = \frac{K \cdot Q \cdot q \cdot dy}{y^2 \cdot l}$$

All forces are along the same direction

$$\therefore F = \sum dF \quad \text{This sum can be calculated using integration,}$$

$$\text{therefore } F = \int_{y=a}^{y=a+l} \frac{KQq}{y^2} dy = \frac{KQq}{l} \left[-\frac{1}{y} \right]_a^{a+l} = \frac{KQq}{l} \left[\frac{1}{a} - \frac{1}{a+l} \right] = \frac{KQq}{a(a+l)}$$

Note : (1)

The total charge of the rod cannot be considered to be placed at the centre of the rod as we do in mechanics for mass in many problems.

$$\frac{KQq}{a^2}$$

Note : (2)

If $a \gg l$ then $F = \frac{KQq}{a^2}$
behaviour of the rod is just like a point charge.

5. ELECTROSTATIC EQUILIBRIUM

The point where the resultant force on a charged particle becomes zero is called equilibrium position.

5.1 Stable Equilibrium : A charge is initially in equilibrium position and is displaced by a small distance. If the charge tries to return back to the same equilibrium position then this equilibrium is called position of stable equilibrium.

5.2 Unstable Equilibrium : If charge is displaced by a small distance from its equilibrium position and the charge has no tendency to return to the same equilibrium position. Instead it goes away from the equilibrium position.

5.3 Neutral Equilibrium : If charge is displaced by a small distance and it is still in equilibrium condition then it is called neutral equilibrium.

Solved Examples

Example 15. Two equal positive point charges 'Q' are fixed at points B(a, 0) and A(-a, 0). Another test charge q_0 is also placed at O(0, 0). Show that the equilibrium at 'O' is
(i) stable for displacement along X-axis.
(ii) unstable for displacement along Y-axis.

Solution.

(i) Initially $\vec{F}_{AO} + \vec{F}_{BO} = 0 \Rightarrow |\vec{F}_{AO}| = |\vec{F}_{BO}| = \frac{KQq_0}{a^2}$
When charge is slightly shifted towards +x axis by a small distance Δx , then
 $|\vec{F}_{AO}| < |\vec{F}_{BO}|$

Therefore the particle will move towards origin (its original position) hence the equilibrium is stable.

(ii) When charge is shifted along y axis

After resolving components net force will be along y axis so the particle will not return to its original position so it is unstable equilibrium. Finally the charge will move to infinity.

Example 16. Two point charges of charge q_1 and q_2 (both of same sign) and each of mass m are placed such that gravitation attraction between them balances the electrostatic repulsion. Are they in stable equilibrium? If not then what is the nature of equilibrium?

$$\frac{Kq_1q_2}{r^2} = \frac{Gm^2}{r^2}$$

Solution. In given example : $\frac{Kq_1q_2}{r^2} = \frac{Gm^2}{r^2}$. We can see that irrespective of distance between them charges will remain in equilibrium. If now distance is increased or decreased then there is no effect in their equilibrium. Therefore it is a neutral equilibrium.

Example 17. A particle of mass m and charge q is located midway between two fixed charged particles each having a charge q and a distance 2ℓ apart. Prove that the motion of the particle will be SHM if it is displaced slightly along the line connecting them and released. Also find its time period.

Solution. Let the charge q at the mid-point be displaced slightly to the left. The force on the displaced charge q due to charge q at A,

$$F_1 = \frac{1}{4\pi\epsilon_0} \frac{q^2}{(\ell+x)^2}$$

The force on the displaced charge q due to charge at B,

$$F_2 = \frac{1}{4\pi\epsilon_0} \frac{q^2}{(\ell-x)^2}$$

Net restoring force on the displaced charge q .

$$F = F_2 - F_1 \text{ or } F = \frac{1}{4\pi\epsilon_0} \frac{q^2}{(\ell-x)^2} - \frac{1}{4\pi\epsilon_0} \frac{q^2}{(\ell+x)^2}$$

$$\text{or } F = \frac{q^2}{4\pi\epsilon_0} \left[\frac{1}{(\ell-x)^2} - \frac{1}{(\ell+x)^2} \right] = \frac{q^2}{4\pi\epsilon_0} \frac{4\ell x}{(\ell^2 - x^2)^2}$$

$$\text{Since } \ell \gg x, \therefore F = \frac{q^2 \ell x}{\pi\epsilon_0 \ell^4} \text{ or } F = \frac{q^2 x}{\pi\epsilon_0 \ell^3}$$

We see that $F \propto x$ and it is opposite to the direction of displacement. Therefore, the motion is SHM.

$$T = 2\pi\sqrt{\frac{m}{k}}, \text{ here } k = \frac{q^2}{\pi\epsilon_0 \ell^3} = 2\pi\sqrt{\frac{m\pi\epsilon_0 \ell^3}{q^2}}$$

Example 18. Find out mass of the charge Q so, that it remains in equilibrium for the given configuration.

Solution.

$$\Rightarrow 4 F \cos\theta = mg \Rightarrow 4 \times \frac{KQq}{\left(\frac{\ell^2}{4} + h^2\right)^{3/2}} h = mg$$

Example 19. Two identical charged spheres are suspended by strings of equal length. Each string makes an angle θ with the vertical. When suspended in a liquid of density $\sigma = 0.8 \text{ gm/cc}$, the angle remains the same. What is the dielectric constant of the liquid? (Density of the material of sphere is $\rho = 1.6 \text{ gm/cc}$.)

Solution. Initially as the forces acting on each ball are tension T , weight mg and electric force F , for its equilibrium along vertical,

$$T \cos \theta = mg \quad \dots(1)$$

and along horizontal

$$T \sin \theta = F \quad \dots(2)$$

Dividing Eqn. (2) by (1), we have

$$\tan \theta = \frac{F}{mg} \quad \dots(3)$$

When the balls are suspended in a liquid of density σ and dielectric constant K , the electric force will become $(1/K)$ times, i.e., $F' = (F/K)$ while weight.

$mg' = mg - F_B = mg - V\sigma g$ [as $F_B = V\sigma g$, where σ is density of material of sphere]

$$\text{i.e., } mg' = mg \left[1 - \frac{\sigma}{\rho} \right] \quad \left[\text{as } V = \frac{m}{\rho} \right]$$

So for equilibrium of ball,

$$\tan \theta' = \frac{F'}{mg'} = \frac{F}{Kmg[1 - (\sigma/\rho)]} \quad \dots (4)$$

According to given information $\theta' = \theta$; so from equations (4) and (3), we have

$$K = \frac{\rho}{(\rho - \sigma)} = \frac{1.6}{(1.6 - 0.8)} = 2 \quad \text{Ans.}$$

6. ELECTRIC FIELD

Electric field is the region around charged particle or charged body in which if another charge is placed, it experiences electrostatic force.

6.1 Electric field intensity \vec{E} : Electric field intensity at a point is equal to the electrostatic force experienced by a unit positive point charge both in magnitude and direction.

If a test charge q_0 is placed at a point in an electric field and experiences a force \vec{F} due to some charges

$$\vec{E} = \frac{\vec{F}}{q_0}$$

(called source charges), the electric field intensity at that point due to source charges is given by

;

If the \vec{E} is to be determined practically then the test charge q_0 should be small otherwise it will affect the charge distribution on the source which is producing the electric field and hence modify the quantity which is measured.

Solved Examples

Example 20. A positively charged ball hangs from a long silk thread. We wish to measure E at a point P in the same horizontal plane as that of the hanging charge. To do so, we put a positive test charge q_0 at the point and measure F/q_0 . Will F/q_0 be less than, equal to, or greater than E at the point in question?

Solution. When we try to measure the electric field at point P then after placing the test charge at P it repels the source charge (suspended charge)

and the measured value of electric field $E_{\text{measured}} = \frac{F}{q_0}$ will be less than the actual value E_{act} that we wanted to measure.

6.2 Properties of electric field intensity \vec{E} :

- (i) It is a vector quantity. Its direction is the same as the force experienced by positive charge.
- (ii) Direction of electric field due to positive charge is always away from it while due to negative charge always towards it.
- (iii) Its S.I. unit is Newton/Coulomb.
- (iv) Its dimensional formula is $[MLT^{-3}A^{-1}]$
- (v) Electric force on a charge q placed in a region of electric field at a point where the electric field intensity is \vec{E} is given by $\vec{F} = q\vec{E}$.
Electric force on point charge is in the same direction of electric field on positive charge and in opposite direction on a negative charge.
- (vi) It obeys the superposition principle, that is, the field intensity at a point due to a system of charges is vector sum of the field intensities due to individual point charges.
 $\vec{E} = \vec{E}_1 + \vec{E}_2 + \vec{E}_3 + \dots$
- (vii) It is produced by source charges. The electric field will be a fixed value at a point unless we change the distribution of source charges.

Solved Examples

Example 21. Electrostatic force experienced by $-3\mu\text{C}$ charge placed at point 'P' due to a system 'S' of fixed point charges as shown in figure is $\vec{F} = (21\hat{i} + 9\hat{j}) \mu\text{N}$.

(i) Find out electric field intensity at point P due to S.

(ii) If now $2\mu\text{C}$ charge is placed and $-3\mu\text{C}$ is removed at point P then force experienced by it will be.

Solution. (i) $\vec{F} = q\vec{E} \Rightarrow (21\hat{i} + 9\hat{j})\mu\text{N} = -3\mu\text{C}(\vec{E}) \Rightarrow \vec{E} = -7\hat{i} - 3\hat{j} \frac{\mu\text{N}}{\text{C}}$

(ii) Since the source charges are not disturbed the electric field intensity at 'P' will remain same.

$$\vec{F}_{2\mu\text{C}} = +2(\vec{E}) = 2(-7\hat{i} - 3\hat{j}) = -14\hat{i} - 6\hat{j} \mu\text{N}$$

Example 22. Calculate the electric field intensity which would be just sufficient to balance the weight of a particle of charge $-10\mu\text{C}$ and mass 10 mg . (take $g = 10\text{ ms}^{-2}$)

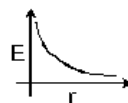

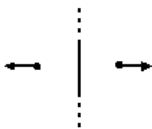

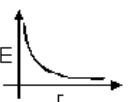

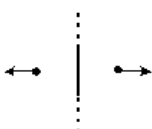

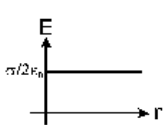

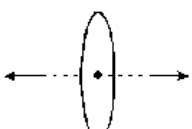

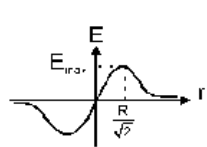

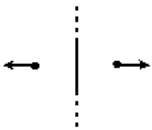

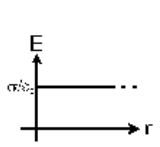

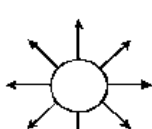

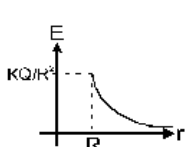

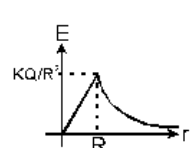

Solution. As force on a charge q in an electric field \vec{E} is $\vec{F}_q = q\vec{E}$
So according to given problem

$$|\vec{F}_q| = |\vec{W}| \quad \text{i.e.,} \quad |q|E = mg$$

$$\text{i.e.,} \quad E = \frac{mg}{|q|} = 10\text{ N/C.}, \text{ in downward direction.}$$

List of formula for Electric Field Intensity due to various types of charge distribution :

Name / Type	Formula	Note	Graph
Point charge 	$\vec{E} = \frac{Kq}{ \vec{r} ^2} \cdot \hat{r}$	* q is source charge. * \hat{r} is vector drawn from source charge to the test point. outwards due to +charges & inwards due to -charges.	
Infinitely long line charge 	$\frac{\lambda}{2\pi\epsilon_0 r} \hat{r} = \frac{2K\lambda \hat{r}}{r}$	* λ is linear charge density (assumed uniform) * r is perpendicular distance of point from line charge. * \hat{r} is radial unit vector drawn from the charge to test point.	
Infinite non-conducting thin sheet 	$\frac{\sigma}{2\epsilon_0} \hat{n}$	* σ is surface charge density (assumed uniform) * \hat{n} is unit normal vector. * x = distance of point on the axis from centre of the ring. * electric field is always along the axis.	
Uniformly charged ring 	$E = \frac{KQx}{(R^2 + x^2)^{3/2}}$ $E_{\text{centre}} = 0$	* Q is total charge of the ring * x = distance of point on the axis from centre of the ring. * electric field is always along the axis.	
Infinitely large charged conducting sheet 	$\frac{\sigma}{\epsilon_0} \hat{n}$	* σ is the surface charge density (assumed uniform) * \hat{n} is the unit vector perpendicular to the surface.	
Uniformly charged hollow conducting/ nonconducting /solid conducting sphere 	(i) for $r > R$ $\vec{E} = \frac{kQ}{ \vec{r} ^2} \hat{r}$ (ii) for $r < R$ $E = 0$	* R is radius of the sphere. * \hat{r} is vector drawn from centre of sphere to the point. * Sphere acts like a point charge, placed at centre for points outside the sphere. * E is always along radial direction. * Q is total charge ($= \sigma 4\pi R^2$). (σ = surface charge density)	
Uniformly charged solid nonconducting sphere (insulating material) 	(i) for $r \geq R$ $\vec{E} = \frac{kQ}{ \vec{r} ^2} \hat{r}$ (ii) for $r \leq R$ $\vec{E} = \frac{kQ}{R^3} r \hat{r}$	* \hat{r} is vector drawn from centre of sphere to the point * Sphere acts like a point charge placed at the centre for points outside the sphere * \vec{E} is always along radial dir. * Q is total charge ($= \rho \frac{4}{3} \pi R^3$). (ρ = volume charge density) * Inside the sphere $E \propto r$. * Outside the sphere $E \propto 1/r^2$.	

Solved Examples

Example 23. Find out electric field intensity at point A (0, 1m, 2m) due to a point charge $-20\mu\text{C}$ situated at point B ($\sqrt{2}$ m, 0, 1m).

Solution. $E = \frac{KQ}{|\vec{r}|^3} \vec{r} = \frac{KQ}{|\vec{r}|^2} \hat{r} \Rightarrow \vec{r} = \text{P.V. of A} - \text{P.V. of B}$ (P.V. = Position vector)

$$= (-\sqrt{2} \hat{i} + \hat{j} + \hat{k}) \quad |\vec{r}| = \sqrt{(\sqrt{2})^2 + (1)^2 + (1)^2} = 2$$

$$E = \frac{9 \times 10^9 \times (-20 \times 10^{-6})}{8} (-\sqrt{2} \hat{i} + \hat{j} + \hat{k}) = -22.5 \times 10^3 (-\sqrt{2} \hat{i} + \hat{j} + \hat{k}) \text{ N/C.}$$

Example 24. Two point charges $2\mu\text{C}$ and $-2\mu\text{C}$ are placed at point A and B as shown in figure. Find out electric field intensity at points C and D. [All the distances are measured in meter].

Solution. Electric field at point C (E_A, E_B are magnitudes only and arrows represent directions)

Electric field due to positive charge is away from it while due to negative charge it is towards the charge. It is clear that $E_B > E_A$.

$$\begin{aligned} \therefore E_{\text{Net}} &= (E_B - E_A) \text{ towards negative X-axis} \\ &= \frac{K(2\mu\text{C})}{(\sqrt{2})^2} - \frac{K(2\mu\text{C})}{(3\sqrt{2})^2} \text{ towards negative X-axis} \\ &= 8000 (-\hat{i}) \text{ N/C} \end{aligned}$$

Electric field at point D :

Since magnitude of charges are same and also $AD = BD$

So $E_A = E_B$

Vertical components of \vec{E}_A and \vec{E}_B cancel each other while horizontal components are in the same direction.

$$\begin{aligned} \text{So, } E_{\text{net}} &= 2E_A \cos \theta = \frac{2.K(2\mu\text{C})}{2^2} \cos 45^\circ \\ &= \frac{K \times 10^{-6}}{\sqrt{2}} = \frac{9000}{\sqrt{2}} \hat{i} \text{ N/C.} \end{aligned}$$

Example 25. Six equal point charges are placed at the corners of a regular hexagon of side 'a'. Calculate electric field intensity at the centre of hexagon?

Answer. Zero

Similarly electric field due to a uniformly charged ring at the centre of ring :

Note : (i) Net charge on a conductor remains only on the outer surface of a conductor. This property will be discussed in the article of the conductor. (article no.17)

(ii) On the surface of isolated spherical conductor charge is uniformly distributed.

6.3 Electric field due to a uniformly charged ring and arc.

Solved Examples

Example 26. Find out electric field intensity at the centre of uniformly charged semicircular ring of radius R and linear charge density λ .

Solution. λ = linear charge density.

The arc is the collection of large no. of point charges.

Consider a part of ring as an element of length $Rd\theta$ which subtends an angle $d\theta$ at centre of ring and it lies between θ and $\theta + d\theta$

$$\vec{dE} = dE_x \hat{i} + dE_y \hat{j}$$

$$E_x = \int dE_x = 0 \quad (\text{due to symmetry})$$

$$E_y = \int dE_y = \int_0^\pi dE \sin \theta = \frac{K\lambda}{R} \int_0^\pi \sin \theta \cdot d\theta = \frac{2K\lambda}{R}$$

Example 27. Find out electric field intensity at the centre of uniformly charged quarter ring of radius R and linear charge density λ .

Solution. Refer to the previous question $\vec{dE} = dE_x \hat{i} + dE_y \hat{j}$ on solving $E_{\text{net}} = \frac{K\lambda}{R} = (\hat{i} + \hat{j})$

By use of symmetry and from the formula of electric field due to half ring.

Above answer can be justified.

- (ii) Derivation of electric field intensity at a point on the axis at a distance x from centre of uniformly charged ring of radius R and total charge Q .

Consider an element of charge dq . Due to this element the electric field at the point on axis, which is at a distance x from the centre of the ring is dE . There are two component of this electric field

The y -component of electric field due to all the elements will be cancelled out to each other. So net electric field intensity at the point will be only due to X -component of each element.

$$E_{\text{net}} = \int dE_x = \int dE \cos \theta = \int_0^Q \frac{K(dq)}{R^2 + x^2} \times \frac{x}{\sqrt{R^2 + x^2}}$$

$$E_{\text{net}} = \frac{KQx}{[R^2 + x^2]^{3/2}}$$

E will be max when $\frac{dE}{dx} = 0$, that is at $x = \frac{R}{\sqrt{2}}$ and $E_{\text{max}} = \frac{2KQ}{3\sqrt{3} R^2}$

Case (i) : if $x \gg R$, $E = \frac{KQ}{x^2}$ Hence the ring will act like a point charge

Case (ii) : if $x \ll R$, $E = \frac{KQx}{R^3}$

Solved Examples

Example 28. Positive charge Q is distributed uniformly over a circular ring of radius R . A point particle having a mass m and a negative charge $-q$, is placed on its axis at a distance x from the centre. Find the force on the particle. Assuming $x \ll R$, find the time period of oscillation of the particle if it is released from there. (Neglect gravity)

Solution. When the negative charge is shifted at a distance x from the centre of the ring along its axis then force acting on the point charge due to the ring :

$F_E = qE$ (towards centre)

$$= q \left[\frac{KQx}{(R^2 + x^2)^{3/2}} \right]$$

if $R \gg x$ then
 $R^2 + x^2 \approx R^2$

$$F_E = \frac{1}{4\pi\epsilon_0} \frac{Qqx}{R^3} \quad (\text{Towards centre})$$

Since restoring force $F_E \propto x$, therefore motion of charge the particle will be S.H.M.
Time period of SHM.

$$T = 2\pi \sqrt{\frac{m}{k}} = 2\pi \sqrt{\frac{m}{\left(\frac{Qq}{4\pi\epsilon_0 R^3}\right)}} = \left[\frac{16\pi^3 \epsilon_0 m R^3}{Qq} \right]^{1/2}$$

Example 29. Derive the expression of electric field intensity at a point 'P' which is situated at a distance x on the axis of uniformly charged disc of radius R and surface charge density σ . Also derive results for

(i) $x \gg R$

(ii) $x \ll R$

Solution.

The disc can be considered to be a collection of large number of concentric rings. Consider an element of the shape of ring of radius r and of width dr . Electric field due to this ring at P is

$$dE = \frac{K \cdot \sigma 2\pi r \cdot dr \cdot x}{(r^2 + x^2)^{3/2}}$$

$$\text{Put } r^2 + x^2 = y^2 \\ 2rdr = 2ydy$$

$$dE = \frac{K \cdot \sigma 2\pi y \cdot dy \cdot x}{y^3} = 2K\sigma\pi x \frac{ydy}{y^3}$$

Electric field at P due to all rings is along the axis.

$$\begin{aligned} \therefore E &= \int dE \Rightarrow E = 2K\sigma\pi x \int_x^{\sqrt{R^2+x^2}} \frac{1}{y^2} dy = 2K\sigma\pi x \left[-\frac{1}{y} \right]_x^{\sqrt{R^2+x^2}} \\ &= 2K\sigma\pi x \left[+\frac{1}{x} - \frac{1}{\sqrt{R^2+x^2}} \right] = 2K\sigma\pi \left[1 - \frac{x}{\sqrt{R^2+x^2}} \right] \\ &= \frac{\sigma}{2\epsilon_0} \left[1 - \frac{x}{\sqrt{R^2+x^2}} \right], \text{ along the axis} \end{aligned}$$

Cases : (i) If $x \gg R$

$$\begin{aligned} E &= \frac{\sigma}{2\epsilon_0} \left[1 - \frac{x}{x\sqrt{\frac{R^2}{x^2} + 1}} \right] = \frac{\sigma}{2\epsilon_0} \left[1 - \left(1 + \frac{R^2}{x^2} \right)^{-1/2} \right] \\ &= \frac{\sigma}{2\epsilon_0} \left[1 - 1 + \frac{1}{2} \frac{R^2}{x^2} + \text{higher order terms} \right] = \frac{\sigma}{4\epsilon_0} \frac{R^2}{x^2} = \frac{\sigma\pi R^2}{4\pi\epsilon_0 x^2} = \frac{Q}{4\pi\epsilon_0 x^2} \end{aligned}$$

i.e. behaviour of the disc is like a point charge.

(ii) If $x \ll R$

$$E = \frac{\sigma}{2\epsilon_0} [1 - 0] = \frac{\sigma}{2\epsilon_0} \quad \text{i.e. behaviour of the disc is like infinite sheet.}$$

6.4 Electric field due to uniformly charged wire

- (i) **Line charge of finite length** : Derivation of expression for intensity of electric field at a point due to line charge of finite size of uniform linear charge density λ . The perpendicular distance of the point from the line charge is r and lines joining ends of line charge distribution make angle θ_1 and θ_2 with the perpendicular line.

Consider a small element dx on line charge distribution at distance x from point A (see fig.). The charge of this element will be $dq = \lambda dx$. Due to this charge (dq), the intensity of electric field at the point P is dE .

$$\text{then } dE = \frac{K(dq)}{r^2 + x^2} = \frac{K(\lambda dx)}{r^2 + x^2}$$

there will be two component of this field

$$E_x = \int dE_x = \int dE \cos \theta = \int \frac{K\lambda dx}{r^2 + x^2} \cdot \cos \theta$$

assuming $x = r \tan \theta \Rightarrow dx = r \sec^2 \theta \cdot d\theta$

$$\text{so } E_x = \int_{-\theta_2}^{+\theta_1} \frac{K\lambda r \sec^2 \theta \cdot \cos \theta \cdot d\theta}{r^2 + r^2 \tan^2 \theta} = \frac{K\lambda}{r} \int_{-\theta_2}^{+\theta_1} \cos \theta \cdot d\theta = \frac{K\lambda}{r} [\sin \theta_1 + \sin \theta_2] \quad \dots(1)$$

Similarly y-component.

$$E_y = \frac{K\lambda}{r} \int_{-\theta_2}^{+\theta_1} \sin \theta \cdot d\theta = \frac{K\lambda}{r} [\cos \theta_2 - \cos \theta_1]$$

Net electric field at the point

$$E_{\text{net}} = \sqrt{E_x^2 + E_y^2}$$

- (ii) **We can derive a result for infinitely long line charge**

In above eq. (1) & (2) if we put $\theta_1 = \theta_2 = 90^\circ$ we can get required result.

$$E_{\text{net}} = E_x = \frac{2K\lambda}{r}$$

- (iii) **For Semi- infinite wire**

$\theta_1 = 90^\circ$ and $\theta_2 = 0^\circ$ so

$$E_x = \frac{K\lambda}{r}, \quad E_y = \frac{K\lambda}{r}$$

Solved Examples

Example 30. A point charge q is placed at a distance r from a very long charge thread of uniform linear charge density λ . Find out total electric force experienced by the line charge due to the point charge. (Neglect gravity).

Solution. Force on charge q due to the thread,

$$F = \left(\frac{2K\lambda}{r} \right) \cdot q$$

By Newton's III law, every action has equal and

opposite reaction so force on the thread = $\frac{2K\lambda}{r} \cdot q$
(away from point charge)

Example 31. Figure shows a long wire having uniform charge density λ as shown in figure. Calculate electric field intensity at point P.

Solution. $\theta_1 = 90^\circ$ and $\theta_2 = 360^\circ - 37^\circ$ so

$$E_x = \frac{K\lambda}{r} [\sin\theta_1 + \sin\theta_2]$$

$$E_y = \frac{K\lambda}{r} [\cos\theta_2 - \cos\theta_1]$$

Example 32. Find electric field at point A, B, C, D infinitely long uniformly charged wire with linear charge density λ and kept along z-axis (as shown in figure). Assume that all the parameters are in S.I. units.

Solution.

$$E_A = \frac{2K\lambda}{3}(\hat{i})$$

$$E_B = \frac{2K\lambda}{4}(\hat{j})$$

$$E_C = \frac{2K\lambda}{5} \hat{OC} = \frac{2K\lambda}{5} \left(\frac{3\hat{i} + 4\hat{j}}{5} \right)$$

$$E_D = \frac{2K\lambda}{5} \left(\frac{3\hat{i} + 4\hat{j}}{5} \right) \Rightarrow E_D = E_C$$

Example 33. A point charge q is placed at a distance r from a very long charge thread of uniform linear charge density λ . Find out total electric force experienced by the line charge due to the point charge. (Neglect gravity).

Solution. Force on charge q due to the thread, $F = \left(\frac{2K\lambda}{r} \right) \cdot q$

By Newton's III law, every action has equal and opposite reaction so force on the thread

$$= \frac{2K\lambda}{r} \cdot q \quad (\text{away from point charge})$$

6.5 Electric field due to uniformly charged infinite sheet

$$E_{\text{net}} = \frac{\sigma}{2\epsilon_0} \text{ toward normal direction}$$

ELECTRIC FIELD DUE TO AN INFINITELY LARGE, UNIFORMLY CHARGED SHEET

Derivation of expression for intensity of electric field at a point which is at a perpendicular distance r from the thin sheet of large size having uniform surface charge density σ .

Assume a thin strip of width dx at distance x from line AB (see figure). Which can be considered as a infinite line charge of charge density $\lambda = \sigma dx$

Due to this line charge the electric field intensity at point P will be $dE = \frac{\sigma K(dx)}{\sqrt{r^2 + x^2}}$

Take another element similar to the first element on the other side of AB . Due to symmetry Y -component of all such elements will be cancelled out.

$$\text{So net electric field will be given by } E_{\text{net}} = \int dE_x = \int dE \cos \theta = \int \frac{2K(\sigma dx)}{\sqrt{r^2 + x^2}} \times \cos \theta$$

assume $x = r \tan \theta \Rightarrow dx = r \sec^2 \theta \cdot d\theta$

$$E_{\text{net}} = 2K\sigma \int_{-\pi/2}^{+\pi/2} \frac{r \sec^2 \theta \cdot d\theta \cdot \cos \theta}{\sqrt{r^2 + r^2 \tan^2 \theta}} = \frac{\sigma}{2\epsilon_0} \text{ away from sheet}$$

Note: (1) The direction of electric field is always perpendicular to the sheet.

(2) The magnitude of electric field is independent of distance from sheet.

Solved Examples

Example 34. An infinitely large plate of surface charge density $+\sigma$ is lying in horizontal xy plane. A particle having charge $-q_0$ and mass m is projected from the plate with velocity u making an angle θ with sheet. Find :

- The time taken by the particle to return on the plate..
- Maximum height achieved by the particle.
- At what distance will it strike the plate (Neglect gravitational force on the particle)

Solution.

Electric force acting on the particle $F_e = q_0 E$: $F_e = (q_0) \left(\frac{\sigma}{2\epsilon_0} \right)$ downward

So acceleration of the particle : $a = \frac{F_e}{m} = \frac{q_0 \sigma}{2\epsilon_0 m} = \text{uniform}$
 this acceleration will act like 'g' (acceleration due to gravity)
 So the particle will perform projectile motion.

$$\begin{aligned} \text{(i) } T &= \frac{2u \sin \theta}{g_{\text{eff}}} = \frac{2u \sin \theta}{\left(\frac{q_0 \sigma}{2\epsilon_0 m} \right)} & \text{(ii) } H &= \frac{u^2 \sin^2 \theta}{2g_{\text{eff}}} = \frac{u^2 \sin^2 \theta}{2 \left(\frac{q_0 \sigma}{2\epsilon_0 m} \right)} \\ \text{(iii) } R &= \frac{u^2 \sin 2\theta}{g_{\text{eff}}} = \frac{u^2 \sin 2\theta}{\left(\frac{q_0 \sigma}{2\epsilon_0 m} \right)} \end{aligned}$$

Example 35. A block having mass m and charge $-q$ is resting on a frictionless plane at a distance L from fixed large non-conducting infinite sheet of uniform charge density σ as shown in Figure. Discuss the motion of the block assuming that collision of the block with the sheet is perfectly elastic. Is it SHM?

Solution. The situation is shown in Figure. Electric force produced by sheet will accelerate the block towards the sheet producing an acceleration. Acceleration will be uniform because electric field E due to the sheet is uniform.

$$a = \frac{F}{m} = \frac{qE}{m}, \text{ where } E = \sigma/2\epsilon_0$$

As initially the block is at rest and acceleration is constant, from second equation of motion, time taken by the block to reach the wall

$$L = \frac{1}{2} at^2 \quad \text{i.e.,} \quad t = \sqrt{\frac{2L}{a}} = \sqrt{\frac{2mL}{qE}} = \sqrt{\frac{4mL\epsilon_0}{q\sigma}}$$

As collision with the wall is perfectly elastic, the block will rebound with same speed and as now its motion is opposite to the acceleration, it will come to rest after travelling same distance L in same time t . After stopping it will be again accelerated towards the wall and so the block will execute oscillatory motion with 'span' L and time period.

$$T = 2t = 2\sqrt{\frac{2mL}{qE}} = 2\sqrt{\frac{4mL\epsilon_0}{q\sigma}}$$

However, as the restoring force $F = qE$ is constant and not proportional to displacement x , the motion is not simple harmonic.

Example 36. If an isolated infinite sheet contains charge Q_1 on its one surface and charge Q_2 on its other

surface then prove that electric field intensity at a point in front of sheet will be $\frac{Q}{2A\epsilon_0}$, where $Q = Q_1 + Q_2$

Solution.

$$\begin{aligned} \text{Electric field at point P : } \vec{E} &= \vec{E}_{Q_1} + \vec{E}_{Q_2} \\ &= \frac{Q_1}{2A\epsilon_0} \hat{n} + \frac{Q_2}{2A\epsilon_0} \hat{n} = \frac{Q_1 + Q_2}{2A\epsilon_0} \hat{n} = \frac{Q}{2A\epsilon_0} \hat{n} \end{aligned}$$

[This shows that the resultant field due to a sheet depends only on the total charge of the sheet and not on the distribution of charge on individual surfaces].

Example 37. Three large conducting parallel sheets are placed at a finite distance from each other as shown in figure. Find out electric field intensity at point A, B, C & D.

Solution. For point A

$$\vec{E}_{\text{net}} = \vec{E}_Q + \vec{E}_{3Q} + \vec{E}_{-2Q} = -\frac{Q}{2A\epsilon_0} \hat{i} - \frac{3Q}{2A\epsilon_0} \hat{i} + \frac{2Q}{2A\epsilon_0} \hat{i} = -\frac{Q}{A\epsilon_0} \hat{i}$$

For point B

$$\vec{E}_{\text{net}} = \vec{E}_{3Q} + \vec{E}_{-2Q} + \vec{E}_Q = -\frac{3Q}{2A\epsilon_0} \hat{i} + \frac{2Q}{2A\epsilon_0} \hat{i} + \frac{Q}{2A\epsilon_0} \hat{i} = 0$$

For point C

$$\vec{E}_{\text{net}} = \vec{E}_Q + \vec{E}_{3Q} + \vec{E}_{-2Q} = +\frac{Q}{2A\epsilon_0} \hat{i} - \frac{3Q}{2A\epsilon_0} \hat{i} - \frac{2Q}{2A\epsilon_0} \hat{i} = -\frac{2Q}{A\epsilon_0} \hat{i}$$

for point D

$$\vec{E}_{\text{net}} = \vec{E}_Q + \vec{E}_{3Q} + \vec{E}_{-2Q} = +\frac{Q}{2A\epsilon_0} \hat{i} + \frac{3Q}{2A\epsilon_0} \hat{i} - \frac{2Q}{2A\epsilon_0} \hat{i} = \frac{Q}{A\epsilon_0} \hat{i}$$

6.6 Electric field due to uniformly charged spherical shell

$$E = \frac{KQ}{r^2}$$

$$r \geq R \Rightarrow$$

For the out side points & point on the surface the uniformly charged spherical shell behaves as a point charge placed at the centre

$$E = 0 \quad r < R$$

Electric field due to spherical shell out side it is always along the radial direction.

Solved Examples

Example 38. Figure shows a uniformly charged sphere of radius R and total charge Q . A point charge q is situated outside the sphere at a distance r from centre of sphere. Find out the following :

- Force acting on the point charge q due to the sphere.
- Force acting on the sphere due to the point charge.

Solution.

- Electric field at the position of point charge

$$\vec{E} = \frac{KQ}{r^2} \hat{r}$$

$$\vec{F} = \frac{KqQ}{r^2} \hat{r} \quad |\vec{F}| = \frac{KqQ}{r^2}$$

so,

- Since we know that every action has equal and opposite reaction so

$$\vec{F}_{\text{sphere}} = -\frac{KqQ}{r^2} \hat{r} \quad |\vec{F}_{\text{sphere}}| = \frac{KqQ}{r^2}$$

Example 39. Figure shows a uniformly charged thin sphere of total charge Q and radius R . A point charge q is also situated at the centre of the sphere. Find out the following :

- Force on charge q
- Electric field intensity at A.
- Electric field intensity at B.

Solution.

- Electric field at the centre of the uniformly charged hollow sphere = 0
So force on charge q = 0
- Electric field at A

$$\vec{E}_A = \vec{E}_{\text{sphere}} + \vec{E}_q = 0 + \frac{Kq}{r^2}$$

$$; r = CA$$

E due to sphere = 0, because point lies inside the charged hollow sphere.

- Electric field \vec{E}_B at point B = $\vec{E}_{\text{sphere}} + \vec{E}_q = \frac{KQ}{r^2} \hat{r} + \frac{Kq}{r^2} \hat{r} = \frac{K(Q+q)}{r^2} \hat{r}$; $r = CB$

Note : Here we can also assume that the total charge of sphere is concentrated at the centre, for calculation of electric field at B.

Example 40. Two concentric uniformly charged spherical shells of radius R_1 and R_2 ($R_2 > R_1$) have total charges Q_1 and Q_2 respectively. Derive an expression of electric field as a function of r for following positions.

- $r < R_1$
- $R_1 \leq r < R_2$
- $r \geq R_2$

Solution.

- For $r < R_1$,
therefore point lies inside both the spheres

$$E_{\text{net}} = E_{\text{inner}} + E_{\text{outer}} = 0 + 0$$

- For $R_1 \leq r < R_2$,

therefore point lies outside inner sphere but inside outer sphere:

$$E_{\text{net}} = E_{\text{inner}} + E_{\text{outer}}$$

$$= \frac{KQ_1}{r^2} \hat{r} + 0 = \frac{KQ_1}{r^2} \hat{r}$$

(iii) For $r \geq R_2$

point lies outside inner as well as outer sphere therefore.

$$E_{\text{Net}} = E_{\text{inner}} + E_{\text{outer}} = \frac{KQ_1}{r^2} \hat{r} + \frac{KQ_2}{r^2} \hat{r} = \frac{K(Q_1 + Q_2)}{r^2} \hat{r}$$

Example 41. A spherical shell having charge $+Q$ (uniformly distributed) and a point charge $+q_0$ are placed as shown. Find the force between shell and the point charge ($r \gg R$).

- (i) Force on the point charge $+q_0$ due to the shell $= q_0 \vec{E}_{\text{shell}} = (q_0) \left(\frac{KQ}{r^2} \right) \hat{r} = \frac{KQq_0}{r^2} \hat{r}$
 where \hat{r} is unit vector along OP.
 From action - reaction principle, force on the shell due to the point charge will also be

$$F_{\text{shell}} = \frac{KQq_0}{r^2} (-\hat{r})$$

Conclusion - To find the force on a hollow sphere due to outside charges, we can replace the sphere by a point charge kept at centre.

Example 42. Find force acting between two shells of radius R_1 and R_2 which have uniformly distributed charges Q_1 and Q_2 respectively and distance between their centre is r .

Solution. The shells can be replaced by point charges kept at centre so force between them

$$F = \frac{KQ_1Q_2}{r^2}$$

6.7 Electric field due to uniformly charged solid sphere

Derive an expression for electric field due to solid sphere of radius R and total charge Q which is uniformly distributed in the volume,

at a point which is at a distance r from centre for given two cases.

(i) $r \geq R$ (ii) $r \leq R$

Assume an elementary concentric shell of charge dq . Due to this shell the electric field at the point ($r > R$) will be

$$dE = \frac{Kdq}{r^2}$$

[from above result of hollow sphere]

$$E_{\text{net}} = \int dE = \frac{KQ}{r^2}$$

For $r < R$, there will be no electric field due to shell of radius greater than r , so electric field at the point will be present only due to shells having radius less than r .

$$E'_{\text{net}} = \frac{KQ'}{r^2}$$

$$\text{here } Q' = \frac{Q}{\frac{4}{3}\pi R^3} \times \frac{4}{3}\pi r^3 = \frac{Qr^3}{R^3}$$

$$E'_{\text{net}} = \frac{KQ'}{r^2} = \frac{KQr}{R^3}$$

away from the centre.

Note : The electric field inside and outside the sphere is always in radial direction.

Solved Examples

Example 43. A solid non conducting sphere of radius R and uniform volume charge density ρ has its centre at origin. Find out electric field intensity in vector form at following positions :

- (i) $(R/2, 0, 0)$ (ii) $\left(\frac{R}{\sqrt{2}}, \frac{R}{\sqrt{2}}, 0\right)$ (iii) $(R, R, 0)$

Solution.

- (i) at $(R/2, 0, 0)$: Distance of point from centre = $\sqrt{(R/2)^2 + 0^2 + 0^2} = R/2 < R$, so point lies inside the sphere so

$$\vec{E} = \frac{\rho r}{3\epsilon_0} = \frac{\rho}{3\epsilon_0} \left[\frac{R}{2} \hat{i} \right]$$

- (ii) At $\left(\frac{R}{\sqrt{2}}, \frac{R}{\sqrt{2}}, 0\right)$; distance of point from centre = $\sqrt{(R/\sqrt{2})^2 + (R/\sqrt{2})^2 + 0^2} = R = R$, so point lies at the surface of sphere, therefore

$$\vec{E} = \frac{KQ}{R^3} \vec{r} = \frac{K \frac{4}{3}\pi R^3 \rho}{R^3} \left[\frac{R}{\sqrt{2}} \hat{i} + \frac{R}{\sqrt{2}} \hat{j} \right] = \frac{\rho}{3\epsilon_0} \left[\frac{R}{\sqrt{2}} \hat{i} + \frac{R}{\sqrt{2}} \hat{j} \right]$$

- (iii) The point is outside the sphere

$$\text{So } \vec{E} = \frac{KQ}{r^3} \vec{r} = \frac{K \frac{4}{3}\pi R^3 \rho}{(\sqrt{2}R)^3} [\hat{R}\hat{i} + \hat{R}\hat{j}] = \frac{\rho}{6\sqrt{2}\epsilon_0} [\hat{R}\hat{i} + \hat{R}\hat{j}]$$

Example 44. A Uniformly charged solid nonconducting sphere of uniform volume charge density ρ and radius R is having a concentric spherical cavity of radius r . Find out electric field intensity at following points, as shown in the figure :

- (i) Point A (ii) Point B
(iii) Point C (iv) Centre of the sphere

Solution.

Method I :

- (i) For point A : We can consider the solid part of sphere to be made of large number of spherical shells which have uniformly distributed charge on its surface. Now since point A lies inside all spherical shells so electric field intensity due to all shells will be zero.

$$\vec{E}_A = 0$$

- (ii) For point B : All the spherical shells for which point B lies inside will make electric field zero at point B. So electric field will be due to charge present from radius r to OB .

$$\text{So, } \vec{E}_B = \frac{K \frac{4}{3} \pi (OB^3 - r^3) \rho}{OB^3} \vec{OB} = \frac{\rho}{3\epsilon_0} \frac{[OB^3 - r^3]}{OB^3} \vec{OB}$$

(iii) For point C, similarly we can say that for all the shells point C lies outside the shell

$$\vec{E}_C = \frac{K [\frac{4}{3} \pi (R^3 - r^3)]}{[OC]^3} \vec{OC} = \frac{\rho}{3\epsilon_0} \frac{R^3 - r^3}{[OC]^3} \vec{OC}$$

Method : II

We can consider that the spherical cavity is filled with charge density ρ and also $-\rho$, thereby making net charge density zero after combining. We can consider two concentric solid spheres one of radius R and charge density ρ and other of radius r and charge density $-\rho$. Applying superposition principle.

$$(i) \vec{E}_A = \vec{E}_\rho + \vec{E}_{-\rho} = \frac{\rho(OA)}{3\epsilon_0} + \frac{[-\rho(OA)]}{3\epsilon_0} = 0$$

$$(ii) \vec{E}_B = \vec{E}_\rho + \vec{E}_{-\rho} = \frac{\rho(OB)}{3\epsilon_0} + \frac{K [\frac{4}{3} \pi r^3 (-\rho)]}{(OB)^3} \vec{OB}$$

$$= \left[\frac{\rho}{3\epsilon_0} - \frac{r^3 \rho}{3\epsilon_0 (OB)^3} \right] \vec{OB} = \frac{\rho}{3\epsilon_0} \left[1 - \frac{r^3}{OB^3} \right] \vec{OB}$$

$$(iii) \vec{E}_C = \vec{E}_\rho + \vec{E}_{-\rho} = \frac{K \left(\frac{4}{3} \pi R^3 \rho \right)}{OC^3} + \frac{K \left(\frac{4}{3} \pi r^3 (-\rho) \right)}{OC^3} \vec{OC}$$

$$= \frac{\rho}{3\epsilon_0 (OC)^3} [R^3 - r^3] \vec{OC}$$

$$(iv) \vec{E}_O = \vec{E}_\rho + \vec{E}_{-\rho} = 0 + 0 = 0$$

Example 45.

Solution.

In above question if cavity is not concentric and centered at point P then repeat all the steps. Again assume ρ and $-\rho$ in the cavity, similar to the previous example.

$$(i) \vec{E}_A = \vec{E}_\rho + \vec{E}_{-\rho} = \frac{\rho(OA)}{3\epsilon_0} + \frac{(-\rho)PA}{3\epsilon_0}$$

$$= \frac{\rho}{3\epsilon_0} [\vec{OA} - \vec{PA}] = \frac{\rho}{3\epsilon_0} \vec{OP}$$

Note : Here we can see that the electric field intensity at point P is independent of position of point P inside the cavity. Also the electric field is along the line joining the centres of the sphere and the spherical cavity.

$$(ii) \vec{E}_B = \vec{E}_\rho + \vec{E}_{-\rho} = \frac{\rho(OB)}{3\epsilon_0} + \frac{K [\frac{4}{3} \pi r^3 (-\rho)]}{[PB]^3} \vec{PB}$$

$$(iii) \vec{E}_C = \vec{E}_\rho + \vec{E}_{-\rho} = \frac{K [\frac{4}{3} \pi R^3 \rho]}{[OC]^3} \vec{OC} + \frac{K [\frac{4}{3} \pi r^3 (-\rho)]}{[PC]^3} \vec{PC}$$

$$(iv) \vec{E}_O = \vec{E}_\rho + \vec{E}_{-\rho} = 0 + \frac{K [\frac{4}{3} \pi r^3 (-\rho)]}{[PO]^3} \vec{PO}$$

Example 46. A nonconducting solid sphere has volume charge density that varies as $\rho = \rho_0 r$, where ρ_0 is a constant and r is distance from centre. Find out electric field intensities at following positions.

- (i) $r < R$ (ii) $r \geq R$

Solution. **Method I :**

- (i) for $r < R$

The sphere can be considered to be made of large number of spherical shells. Each shell has uniform charge density on its surface. So the previous results of the spherical shell can be used. Consider a shell of radius x and thickness dx as an element. Charge on shell $dq = (4\pi x^2 dx)\rho_0 x$

$$\text{Electric field intensity at point P due to shell } dE = \frac{Kdq}{x^2}$$

Since all the shell will have electric field in same direction

$$E = \int_0^R dE = \int_0^r dE + \int_r^R dE$$

Due to shells which lie between region $r < x \leq R$, electric field at point P will be zero.

$$\vec{E} = \int_0^r \frac{Kdq}{r^2} + 0 = \int_0^r \frac{K \cdot 4\pi x^2 dx \rho_0 x}{r^2} = \frac{4\pi K \rho_0}{r^2} \left[\frac{x^4}{4} \right]_0^r = \frac{\rho_0 r^2}{4\epsilon_0} \hat{r}$$

$$(ii) \ r \geq R \quad E = \int_0^R dE = \int_0^R \frac{K \cdot 4\pi x^2 dx \rho_0 x}{r^2} = \frac{\rho_0 R^4}{4\epsilon_0 r^2} \hat{r}$$

Method II :

- (i) The sphere can be considered to be made of large number of spherical shells. Each shell has uniform charge density on its surface. So the previous results of the spherical shell can be used. we can say that all the shells for which point lies inside will make electric field zero at that point,

$$\text{so } \vec{E}_{(r < R)} = \frac{K \int_0^r (4\pi x^2 dx) \rho_0 x}{r^2} = \frac{\rho_0 r^2}{4\epsilon_0} \hat{r}$$

- (ii) similarly for $r \geq R$, all the shells will contribute in electric field, therefore

$$\vec{E}_{(r < R)} = \frac{K \int_0^R (4\pi x^2 dx) \rho_0 x}{r^2} = \frac{\rho_0 R^4}{4\epsilon_0 r^2} \hat{r}$$

7. ELECTRIC POTENTIAL

In electrostatic field the electric potential (due to some source charges) at a point P is defined as the work done by external agent in taking a point unit positive charge from a reference point (generally taken at infinity) to that point P without changing its kinetic energy..

7.1 Mathematical representation :

If $(W_{\infty \rightarrow P})_{\text{ext}}$ is the work required in moving a point charge q from infinity to a point P, the electric potential of the point P is

$$V_p = \left[\frac{W_{\infty \rightarrow P})_{\text{ext}}}{q} \right]_{\Delta K=0} = \frac{-W_{\text{elc}})_{\infty \rightarrow P}}{q} = \frac{\Delta U}{q} = \frac{U_p - U_{\infty}}{q} = \frac{U_p}{q}$$

- Note :** (i) $(W_{\infty \rightarrow P})_{\text{ext}}$ can also be called as the work done by external agent against the electric force on a unit positive charge due to the source charge.
- (ii) Write both W and q with proper sign.

7.2 Properties :

- (i) Potential is a scalar quantity, its value may be positive, negative or zero.
- (ii) S.I. Unit of potential is volt = $\frac{\text{joule}}{\text{coulomb}}$ and its dimensional formula is $[M^1L^2T^{-3}I^{-1}]$.
- (iii) Electric potential at a point is also equal to the negative of the work done by the electric field in taking the point charge from reference point (i.e. infinity) to that point.
- (iv) Electric potential due to a positive charge is always positive and due to negative charge it is always negative except at infinite. (taking $V_{\infty} = 0$).
- (v) Potential decreases in the direction of electric field.
- (vi) $V = V_1 + V_2 + V_3 + \dots$

7.3 Use of potential :

If we know the potential at some point (in terms of numerical value or in terms of formula) then we can find out the work done by electric force when charge moves from point 'P' to ∞ by the formula

$$W_{\text{el}})_{P \rightarrow \infty} = qV_P$$

Solved Examples

Example 47 A charge $2\mu\text{C}$ is taken from infinity to a point in an electric field, without changing its velocity. If work done against electrostatic forces is $-40\mu\text{J}$ then find the potential at that point.

Solution.
$$V = \frac{W_{\text{ext}}}{q} = \frac{-40\mu\text{J}}{2\mu\text{C}} = -20\text{ V}$$

Example 48 When charge $10\mu\text{C}$ is shifted from infinity to a point in an electric field, it is found that work done by electrostatic forces is $-10\mu\text{J}$. If the charge is doubled and taken again from infinity to the same point without accelerating it, then find the amount of work done by electric field and against electric field.

Solution.
$$W_{\text{ext}})_{\infty P} = -W_{\text{el}})_{\infty P} = W_{\text{el}})_{P \rightarrow \infty} = 10\mu\text{J}$$

$$\text{because } \Delta KE = 0 \quad \Rightarrow \quad V_P = \frac{W_{\text{ext}})_{\infty P}}{q} = \frac{10\mu\text{J}}{10\mu\text{C}} = 1\text{V}$$

So if now the charge is doubled and taken from infinity then

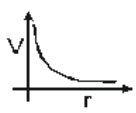

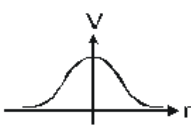

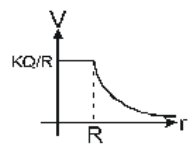

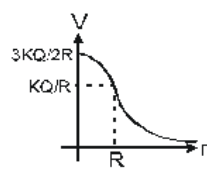

$$1 = \frac{W_{\text{ext}})_{\infty P}}{20\mu\text{C}} \quad \Rightarrow \quad W_{\text{ext}})_{\infty P} = 20\mu\text{J} \quad \Rightarrow \quad W_{\text{el}})_{\infty P} = -20\mu\text{J}$$

Example 49 A charge $3\mu\text{C}$ is released at rest from a point P where electric potential is 20 V then its kinetic energy when it reaches to infinite is :

Solution.
$$W_{\text{el}} = \Delta K = K_f - 0$$

$$W_{\text{el}})_{P \rightarrow \infty} = qV_P = 60\mu\text{J} \quad \text{So, } K_f = 60\mu\text{J}$$

Electric Potential due to various charge distributions are given in table.

Name / Type	Formula	Note	Graph
Point charge	$\frac{Kq}{r}$	<ul style="list-style-type: none"> * q is source charge. * r is the distance of the point from the point charge. 	
Ring (uniform/nonuniform charge distribution)	at centre $\frac{KQ}{R}$ at the axis $\frac{KQ}{\sqrt{R^2 + x^2}}$	<ul style="list-style-type: none"> * Q is source charge. * x is the distance of the point on the axis 	
Uniformly charged hollow conducting/nonconducting /solid conducting sphere	for $r \geq R$ $V = \frac{kQ}{r}$ for $r \leq R$ $V = \frac{kQ}{R}$	<ul style="list-style-type: none"> * R is radius of sphere * r is the distance from centre of sphere to the point * Q is total charge $= \sigma 4\pi R^2$. 	
Uniformly charged solid nonconducting	for $r > R$ $V = \frac{kQ}{r}$ for $r \leq R$ $\frac{KQ(3R^2 - r^2)}{2R^3}$ $= \frac{\rho}{6\epsilon_0} (3R^2 - r^2)$	<ul style="list-style-type: none"> * R is radius of sphere * r is distance from centre to the point * $V_{\text{centre}} = \frac{3}{2} V_{\text{surface}}$ * Q is total charge $= \rho \frac{4}{3} \pi R^3$. * Inside sphere potential varies parabolically * outside potential varies hyperbolically.

Infinite nonconducting thin sheet	Not defined	<ul style="list-style-type: none"> * Absolute potential is not defined. * Potential difference between two points is given by formula $V_B - V_A = -\frac{\sigma}{2\epsilon_0} (r_B - r_A)$ 	
Infinite charged conducting thin sheet	Not defined	<ul style="list-style-type: none"> * Absolute potential is not defined. * Potential difference between two points is given by formula $V_B - V_A = \frac{\sigma}{\epsilon_0} (r_B - r_A)$ 	

7.4 Potential due to a point charge :

Derivation of expression for potential due to point charge Q, at a point which is at a distance r from the point charge.
from definition potential

$$V = \frac{W_{\text{ext}(\infty \rightarrow P)}}{q_0} = \frac{-\int_{\infty}^r (q_0 \vec{E}) \cdot d\vec{r}}{q_0} = -\int_{\infty}^r \vec{E} \cdot d\vec{r} \Rightarrow V = -\int_{\infty}^r \frac{KQ}{r^2} (-dr) \cos 180^\circ = \frac{KQ}{r}$$

Solved Examples

Example 50 Four point charges are placed at the corners of a square of side ℓ calculate potential at the centre of square.

Solution. $V = 0$ at 'C'.

Example 51 Two point charges $2\mu\text{C}$ and $-4\mu\text{C}$ are situated at points $(-2\text{m}, 0\text{m})$ and $(2\text{m}, 0\text{m})$ respectively. Find out potential at point C. $(4\text{m}, 0\text{m})$ and D $(0\text{m}, \sqrt{5}\text{m})$.

Solution. Potential at point C

$$V_C = V_{q_1} + V_{q_2} = \frac{K(2\mu\text{C})}{6} + \frac{K(-4\mu\text{C})}{2} = \frac{9 \times 10^9 \times 2 \times 10^{-6}}{6} - \frac{9 \times 10^9 \times 4 \times 10^{-6}}{2} = -15000 \text{ V.}$$

$$\text{Similarly, } V_D = V_{q_1} + V_{q_2} = \frac{K(2\mu\text{C})}{\sqrt{(\sqrt{5})^2 + 2^2}} + \frac{K(-4\mu\text{C})}{\sqrt{(\sqrt{5})^2 + 2^2}} = \frac{K(2\mu\text{C})}{3} + \frac{K(-4\mu\text{C})}{3} = -6000 \text{ V.}$$

Finding potential due to continuous charges

If formula of E is tough, then we take

a small element and integrate

$$V = \int dv$$

If formula of E is easy then we use

$$V = -\int_{r \rightarrow \infty}^{r=r} \vec{E} \cdot d\vec{r}$$

(i.e. for sphere, plate infinite wire etc.)

Solved Examples

Example 52 A rod of length ℓ is uniformly charged with charge q calculate potential at point P.

Solution. Take a small element of length dx , at a distance x from left end. Potential due to this small element

$$dV = \frac{K(dq)}{x} \quad \text{total potential} \quad V = \int_{x=0}^{x=\ell} \frac{k dq}{x}$$

$$dq = \frac{q}{\ell} dx \Rightarrow V = \int_{x=r}^{x=r+\ell} \frac{K\left(\frac{q}{\ell} dx\right)}{x} = \frac{Kq}{\ell} \log_e \left(\frac{\ell+r}{r} \right)$$

7.5 Potential due to a ring :

(i) Potential at the centre of uniformly charged ring :Potential due to the small element dq

$$dV = \frac{Kdq}{R}$$

$$\text{Net potential } V = \int \frac{Kdq}{R}$$

$$V = \frac{K}{R} \int dq = \frac{Kq}{R}$$

**(ii) For non-uniformly charged ring potential at the center is**

$$V = \frac{Kq_{\text{total}}}{R}$$

**(iii) Potential due to half ring at center is :**

$$V = \frac{Kq}{R}$$

**(iv) Potential at the axis of a ring:**

Calculation of potential at a point on the axis which is a distance x from centre of uniformly charged (total charge Q) ring of radius R .

Consider an element of charge dq on the ring.

Potential at point p due to charge dq will be

$$dv = \frac{K(dq)}{\sqrt{R^2 + x^2}}$$

Net potential at point P due to all such element will be

$$V = \int dv = \frac{KQ}{\sqrt{R^2 + x^2}}$$

Solved Examples

Example 53

Figure shows two rings having charges Q and $-\sqrt{5}Q$. Find Potential difference between A and B ($V_A - V_B$).

Solution.

$$V_A = \frac{KQ}{R} + \frac{K(-\sqrt{5}Q)}{\sqrt{(2R)^2 + (R)^2}} \quad V_B = \frac{K(-\sqrt{5}Q)}{2R} + \frac{K(Q)}{\sqrt{(R)^2 + (R)^2}}$$

From above we can easily find $V_A - V_B$.

**Example 54**

A point charge q_0 is placed at the centre of uniformly charged ring of total charge Q and radius R . If the point charge is slightly displaced with negligible force along axis of the ring then find out its speed when it reaches to a large distance.

Solution.

Only electric force is acting on q_0

$$\begin{aligned} \therefore W_{el} = \Delta K &= \frac{1}{2} mv^2 - 0 \\ \Rightarrow \text{Now } W_{el})_{c \rightarrow \infty} &= q_0 V_c = q_0 \cdot \frac{KQ}{R} \\ \therefore \frac{Kq_0 Q}{R} &= \frac{1}{2} mv^2 \quad \Rightarrow \quad v = \sqrt{\frac{2Kq_0 Q}{mR}} \end{aligned}$$

7.6 Potential due to uniformly charged disc :

$V = \frac{\sigma}{2\epsilon_0} \left(\sqrt{R^2 + x^2} - x \right)$, where σ is the charged density and x is the distance of the point on the axis from the center of the disc, R is the radius of disc.

Finding potential due to a uniformly charged disc:

A disc of radius ' R ' has surface charge density (charge/area) = σ . We have to find potential at its axis, at point ' P ' which is at a distance x from the centre.

For this We can divide the disc into thin rings and let's consider a thin ring of radius r and thickness dr . Suppose charge on the small ring element = dq . Potential due to this ring at point ' P ' is

$$dV = \frac{Kdq}{\sqrt{r^2 + x^2}}$$

$$\text{So, net potential : } V_{net} = \int \frac{Kdq}{\sqrt{r^2 + x^2}}$$

Here, $\sigma = \text{charge/area} = \frac{dq}{d(\text{area})}$

So, $dq = \sigma \times d(\text{area}) = \sigma (2\pi r dr)$

(here $d(\text{area}) = \text{area of the small ring element} = (\text{length of ring}) \times (\text{width of the ring}) = (2\pi r) \cdot (dr)$)

$$\text{So, } V_{net} = \int_{r=0}^{r=R} \frac{K\sigma(2\pi r dr)}{\sqrt{r^2 + x^2}}$$

to integrate it let $r^2 + x^2 = y^2$

$2r dr = 2y dy$, substituting we will get :

$$V_{net} = \int_{r=0}^{r=R} \frac{1}{4\pi\epsilon_0} \frac{\sigma(2\pi)y dy}{y} \quad \Rightarrow \quad V_{net} = \frac{\sigma}{2\epsilon_0} [y]_{r=0}^{r=R}$$

$$V_{net} = \frac{\sigma}{2\epsilon_0} \left(\sqrt{r^2 + x^2} \right)_{r=0}^{r=R} \quad \Rightarrow \quad V_{net} = \frac{\sigma}{2\epsilon_0} \left(\sqrt{R^2 + x^2} - x \right)$$

If a test charge q_0 is placed at point P , then potential energy of this charge q_0 due to the disc = $U = q_0 V$

$$\Rightarrow U = q_0 \left[\frac{\sigma}{2\epsilon_0} \left(\sqrt{R^2 + x^2} - x \right) \right]$$

Graph of V v/s x : $V = \frac{\sigma}{2\epsilon_0} \left(\sqrt{R^2 + x^2} - x \right)$ at $x = 0$ $V = \frac{\sigma R}{2\epsilon_0}$

to check whether V will increase with x or decrease, let's multiply and divide by conjugate.

$$V = \frac{\sigma}{2\epsilon_0} \left(\sqrt{R^2 + x^2} - x \right) \times \frac{\left(\sqrt{R^2 + x^2} + x \right)}{\left(\sqrt{R^2 + x^2} + x \right)} \Rightarrow V = \frac{\sigma R^2}{2\epsilon_0} \left(\frac{1}{\left(\sqrt{R^2 + x^2} + x \right)} \right)$$

Now we can say that as $x \uparrow \Rightarrow V \downarrow$ so curve will be like this

7.7 Potential Due To Uniformly Charged Spherical shell :

Derivation of expression for potential due to uniformly charged hollow sphere of radius R and total charge Q , at a point which is at a distance r from centre for the following situation

(i) $r > R$ (ii) $r < R$

$$V = - \int_{r \rightarrow \infty}^{r=r} \vec{E} \cdot d\vec{r}$$

As the formula of E is easy, we use

(i) **At outside point ($r \geq R$):**

$$V_{\text{out}} = - \int_{r \rightarrow \infty}^{r=r} \left(\frac{KQ}{r^2} \right) dr \Rightarrow V_{\text{out}} = \frac{KQ}{r} = \frac{KQ}{(\text{Distance from centre})}$$

For outside point, the hollow sphere act like a point charge.

(ii) **Potential at the centre of the sphere ($r=0$):**

As all the charges are at a distance R from the centre,

$$\text{So } V_{\text{centre}} = \frac{KQ}{R} = \frac{KQ}{(\text{Radius of the sphere})}$$

(iii) **Potential at inside point ($r < R$):**

Suppose we want to find potential at point P , inside the sphere.

Potential difference between Point P and O :

$$V_P - V_O = - \int_O^P \vec{E}_{\text{in}} \cdot d\vec{r} \quad \text{Where } E_{\text{in}} = 0$$

$$\text{So } V_P - V_O = 0 \Rightarrow V_P = V_O = \frac{KQ}{R}$$

$$\Rightarrow V_{\text{in}} = \frac{KQ}{R} = \frac{KQ}{(\text{Radius of the sphere})}$$

7.8 Potential Due To Uniformly Charged Solid Sphere :

Derivation of expression for potential due to uniformly charged solid sphere of radius R and total charge Q (distributed in volume), at a point which is at a distance r from centre for the following situations.

(i) $r \geq R$ (ii) $r \leq R$

Consider an elementary shell of radius x and width dx

(i) for $r \geq R$

$$V = \int_0^R \frac{K \cdot 4\pi x^2 dx \rho}{r} = \frac{KQ}{r}$$

(ii) for $r \leq R$

$$V = \int_0^r \frac{K \cdot 4\pi x^2 dx \rho}{r} + \int_r^R \frac{K 4\pi x^2 dx \rho}{x}$$

$$= \frac{KQ}{2R^3} (3R^2 - r^2) \Rightarrow \rho = \frac{Q}{\frac{4}{3}\pi R^3}$$

From definition of potential(i) $r \geq R$

$$V = - \int_{\infty}^r \frac{KQ}{r^2} \hat{r} \cdot d\mathbf{r} = \frac{KQ}{r}$$

(ii) $r \leq R$

$$V = - \int_{\infty}^R \frac{KQ}{r^2} \cdot dr - \int_R^r \frac{KQr}{R^3} dr$$

$$V = \frac{KQ}{R} - \frac{KQ}{2R^3} [r^2 - R^2] = \frac{KQ}{2R^3} [2R^2 - r^2 + R^2] = \frac{KQ}{2R^3} (3R^2 - r^2)$$

Solved Examples

Example 55

Two concentric spherical shells of radius R_1 and R_2 ($R_2 > R_1$) are having uniformly distributed charges Q_1 and Q_2 respectively. Find out potential

(i) at point A

(ii) at surface of smaller shell (i.e. at point B)

(iii) at surface of larger shell (i.e. at point C)

(iv) at $r \leq R_1$ (v) at $R_1 \leq r \leq R_2$ (vi) at $r \geq R_2$ **Solution.**

Using the results of hollow sphere as given in the table 7.4.

$$(i) \quad V_A = \frac{KQ_1}{R_1} + \frac{KQ_2}{R_2}$$

$$(ii) \quad V_B = \frac{KQ_1}{R_1} + \frac{KQ_2}{R_2}$$

$$(iii) \quad V_C = \frac{KQ_1}{R_2} + \frac{KQ_2}{R_2}$$

$$(iv) \quad \text{for } r \leq R_1 \Rightarrow V = \frac{KQ_1}{R_1} + \frac{KQ_2}{R_2}$$

$$(v) \quad \text{for } R_1 \leq r \leq R_2 \quad V = \frac{KQ_1}{r} + \frac{KQ_2}{R_2}$$

$$(vi) \quad \text{for } r \geq R_2 \quad V = \frac{KQ_1}{r} + \frac{KQ_2}{r}$$

Example 56

Two hollow concentric nonconducting spheres of radius a and b ($a > b$) contains charges Q_a and Q_b respectively. Prove that potential difference between two spheres is independent of charge on outer sphere. If outer sphere is given an extra charge, is there any change in potential difference?

Solution.

$$V_{\text{inner sphere}} = \frac{KQ_b}{b} + \frac{KQ_a}{a}$$

$$V_{\text{outer sphere}} = \frac{KQ_b}{a} + \frac{KQ_a}{a}$$

$$V_{\text{inner sphere}} - V_{\text{outer sphere}} = \frac{KQ_b}{b} - \frac{KQ_b}{a} \Rightarrow \Delta V = KQ_b \left[\frac{1}{b} - \frac{1}{a} \right]$$

Which is independent of charge on outer sphere. If outer sphere is given any extra charge then there will be no change in potential difference.

8. POTENTIAL DIFFERENCE

The potential difference between two points A and B is work done by external agent against electric field in taking a unit positive charge from A to B without acceleration (or keeping Kinetic Energy constant or $K_i = K_f$)

(a) Mathematical representation :

If $(W_{A \rightarrow B})_{\text{ext}}$ = work done by external agent against electric field in taking the unit charge from A to B.

$$V_B - V_A = \frac{(W_{A \rightarrow B})_{\text{ext}}}{q} \Big|_{\Delta K=0} = \frac{-(W_{A \rightarrow B})_{\text{electric}}}{q} = \frac{U_B - U_A}{q} = \frac{-\int_A^B \vec{F}_e \cdot d\vec{r}}{q} = \frac{-\int_A^B \vec{E} \cdot d\vec{r}}{q}$$

Note : Take W and q both with sign

(b) Properties :

- (i) The difference of potential between two points is called potential difference. It is also called voltage.
- (ii) Potential difference is a scalar quantity. Its S.I. unit is also volt.
- (iii) If V_A and V_B be the potential of two points A and B, then work done by an external agent in taking the charge q from A to B is
 $(W_{\text{ext}})_{AB} = q(V_B - V_A)$ or $(W_{\text{el}})_{AB} = q(V_A - V_B)$.
- (iv) Potential difference between two points is independent of reference point.

8.1 Potential difference in a uniform electric field :

$$V_B - V_A = -\vec{E} \cdot \vec{AB}$$

$$\Rightarrow V_B - V_A = -|E| |AB| \cos \theta \\ = -|E| d = -Ed$$

d = effective distance between A and B along electric field.

$$\text{or we can also say that } E = \frac{\Delta V}{\Delta d}$$

Special Cases :

Case 1. Line AB is parallel to electric field.

$$\therefore V_A - V_B = Ed$$

Case 2. Line AB is perpendicular to electric field.

$$\therefore V_A - V_B = 0 \Rightarrow V_A = V_B$$

Note : In the direction of electric field potential always decreases.

Solved Examples

Example 57. $1\mu\text{C}$ charge is shifted from A to B and it is found that work done by an external force is $40\mu\text{J}$ in doing so against electrostatic forces then, find potential difference $V_A - V_B$

Solution. $(W_{AB})_{\text{ext}} = q(V_B - V_A) \Rightarrow 40\mu\text{J} = 1\mu\text{C} (V_B - V_A) \Rightarrow V_A - V_B = -40$

Example 58. A uniform electric field is present in the positive x-direction. If the intensity of the field is 5N/C then find the potential difference $(V_B - V_A)$ between two points A (0m, 2 m) and B (5 m, 3 m)

Solution. $V_B - V_A = -\vec{E} \cdot \vec{AB} = -(5\hat{i}) \cdot (5\hat{i} + \hat{j}) = -25\text{V}.$

$$\frac{\Delta V}{\Delta d}$$

The electric field intensity in uniform electric field, $E = \frac{\Delta V}{\Delta d}$

Where ΔV = potential difference between two points.

Δd = effective distance between the two points.

(projection of the displacement along the direction of electric field.)

Example 59. Find out following

(i) $V_A - V_B$ (ii) $V_B - V_C$

(iii) $V_C - V_A$ (iv) $V_D - V_C$

(v) $V_A - V_D$

(vi) Arrange the order of potential for points A, B, C and D.

Solution.

(i) $|\Delta V_{AB}| = Ed = 20 \times 2 \times 10^{-2} = 0.4$

so, $V_A - V_B = 0.4\text{ V}$

because **In the direction of electric field potential always decreases.**

(ii) $|\Delta V_{BC}| = Ed = 20 \times 2 \times 10^{-2} = 0.4$ so, $V_B - V_C = 0.4\text{ V}$

(iii) $|\Delta V_{CA}| = Ed = 20 \times 4 \times 10^{-2} = 0.8$ so, $V_C - V_A = -0.8\text{ V}$

because **In the direction of electric field potential always decreases.**

(iv) $|\Delta V_{DC}| = Ed = 20 \times 0 = 0$ so, $V_D - V_C = 0$

because the effective distance between D and C is zero.

(v) $|\Delta V_{AD}| = Ed = 20 \times 4 \times 10^{-2} = 0.8$ so, $V_A - V_D = 0.8\text{ V}$

because **In the direction of electric field potential always decreases.**

(vi) The order of potential

$V_A > V_B > V_C = V_D$.

8.2 Potential difference due to infinitely long wire :

Derivation of expression for potential difference between two points, which have perpendicular distance r_A and r_B from infinitely long line charge of uniform linear charge density λ .

From definition of potential difference

$$V_{AB} = V_B - V_A = -\int_{r_A}^{r_B} \vec{E} \cdot d\vec{r} = -\int_{r_A}^{r_B} \frac{2K\lambda}{r} \hat{r} \cdot d\vec{r}$$

$$V_{AB} = -2K\lambda \ln \left(\frac{r_B}{r_A} \right)$$

8.3 Potential difference due to infinitely long thin sheet:

Derivation of expression for potential difference between two points, having separation d in the direction perpendicularly to a very large uniformly charged thin sheet of uniform surface charge density σ .

Let the points A and B have perpendicular distance r_A and r_B respectively then from definition of potential difference.

$$V_{AB} = V_B - V_A = - \int_{r_A}^{r_B} \vec{E} \cdot d\vec{r} = - \int_{r_A}^{r_B} \frac{\sigma}{2\epsilon_0} \hat{r} \cdot d\vec{r} \Rightarrow V_{AB} = - \frac{\sigma}{2\epsilon_0} (r_B - r_A) = - \frac{\sigma d}{2\epsilon_0}$$

**9. EQUIPOTENTIAL SURFACE :**

9.1 Definition : If potential of a surface (imaginary or physically existing) is same throughout then such surface is known as a equipotential surface.

9.2 Properties of equipotential surfaces :

- (i) When a charge is shifted from one point to another point on an equipotential surface then work done against electrostatic forces is zero.
- (ii) Electric field is always perpendicular to equipotential surfaces.
- (iii) Two equipotential surfaces do not cross each other.

9.3 Examples of equipotential surfaces :**(i) Point charge :**

Equipotential surfaces are concentric and spherical as shown in figure. In figure we can see that sphere of radius R_1 has potential V_1 throughout its surface and similarly for other concentric sphere potential is same.

**(ii) Line charge :**

Equipotential surfaces have curved surfaces as that of coaxial cylinders of different radii.

**(iii) Uniformly charged large conducting / non conducting sheets**
Equipotential surfaces are parallel planes.

Note : In uniform electric field equipotential surfaces are always parallel planes.

Solved Examples

Example 60 Some equipotential surfaces are shown in figure. What can you say about the magnitude and the direction of the electric field ?

Solution. Here we can say that the electric field will be perpendicular to equipotential surfaces.

Also $|\vec{E}| = \frac{\Delta V}{\Delta d}$

where ΔV = potential difference between two equipotential surfaces.
 Δd = perpendicular distance between two equipotential surfaces.

So $|\vec{E}| = \frac{10}{(10 \sin 30^\circ) \times 10^{-2}} = 200 \text{ V/m}$

Now there are two perpendicular directions either direction 1 or direction 2 as shown in figure, but since we know that in the direction of electric field electric potential decreases so the correct direction is direction 2.

Hence $E = 200 \text{ V/m}$, making an angle 120° with the x-axis

Example 61 Figure shows some equipotential surface produce by some charges. At which point the value of electric field is greatest?

Solution. E is larger where equipotential surfaces are closer. E is \perp to equipotential surfaces. In the figure we can see that for point B they are closer so E at point B is maximum

10. ELECTROSTATIC POTENTIAL ENERGY

10.1 Electrostatic potential energy of a point charge due to many charges :

The electrostatic potential energy of a point charge at a point in electric field is the work done in taking the charge from reference point (generally at infinity) to that point without acceleration (or keeping KE const. or $K_i = K_f$).

Its Mathematical formula is

$$U = W_{\alpha P)_{\text{ext}}}]_{\text{acc} = 0} = qV = -W_{P\alpha)_{\text{el}}}$$

Here q is the charge whose potential energy is being calculated and V is the potential at its position due to the source charges.

Note : Always put q and V with sign.

10.2 Properties :

- Electric potential energy is a scalar quantity but may be positive, negative or zero.
- Its unit is same as unit of work or energy that is joule (in S.I. system).
 Some times energy is also given in electron-volts.
 $1\text{eV} = 1.6 \times 10^{-19} \text{ J}$
- Electric potential energy depends on reference point. (Generally Potential Energy at $r = \infty$ is taken zero)

Solved Examples

Example 62 The four identical charges q each are placed at the corners of a square of side a . Find the potential energy of one of the charges due to the remaining charges.

Solution. The electric potential of point A due to the charges placed at B, C and D is

$$V = \frac{1}{4\pi\epsilon_0} \frac{q}{a} + \frac{1}{4\pi\epsilon_0} \frac{q}{\sqrt{2}a} + \frac{1}{4\pi\epsilon_0} \frac{q}{a} = \frac{1}{4\pi\epsilon_0} \left(2 + \frac{1}{\sqrt{2}} \right) \frac{q}{a}$$

$$\therefore \text{Potential energy of the charge at A is } = qV = \frac{1}{4\pi\epsilon_0} \left(2 + \frac{1}{\sqrt{2}} \right) \frac{q^2}{a}$$

Example 63 A particle of mass 40 mg and carrying a charge 5×10^{-9} C is moving directly towards a fixed positive point charge of magnitude 10^{-8} C. When it is at a distance of 10 cm from the fixed point charge it has speed of 50 cm/s. At what distance from the fixed point charge will the particle come momentarily to rest? Is the acceleration constant during the motion?

Solution. If the particle comes to rest momentarily at a distance r from the fixed charge, then from conservation of energy we have

$$\frac{1}{2}mu^2 + \frac{1}{4\pi\epsilon_0} \frac{Qq}{a} = \frac{1}{4\pi\epsilon_0} \frac{Qq}{r}$$

Substituting the given data, we get

$$\frac{1}{2} \times 40 \times 10^{-6} \times \frac{1}{2} \times \frac{1}{2} = 9 \times 10^9 \times 5 \times 10^{-8} \times 10^{-9} \left[\frac{1}{r} - 10 \right]$$

$$\text{or } -10 = \frac{5 \times 10^{-6}}{9 \times 5 \times 10^{-8}} = \frac{100}{9} \Rightarrow \frac{1}{r} = \frac{190}{9} \Rightarrow r = \frac{9}{190} \text{ m} \quad \text{or i.e., } r = 4.7 \times 10^{-2} \text{ m}$$

$$\text{As here, } F = \frac{1}{4\pi\epsilon_0} \frac{Qq}{r^2} \quad \text{so } \text{acc.} = \frac{F}{m} \propto \frac{1}{r^2}$$

i.e., acceleration is not constant during the motion.

Example 64 A proton moves from a large distance with a speed u m/s directly towards a free proton originally at rest. Find the distance of closest approach for the two protons in terms of mass of proton m and its charge e .

Solution. As here the particle at rest is free to move, when one particle approaches the other, due to electrostatic repulsion other will also start moving and so the velocity of first particle will decrease while of other will increase and at closest approach both will move with same velocity. So if v is the common velocity of each particle at closest approach, then by 'conservation of momentum' of the two protons system.

$$mu = mv + mv \quad \text{i.e., } v = \frac{1}{2}u$$

And by conservation of energy

$$\frac{1}{2}mu^2 = \frac{1}{2}mv^2 + \frac{1}{2}mv^2 + \frac{1}{4\pi\epsilon_0} \frac{e^2}{r} \Rightarrow \frac{1}{2}mu^2 - m\left(\frac{u}{2}\right)^2 = \frac{1}{4\pi\epsilon_0} \frac{e^2}{r} \quad [\text{as } v = \frac{u}{2}]$$

$$\Rightarrow \frac{1}{4}mu^2 = \frac{e^2}{4\pi\epsilon_0 r} \Rightarrow r = \frac{e^2}{\pi m \epsilon_0 u^2}$$

11. ELECTROSTATIC POTENTIAL ENERGY OF A SYSTEM OF CHARGES

(This concept is useful when more than one charges move.)

It is the work done by an external agent against the internal electric field required to make a system of charges in a particular configuration from infinite separation without accelerating it.

11.1 Types of system of charge

- (i) Point charge system (ii) Continuous charge system.

11.2 Derivation for a system of point charges:

- (i) Keep all the charges at infinity. Now bring the charges one by one to its corresponding position and find work required. PE of the system is algebraic sum of all the works.

Let W_1 = work done in bringing first charge

W_2 = work done in bringing second charge against force due to 1st charge.

W_3 = work done in bringing third charge against force due to 1st and 2nd charge.

$$PE = W_1 + W_2 + W_3 + \dots \quad \left(\text{This will contain } \frac{n(n-1)}{2} = {}^nC_2 \text{ terms} \right)$$

- (ii) Method of calculation (to be used in problems)

U = sum of the interaction energies of the charges.

$$= (U_{12} + U_{13} + \dots + U_{1n}) + (U_{23} + U_{24} + \dots + U_{2n}) + (U_{34} + U_{35} + \dots + U_{3n}) \dots$$

- (iii) Method of calculation useful for symmetrical point charge systems.

Find PE of each charge due to rest of the charges.

If U_1 = PE of first charge due to all other charges.

$$= (U_{12} + U_{13} + \dots + U_{1n})$$

U_2 = PE of second charge due to all other charges.

$$= (U_{21} + U_{23} + \dots + U_{2n}) \quad \text{then } U = PE \text{ of the system} = \frac{U_1 + U_2 + \dots + U_n}{2}$$

Solved Examples

Example 65. Find out potential energy of the two point charge system having q_1 and q_2 charges separated by distance r .

Solution. Let both the charges be placed at a very large separation initially.

Let W_1 = work done in bringing charge q_1 in absence of q_2 = $q(V_f - V_i) = 0$

W_2 = work done in bringing charge q_2 in presence of q_1 = $q(V_f - V_i) = q_1(Kq_2/r - 0)$

$$PE = W_1 + W_2 = 0 + Kq_1q_2/r = Kq_1q_2/r$$

Example 66. Figure shows an arrangement of three point charges. The total

potential energy of this arrangement is zero. Calculate the ratio $\frac{q}{Q}$.

Solution.
$$U_{\text{sys}} = \frac{1}{4\pi\epsilon_0} \left[\frac{-qQ}{r} + \frac{(+q)(+q)}{2r} + \frac{Q(-q)}{r} \right] = 0 \Rightarrow -Q + \frac{q}{2} - Q = 0 \quad \text{or} \quad 2Q = \frac{q}{2} \quad \text{or} \quad \frac{q}{Q} = \frac{4}{1}.$$

Example 67 Two point charges each of mass m and charge q are released when they are at a distance r from each other. What is the speed of each charge particle when they are at a distance $2r$?

Solution. According to momentum conservation both the charge particles will move with same speed now applying energy conservation.

$$0 + 0 + \frac{Kq^2}{r} = 2 \cdot \frac{1}{2}mv^2 + \frac{Kq^2}{2r} \Rightarrow v = \sqrt{\frac{Kq^2}{2rm}}$$

Example 68 Two charged particles each having equal charges 2×10^{-5} C are brought from infinity to within a separation of 10 cm. Calculate the increase in potential energy during the process and the work required for this purpose.

Solution. $\Delta U = U_f - U_i = U_f - 0 = U_f$

We have to simply calculate the electrostatic potential energy of the given system of charges

$$\Delta U = U_f = \frac{1}{4\pi\epsilon_0} \frac{q_1q_2}{r} = \frac{9 \times 10^9 \times 2 \times 10^{-5} \times 2 \times 10^{-5} \times 100}{10} \text{ J} = 36 \text{ J}$$

work required = 36 J.

Example 69 Three equal charges q are placed at the corners of an equilateral triangle of side a .

- (i) Find out potential energy of charge system.
 (ii) Calculate work required to decrease the side of triangle to $a/2$.
 (iii) If the charges are released from the shown position and each of them has same mass m then find the speed of each particle when they lie on triangle of side $2a$.

Solution.

(i) Method I (Derivation)

Assume all the charges are at infinity initially.

work done in putting charge q at corner A

$$W_1 = q(v_f - v_i) = q(0 - 0)$$

Since potential at A is zero in absence of charges, work done in putting q at corner B in presence of charge at A :

$$W_2 = \left(\frac{Kq}{a} - 0 \right) = \frac{Kq^2}{a}$$

Similarly work done in putting charge q at corner C in presence of charge at A and B.

$$W_3 = q(v_f - v_i) = q \left[\left(\frac{Kq}{a} + \frac{Kq}{a} \right) - 0 \right]$$

So net potential energy $PE = W_1 + W_2 + W_3$

$$= 0 + \frac{Kq^2}{a} + \frac{2Kq^2}{a} = \frac{3Kq^2}{a}$$

Method II (using direct formula)

$$U = U_{12} + U_{13} + U_{23} = \frac{Kq^2}{a} + \frac{Kq^2}{a} + \frac{Kq^2}{a} = \frac{3Kq^2}{a}$$

(ii) Work required to decrease the sides $W = U_f - U_i = \frac{3Kq^2}{a/2} - \frac{3Kq^2}{a} = \frac{3Kq^2}{a}$

(iii) Work done by electrostatic forces = change in kinetic energy of particles.

$$U_i - U_f = K_f - K_i \Rightarrow \frac{3Kq^2}{a} - \frac{3Kq^2}{2a} = 3\left(\frac{1}{2}mv^2\right) - 0 \Rightarrow v = \sqrt{\frac{Kq^2}{am}}$$

Example 70

Four identical point charges q are placed at four corners of a square of side a . Find out potential energy of the charge system

Solution.

Method 1 (using direct formula) : $U = U_{12} + U_{13} + U_{14} + U_{23} + U_{24} + U_{34}$

$$= \frac{Kq^2}{a} + \frac{Kq^2}{a\sqrt{2}} + \frac{Kq^2}{a} + \frac{Kq^2}{a} + \frac{Kq^2}{a\sqrt{2}} + \frac{Kq^2}{a}$$

$$= \left[\frac{4Kq^2}{a} + \frac{2Kq^2}{a\sqrt{2}} \right] = \frac{2Kq^2}{a} \left[2 + \frac{1}{\sqrt{2}} \right]$$

Method 2 [using $U = \frac{1}{2} (U_1 + U_2 + \dots)$]:

U_1 = total P.E. of charge at corner 1 due to all other charges

U_2 = total P.E. of charge at corner 2 due to all other charges

U_3 = total P.E. of charge at corner 3 due to all other charges

U_4 = total P.E. of charge at corner 4 due to all other charges

Since due to symmetry $U_1 = U_2 = U_3 = U_4$

$$U_{\text{Net}} = \frac{U_1 + U_2 + U_3 + U_4}{2} = 2U_1 = 2 \left[\frac{Kq^2}{a} + \frac{Kq^2}{a} + \frac{Kq^2}{\sqrt{2}a} \right] = \frac{2Kq^2}{a} \left[2 + \frac{1}{\sqrt{2}} \right]$$

Example 71

Six equal point charges q are placed at six corners of a hexagon of side

a. Find out potential energy of charge system

Solution. $U_{\text{Net}} = \frac{U_1 + U_2 + U_3 + U_4 + U_5 + U_6}{2}$

Due to symmetry $U_1 = U_2 = U_3 = U_4 = U_5 = U_6$ so $U_{\text{net}} = 3U_1 = \frac{3Kq^2}{a} \left[2 + \frac{2}{\sqrt{3}} + \frac{1}{2} \right]$

11.3 Derivation of electric potential energy for continues charge system :

This energy is also known as self energy.

(i) Finding P.E. (Self Energy) of a uniformly Charged spherical shell :-

For this, lets use method 1. Take an uncharged shell Now bring charges one by one from infinite to the surface fo the shell. The work required in this process will be stored as potential Energy.

Suppose we have given q charge to the sphere and now we are giving extra dq charge to it.

Work required to bring dq charge from infinite to them shell is

$$dw = (dq) (V_f - V_i)$$

$$\Rightarrow dW = (dq) \left(\frac{Kq}{R} - 0 \right) = \frac{Kq}{R} dq$$

$$\Rightarrow \text{total work required to give } Q \text{ charge is } W = \int_{q=0}^{q=Q} \frac{Kq}{R} dq = \frac{KQ^2}{2R}$$

This work will stored as a form of P.E. (self energy)

$$\text{So P.E. of a charged spherical shall } U = \frac{KQ^2}{2R}$$

(ii) Self energy of uniformly charged solid sphere :

In this case we have to assemble a solid charged sphere. So as we bring the charges one-by-one from infinite to the sphere, the size of me sphere will increase. Suppose we have given q charge to the sphere, and its radius becomes ' x '. Now we are giving extra dq charge to it, which will increase its radius by ' dx ' work required to bring dq charge from infinite to the sphere

$$= dq (V_f - V_i) = (dq) \left(\frac{Kq}{x} - 0 \right) = \frac{Kq dq}{x}$$

$$\text{total work required to give } Q \text{ charge : } W = \int \frac{Kq dq}{x} \quad q = \rho \left(\frac{4}{3} \pi x^3 \right)$$

$$dq = \rho (4 \pi x^2 dx) \Rightarrow W = \int_{x=0}^{x=R} K \frac{\rho \left(\frac{4}{3} \pi x^3 \right) \rho (4 \pi x^2 dx)}{x}$$

$$\text{solving well get } W = \frac{3}{5} \frac{KQ^2}{R} = U_{\text{self}} \text{ for a solid sphere}$$

Solved Examples

Example 72 A spherical shell of radius R with uniform charge q is expanded to a radius $2R$. Find the work performed by the electric forces and external agent against electric forces in this process (slow process).

Solution.

$$W_{\text{ext}} = U_f - U_i = \frac{q^2}{16\pi\epsilon_0 R} - \frac{q^2}{8\pi\epsilon_0 R} = -\frac{q^2}{16\pi\epsilon_0 R}$$

$$W_{\text{elec}} = U_i - U_f = \frac{q^2}{8\pi\epsilon_0 R} - \frac{q^2}{16\pi\epsilon_0 R} = \frac{q^2}{16\pi\epsilon_0 R}$$

Example 73 Two nonconducting hollow uniformly charged spheres of radii R_1 and R_2 with charge Q_1 and Q_2 respectively are placed at a distance r . Find out total energy of the system.

Solution.

$$U_{\text{total}} = U_{\text{self}} + U_{\text{interaction}} = \frac{Q_1^2}{8\pi\epsilon_0 R_1} + \frac{Q_2^2}{8\pi\epsilon_0 R_2} + \frac{Q_1 Q_2}{4\pi\epsilon_0 r}$$

Example 74 Two concentric spherical shells of radius R_1 and R_2 ($R_2 > R_1$) are having uniformly distributed charges Q_1 and Q_2 respectively. Find out total energy of the system.

Solution.

$$U_{\text{total}} = U_{\text{self } 1} + U_{\text{self } 2} + U_{\text{interaction}} = \frac{Q_1^2}{8\pi\epsilon_0 R_1} + \frac{Q_2^2}{8\pi\epsilon_0 R_2} + \frac{Q_1 Q_2}{4\pi\epsilon_0 R_2}$$

11.4 Energy density :

Def: Energy density is defined as energy stored in unit volume in any electric field. Its mathematical

formula is given as following : Energy density = $\frac{1}{2} \epsilon E^2$

where E = electric field intensity at that point ; $\epsilon = \epsilon_0 \epsilon_r$ electric permittivity of medium

Solved Examples

Example 75 Find out energy stored in an imaginary cubical volume of side a in front of a infinitely large nonconducting sheet of uniform charge density σ .

Solution.

Energy stored $U = \int \frac{1}{2} \epsilon_0 E^2 dV$ where dV is small volume

$$= \frac{1}{2} \epsilon_0 E^2 \int dV$$

\therefore E is constant = $\frac{1}{2} \epsilon_0 \frac{\sigma^2}{4\epsilon_0^2} \cdot a^3 = \frac{\sigma^2 a^3}{8\epsilon_0}$

Example 76. Find out energy stored in the electric field of uniformly charged thin spherical shell of total charge Q and radius R .

Solution. We know that electric field inside the shell is zero so the energy is stored only outside the shell. Which can be calculated by using energy density formula.

$$U_{\text{self}} = \int_{x=R}^{x \rightarrow \infty} \frac{1}{2} \epsilon_0 E^2 dV$$

Consider an elementary shell of thickness dx and radius x ($x > R$).
Volume of the shell = $(4\pi x^2 dx)$

$$U = \int_R^\infty \frac{1}{2} \epsilon_0 \left[\frac{KQ}{x^2} \right]^2 \cdot 4\pi x^2 dx = \frac{1}{2} \epsilon_0 K^2 Q^2 4\pi \int_R^\infty \frac{1}{x^2} dx$$

$$= \frac{4\pi\epsilon_0}{2} \frac{Q^2}{(4\pi\epsilon_0)^2} \cdot \left(-\frac{1}{R} \right) = \frac{Q^2}{8\pi\epsilon_0 R} = \frac{KQ^2}{2R}$$

Example 77. Find out energy stored inside a solid nonconducting sphere of total charge Q and radius R . [Assume charge is uniformly distributed in its volume.]

Solution. We can consider solid sphere to be made of large number of concentric spherical. Also electric field intensity at the location of any particular shell is constant.

$$U_{\text{inside}} = \int_0^R \frac{1}{2} \epsilon_0 E^2 dV$$

Consider an elementary shell of thickness dx and radius x .

Volume of the shell $= (4\pi x^2 dx)$

$$\begin{aligned} U_{\text{inside}} &= \int_0^R \frac{1}{2} \epsilon_0 \left[\frac{KQx}{R^3} \right]^2 \cdot 4\pi x^2 dx = \frac{1}{2} \epsilon_0 \frac{K^2 Q^2 4\pi}{R^6} \int_0^R x^4 dx \\ &= \frac{4\pi \epsilon_0}{2R^6} \frac{Q^2}{(4\pi \epsilon_0)^2} \cdot \frac{R^5}{5} = \frac{Q^2}{40\pi \epsilon_0 R} = \frac{KQ^2}{10R} \end{aligned}$$

12. RELATION BETWEEN ELECTRIC FIELD INTENSITY AND ELECTRIC POTENTIAL

12.1 For uniform electric field :

- (i) Potential difference between two points A and B

$$V_B - V_A = - \vec{E} \cdot \vec{AB}$$

12.2 Non uniform electric field

$$\begin{aligned} \text{(i)} \quad E_x &= -\frac{\partial V}{\partial x}, E_y = -\frac{\partial V}{\partial y}, E_z = -\frac{\partial V}{\partial z} \Rightarrow \vec{E} = E_x \hat{i} + E_y \hat{j} + E_z \hat{k} \\ &= - \left[\hat{i} \frac{\partial}{\partial x} V + \hat{j} \frac{\partial}{\partial y} V + \hat{k} \frac{\partial}{\partial z} V \right] = - \left[\hat{i} \frac{\partial}{\partial x} + \hat{j} \frac{\partial}{\partial y} + \hat{k} \frac{\partial}{\partial z} \right] V \\ &= - \nabla V = -\text{grad } V \end{aligned}$$

Where $\frac{\partial V}{\partial x}$ = derivative of V with respect to x (keeping y and z constant)

$\frac{\partial V}{\partial y}$ = derivative of V with respect to y (keeping z and x constant)

$\frac{\partial V}{\partial z}$ = derivative of V with respect to z (keeping x and y constant)

12.3 If electric potential and electric field depends only on one coordinate, say r :

$$\text{(i)} \quad \vec{E} = - \frac{\partial V}{\partial r} \hat{r} \quad \text{where } \hat{r} \text{ is a unit vector along increasing } r.$$

$$\text{(ii)} \quad \int_{r_A}^{r_B} dV = - \int_{r_A}^{r_B} \vec{E} \cdot \frac{d\vec{r}}{dr} \Rightarrow V_B - V_A = - \int_{r_A}^{r_B} \vec{E} \cdot \vec{dr}$$

$\frac{d\vec{r}}{dr}$ is along the increasing direction of r .

$$\text{(iii)} \quad \text{The potential of a point } V = - \int_{\infty}^r \vec{E} \cdot \vec{dr}$$

Solved Examples

Example 78 A uniform electric field is along x - axis . The potential difference $V_A - V_B = 10$ V between two points A (2m , 3m) and B (4m, 8m). Find the electric field intensity.

$$\text{Solution.} \quad E = \frac{\Delta V}{\Delta d} = \frac{10}{2} = 5 \text{ V / m.}$$

It is along + ve x -axis.

Example 79 $V = x^2 + y$, Find \vec{E} .

Solution. $\frac{\partial V}{\partial x} = 2x$, $\frac{\partial V}{\partial y} = 1$ and $\frac{\partial V}{\partial z} = 0$

$$\vec{E} = -\left(\hat{i}\frac{\partial V}{\partial x} + \hat{j}\frac{\partial V}{\partial y} + \hat{k}\frac{\partial V}{\partial z}\right) = -(2x\hat{i} + \hat{j}) \quad \text{Electric field is nonuniform.}$$

Example 80 For given $\vec{E} = 2x\hat{i} + 3y\hat{j}$ find the potential at (x, y) if V at origin is 5 volts.

$$\int_5^V dV = -\int \vec{E} \cdot d\vec{r} = -\int_0^x E_x dx - \int_0^y E_y dy \Rightarrow V - 5 = -\frac{2x^2}{2} - \frac{3y^2}{2} \Rightarrow V = -\frac{2x^2}{2} - \frac{3y^2}{2} + 5$$

13. ELECTRIC DIPOLE

13.1 Electric Dipole

If two point charges equal in magnitude q and opposite in sign separated by a distance a such that the distance of field point $r \gg a$, the system is called a dipole. The electric dipole moment is defined as a vector quantity having magnitude $p = (q \times a)$ and direction from negative charge to positive charge.

Note: [In chemistry, the direction of dipole moment is assumed to be from positive to negative charge.] The C.G.S unit of electric dipole moment is **debye** which is defined as the dipole moment of two equal and opposite point charges each having charge 10^{-10} frankline and separation of 1 Å, i.e.,

$$1 \text{ debye (D)} = 10^{-10} \times 10^{-8} = 10^{-18} \text{ Fr} \times \text{cm}$$

$$1 \text{ D} = 10^{-18} \times \frac{1 \text{ C}}{3 \times 10^9} \times 10^{-2} \text{ m} = 3.3 \times 10^{-30} \text{ C} \times \text{m}.$$

S.I. Unit is coulomb \times metre = C . m

Solved Examples

Example 81 A system has two charges $q_A = 2.5 \times 10^{-7} \text{ C}$ and $q_B = -2.5 \times 10^{-7} \text{ C}$ located at points A : (0, 0, -0.15 m) and B ; (0, 0, +0.15 m) respectively. What is the net charge and electric dipole moment of the system ?

Solution. Net charge = $2.5 \times 10^{-7} - 2.5 \times 10^{-7} = 0$
Electric dipole moment,
 $P = (\text{Magnitude of charge}) \times (\text{Separation between charges})$
 $= 2.5 \times 10^{-7} [0.15 + 0.15] \text{ C m} = 7.5 \times 10^{-8} \text{ C m}$
The direction of dipole moment is from B to A.

13.2 Electric Field Intensity Due to Dipole :

(i) At the axial point :

$$\vec{E} = \frac{Kq}{\left(r - \frac{a}{2}\right)^2} - \frac{Kq}{\left(r + \frac{a}{2}\right)^2} \text{ along the } \hat{P} = \frac{Kq(2ra)}{\left(r^2 - \frac{a^2}{4}\right)^2} \hat{P}$$

$$\text{If } r \gg a \text{ then } \vec{E} = \frac{Kq2ra}{r^4} \hat{P} = \frac{2KP}{r^3},$$

As the direction of electric field at axial position is along the dipole moment (\vec{P})

$$\text{so } \vec{E}_{\text{axial}} = \frac{2K\vec{P}}{r^3}$$

(ii) **Electric field at perpendicular Bisector (Equatorial Position)**

$$E_{\text{net}} = 2 E \cos \theta \text{ (along } -\hat{P} \text{)}$$

$$\vec{E}_{\text{net}} = 2 \left(\frac{Kq}{\left(\sqrt{r^2 + \left(\frac{a}{2}\right)^2} \right)^2} \right) \frac{\frac{a}{2}}{\sqrt{r^2 + \left(\frac{a}{2}\right)^2}} (-\hat{P}) = 2 \left(\frac{Kqa}{\left(r^2 + \left(\frac{a}{2}\right)^2 \right)^{3/2}} \right) (-\hat{P})$$

If $r \gg a$ then

$$\vec{E}_{\text{net}} = \frac{KP}{r^3} (-\hat{P})$$

As the direction of \vec{E} at equatorial position is opposite of \vec{P} so we can write in vector form:

$$\vec{E}_{\text{eqt}} = -\frac{K\vec{P}}{r^3}$$

(iii) **Electric field at general point (r, θ) :**

For this, Lets resolve the dipole moment into components.

One component is along radial line ($=P \cos \theta$) and other component is \perp to the radial line ($=P \sin \theta$)

$$\sqrt{E_r^2 + E_t^2} = \sqrt{\left(\frac{2KP \cos \theta}{r^3} \right)^2 + \left(\frac{KP \sin \theta}{r^3} \right)^2} = \frac{KP}{r^3} \sqrt{1 + 3 \cos^2 \theta}$$

From the given figure $E_{\text{net}} =$

$$\frac{E_t}{E_r} = \frac{\frac{KP \sin \theta}{r^3}}{\frac{2KP \cos \theta}{r^3}} = \frac{\tan \theta}{2}$$

$$\tan \varphi = \frac{KP}{r^3} \sqrt{1 + 3 \cos^2 \theta} \quad ; \quad \tan \varphi = \frac{\tan \theta}{2}$$

Solved Examples

Example 82 The electric field due to a short dipole at a distance r , on the axial line, from its mid point is the same as that of electric field at a distance r' , on the equatorial line, from its mid-point. Determine

the ratio $\frac{r}{r'}$.

Solution. $\frac{1}{4\pi\epsilon_0} \frac{2p}{r^3} = \frac{1}{4\pi\epsilon_0} \frac{p}{r'^3}$ or $\frac{2}{r^3} = \frac{1}{r'^3}$ or $\frac{r^3}{r'^3} = 2$ or $\frac{r}{r'} = 2^{1/3}$

Example 83 Two charges, each of $5 \mu\text{C}$ but opposite in sign, are placed 4 cm apart. Calculate the electric field intensity of a point that is at a distance 4 cm from the mid point on the axial line of the dipole.

Solution. We can not use formula of short dipole here because distance of the point is comparable to the distance between the two point charges.

$$q = 5 \times 10^{-6} \text{ C}, \quad a = 4 \times 10^{-2} \text{ m}, \quad r = 4 \times 10^{-2} \text{ m}$$

$$E_{\text{res}} = E_+ + E_- = \frac{K(5\mu\text{C})}{(2\text{cm})^2} - \frac{K(5\mu\text{C})}{(6\text{cm})^2} = \frac{144}{144 \times 10^{-8}} \text{ NC}^{-1} = 10^8 \text{ N C}^{-1}$$

Example 84 Two charges $\pm 10 \mu\text{C}$ are placed $5 \times 10^{-3} \text{ m}$ apart. Determine the electric field at a point Q which is 0.15 m away from O, on the equatorial line.

Solution. In the given problem, $r \gg a$

$$\therefore E = \frac{1}{4\pi\epsilon_0} \frac{p}{r^3} = \frac{1}{4\pi\epsilon_0} \frac{q(a)}{r^3}$$

$$\text{or } E = 9 \times 10^9 \frac{10 \times 10^{-6} \times 5 \times 10^{-3}}{0.15 \times 0.15 \times 0.15} \text{ NC}^{-1} = 1.33 \times 10^5 \text{ NC}^{-1}$$

13.3 Electric Potential due to a small dipole :

(i) **Potential at axial position :**

$$V = \frac{Kq}{\left(r - \frac{a}{2}\right)} + \frac{K(-q)}{\left(r + \frac{a}{2}\right)}$$

$$V = \frac{Kqa}{\left(r^2 - \left(\frac{a}{2}\right)^2\right)}$$

If $r \gg a$ then

$$V = \frac{Kqa}{r^2} \text{ where } qa = p \Rightarrow V_{\text{axial}} = \frac{Kp}{r^2}$$

(ii) **Potential at equatorial position :**

$$V = \frac{Kq}{\sqrt{r^2 + \left(\frac{a}{2}\right)^2}} + \frac{K(-q)}{\sqrt{r^2 + \left(\frac{a}{2}\right)^2}} = 0$$

$$\Rightarrow V_{\text{eqt}} = 0$$

(iii) Potential at general point (r, θ) :

Lets resolve the dipole moment \vec{P} into components $P \cos \theta$ component along radial line and $P \sin \theta$ component \perp to the radial line.

For the $P \cos \theta$ component, the point A is an axial point, so, potential

$$\frac{K(P \cos \theta)}{r^2}$$

at A due to $P \cos \theta$ component = $\frac{K(P \cos \theta)}{r^2}$ and for $P \sin \theta$ component, the point A is an equatorial point, so potential at A due to $P \sin \theta$ component = 0

$$V_{\text{net}} = \frac{K(P \cos \theta)}{r^2} \Rightarrow V = \frac{K(\vec{P} \cdot \vec{r})}{r^3}$$

13.4 Dipole in uniform electric field

(i) Dipole is placed along electric field :

In this case $F_{\text{net}} = 0$, $\tau_{\text{net}} = 0$ so it is an equilibrium state. And it is a stable equilibrium position.

(ii) If the dipole is placed at θ angle from \vec{E} :

In this case $F_{\text{net}} = 0$ but

Net torque $\tau = (qE \sin \theta) (a)$

Here $qa = P \Rightarrow \tau = PE \sin \theta$

in vector form $\tau = \vec{P} \times \vec{E}$

Solved Examples

Example 85 A dipole is formed by two point charge $-q$ and $+q$, each of mass m , and both the point charges are connected by a rod of length ℓ and mass m_1 . This dipole is placed in uniform electric field \vec{E} . If the dipole is disturbed by a small angle θ from stable equilibrium position, prove that its motion will be almost SHM. Also find its time period.

Solution.

If the dipole is disturbed by θ angle,

$\tau_{\text{net}} = -PE \sin \theta$ (here -ve sign indicates that direction of torque is opposite of θ)

If θ is very small, $\sin \theta = \theta \Rightarrow \tau_{\text{net}} = -(PE)\theta$

$\tau_{\text{net}} \propto (-\theta)$ so motion will be almost SHM. $T = 2\pi \sqrt{\frac{I}{K}}$

(iii) **Potential energy of a dipole placed in uniform electric field :**

$$U_B - U_A = - \int_A^B \vec{F} \cdot d\vec{r} \quad \text{Here} \quad U_B - U_A = - \int_A^B \vec{\tau} \cdot d\vec{\theta}$$

In the case of dipole, at $\theta = 90^\circ$, P.E. is assumed to be zero.

$$\int_{\theta=90^\circ}^{\theta=\theta} (-PE \sin \theta) (d\theta)$$

$$U_\theta - U_{90^\circ} = - \int_{\theta=90^\circ}^{\theta=\theta} PE \sin \theta (d\theta)$$

(As the direction of torque is opposite of θ)

$U_\theta - 0 = -PE \cos \theta \Rightarrow \theta = 90^\circ$ is chosen as reference, so that the lower limit comes out to be zero.

$$U_\theta = -P \cdot E$$

From the potential energy curve, we can conclude :

- (i) at $\theta = 0$, there is minimum of P.E. so it is a stable equilibrium position.
- (ii) at $\theta = 180^\circ$, there is maxima of P.E. so it is a position of unstable equilibrium.

**13.5 Dipole in nonuniform electric field :**

(If the dipole is placed in the along \vec{E})

Net force on the dipole $F_{\text{net}} = qE(x+dx) - qE(x)$

$$F_{\text{net}} = q \frac{E(x+dx) - E(x)}{dx} (dx) \text{ here } q(dx) = P$$

$$F_{\text{net}} = P \left(\frac{dE}{dx} \right)$$

**Solved Examples**

Example 86 A short dipole is placed on the axis of uniformly charged ring (total charge $-Q$, radius R) at a distance $\frac{R}{\sqrt{2}}$ from centre of ring as shown in figure. Find the Force on the dipole due to the ring.

Solution. $F = P \left(\frac{dE}{dx} \right) \Rightarrow F = P \frac{d}{dx} \left(\frac{KQx}{(R^2 + x^2)^{3/2}} \right)$ at $x = \frac{R}{\sqrt{2}}$

Solving we get $F = 0$

**13.6 Force between a dipole and a point charge :****Solved Examples**

Example 87 A short dipole of dipole moment P is placed near a point charge as shown in figure. Find force on the dipole due to the point charge

Solution.

Force on the point charge due to the dipole

$$F = (Q) E_{\text{dipole}}$$

$$F = (Q) \left(\frac{2KP}{r^3} \right) \text{ (right)}$$

From action reaction concept, force on the dipole due to point charge will also be

$$F = \frac{2KPQ}{r^3} \text{ (left)}$$

**Example 88**

A short dipole of dipole moment P is placed near a point charge as shown in figure. Find force on the dipole due to the point charge.

**Solution.**

Force on the point charge due to dipole $F = (Q) (E_{\text{dipole}})$

$$F = (Q) \left(\frac{KP}{r^3} \right) (\downarrow)$$

So force on the dipole due to the point charge will also be

$$F = \left(\frac{KPQ}{r^3} \right) (\uparrow) \text{ but in opposite direction.}$$

Example 89

Find force on short dipole P_2 due to short dipole P_1 if they are placed at a distance r as shown in figure.

**Solution.**

Force P_2 due to P_1

$$F_2 = (P_2) \left(\frac{dE_1}{dr} \right)$$

$$F_2 = (P_2) \left(\frac{d}{dr} \left(\frac{2KP_1}{r^3} \right) \right)$$

$$F_2 = - \frac{6KP_1P_2}{r^4}$$

here – sign indicates that this force will be attractive (opposite) to r

14. ELECTRIC LINES OF FORCE (ELOF)

The line of force in an electric field is an imaginary line, the tangent to which at any point on it represents the direction of electric field at the given point.

14.1 Properties :

- (i) Line of force originates out from a positive charge and terminates on a negative charge. If there is only one positive charge then lines start from positive charge and terminate at ∞ . If there is only one negative charge then lines start from ∞ and terminate at negative charge.

ELOF of Isolated positive charge

ELOF of Isolated negative charge

ELOF due to positive and negative charge

ELOF due to two positive charges

- (ii) Two lines of force never intersect each other because there cannot be two directions of \vec{E} at a single Point

impossible

- (iii) Electric lines of force produced by static charges do not form close loop. If lines of force make a closed loop, then work done to move a $+q$ charge along the loop will be non-zero. So it will not be conservative field. So these type of lines of force are not possible in electrostatics.

- (iv) The Number of lines per unit area (line density) represents the magnitude of electric field.
If lines are dense, $\Rightarrow E$ will be more
If Lines are rare, $\Rightarrow E$ will be less
and if $E = 0$, no line of force will be found there

$$E_A > E_B$$

- (v) Number of lines originating (terminating) is proportional to the charge.

Solved Examples

Example 90. If number of electric lines of force from charge q are 10 then find out number of electric lines of force from $2q$ charge.

Solution. No. of ELOF \propto charge
 $10 \propto q \Rightarrow 20 \propto 2q$
 So number of ELOF will be 20.

- (vi) Electric lines of force end or start perpendicularly on the surface of a conductor.
 (vii) Electric lines of force never enter into conductors.

Solved Examples

Example 91 Some electric lines of force are shown in figure, for point A and B

Solution. (A) $E_A > E_B$ (B) $E_B > E_A$ (C) $V_A > V_B$ (D) $V_B > V_A$
 lines are more dense at B so $E_A > E_B$ In the direction of Electric field, potential decreases so $V_A > V_B$

Example 92. If a charge is released in electric field, will it follow lines of force?

Solution. **Case I :** If lines of force are parallel (in uniform electric field) :

In this type of field, if a charge is released, force on it will be $q_0 E$ and its direction will be along \vec{E} . So the charge will move in a straight line, along the lines of force.

Case II : If lines of force are curved (in non-uniform electric field) :

The charge will not follow lines of force.

15. ELECTRIC FLUX

Consider some surface in an electric field \vec{E} . Let us select a small area element $d\vec{S}$ on this surface. The electric flux of the field over the area element is given by $d\phi_E = \vec{E} \cdot d\vec{S}$

Direction of $d\vec{S}$ is normal to the surface. It is along \hat{n}
 or $d\phi_E = E dS \cos \theta$ or $d\phi_E = (E \cos \theta) dS$ or $d\phi_E = E_n dS$

where E_n is the component of electric field in the direction of $d\vec{S}$.

The electric flux over the whole area is given by $\phi_E = \int_S \vec{E} \cdot d\vec{S} = \int_S E_n dS$

If the electric field is uniform over that area then $\phi_E = \vec{E} \cdot \vec{S}$

Special Cases :**Case I:** If the electric field is normal to the surface,then angle of electric field \vec{E} with normal will be zero

So $\phi = ES \cos 0$

$\phi = ES$

**Case II :** If electric field is parallel of the surface (glazing), then angle made by \vec{E} with normal = 90° 

So $\phi = ES \cos 90^\circ = 0$

15.1 Physical Meaning :

The electric flux through a surface inside an electric field represents the total number of electric lines of force crossing the surface. It is a property of electric field

15.2 Unit

- (i) The SI unit of electric flux is $\text{Nm}^2 \text{C}^{-1}$ (gauss) or J m C^{-1} .
- (ii) Electric flux is a scalar quantity. (It can be positive, negative or zero)

Solved Examples

Example 93. The electric field in a region is given by $\vec{E} = \frac{3}{5}E_0\vec{i} + \frac{4}{5}E_0\vec{j}$ with $E_0 = 2.0 \times 10^3 \text{ N/C}$. Find the flux of this field through a rectangular surface of area 0.2 m^2 parallel to the Y-Z plane.

Solution. $\phi_E = \vec{E} \cdot \vec{S} = \left(\frac{3}{5}E_0\vec{i} + \frac{4}{5}E_0\vec{j} \right) \cdot (0.2\vec{i}) = 240 \frac{\text{N-m}^2}{\text{C}}$

Example 94. A point charge Q is placed at the corner of a square of side a , then find the flux through the square.

Solution. The electric field due to Q at any point of the square will be along the plane of square and the electric field lines are perpendicular to square ; so $\phi = 0$.
In other words we can say that no line is crossing the square so flux = 0.

Example 95 Find the electric flux due to point charge ' Q ' through the circular region of radius R if the charge is placed on the axis of ring at a distance x .

Solution. We can divide the circular region into small rings.

Lets take a ring of radius r and width dr .
flux through this small element
 $d\phi = E ds \cos \theta$

$$\begin{aligned}\phi_{\text{net}} &= \int E ds \cos \theta = \int_{r=0}^{r=R} \frac{KQ}{(x^2 + r^2)^{3/2}} (2\pi r dr) \left(\frac{x}{\sqrt{x^2 + r^2}} \right) \\ &= \frac{Q}{2\epsilon_0} \left[1 - \frac{x}{\sqrt{x^2 + R^2}} \right]\end{aligned}$$

Case-III : Curved surface in uniform electric field.

Suppose a circular surface of radius R is placed in a uniform electric field as shown.

Flux passing through the surface $\phi = E (\pi R^2)$

(ii) Now suppose, a hemispherical surface is placed in the electric field flux through hemispherical surface

$\phi = \int E ds \cos \theta$
 $\phi = E \int ds \cos \theta$
where $\int ds \cos \theta$ is
projection of the spherical surface Area on base.

$\int ds \cos \theta = \pi R^2$
so $\phi = E(\pi R^2) = \text{same}$ Ans. as in previous case
so we can conclude that

If the number of electric field lines passing through two surfaces are same, then flux passing through these surfaces will also be same, irrespective of the shape of surface

Case IV : Flux through a closed surface

Suppose there is a spherical surface and a charge ' q ' is placed at centre.
flux through the spherical surface

$$\varphi = \int \vec{E} \cdot \vec{ds} = \int E ds \quad \text{as } \vec{E} \text{ is along } \vec{ds} \text{ (normal)}$$

$$\varphi = \frac{1}{4\pi\epsilon_0} \frac{Q}{R^2} \int ds \quad \text{where } \int ds = 4\pi R^2$$

$$\varphi = \left(\frac{1}{4\pi R^2} \frac{Q}{R^2} \right) (4\pi R^2) \Rightarrow \varphi = \frac{Q}{\epsilon_0}$$

Now if the charge Q is enclosed by any other closed surface, still same lines of force will pass through the surface.

So here also flux will be $\varphi = \frac{Q}{\epsilon_0}$, that's what Gauss Theorem is.

16. GAUSS'S LAW IN ELECTROSTATICS OR GAUSS'S THEOREM

This law was stated by a mathematician Karl F Gauss. This law gives the relation between the electric field at a point on a closed surface and the net charge enclosed by that surface. This surface is called Gaussian surface. It is a closed hypothetical surface. Its validity is shown by experiments. It is used to determine the electric field due to some symmetric charge distributions.

16.1 Statement and Details :

Gauss's law is stated as given below.

The surface integral of the electric field intensity over any closed hypothetical surface (called Gaussian

surface) in free space is equal to $\frac{1}{\epsilon_0}$ times the total charge enclosed within the surface. Here, ϵ_0 is the permittivity of free space.

If S is the Gaussian surface and $\sum_{i=1}^n q_i$ is the total charge enclosed by the Gaussian surface, then according to Gauss's law,

$$\varphi_E = \oint \vec{E} \cdot \vec{dS} = \frac{1}{\epsilon_0} \sum_{i=1}^n q_i$$

The circle on the sign of integration indicates that the integration is to be carried out over the closed surface.

Note :

- (i) Flux through gaussian surface is independent of its shape.
- (ii) Flux through gaussian surface depends only on total charge present inside gaussian surface.
- (iii) Flux through gaussian surface is independent of position of charges inside gaussian surface.
- (iv) Electric field intensity at the gaussian surface is due to all the charges present inside as well as outside the gaussian surface.
- (v) In a close surface incoming flux is taken negative while outgoing flux is taken positive, because \hat{n} is taken positive in outward direction.
- (vi) In a gaussian surface $\varphi = 0$ does not imply $E = 0$ at every point of the surface but $E = 0$ at every point implies $\varphi = 0$.

Solved Examples

Example 96 Find out flux through the given gaussian surface.

Solution.
$$\varphi = \frac{Q_{in}}{\epsilon_0} = \frac{2\mu C - 3\mu C + 4\mu C}{\epsilon_0} = \frac{3 \times 10^{-6}}{\epsilon_0} \text{ Nm}^2/\text{C}$$

Example 97. If a point charge q is placed at the centre of a cube then find out flux through any one surface of cube.

Solution. Flux through 6 surfaces = $\frac{q}{\epsilon_0}$. Since all the surfaces are symmetrical

$$\text{so, flux through one surfaces} = \frac{1}{6} \frac{q}{\epsilon_0}$$

16.2 Flux through open surfaces using Gauss's Theorem :

Solved Examples

Example 98 A point charge $+q$ is placed at the centre of curvature of a hemisphere. Find flux through the hemispherical surface.

Solution. Lets put an upper half hemisphere.

Now flux passing through the entire sphere = $\frac{q}{\epsilon_0}$
 As the charge q is symmetrical to the upper half and lower half hemispheres, so half-half flux will emit from both the surfaces.

$$\begin{array}{l} \downarrow \qquad \qquad \qquad \downarrow \\ \text{Flux emitting from lower half surface} = \frac{q}{2\epsilon_0} \qquad \text{Flux emitting from upper half surface} = \frac{q}{2\epsilon_0} \end{array}$$

Example 99 A charge Q is placed at a distance $a/2$ above the centre of a horizontal, square surface of edge a as shown in figure. Find the flux of the electric field through the square surface.

Solution. We can consider imaginary faces of cube such that the charge lies at the centre of the cube. Due to symmetry we can say that flux through the given area (which is one face of cube)

$$\phi = \frac{Q}{6\epsilon_0}$$

Example 100 Find flux through the hemispherical surface

- Solution.**
- Flux through the hemispherical surface due to $+q = \frac{q}{2\epsilon_0}$ (we have seen in previous examples)
 - Flux through the hemispherical surface due to $+q_0$ charge = 0, because due to $+q_0$ charge field lines entering the surface = field lines coming out of the surface.

16.3 Finding q_{in} from flux :

Solved Examples

Example 101

Flux (in S.I.units) coming out and entering a closed surface is shown in the figure . Find charge enclosed by the closed surface.

Solution.

Net flux through the closed surface = + 20 + 30 + 10 -15 = 45 N.m²/c from Gauss`s theorem

$$\varphi_{\text{net}} = \frac{q_{\text{in}}}{\epsilon_0}$$

$$45 = \frac{q_{\text{in}}}{\epsilon_0} \Rightarrow q_{\text{in}} = (45)\epsilon_0$$

16.4 Finding electric field from Gauss`s Theorem :

From gauss`s theorem, we can say

$$\int \vec{E} \cdot d\vec{s} = \varphi_{\text{net}} = \frac{q_{\text{in}}}{\epsilon_0}$$

16.4.1 Finding E due to a spherical shell :

Electric field outside the Sphere :

Since, electric field due to a shell will be radially outwards. So lets choose a spherical Gaussian surface Applying Gauss`s theorem for this spherical Gauss`s surface,

$$\int \vec{E} \cdot d\vec{s} = \varphi_{\text{net}} = \frac{q_{\text{in}}}{\epsilon_0} = \frac{q}{\epsilon_0}$$

↓

$$\int |\vec{E}| |d\vec{s}| \cos 0 \quad (\text{because the } \vec{E} \text{ is normal to the surface})$$

↓

$$E \int ds \quad (\text{because value of } E \text{ is constant at the surface})$$

$$E (4\pi r^2) \left(\int ds \text{ total area of the spherical surface} = 4\pi r^2 \right)$$

$$\Rightarrow E (4\pi r^2) = \frac{q_{in}}{\epsilon_0} \Rightarrow E_{out} = \frac{q}{4\pi\epsilon_0 r^2}$$

Electric field inside a spherical shell :

Lets choose a spherical gaussian surface inside the shell.
Applying Gauss's theorem for this surface

$$\int \vec{E} \cdot d\vec{s} = \varphi_{net} = \frac{q_{in}}{\epsilon_0} = 0$$

↓

$$\int |\vec{E}| |d\vec{s}| \cos 0$$

↓

$$E \int ds$$

↓

$$E (4\pi r^2) \Rightarrow E (4\pi r^2) = 0 \Rightarrow E_{in} = 0$$

16.4.2 Electric field due to solid sphere (having uniformly distributed charge Q and radius R) :**Electric field outside the sphere :**

Direction of electric field is radially outwards, so we will choose a spherical gaussian surface Applying Gauss's theorem

$$\int \vec{E} \cdot d\vec{s} = \varphi_{net} = \frac{q_{in}}{\epsilon_0} = \frac{Q}{\epsilon_0}$$

↓

$$\int |\vec{E}| |d\vec{s}| \cos 0$$

↓

$$E \int ds$$

↓

$$E (4\pi r^2) \Rightarrow E (4\pi r^2) = \frac{Q}{\epsilon_0} \Rightarrow E_{out} = \frac{Q}{4\pi\epsilon_0 r^2}$$

Electric field inside a solid sphere :

For this choose a spherical gaussian surface inside the solid sphere Applying gauss's theorem for this surface

$$\int \vec{E} \cdot d\vec{s} = \phi_{\text{net}} = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\frac{Q}{\frac{4}{3}\pi R^3} \times \frac{4}{3}\pi r^3}{\epsilon_0} = \frac{Qr^3}{\epsilon_0 R^3}$$

$$\downarrow$$

$$\int E \, ds$$

$$\downarrow$$

$$E(4\pi r^2) \Rightarrow E(4\pi r^2) = \frac{Qr^3}{\epsilon_0 R^3}$$

$$E = \frac{Qr}{4\pi\epsilon_0 R^3} \Rightarrow E_{\text{in}} = \frac{kQ}{R^3} r$$

16.4.3 Electric field due to infinite line charge (having uniformly distributed charged of charge density λ) :

Electric field due to infinite wire is radial so we will choose cylindrical Gaussian surface as shown is figure.

$$\begin{aligned} \phi_{\text{net}} & \begin{cases} \phi_1 = 0 \\ \phi_2 = 0 \\ \phi_3 \neq 0 \end{cases} = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\lambda l}{\epsilon_0} \\ \phi_3 &= \int \vec{E} \cdot d\vec{s} = \int E \, ds = E \int ds = E(2\pi r l) \\ E(2\pi r l) &= \frac{\lambda l}{\epsilon_0} \Rightarrow E = \frac{\lambda}{2\pi\epsilon_0 r} = \frac{2k\lambda}{r} \end{aligned}$$

16.4.4 Electric field due to infinity long charged tube (having uniform surface charge density σ and radius R):

- (i) **E out side the tube :-** lets choose a cylindrical gaussian surface

$$\varphi_{\text{net}} = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\sigma 2\pi R l}{\epsilon_0} \Rightarrow E_{\text{out}} \times 2\pi r l = \frac{\sigma 2\pi R l}{\epsilon_0} \Rightarrow E = \frac{\sigma R}{r \epsilon_0}$$

- (ii) **E inside the tube :**

lets choose a cylindrical gaussian surface in side the tube.

$$\frac{q_{\text{in}}}{\epsilon_0} = 0$$

So $E_{\text{in}} = 0$

16.4.5 E due to infinitely long solid cylinder of radius R (having uniformly distributed charge in volume(charge density ρ)) :

- (i) **E at outside point :-**

Lets choose a cylindrical gaussian surface.

Applying gauss's theorem

$$E \times 2\pi r l = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\rho \times \pi R^2 l}{\epsilon_0}$$

$$E_{\text{out}} = \frac{\rho R^2}{2r \epsilon_0}$$

- (ii) **E at inside point :**

lets choose a cylindrical gaussian surface inside the solid cylinder.

Applying gauss's theorem $E \times 2\pi r \ell = \frac{q_{in}}{\epsilon_0} = \frac{\rho \times \pi r^2 \ell}{\epsilon_0}$

$$E_{in} = \frac{\rho r}{2\epsilon_0}$$

17. CONDUCTOR AND IT'S PROPERTIES [FOR ELECTROSTATIC CONDITION]

- (i) Conductors are materials which contains large number of free electrons which can move freely inside the conductor.
- (ii) In electrostatics conductors are always equipotential surfaces.
- (iii) Charge always resides on outer surface of conductor.
- (iv) If there is a cavity inside the conductor having no charge then charge will always reside only on outer surface of conductor.
- (v) Electric field is always perpendicular to conducting surface.
- (vi) Electric lines of force never enter into conductors.
- (vii) Electric field intensity near the conducting surface is given by formula

$$E = \frac{\sigma}{\epsilon_0} \hat{n}$$

$$E_A = \frac{\sigma_A}{\epsilon_0} \hat{n} ; E_B = \frac{\sigma_B}{\epsilon_0} \hat{n} \text{ and } E_C = \frac{\sigma_C}{\epsilon_0} \hat{n}$$

- (viii) When a conductor is grounded its potential becomes zero.

- (ix) When an isolated conductor is grounded then its charge becomes zero.
- (x) When two conductors are connected there will be charge flow till their potential becomes equal.
- (xi) Electric pressure : Electric pressure at the surface of a conductor is given by formula

$$\frac{\sigma^2}{2\epsilon_0}$$

$$P = \frac{\sigma^2}{2\epsilon_0} \text{ where } \sigma \text{ is the local surface charge density.}$$

- (xii) Inside conductor net electric field is zero.

FINDING FIELD DUE TO A CONDUCTOR

Suppose we have a conductor, and at any 'A', local surface charge density = σ . We have to find electric field just outside the conductor surface.

For this let's consider a small cylindrical gaussian surface, which is partly inside and partly outside the conductor surface, as shown in figure. It has a small cross section area ds and negligible height.

Applying gauss's theorem for this surface

$$\phi_{\text{net}} = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\sigma ds}{\epsilon_0}$$

flux through surface (1) $\phi_1 = E ds$ (because \vec{E} is normal to the surface of conductor)

flux through surface (2) $\phi_2 = 0$ (\vec{E} is normal to curved Gaussian surface)

flux through surface (3) $\phi_3 = 0$ (as E inside the conductor = 0)

So, $E ds = \frac{\sigma ds}{\epsilon_0} \Rightarrow E = \frac{\sigma}{\epsilon_0}$
 Electric field just outside the surface of conductor

$E = \frac{\sigma}{\epsilon_0}$ direction will be normal to the surface
 in vector form $\vec{E} = \frac{\sigma}{\epsilon_0} \hat{n}$ (here \hat{n} = unit vector normal to the conductor surface)

Electric field due to a conducting and nonconducting uniformly charge infinite sheets

Suppose Q charge is given to

Conducting plate Non-conducting plate

Electric field for both the cases

$$E = \frac{Q}{2A\epsilon_0}$$

$E = \frac{\sigma_{\text{conducting}}}{\epsilon_0}$ where $\sigma_{\text{conducting}} = \frac{Q}{2A}$ Because Q is distributed in '2A' area.

$E = \frac{\sigma_{\text{non-conducting}}}{2\epsilon_0}$ where $\sigma_{\text{non-conducting}} = \frac{Q}{A}$ Because Q is distributed in 'A' area.

Solved Examples

Example 102 A charge + Q is fixed at a distance of d in front of an infinite metal plate. Draw the lines of force indicating the directions clearly.

Solution.

There will be induced charge on two surfaces of conducting plate, so ELOF will start from +Q charge and terminate at conductor and then will again start from other surface of conductor.

**Example 103**

Prove that if an isolated (isolated means no charges are near the sheet) large conducting sheet is given a charge then the charge distributes equally on its two surfaces.

Solution.

Let there is x charge on left side of sheet and $Q-x$ charge on right side of sheet. Since point P lies inside the conductor so $E_P = 0$

$$\frac{x}{2A\epsilon_0} - \frac{Q-x}{2A\epsilon_0} = 0 \Rightarrow \frac{2x}{2A\epsilon_0} = \frac{Q}{2A\epsilon_0} \Rightarrow x = \frac{Q}{2} \quad Q-x = \frac{Q}{2}$$

So charge is equally distributed on both sides

Example 104

If an isolated infinite sheet contains charge Q_1 on its one surface and charge Q_2 on its other surface then prove that electric field intensity at a point in front of sheet will be $\frac{Q}{2A\epsilon_0}$, where $Q = Q_1 + Q_2$

Solution.

Electric field at point P :

$$\vec{E} = \vec{E}_{Q_1} + \vec{E}_{Q_2}$$

$$= \frac{Q_1}{2A\epsilon_0} \hat{n} + \frac{Q_2}{2A\epsilon_0} \hat{n} = \frac{Q_1 + Q_2}{2A\epsilon_0} \hat{n} = \frac{Q}{2A\epsilon_0} \hat{n}$$

[This shows that the resultant field due to a sheet depends only on the total charge of the sheet and not on the distribution of charge on individual surfaces].

Example 105

Three large conducting sheets placed parallel to each other at finite distance contain charges Q , $-2Q$ and $3Q$ respectively. Find electric field at points A, B, C, and D.

Solution.

$$E_A = E_Q + E_{-2Q} + E_{3Q}$$

Here E_Q means electric field due to 'Q'.

$$E_A = \frac{(Q - 2Q + 3Q)}{2A\epsilon_0} = \frac{2Q}{2A\epsilon_0} = \frac{Q}{A\epsilon_0}, \text{ towards left}$$

$$(ii) E_B = \frac{Q - (-2Q + 3Q)}{2A\epsilon_0} = 0$$

$$(iii) E_C = \frac{(Q - 2Q) - (3Q)}{2A\epsilon_0} = \frac{-4Q}{2A\epsilon_0} = \frac{-2Q}{A\epsilon_0}, \text{ towards right} \Rightarrow \frac{2Q}{A\epsilon_0} \text{ towards left}$$

$$(iv) E_D = \frac{(Q - 2Q + 3Q)}{2A\epsilon_0} = \frac{2Q}{2A\epsilon_0} = \frac{Q}{A\epsilon_0}, \text{ towards right}$$

**Example 106**

Two conducting plates A and B are placed parallel to each other. A is given a charge Q_1 and B a charge Q_2 . Prove that the charges on the inner facing surfaces are of equal magnitude and opposite sign.

Solution.

Consider a Gaussian surface as shown in figure. Two faces of this closed surface lie completely inside the conductor where the electric field is zero. The flux through these faces is, therefore, zero. The other parts of the closed surface which are outside the conductor are parallel to the

electric field and hence the flux on these parts is also zero. The total flux of the electric field through the closed surface is, therefore zero. From Gauss's law, the total charge inside this closed surface should be zero. The charge on the inner surface of A should be equal and opposite to that on the inner surface of B.

The distribution should be like the one shown in figure. To find the value of q , consider the field at a point P inside the plate A. Suppose, the surface area of the plate (one side) is A . Using the

equation $E = \sigma / (2\epsilon_0)$, the electric field at P due to the charge $Q_1 - q = \frac{Q_1 - q}{2A\epsilon_0}$ (downward)

due to the charge $+q = \frac{q}{2A\epsilon_0}$ (upward),

due to the charge $-q = \frac{q}{2A\epsilon_0}$ (downward),

and due to the charge $Q_2 + q = \frac{Q_2 + q}{2A\epsilon_0}$ (upward).

The net electric field at P due to all the four charged surfaces is (in the downward direction)

$$E_p = \frac{Q_1 - q}{2A\epsilon_0} - \frac{q}{2A\epsilon_0} + \frac{q}{2A\epsilon_0} - \frac{Q_2 + q}{2A\epsilon_0}$$

As the point P is inside the conductor, this field should be zero. Hence,

$$Q_1 - q - q + q - Q_2 - q = 0 \quad \text{or} \quad q = \frac{Q_1 - Q_2}{2}$$

This result is a special case of the following result. When charged conducting plates are placed parallel to each other, the two outermost, surfaces get equal charges and the facing surfaces get equal and opposite charges.

Example 107 Two large parallel conducting sheets (placed at finite distance) are given charges Q and $2Q$ respectively. Find out charges appearing on all the surfaces.

Solution.

Let there is x amount of charge on left side of first plate, so on its right side charge will be $Q - x$, similarly for second plate there is y charge on left side and $2Q - y$ charge is on right side of second plate

$E_p = 0$ (By property of conductor)

$$\Rightarrow \frac{x}{2A\epsilon_0} - \left\{ \frac{Q-x}{2A\epsilon_0} + \frac{y}{2A\epsilon_0} + \frac{2Q-y}{2A\epsilon_0} \right\} = 0$$

we can also say that charge on left side of P = charge on right side of P

$$x = Q - x + y + 2Q - y$$

$$\Rightarrow x = \frac{3Q}{2}, \quad Q - x = \frac{-Q}{2}$$

Similarly for point Q :

$$x + Q - x + y = 2Q - y$$

$$\Rightarrow y = Q/2, \quad 2Q - y = 3Q/2$$

So final charge distribution of plates is : -

Example 108 Figure shows three large metallic plates with charges $-Q$, $3Q$ and Q respectively. Determine the final charges on all the surfaces.

Solution.

We assume that charge on surface 2 is x . Following conservation of charge, we see that surface 1 has charge $(-Q - x)$. The electric field inside the metal plate is zero so field at P is zero.

Resultant field at P -

$$E_P = 0$$

$$\Rightarrow \frac{-Q - x}{2A\epsilon_0} = \frac{x + 3Q + Q}{2A\epsilon_0} \Rightarrow -Q - x = x + 4Q \Rightarrow x = \frac{-5Q}{2}$$

Note : We see that charges on the facing surfaces of the plates are of equal magnitude and opposite sign. This can be in general proved by gauss theorem also. Remember this it is important result. Thus the final charge distribution on all the surfaces is as shown in figure :

Example 109 An isolated conducting sheet of area A and carrying a charge Q is placed in a uniform electric field E , such that electric field is perpendicular to sheet and covers all the sheet. Find out charges appearing on its two surfaces.

Solution. Let there is x charge on left side of plate and $Q - x$ charge on right side of plate

$$E_P = 0$$

$$\frac{x}{2A\epsilon_0} + E = \frac{Q-x}{2A\epsilon_0}$$

$$\Rightarrow \frac{x}{A\epsilon_0} = \frac{Q}{2A\epsilon_0} - E$$

$$\Rightarrow x = \frac{Q}{2} - EA\epsilon_0 \text{ and } Q-x = \frac{Q}{2} + EA\epsilon_0$$

So charge on one side is $\frac{Q}{2} - EA\epsilon_0$ and other side $\frac{Q}{2} + EA\epsilon_0$

Note : Solve this question for $Q = 0$ without using the above answer and match that answers with the answers that you will get by putting $Q = 0$ in the above answer.

17.1 Some other important results for a closed conductor.

- (i) If a charge q is kept in the cavity then $-q$ will be induced on the inner surface and $+q$ will be induced on the outer surface of the conductor (it can be proved using gauss theorem)

- (ii) If a charge q is kept inside the cavity of a conductor and conductor is given a charge Q then $-q$ charge will be induced on inner surface and total charge on the outer surface will be $q + Q$. (it can be proved using gauss theorem)

- (iii) Resultant field, due to q (which is inside the cavity) and induced charge on S_1 , at any point outside S_1 (like B,C) is zero. Resultant field due to $q + Q$ on S_2 and any other charge outside S_2 , at any point inside of surface S_2 (like A, B) is zero

- (iv) Resultant field in a charge free cavity in a closed conductor is zero. There can be charges outside the conductor and on the surface also. Then also this result is true. No charge will be induced on the inner most surface of the conductor.

- (v) Charge distribution for different types of cavities in conductors

- (A) charge is at the common centre
($S_1, S_2 \rightarrow$ spherical)

- (B) charge is not at the common centre
($S_1, S_2 \rightarrow$ spherical)

- (C) charge is at the centre of S_1
($S_2 \rightarrow$ spherical)

- (D) charge is not at the centre of S_2
($S_2 \rightarrow$ spherical)

- (E) charge is at the centre of S_1 (Spherical)

- (F) charge not at the centre of S_1 (Spherical)

- (G) charge is at the geometrical centre

- (H) charges is not at the geometrical centre

Using the result that \vec{E}_{res} in the conducting material should be zero and using result (iii) We can show that

Case	A	B	C	D	E	F	G	H
S ₁	Uniform	Nonuniform	Nonuniform	Nonuniform	Uniform	Nonuniform	Nonuniform	Nonuniform
S ₂	Uniform	Uniform	Uniform	Uniform	Nonuniform	Nonuniform	Nonuniform	NonUniform

Note : In all cases charge on inner surface $S_1 = -q$ and on outer surface $S_2 = q$. The distribution of charge on 'S₁' will not change even if some charges are kept outside the conductor (i.e. outside the surface S₂). But the charge distribution on 'S₂' may change if some charges(s) is/are kept outside the conductor.

Solved Examples

Example 110 An uncharged conductor of inner radius R_1 and outer radius R_2 contains a point charge q at the centre as shown in figure

- (i) Find \vec{E} and V at points A, B and C
(ii) If a point charge Q is kept outside the sphere at a distance ' r ' ($> R_2$) from centre then find out resultant force on charge Q and charge q .

Solution.

At point A :

$$V_A = \frac{Kq}{OA} + \frac{Kq}{R_2} + \frac{K(-q)}{R_1}, \quad \vec{E}_A = \frac{Kq}{OA^3} \vec{OA}$$

Note :

Electric field due at 'A' due to $-q$ of S_1 and $+q$ of S_2 is zero individually because they are uniformly distributed

At point B :
$$V_B = \frac{Kq}{OB} + \frac{K(-q)}{OB} + \frac{Kq}{R_2} = \frac{Kq}{R_2}, \quad E_B = 0$$

At point C :
$$V_C = \frac{Kq}{OC}, \quad \vec{E}_C = \frac{Kq}{OC^3} \vec{OC}$$

- (ii) Force on point charge Q :

(**Note :** Here force on 'Q' will be only due to 'q' of S_2 see result (iii))

$$\vec{F}_Q = \frac{KqQ}{r^2} \hat{r} \quad (r = \text{distance of 'Q' from centre 'O'})$$

Force on point charge q :

$$\vec{F}_q = 0 \quad (\text{using result (iii) \& charge on } S_1 \text{ uniform})$$

Example 111 An uncharged conductor of inner radius R_1 and outer radius R_2 contains a point charge q placed at point P (not at the centre) as shown in figure ? Find out the following :

- (i) V_C (ii) V_A (iii) V_B (iv) E_A (v) E_B
(vi) force on charge Q if it is placed at B

Solution. (i)
$$V_C = \frac{Kq}{CP} + \frac{K(-q)}{R_1} + \frac{Kq}{R_2}$$

Note : $-q$ on S_1 is nonuniformly distributed still it produces potential $\frac{K(-q)}{R_1}$ at 'C' because 'C' is at distance ' R_1 ' from each points of ' S_1 '.

$$\begin{aligned}
 \text{(ii)} \quad V_A &= \frac{Kq}{R_2} & \text{(iii)} \quad V_B &= \frac{Kq}{CB} & \text{(iv)} \quad E_A &= 0 \text{ (point is inside metallic conductor)} \\
 \text{(v)} \quad E_B &= \frac{Kq}{CB^2} \hat{CB} & \text{(vi)} \quad F_Q &= \frac{KQq}{CB^2} \hat{CB}
 \end{aligned}$$

(vi) Sharing of charges :

Two conducting hollow spherical shells of radii R_1 and R_2 having charges Q_1 and Q_2 respectively and separated by large distance, are joined by a conducting wire

Let final charges on spheres are q_1 and q_2 respectively.

Potential on both spherical shell become equal after joining, therefore

$$\frac{Kq_1}{R_1} = \frac{Kq_2}{R_2} \Rightarrow \frac{q_1}{q_2} = \frac{R_1}{R_2}$$

$$\text{and, } q_1 + q_2 = Q_1 + Q_2$$

$$\text{from (i) and (ii)} \quad q_1 = \frac{(Q_1 + Q_2)R_1}{R_1 + R_2} \quad q_2 = \frac{(Q_1 + Q_2)R_2}{R_1 + R_2}$$

$$\text{ratio of charges} \quad \frac{q_1}{q_2} = \frac{R_1}{R_2} \Rightarrow \frac{\sigma_1 4\pi R_1^2}{\sigma_2 4\pi R_2^2} = \frac{R_1}{R_2}$$

$$\text{ratio of surface charge densities} \quad \frac{\sigma_1}{\sigma_2} = \frac{R_2}{R_1}$$

$$\text{Ratio of final charges} \quad \frac{q_1}{q_2} = \frac{R_1}{R_2}$$

$$\text{Ratio of final surface charge densities.} \quad \frac{\sigma_1}{\sigma_2} = \frac{R_2}{R_1}$$

Solved Examples

Example 112 The two conducting spherical shells are joined by a conducting wire and cut after some time when charge stops flowing. Find out the charge on each sphere after that.

Solution. After cutting the wire, the potential of both the shells is equal

$$\text{Thus, potential of inner shell } V_{in} = \frac{Kx}{R} + \frac{K(-2Q - x)}{2R} = \frac{K(x - 2Q)}{2R}$$

$$\text{and potential of outer shell } V_{out} = \frac{Kx}{2R} + \frac{K(-2Q - x)}{2R} = \frac{-KQ}{R}$$

$$\text{As } V_{out} = V_{in} \Rightarrow \frac{-KR}{R} = \frac{K(x - 2Q)}{2R} \Rightarrow -2Q = x - 2Q \Rightarrow x = 0$$

So charge on inner spherical shell = 0 and outer spherical shell = $-2Q$.

Example 113 Find charge on each spherical shell after joining the inner most shell and outer most shell by a conducting wire. Also find charges on each surface.

Solution.Let the charge on the innermost sphere be x .

Finally potential of shell 1 = Potential of shell 3

$$\frac{Kx}{R} + \frac{K(-2Q)}{2R} + \frac{K(6Q-x)}{3R} = \frac{Kx}{3R} + \frac{K(-2Q)}{3R} + \frac{K(6Q-x)}{3R}$$

$$3x - 3Q + 6Q - x = 4Q \quad ; \quad 2x = Q \quad ; \quad x = \frac{Q}{2}$$

$$\text{Charge on innermost shell} = \frac{Q}{2}$$

$$\text{charge on outermost shell} = \frac{5Q}{2} \quad \text{middle shell} = -2Q$$

Final charge distribution is as shown in figure.

Example 114 Two conducting hollow spherical shells of radii R and $2R$ carry charges $-Q$ and $3Q$ respectively. How much charge will flow into the earth if inner shell is grounded?

**Solution.**

When inner shell is grounded to the Earth then the potential of inner shell will become zero because potential of the Earth is taken to be zero.

$$\frac{Kx}{R} + \frac{K3Q}{2R} = 0$$

$$x = -\frac{3Q}{2}, \quad \text{the charge that has increased}$$

$$= -\frac{3Q}{2} - (-Q) = -\frac{Q}{2} \quad \text{hence charge flows into the Earth} = \frac{Q}{2}$$

Example 115. An isolated conducting sphere of charge Q and radius R is connected to a similar uncharged sphere (kept at a large distance) by using a high resistance wire. After a long time what is the amount of heat loss?

Solution.

When two conducting spheres of equal radius are connected charge is equally distributed on them (Result VI). So we can say that heat loss of system

$$\Delta H = U_i - U_f$$

$$= \left(\frac{Q^2}{8\pi\epsilon_0 R} - 0 \right) - \left(\frac{Q^2/4}{8\pi\epsilon_0 R} + \frac{Q^2/4}{8\pi\epsilon_0 R} \right) = \frac{Q^2}{16\pi\epsilon_0 R}$$

18. VAN DE GRAAFF GENERATOR (HIGH VOLTAGE GENERATOR)

- (i) Designed by R.J. Van de Graaff in 1931.
- (ii) It is an electrostatic generator capable of generating very high potential of the order of 5×10^6 V.
- (iii) This high potential is used in accelerating the charged particles.

Principle : It is based on the following two electrostatic phenomena :

- (1). The electric discharge takes place in air or gases readily at pointed conductors.
- (2) (i) If a hollow conductor is in contact with an other conductor, which lies inside the hollow conductor. Then as charge is supplied to inner conductor. The charge immediately shifts to outer surface of the hollow conductor.
Consider a large spherical conducting shell A having radius R and charge +Q, potential inside the shell is constant and it is equal to that at its surface.

Therefore, potential inside the charged conducting shell A, $V_1 = \frac{1}{4\pi\epsilon_0} \cdot \frac{Q}{R}$

Suppose that a small conducting sphere B having radius r and charge +q is placed at the centre of the shell A.

Then, potential due to the sphere B at the surface of shell A, $V_2 = \frac{1}{4\pi\epsilon_0} \cdot \frac{q}{R}$

and potential due to the sphere B at its surface, $V_3 = \frac{1}{4\pi\epsilon_0} \cdot \frac{q}{r}$

Thus, total potential at the surface of shell A due to the charges Q and q,

$$V_A = V_1 + V_2 = \frac{1}{4\pi\epsilon_0} \cdot \frac{Q}{R} + \frac{1}{4\pi\epsilon_0} \cdot \frac{q}{R} \quad \text{or} \quad V_A = \frac{1}{4\pi\epsilon_0} \left(\frac{Q}{R} + \frac{q}{R} \right)$$

and the total potential at the surface of sphere B due to the charges Q and q,

$$V_B = V_1 + V_3 = \frac{1}{4\pi\epsilon_0} \cdot \frac{Q}{R} + \frac{1}{4\pi\epsilon_0} \cdot \frac{q}{r} \quad \text{or} \quad V_B = \frac{1}{4\pi\epsilon_0} \left(\frac{Q}{R} + \frac{q}{r} \right)$$

It follows that $V_B > V_A$. Hence, potential difference between the sphere and the shell,

$$V = V_B - V_A = \frac{1}{4\pi\epsilon_0} \left(\frac{Q}{R} + \frac{q}{r} \right) - \frac{1}{4\pi\epsilon_0} \left(\frac{Q}{R} + \frac{q}{R} \right) \quad V = \frac{1}{4\pi\epsilon_0} \cdot q \left(\frac{1}{r} - \frac{1}{R} \right)$$

It follows that potential difference between the sphere and the shell is independent of the charge Q on the shell. Therefore, if the sphere is connected to the shell by a wire, the charge supplied to the sphere will immediately flow to the shell.

It is because, the potential of the sphere is higher than that of the shell and the charge always flows from higher to lower potential.

It forms the basic principle of Van de Graaff generator.

Construction :

Working :

- (i) An endless belt of an insulating material is made to run on two pulleys P_1 and P_2 with the help of an electric motor.
- (ii) The metal comb C_1 , called spray comb is held potential with the help of E.H.T. source ($\approx 10^4$ V), it produces ions in its vicinity. The positive ions get sprayed on the belt due to the repulsive action of comb C_1 .
- (iii) These positive ions are carried upward by the moving belt. A comb C_2 , called collecting comb is positioned near the upper end of the belt, such that the pointed ends touch the belt and the other end is in contact with the inner surface of the metallic sphere S . The comb C_2 collects the positive ions and transfers them to the metallic sphere.
- (iv) The charge transferred by the comb C_2 immediately moves on to the outer surface of the hollow sphere. As the belt goes on moving, the accumulation of positive charge on the sphere also keeps on taking place continuously and its potential rises considerably.
- (v) With the increase of charge on the sphere, its leakage due to ionisation of surrounding air also becomes faster.
- (vi) The maximum potential to which the sphere can be raised is reached, when the rate of loss of charge due to leakage becomes equal to the rate at which the charge is transferred to the sphere.
- (vii) To prevent the leakage of charge from the sphere, the generator is completely enclosed inside an earth-connected steel tank, which is filled with air under pressure.
- (viii) If the charged particles, such as protons, deuterons, etc. are now generated in the discharge tube D with lower end earthed and upper end inside the hollow sphere, they get accelerated in downward direction along the length of the tube. At the other end, they come to hit the target with large kinetic energy.
- (ix) Van de Graaff generator of this type was installed at the Carnegie institute in Washington in 1937. One such generator was installed at Indian Institute of Technology, Kanpur in 1970 and it accelerates particles to 2 MeV energy.

Solved Miscellaneous Problems

Problem 1. Two equal positive point charges ' Q ' are fixed at points $B(a, 0)$ and $A(-a, 0)$. Another negative point charge q_0 is also placed at $O(0, 0)$ then prove that the equilibrium at ' O ' is

- (i) stable for displacement in Y-direction.
- (ii) unstable for displacement in X-direction.

Solution.

(i) When charge is shifted along y-axis

Let x-y direction as :-

After resolving into components, net force will be along negative y-axis so the particle will return to its original position. So it is stable equilibrium

(ii) When negative charge q_0 is shifted along x-axis.

$$\text{Initially } \vec{F}_{AO} + \vec{F}_{BO} = 0 \Rightarrow |\vec{F}_{AO}| = |\vec{F}_{BO}| = \frac{KQq_0}{d^2}$$

When charge q_0 is slightly shifted towards + x axis by small distance Δx then

$$|\vec{F}_{BO}| > |\vec{F}_{AO}|$$

Also these forces are attractive forces (due to negative charge)

Therefore the particle will move towards positive x-axis and will not return to its original position so it is unstable equilibrium for negative charge.

Problem 2. A particle of mass m and charge $-q$ is located midway between two fixed charged particles each having a charge q and a distance 2ℓ apart. Prove that the motion of the particle will be SHM if it is displaced slightly along perpendicular bisector and released. Also find its time period.

Solution.

Let x-y direction as :-

When particle is shift along y-axis with a small displacement
 After resolving component of forces between q and -q charges
 by figure F_{net} in x-axis = 0 [F_{net} = net force on -q charge]
 Net force on -q charge in y direction = $-2F \cos \theta$

$$= -2 \cdot \frac{kQq}{(x^2 + l^2)} \cdot \frac{x}{(x^2 + l^2)^{1/2}}$$

$$|\vec{F}| = \frac{2Kq^2x}{(x^2 + l^2)^{3/2}}$$

$$\Rightarrow ma = \frac{2Kq^2x}{l^3} \quad (\text{for } x \ll l) \quad (a = \text{acceleration of } -q \text{ charge})$$

$$\Rightarrow a = -\frac{2Kq^2}{ml^3} \cdot x$$

This is equation of S.H.M. ($a = -\omega^2x$)

$$\text{so time period of this charge } (-q) :- \quad T = 2\pi \sqrt{\frac{ml^3}{2Kq^2}} \quad \text{Ans.}$$

Problem 3.

Two charges of Q each are placed at two opposite corners of a square. A charge q is placed at each of the other two corners.

- (a) If the resultant force on Q is zero, how are Q and q related ?
 (b) Could q be chosen to make the resultant force on each charge zero ?

Solution.

(a) Let at a square ABCD charges are placed as shown

Now forces on charge Q (at point A) due to other charge are \vec{F}_{QQ} , \vec{F}_{Qq} and \vec{F}_{Qq} respectively shown in figure.

$$F_{\text{net on Q}} = \vec{F}_{Q,Q} + \vec{F}_{Q,q} + \vec{F}_{Q,q} \quad (\text{at point A})$$

But $F_{\text{net}} = 0$

So, $\Sigma F_x = 0$

$$\Sigma F_x = -F_{QQ} \cos 45^\circ - F_{Qq}$$

$$\Rightarrow \frac{KQ^2}{(\sqrt{2}a)^2} \cdot \frac{1}{\sqrt{2}} + \frac{KQq}{a^2} = 0 \quad \Rightarrow \quad q = -\frac{Q}{2\sqrt{2}} \quad \text{Ans.}$$

(b) For resultant force on each charge to be zero :

From previous data, force on charge Q is zero when $q = -\frac{Q}{2\sqrt{2}}$ if for this value of charge q, force on q is zero then and only then the value of q exists for which the resultant force on each charge is zero.

Force on q :-

Forces on charge q (at point D) due to other three charges are \vec{F}_{qQ} , \vec{F}_{qq} and \vec{F}_{qQ} respectively shown in figure.

Net force on charge q :-

$$\vec{F}_{\text{net}} = \vec{F}_{qq} + \vec{F}_{qQ} + \vec{F}_{qQ} \quad \text{But } \vec{F}_{\text{net}} = 0$$

$$\text{So, } \Sigma F_x = 0$$

$$\Sigma F_x = -\frac{Kq^2}{(\sqrt{2}a)^2} + \frac{1}{\sqrt{2}} - \frac{KQq}{(a)^2} \Rightarrow q = -\frac{Q}{2\sqrt{2}}$$

But from previous condition, $q = -\frac{Q}{2\sqrt{2}}$

So, no value of q makes the resultant force on each charge zero.

Problem 4.

Figure shows a uniformly charged thin non-conducting sphere of total charge Q and radius R . If point charge q is situated at point 'A' which is at a distance $r < R$ from the centre of the sphere then find out following

- Force acting on charge q .
- Electric field at centre of sphere.
- Electric field at point B.

Solution.

- Electric field inside a hollow sphere = 0

\therefore Force on charge q .

$$F = qE = q \times 0 = 0$$

- Net electric field at centre of sphere

$$E_{\text{net}} = E_1 + E_2$$

$$E_1 = \text{field due to sphere} = 0$$

$$E_2 = \text{field due to this charge} = \frac{Kq}{r^2}$$

$$E_{\text{net}} = \frac{Kq}{r^2}$$

- Electric field at B due to charge on sphere, $\vec{E}_1 = \frac{KQ}{r_1^2} \hat{r}_1$

and due to charge q at A, $\vec{E}_2 = \frac{Kq}{r_2^2} \hat{r}_2$

$$\text{So, } \vec{E}_{\text{net}} = \vec{E}_1 + \vec{E}_2 = \frac{KQ}{r_1^2} \hat{r}_1 + \frac{Kq}{r_2^2} \hat{r}_2 \quad \text{where } r_1 = CB \text{ and } r_2 = AB$$

Problem 5. Figure shows two concentric sphere of radius R_1 and R_2 ($R_2 > R_1$) which contains uniformly distributed charges Q and $-Q$ respectively. Find out electric field intensities at the following positions :

- (i) $r < R_1$ (ii) $R_1 \leq r < R_2$ (iii) $r \geq R_2$

Solution.

Net electric field = $E_1 + E_2$
 E_1 = field due to sphere of radius R_1
 E_2 = field due of sphere of radius R_2

- (i) $E_1 = 0, E_2 = 0$
 $E_{\text{net}} = 0$

(ii) $E_1 = \frac{KQ}{r^2}, E_2 = 0 \quad \Rightarrow \quad \vec{E} = \frac{Kq}{r^2} \hat{r}$

(iii) $\vec{E}_1 = \frac{Kq}{r^2} \hat{r} \quad \vec{E}_2 = \frac{Kq}{r^2} (-\hat{r}) \quad \Rightarrow \quad \vec{E}_{\text{net}} = \vec{E}_1 + \vec{E}_2 = 0$

Problem 6.

A solid non conducting sphere of radius R and uniform volume charge density ρ has centre at origin. Find out electric field intensity in vector form at following positions.

- (i) $(R, 0, 0)$ (ii) $(0, 0, R/2)$ (iii) (R, R, R)

Solution.

For uniformly charged non-conducting sphere. Electric field inside the sphere :-

$$\vec{E} = k \frac{Qr}{R^3} = \frac{\rho r}{3\epsilon_0} \quad \text{for } r < R \quad \text{and electric field outside the sphere}$$

$$\vec{E}_o = \frac{KQ}{r^2} \cdot \hat{r} = \frac{1}{4\pi\epsilon_0} \cdot \frac{\frac{4}{3}\pi R^3 \rho}{r^2} \cdot \hat{r} = \frac{\rho R^3}{3\epsilon_0 r^2} \cdot \hat{r} \quad \text{for } r \geq R$$

- (i) $(R, 0, 0)$ means it is at the surface $\vec{r} = R\hat{i}$ and $\hat{r} = \hat{i}$

$$\vec{E}_o = \frac{\rho R^3}{3\epsilon_0 R^2} (\hat{i}) = \frac{\rho R}{3\epsilon_0} \cdot \hat{i}$$

- (ii) $(0, 0, \frac{R}{2})$

means point is inside the sphere

$$\vec{r} = \frac{R}{2} \hat{k} \quad \Rightarrow \quad \vec{E} = \frac{\rho R}{6\epsilon_0} \hat{k}$$

- (iii) For position (R, R, R)

$$\vec{r} = R(\hat{i} + \hat{j} + \hat{k}) \quad \Rightarrow \quad \hat{r} = \frac{\hat{i} + \hat{j} + \hat{k}}{\sqrt{3}}, \quad r = R\sqrt{3}$$

means point (R, R, R) is outside the sphere

$$\vec{E} = \frac{\rho R^3}{3\epsilon_0 (3R^2)} \cdot \frac{(\hat{i} + \hat{j} + \hat{k})}{\sqrt{3}} = \frac{\rho R}{9\sqrt{3}\epsilon_0} (\hat{i} + \hat{j} + \hat{k}) \quad \text{Ans.}$$

Problem 7.

Three identical spheres each having a charge q (uniformly distributed) and radius R , are kept in such a way that each touches the other two. Find the magnitude of the electric force on any sphere due to other two.

Solution.

Given three identical spheres each having a charge q and radius R are kept as shown :-

For any external point ; sphere behaves like a point charge. So it becomes a triangle having point charges on its corner.

$$|\vec{F}_{qq}| = \frac{kq^2}{4R^2}$$

$$\text{So net force (F)} = 2 \cdot \frac{kq^2}{4R^2} \cdot \cos \frac{60}{2} = 2 \cdot \frac{kq^2}{4R^2} \cdot \frac{\sqrt{3}}{2} = \frac{\sqrt{3}}{4} \cdot \frac{kq^2}{R^2} \quad \text{Ans.}$$

Problem 8. A uniform electric field of 10 N/C exists in the vertically downward direction. Find the increase in the electric potential as one goes up through a height of 50cm.

Solution. $E = -\frac{dv}{dr} \Rightarrow dv = -\vec{E} \cdot d\vec{r}$

for $\vec{E} = \text{constant} \Rightarrow \Delta v = -\vec{E} \cdot \Delta \vec{r}$; $\Delta v = -10(-\hat{j}) \cdot (50 \times 10^{-2})\hat{j} = 5 \text{ volts.}$

Problem 9. An electric field of 20 N/C exists along the x-axis in space. Calculate the potential difference $V_B - V_A$ where the point A and B are given by –

- (a) A = (0,0) ; B = (4m , 2m) (b) A = (4m,2m) ; B = (6m , 5m)
 (c) A = (0,0) ; B = (6m , 5m)

Solution. Electric field in x - axis mean $\vec{E} = 20 \hat{i}$

(a) $|\Delta V_{AB}| = \vec{E} \cdot d = 20 \hat{i} \cdot 4 \hat{i} = 80 \text{ V} \Rightarrow V_B - V_A = -80 \text{ V}$

(b) $|\Delta V_{BC}| = \vec{E} \cdot d = 20 \hat{i} \cdot 2 \hat{i} = 40 \text{ volt} \Rightarrow V_C - V_B = -40 \text{ V}$

(c) $|\Delta V_{AC}| = \vec{E} \cdot d = 20 \hat{i} \cdot 6 \hat{i} = 120 \text{ volt} \Rightarrow V_C - V_A = -120 \text{ V}$

Problem 10. Some equipotential surfaces are shown in figure. What can you say about the magnitude and the direction of the electric field ?

Solution.

We know, that the electric field is always perpendicular to equipotential surface. So, making electric field lines perpendicular to the surface, we find that these lines are originating from the centre. So, the field is similar to that due to a point charge placed at the centre. So, comparing the given potentials with that due to point charge, we have,

$$\frac{KQ}{r}$$

$$V = \frac{KQ}{r} \Rightarrow KQ = V_A r_A = V_B r_B = V_C r_C = 6 \text{ V-m}$$

Hence electric field at distance at radius r can be given by

$$E = \frac{KQ}{r^2} = \frac{6}{r^2} \text{ V/m}$$

As the electric field lines are directed towards the decreasing potential. So, electric field is along radially outward direction.

**Problem 11.**

A point charge of charge $-q$ and mass m is released with negligible speed from a distance $\sqrt{3}R$ on the axis of fixed uniformly charged ring of charge Q and radius R . Find out its velocity when it reaches at the centre of the ring.

**Solution :**

As potential due to uniform charged ring at its axis (at x distance)

$$V = \frac{kQ}{\sqrt{R^2 + x^2}} ; \text{ So potential at point A due to ring}$$

$$V_1 = \frac{kQ}{\sqrt{R^2 + 3R^2}} = \frac{kQ}{2R}$$

So potential energy of charge $-q$ at point A

$$\text{P.E.}_1 = \frac{-kQq}{2R} \text{ and potential at point B } V_2 = \frac{kQ}{R}$$

So potential energy of charge $-q$ at point B

$$\text{P.E.}_2 = \frac{-kQq}{R}$$

Now by energy conservation

$$\text{P.E.}_1 + \text{K.E.}_1 = \text{P.E.}_2 + \text{K.E.}_2$$

$$\frac{-kQq}{2R} + 0 = \frac{-kQq}{R} + \frac{1}{2}mv^2 \Rightarrow v^2 = \frac{kQq}{mR}$$

$$\text{So velocity of charge } -q \text{ at point B } v = \sqrt{\frac{kQq}{mR}} \quad \text{Ans.}$$

Problem 12.

Four small point charges each of equal magnitude q are placed at four corners of a regular tetrahedron of side a . Find out potential energy of charge system

**Solution.**

Potential energy of system :

$$U = U_{12} + U_{13} + U_{14} + U_{23} + U_{24} + U_{34}$$

$$U = \frac{-kq^2}{a} + \frac{kq^2}{a} + \frac{-kq^2}{a} + \frac{-kq^2}{a} + \frac{kq^2}{a} + \frac{-kq^2}{a}$$

$$\text{Total potential energy of this charge system } U = \frac{-2kq^2}{a}$$

Problem 13. If $V = x^2y + y^2z$ then find \vec{E} at (x, y, z)

Solution. Given $V = x^2y + y^2z$ and $\vec{E} = -\frac{\partial V}{\partial \vec{r}}$

$$\vec{E} = -\left[\frac{\partial V}{\partial x}\hat{i} + \frac{\partial V}{\partial y}\hat{j} + \frac{\partial V}{\partial z}\hat{k}\right] \Rightarrow \vec{E} = -[2xy\hat{i} + (x^2+2yz)\hat{j} + y^2\hat{k}]$$

Problem 14. Magnitude of electric field depends only on the x – coordinate given $\vec{E} = \frac{20}{x^2}\hat{i}$ V/m . Find

- the potential difference between two point A (5m, 0) and B (10m, 0).
- potential at $x = 5$ if V at ∞ is 10 volt.
- in part (i) does the potential difference between A and B depend on whether the potential at ∞ is 10 volt or something else.

Solution. Given $\vec{E} = \frac{20}{x^2}\hat{i}$ V/m

we know that $\int dV = -\int \vec{E} \cdot d\vec{r}$

$$\int_{V_1}^{V_2} dV = -\int_{x_1}^{x_2} E_x dx = -\int_{x_1}^{x_2} \frac{20}{x^2} dx$$

$$\text{Potential difference } \Delta V = \left. \frac{20}{x} \right|_{x_1}^{x_2} \Rightarrow V_2 - V_1 = \frac{20}{x_2} - \frac{20}{x_1}$$

- Potential difference between point A and B (ΔV for A to B) $V_B - V_A = \frac{20}{10} - \frac{20}{5} = -2$ volt
- ΔV for $x = \infty$ to $x = 5$

$$V_5 - V_\infty = \frac{20}{5} - \frac{20}{\infty}$$

$$V_5 = 10 + 4 = 14 \text{ volt}$$

- Potential difference between two points does not depend on reference value of potential so the potential difference between A and B does not depend on whether the potential at ∞ is 10 volt or something else.

Problem 15. If $E = 2r^2$ then find $V(r)$

Solution. Given $E = 2r^2$

we know that $\int dv = -\int \vec{E} \cdot d\vec{r} = -\int 2r^2 dr$

$$\Rightarrow V(r) = \frac{-2r^3}{3} + c \quad \text{Ans.}$$

Problem 16. A charge Q is uniformly distributed over a rod of length ℓ . Consider a hypothetical cube of edge ℓ with the centre of the cube at one end of the rod. Find the minimum possible flux of the electric field through the entire surface of the cube.

Solution.

According to Gauss law : flux depend upon charge inside the closed hypothetical surface so for minimum possible flux through the entire surface of the cube = charge inside should be minimum.

$$\text{Linear charge density of rod} = \frac{Q}{\ell}$$

$$\text{and minimum length of rod inside the cube} = \frac{\ell}{2}$$

$$\text{So charge inside the cube} = \frac{\ell}{2} \cdot \frac{Q}{\ell} = \frac{Q}{2}$$

$$\text{so flux through the entire surface of the cube} = \frac{\Sigma q}{\epsilon_0} = \frac{Q}{2\epsilon_0}$$

Problem 17.

A charge Q is placed at a corner of a cube. Find the flux of the electric field through the six surfaces of the cube.

**Solution.**

$$\text{By Gauss law, } \phi = \frac{q_{\text{in}}}{\epsilon_0}$$

Here, since Q is kept at the corner so only $\frac{Q}{8}$ charge is inside the cube. (since complete charge can be enclosed by 8 such cubes)

$$\therefore q_{\text{in}} = \frac{Q}{8}$$

$$\text{So, } \phi = \frac{q_{\text{in}}}{\epsilon_0} = \frac{Q}{8\epsilon_0} \quad \text{Ans.}$$

Problem 18.

An isolated conducting sphere of charge Q and radius R is grounded by using a high resistance wire. What is the amount of heat loss ?

Solution.

When sphere is grounded its potential become zero which means all charge goes to earth (due to sphere is conducting and isolated)
so all energy in sphere is converted into heat

$$\text{so, total heat loss} = \frac{kQ^2}{2R}$$
