The compounds which have positive enthalpies of formation are called endothermic compounds (less stable) and which have negative enthalpies of formation are called exothermic compounds (stable).

14. Heat of combustion or enthalpy of combustion: It is the amount of heat evolved when one mole of the substance is completely oxidised. It has a number of applications:

(i) Determination of calorific values of foods and fuels.
(ii) Enthalpy of formation can be determined by application of Hess's law.
(iii) Structural problems can be evaluated.

15. Enthalpy of hydrogenation: The enthalpy change associated when one mole of an unsaturated organic compound is fully hydrogenated.

16. Enthalpy of solution: The amount of heat evolved or absorbed when one mole of the substance is dissolved in excess of water so that further dilution does not bring any heat change.

17. Enthalpy or heat of neutralisation: The amount of heat evolved when one gram equivalent of an acid is neutralised by one gram equivalent of a base in dilute solution. Heat of neutralisation of a strong acid against a strong base is always constant, *i.e.*, 13.7 kcal or 57.1 kJ. It is due to common reaction between H^+ and OH^- ions. The heat of formation of water from these ions is 13.7 kcal.

$$H^+ + OH^- \longrightarrow H_2O; \qquad \Delta H = -13.7\,\text{kcal}$$

In the case of weak acids and weak bases, the heat of neutralisation is always less than 13.7 kcal because some of the evolved heat energy is utilised in bringing about complete ionisation of acid or base in solution.

18. Enthalpy of fusion: Heat absorbed in converting one mole of solid into liquid at its melting point.

19. Enthalpy of vaporisation: Heat absorbed in converting one mole of a liquid into its vapours at its boiling point.

Enthalpy of sublimation: Heat absorbed in converting one mole of solid directly into its vapour.

20. Laws of thermochemistry:

(i) Lavoisier and Laplace law: The heat which is required to break a compound into its elements is equal to the heat evolved during its formation from its elements.

$$\Delta H_{\text{decomposition}} = -\Delta H_f$$

(ii) Hess's law (the law of constant heat summation): If a chemical reaction can be made to take place in a number of ways in one or in several steps, the total change is always the same, *i.e.*, heat change depends upon the initial and final stages only and independent of intermediate steps. The thermochemical equations can be added, subtracted or multiplied by a number to obtain a desired equation.

21. Bond energy: The energy required to break one mole of bond of a particular type is termed bond dissociation energy. It depends upon the nature of bond and also the molecule in which the bond is present. The bond energies can be used for determining heats of reactions.

[Heat of reaction = Sum of bond energies of reactants
– Sum of bond energies of products]

The bond energies can also be used for determining resonance energy.

Resonance energy = Observed heat of formation
– Calculated heat of formation

22. Experimental determination of heat of reaction: The apparatus used is called calorimeter. Two of the common types of calorimeters are: (i) Water calorimeter (ii) Bomb-calorimeter. The principle of measurement is that heat given out is equal to heat taken, *i.e.*,

$$Q = (W + m) \times s \times (T_2 - T_1)$$

where, W = Water equivalent of the calorimeter, m = mass of the liquid, s = its sp. heat, T_2 = final temperature and T_1 = initial temperature.

23. Spontaneous process: A process which proceeds of its own accord without any outside help is termed spontaneous process. All natural processes proceed spontaneously and are thermodynamically irreversible.

Driving force: It is the force which makes the process to occur by itself. It is the resultant of two basic tendencies:

(i) Tendency to attain a state of minimum energy.
(ii) Tendency to attain a state of maximum randomness.

The disorder or randomness in a system is measured in terms of a thermodynamic property known as **entropy.** The absolute value of entropy cannot be determined. The change in entropy is denoted by ΔS.

$$\Delta S = \frac{q_{\text{reversible}}}{T}$$

where, q is the heat supplied at temperature T.

$\Delta S = +$ indicates increase in randomness whereas, $\Delta S = -$ indicates the decrease in randomness.

$$\Delta S = S_{\text{final}} - S_{\text{initial}}$$

24. Free energy: Free energy change, ΔG, was introduced by Gibbs. The Gibbs-Helmholtz equation is:

$$\Delta G = \Delta H - T\,\Delta S \quad \text{or} \quad G = H - TS$$

and $$\Delta G = G_{\text{products}} - G_{\text{reactants}}$$

where, G is known as free energy. This is the maximum energy available to a system during a process which can be converted into useful work.

Negative value of ΔG indicates that the process is spontaneous. Zero value means that there is a state of equilibrium.

25. Second law of thermodynamics: It is impossible to construct a machine that is able to convey heat by a cyclic process from a colder to a hotter body unless work is done on the machine by some outside agency.

Or

Work can always be converted into heat but the conversion of heat into work does not take place under all conditions.

26. Carnot cycle: It demonstrates the maximum convertibility of heat into work in a theoretical and an imaginary cycle.

$$\text{Thermodynamic efficiency} = \frac{W}{q_2} = \frac{T_2 - T_1}{T_2}$$

The efficiency of a heat engine is always less than 1.

27. Third law of thermodynamics: The entropy of all pure crystals is zero at the absolute zero of temperature.

Questions

1. **Matrix-Matching Problems (For IIT Aspirants):**

[A] Match the List-I with List-II:

List-I	List-II
(a) $\Delta S_{\text{system}} > 0$ (Isolated system)	(p) Spontaneous
(b) $\Delta G < 0$	(q) Non-spontaneous photochemical reaction
(c) $\Delta S_{\text{Total}} = 0$	(r) Equilibrium
(d) $(\Delta G)_{TP} > 0$	(s) Non-spontaneous

[B] Match the Column-I with Column-II:

Column-I	Column-II
(a) Isothermal process (reversible)	(p) $W = 2.303nRT \log\left(\frac{P_1}{P_2}\right)$
(b) Adiabatic process	(q) $PV^{\gamma} = \text{constant}$
(c) $W = \frac{nR}{r-1}(T_2 - T_1)$	(r) $W = 2.303nRT \log\left(\frac{V_2}{V_1}\right)$
(d) Irreversible isothermal process	(s) $W = -P_{\text{ext}}(V_2 - V_1)$

[C] Match the physical properties in List-I with their relations in List-II:

List-I (Quantity)	List-II (Relation)
(a) ΔG	(p) $-nFE$ or $-nFE^{\circ}$
(b) ΔG°	(q) $\Delta H - T\,\Delta S$
(c) W or $W_{\max}$	(r) $-RT \log_e K$
(d) ΔS°	(s) $2.303nR \log_{10}\left(\frac{V_2}{V_1}\right)$

[D] Match the Column-I with Column-II:

Column-I (Gas)	Column-II (Thermodynamic property)
(a) O_2	(p) $\gamma = 1.4$
(b) N_2	(q) $C_P = \frac{7}{2}R$
(c) CO_2, CH_4	(r) $\frac{23}{6}R$
(d) 1 mol O_2 + 2 mol O_3	(s) $\gamma = 1.33$

Here: C_P = Heat capacity at constant pressure
$\gamma = C_P/C_V$

[E] Match the reactions in Column-I with relations of Column - II:

Column-I (Reaction)	Column-II (Relation)
(a) $H_2(g) + Cl_2(g) \rightarrow 2HCl(g)$	(p) $\Delta H = \Delta U + RT$
(b) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$	(q) $\Delta H = \Delta U$
(c) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$	(r) $\Delta H = \Delta U - 2RT$
(d) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$	(s) Forward shift by increasing pressure

[F] Match the processes of Column-I with entropy or enthalpy changes in Column-II:

Column-I	Column-II
(a) $N_2(g) + O_2(g) \rightarrow 2NO(g)$	(p) $\Delta S = 0$
(b) $2KI(aq.) + HgI_2(aq.) \rightarrow K_2[HgI_4](aq.)$	(q) $\Delta S < 0$
(c) $PCl_3(g) + Cl_2(g) \rightarrow PCl_5(g)$	(r) $\Delta H > 0$
(d) $NH_3(g) + HCl(g) \rightarrow NH_4Cl(s)$	(s) $\Delta H < 0$

[G] Match the List-I with List-II:

List-I (Reaction)	List-II (Process)
(a) $C(s) + \frac{1}{2}O_2(g) \rightarrow CO(g)$	(p) Combustion
(b) $CO(g) + \frac{1}{2}O_2(g) \rightarrow CO_2(g)$	(q) Neutralization
(c) $NaOH(aq.) + HCl(aq.) \rightarrow NaCl(aq.) + H_2O$	(r) Process of formation
(d) $H_2(g) + \frac{1}{2}O_2(g) \rightarrow H_2O(l)$	(s) Reaction of apollo fuel cell

[H] Match the relations of Column-I with their names in Column-II:

Column-I	Column-II
(a) $\frac{\Delta H_2 - \Delta H_1}{T_2 - T_1} = \Delta C_P$	(p) Trouton equation
(b) $\frac{\Delta U_2 - \Delta U_1}{T_2 - T_1} = \Delta C_V$	(q) Effect of temperature on the heat of reaction
(c) $\frac{\Delta H_{\text{fusion}}}{T_{\text{mp}}} = \Delta S_{\text{fusion}}$	(r) Kirchhoff's equation
(d) $\lim\limits_{T \to 0\,\text{K}} S \rightarrow 0$	(s) Third law of thermodynamics

[I] Match the Column-I with Column-II:

	Column-I		Column-II
(a)	Amount of heat required to raise the temperature of 1 mol substance by 1°C	(p)	Specific heat × molar mass
(b)	$\frac{\Delta H}{\Delta T}$ or $\frac{\Delta U}{\Delta T}$	(q)	Heat capacity = C, C_P or C_V
(c)	Heat evolved in the combustion of 1 g of a substance	(r)	Electron gain enthalpy
(d)	Heat evolved when an extra electron is added to valence shell of an isolated gaseous atom	(s)	Calorific value

[J] Match the Column-I with Column-II :

	Column-I		Column-II
(a)	$\Delta H = +$ ve, $\Delta S = +$ ve	(p)	Spontaneous at all temperature
(b)	$\Delta H = -$ ve, $\Delta S = +$ ve	(q)	Non-spontaneous at all temperature
(c)	$\Delta H = +$ ve, $\Delta S = -$ ve	(r)	Non-spontaneous at high temperature
(d)	$\Delta H = -$ ve, $\Delta S = -$ ve	(s)	Spontaneous at high temperature

Answers

1. [A] (a—p); (b—p, q); (c—r); (d—s)
   [B] (a—p, r); (b—q); (c—q); (d—s)
   [C] (a—p, q); (b—p, r); (c—p); (d—s)
   [D] (a—p, q); (b—p, q); (c—s); (d—r)
   [E] (a—q); (b—q); (c—p); (d—r, s)
   [F] (a—p, r); (b—q, s); (c—q, r); (d—q, s)
   [G] (a—p, r); (b—p); (c—q); (d—p, r, s)
   [H] (a—q, r); (b—q, r); (c—p); (d—s)
   [I] (a—p, q); (b—p, q); (c—s); (d—r)
   [J] (a—s); (b—p); (c—q); (d—r)

• PRACTICE PROBLEMS •

1. Write 'yes' if heat, work or matter are able to cross the boundary of the corresponding system and 'no' if passage is forbidden:

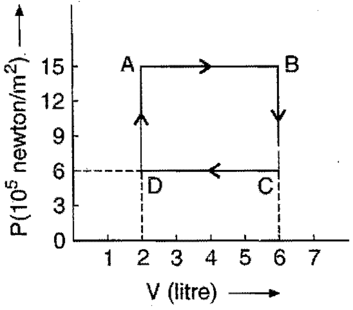
Property	Open system	Close system	Isolated system	Adiabatic system
Heat	Yes/No	Yes/No	Yes/No	Yes/No
Work	Yes/No	Yes/No	Yes/No	Yes/No
Matter	Yes/No	Yes/No	Yes/No	Yes/No

2. Which of the following are state functions?
(i) Q (ii) W (iii) $Q + W$ (iv) $Q - W$ (v) Q_V (vi) Q_P
(vii) $\frac{Q}{W}$ (viii) $\frac{Q}{T}$ (ix) $\frac{\Delta H}{T}$ (x) $E + PV$ (xi) $E - PV$

[**Ans.** (iv), (v), (vi), (viii), (ix), (x).]

3. In the adjoining diagram, the P-V graph of an ideal gas is shown. Find out from the graph (i) Work done in taking the gas from the state $A \rightarrow B$ (ii) Work done in taking the gas from $B \rightarrow C$ (iii) Work done in a complete cycle. (1 litre = 10^{-3} m^3)

[**Ans.** (i) -60×10^2 J (ii) zero (iii) 36×10^2 J, *i.e.,* net work is done by the gas]



4. A sample of a gas contracts 200 cm^3 by an average of 0.5 atmosphere while 8.5 J heat flows out into the surroundings. What is the change in energy of the system?
(1 litre-atm = 101.3 J)

[**Ans.** Energy of the system increases by 1.63 J]

5. Calculate the pressure-volume work done by the system when the gas expands from 1.0 litre to 2.0 litre against a constant external pressure of 10 atmospheres. Express the answer in calorie and joule.

[**Ans.** –10 litre-atm, –242.2 cal, –1013.28 J]

6. A sample of a gas in a cylinder contracts by 7.5 litre at a constant pressure of 5.0 atmosphere. How much work is done on the gas by the surroundings?

[**Ans.** 37.5 litre-atm or 3801.75 J]

7. A sample of a gas expands from 200 cm^3 to 500 cm^3 against an average pressure of 750 torr while 1.5 J heat flows into the system. What is the change in energy of the system? (1 litre-atm = 101.3 J)

[**Ans.** Energy of the system is decreased by 28.5 J; $\Delta E = -28.5$ J]

8. Calculate the work done when 65.38 g of zinc dissolves in hydrochloric acid in an open beaker at 300 K. (At. mass of Zn = 65.38)

[**Ans.** – 2494.2 J, *i.e.*, work is done by the system]

9. 6 moles of an ideal gas expand isothermally and reversibly from a volume of 1 dm^3 to a volume of 10 dm^3 at 27° C. What is the maximum work done? Express your answer in joule.
[**Ans.** – 34464.8 J, work is done by the system]

10. 1 mole of an ideal gas at 25° C is allowed to expand reversibly at constant temperature from a volume of 10 litre to 20 litre. Calculate the work done by the gas in joule and calorie.
[**Ans.** – 1717.46 J or –411 cal, *i.e.*, work is done by the gas]

11. Find the work done when 1 mole of the gas is expanded reversibly and isothermally from 5 atm to 1 atm at 25° C.
[**Ans.** – 3984 J]
[**Hint:** Use $w = -2.303\, nRT \log \frac{P_1}{P_2}$]

12. How much energy is absorbed by 10 moles of an ideal gas if it expands from an initial pressure of 8 atmosphere to 4 atmosphere at a constant temperature of 27° C?
($R = 8.31\,J\,mol^{-1}\,K^{-1}$)
[**Ans.** 1.728×10^4 J]
[**Hint:** In isothermal process, $\Delta E = 0$,
so q (heat absorbed) = – w. Thus, apply the equation

$$q = 2.303 nRT \log \frac{P_1}{P_2}]$$

13. A given mass of a gas at 0° C is compressed reversibly and adiabatically to a pressure 20 times the initial value. Calculate the final temperature of the gas. $\left[\frac{C_P}{C_V} = 1.42\right]$
[**Ans.** $T_2 = 662.2$ K]
[**Hint:** Apply the formula $\left(\frac{T_1}{T_2}\right)^{\gamma} = \left(\frac{P_2}{P_1}\right)^{1-\gamma}$]

14. 3 moles of hydrogen are compressed isothermally and reversibly from 60 dm^3 to 20 dm^3 and 8.22 kJ of work is done on it. Assuming ideal behaviour, calculate the temperature of the gas.
[**Ans.** 300 K]

15. To what pressure must a certain ideal gas ($\gamma = 1.4$) at 373 K and 1 atmospheric pressure be compressed adiabatically in order to raise its temperature to 773 K?
[**Ans.** 7.89 atm]

16. 1 mole of an ideal gas ($C_V = 12.55\,J\,K^{-1}\,mol^{-1}$) at 300 K is compressed adiabatically and reversibly to one-fourth of its original volume. What is the final temperature of the gas?
[**Ans.** 752 K]

17. Calculate $q, w, \Delta E$ and ΔH for the reversible isothermal expansion of 1 mole of ideal gas at 27° C from a volume of 10 dm^3 to a volume of 20 dm^3.
[**Ans.** $q = -w = 1729$ J]

18. Calculate the internal energy change for the process in which 1.0 kcal of heat is added to 1.2 litre of O_2 gas in a cylinder at constant pressure of 1.0 atm and the volume changes to 1.5 litre.
[**Ans.** 0.993 kcal]

19. Calculate ΔE and ΔH when 10 dm^3 of helium at NTP is heated in a cylinder to 100° C, assuming that the gas behaves ideally. ($C_V = 3/2R$)
[**Ans.** $\Delta E = 556.74$ J
$\Delta H = 927.9$ J]
[**Hint:** $\Delta E = n \cdot C_V \cdot \Delta T$ and $\Delta H = n \cdot C_P \cdot \Delta T$

$$= \frac{10}{22.4} \times \frac{3}{2} \times 8.314 \times 100 \qquad = \frac{10}{22.4} \times \frac{5}{2} \times 8.314 \times 100$$
$$= 556.74 \text{ J} \qquad = 927.9 \text{ J}]$$

20. For the conversion of 1 mole of $SO_2(g)$ into $SO_3(g)$ the enthalpy of reaction at constant volume, ΔE, at 298 K is –97.027 kJ. Calculate the enthalpy of reaction, ΔH, at constant pressure.
[**Ans.** $\Delta H = -98.267$ kJ]
[**Hint:** Use the reaction,

$$SO_2(g) + \frac{1}{2} O_2(g) \longrightarrow SO_3(g), \ \Delta n = 1 - \frac{3}{2} = -\frac{1}{2}]$$

21. The heat liberated on complete combustion of 7.8 g benzene is 327 kJ. This heat has been measured at constant volume and at 27° C. Calculate the heat of combustion of benzene at constant pressure. ($R = 8.3\,JK^{-1}\,mol^{-1}$) **(IIT 1996)**
[**Ans.** –3273.7 kJ mol^{-1}]

22. 1 mole of naphthalene ($C_{10}H_8$) was burnt in oxygen gas at 25° C at constant volume. The heat evolved was found to be 5138.8 kJ. Calculate the heat of reaction at constant pressure. ($R = 8.3\,JK^{-1}\,mol^{-1}$)
[**Ans.** 5143.8 kJ]
[**Hint:** Water is present in liquid state at 25° C and naphthalene in solid state.]

23. The enthalpy of formation of methane at constant pressure and 300 K is –75.83 kJ. What will be the heat of formation at constant volume? ($R = 8.3\,J\,K^{-1}\,mol^{-1}$)
[**Ans.** –73.34 kJ]

24. The heat change for the reaction,

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

is – 92.2 kJ. Calculate the heat of formation of ammonia.
[**Ans.** – 46.1 kJ mol^{-1}]

25. $\Delta H°$ for the reaction,

$$4S(s) + 6O_2(g) \longrightarrow 4SO_3(g)$$

is –1583.2 kJ. Calculate ΔH_f° of sulphur trioxide.
[**Ans.** – 395.8 kJ]

26. Calculate the heat change in the reaction,

$$4NH_3(g) + 3O_2(g) \longrightarrow 2N_2(g) + 6H_2O(l)$$

at 298 K given that heats of formation at 298 K for $NH_3(g)$ and $H_2O(l)$ are – 46.0 and – 286.0 kJ mol^{-1} respectively.
[**Ans.** $\Delta H° = -1532$ kJ]

27. Calculate the heat of combustion of 1 mole of $C_2H_4(g)$ to form $CO_2(g)$ and $H_2O(g)$ at 398 K and 1 atmosphere, given that the heats of formation of $CO_2(g)$, $H_2O(g)$ and $C_2H_4(g)$ are – 94.1, – 57.8 and + 12.5 kcal mol^{-1} respectively.
[**Ans.** – 316.3 kcal]

28. The heats of combustion of $CH_4(g)$ and $C_2H_6(g)$ are –890.3 and – 1560 kJ mol^{-1} respectively. Which has higher calorific value?
[**Ans.** Methane has higher calorific value.]

29. The heat of combustion of butane is 2880 kJ mol^{-1}. What is the heat liberated by burning 1 kg of butane in excess of oxygen supply?
[**Ans.** 49655 kJ]

30. The heat of formation of $CH_4(g)$, $C_2H_6(g)$ and $C_4H_{10}(g)$ are – 74.8, – 84.7 and – 126.1 kJ mol^{-1} respectively. Arrange them in order of their efficiency as fuel per gram. Heats of formation of $CO_2(g)$ and $H_2O(l)$ are – 393.5 and – 285.8 kJ mol^{-1} respectively.
[**Ans.** $CH_4 > C_2H_6 > C_4H_{10}$]
[**Hint:** First determine heat of combustion in each case and then find the calorific value.]

31. The heat of combustion of carbon to $CO_2(g)$ is – 393.5 kJ mol^{-1}. Calculate the heat released upon formation of 35.2 g of $CO_2(g)$ from carbon and oxygen gas.
[**Ans.** – 315 kJ]

32. Calculate ΔH_f° of $C_6H_{12}O_6(s)$ from the following data:
ΔH_{comb} of $C_6H_{12}O_6(s) = -2816$ kJ mol^{-1}, ΔH_f° of $CO_2(g)$ $= -393.5$ kJ mol^{-1} and $\Delta H^\circ_{f\,(H_2O)} = -285.9$ kJ mol^{-1}.
[**Ans.** – 1260 kJ mol^{-1}]

33. Calculate the amount of heat released when:
(i) 100 mL of 0.2 *M* HCl solution is mixed with 50 mL of 0.2 *M* KOH.
(ii) 200 mL of 0.1 *M* H_2SO_4 is mixed with 200 mL of 0.2 *M* KOH solution.
[**Ans.** (i) 0.57 kJ (ii) 2.18 kJ]

34. When 100 mL each of HCl and NaOH solutions are mixed, 5.71 kJ of heat was evolved. What is the molarity of two solutions? The heat of neutralisation of HCl is 57.1 kJ.
[**Ans.** 1 *M*]

35. Determine the enthalpy of the reaction,

$$C_3H_8(g) + H_2(g) \longrightarrow C_2H_6(g) + CH_4(g)$$

at 25° C, using the given heat of combustion values under standard conditions.

Compound	$H_2(g)$	$CH_4(g)$	$C_2H_6(g)$	C (graphite)
ΔH° (kJ mol^{-1})	–285.8	–890.0	–1560.0	–393.5

The standard heat of formation of $C_3H_8(g)$ is – 103.8 kJ mol^{-1}. (IIT 1992)
[**Ans.** – 55.7 kJ]
[**Hint:**

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O; \quad (\Delta H = -285.8 \text{ kJ}) \quad ...(i)$$

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O; \quad ...(ii) \quad (\Delta H = -890.0 \text{ kJ})$$

$$C_2H_6(g) + \frac{7}{2}O_2(g) \longrightarrow 2CO_2(g) + 3H_2O; \quad ...(iii) \quad (\Delta H = -1560.0 \text{ kJ})$$

$$C + O_2(g) \longrightarrow CO_2(g); \quad (\Delta H = -393.5 \text{ kJ}) \quad ...(iv)$$

$$3C + 4H_2(g) \longrightarrow C_3H_8(g); \quad (\Delta H = -103.8 \text{ kJ}) \quad ...(v)$$

Multiplying eq. (i) by 5 and eq. (iv) by 3 and adding both the equations and subtracting eqs. (ii), (iii) and (v).]

36. The standard enthalpy of combustion at 25° C of hydrogen, cyclohexene (C_6H_{10}) and cyclohexane (C_6H_{12}) are – 241, – 3800 and – 3920 kJ mol^{-1} respectively. Calculate the heat of hydrogenation of cyclohexene. [ISM (Dhanbad) 1992]
[**Ans.** –121 kJ mol^{-1}]
[**Hint:**

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g); \quad ...(i) \quad (\Delta H = -241 \text{ kJ mol}^{-1})$$

$$C_6H_{10}(g) + \frac{17}{2}O_2(g) \longrightarrow 6CO_2(g) + 5H_2O(g); \quad ...(ii) \quad (\Delta H = -3800 \text{ kJ mol}^{-1})$$

$$C_6H_{12}(g) + 9O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g); \quad ...(iii) \quad (\Delta H = -3920 \text{ kJ mol}^{-1})$$

Adding eqs. (i) and (ii) and subtracting eq. (iii),

$$C_6H_{10}(s) + H_2(g) \longrightarrow C_6H_{12}(s);$$

$$\Delta H = -241 - 3800 - (-3920) = -121 \text{ kJ mol}^{-1}]$$

37. From the following data of heats of combustion, find the heat of formation of $CH_3OH(l)$:

$$CH_3OH(l) + \frac{3}{2}O_2(g) \longrightarrow CO_2(g) + 2H_2O(l); \quad \Delta H = -726 \text{ kJ}$$

$$C(s) + O_2(g) \longrightarrow CO_2(g); \quad \Delta H = -394 \text{ kJ}$$

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l); \quad \Delta H = -286 \text{ kJ}$$

[BIT (Ranchi) 1991]
[**Ans.** –240 kJ mol^{-1}]

38. Calculate the heat of formation of methane, given that
heat of formation of water = – 286 kJ mol^{-1}
heat of combustion of methane = – 890 kJ mol^{-1}
heat of combustion of carbon = – 393.5 kJ mol^{-1}
[ISM (Dhanbad) 1993]
[**Ans.** – 75.5 kJ mol^{-1}]

39. Calculate the standard heat of formation of $C_{10}H_8$ (naphthalene) if standard heat of combustion of naphthalene is – 1231.0 kcal at 298 K and standard heat of formation of $CO_2(g)$ and $H_2O(l)$ are – 94.0 kcal and – 68.4 kcal respectively.
[**Ans.** 17.4 kcal]

40. The heat of combustion of liquid ethanol is – 327.0 kcal. Calculate the heat of formation of ethanol, given that the heats of formation of $CO_2(g)$ and $H_2O(l)$ are – 94.0 kcal and – 68.4 kcal respectively.
[**Ans.** – 66.2 kcal]

41. Calculate heat of formation of cane sugar from following data:

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g); \quad \Delta H = -68.4 \text{ kcal}$$

$$C(g) + O_2(g) \longrightarrow CO_2(g); \quad \Delta H = -94.4 \text{ kcal}$$

$$C_{12}H_{22}O_{11}(s) + 12O_2(g) \longrightarrow 12CO_2(g) + 11H_2O(l); \quad \Delta H = -1350.0 \text{ kcal}$$

[**Ans.** – 535.2 kcal]

42. The heats of formation of $C_6H_6(l)$, $H_2O(l)$ and CO_2(g) are 11.70, – 68.4 and – 94.0 kcal respectively. Calculate the heat of combustion of benzene (l).
[**Ans.** –780.9 kcal]

[**Hint:** $C_6H_6(l) + \frac{15}{2} O_2(g) \longrightarrow 6CO_2(g) + 3H_2O(l); \Delta H = ?$

$\Delta H = 6 \times \Delta H_{f\,(CO_2)} + 3 \times \Delta H_{f\,(H_2O)} - \Delta H_{f\,(C_6H_6)}$]

43. Calculate the heat of hydrogenation of C_2H_2 to C_2H_4.

$$H_2(g) + \frac{1}{2} O_2(g) \longrightarrow H_2O(l); \quad \Delta H = -68.32 \text{ kcal}$$

$$C_2H_2(g) + \frac{5}{2} O_2(g) \longrightarrow 2CO_2(g) + H_2O(l);$$

$$\Delta H = -310.61 \text{ kcal}$$

$$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(l);$$

$$\Delta H = -337.32 \text{ kcal}$$

[**Ans.** -41.61 kcal]

44. Calculate the heat of hydrogenation,

$$C_2H_4(g) + H_2(g) \longrightarrow C_2H_6(g)$$

given that, the heat of combustion of ethylene, hydrogen and ethane are -337.0, -68.4 and -373.0 kcal respectively.

[**Ans.** -32.4 kcal]

45. If the heat of formation of $Al_2O_3(s)$ and $Cr_2O_3(s)$ are 1596 kJ and 1134 kJ (both exothermic) respectively. Calculate ΔH of the thermite reaction.

$$Cr_2O_3(s) + 2Al(s) \longrightarrow 2Cr(s) + Al_2O_3(s)$$

[**Ans.** -462 kJ]

46. Calculate the enthalpy of transition of rhombic sulphur to monoclinic sulphur from the following data:

$$S_{(rhombic)} + O_2(g) \longrightarrow SO_2(g); \quad \Delta H = -297.5 \text{ kJ}$$

$$S_{(monoclinic)} + O_2(g) \longrightarrow SO_2(g); \quad \Delta H = -299.9 \text{ kJ}$$

[**Ans.** $+2.4$ kJ]

47. Calculate ΔH for the reaction,

$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)$$

given that bond energies of H—H and O$=$O bond and O—H bond are 433 kJ mol^{-1}, 492 kJ mol^{-1} and 464 kJ mol^{-1}.

[**Ans.** -249 kJ]

48. Using the bond enthalpy data, calculate ΔH of the following reaction:

$$2Cl_2(g) + 2H_2O(g) \longrightarrow 4HCl(g) + O_2(g)$$

given that, bond energies of Cl—Cl, H—Cl, O—H and O$=$O are 242.8, 431.8, 464 and 442 kJ mol^{-1} respectively.

[**Ans.** 172.4 kJ mol^{-1}]

49. Calculate the enthalpy of the reaction,

$$SnO_2(s) + 2H_2(g) \longrightarrow Sn(s) + 2H_2O(l)$$

given that, enthalpy of formation of $SnO_2(s)$ and $H_2O(l)$ are -580.7 kJ and -285.8 kJ respectively.

[**Ans.** $+9.1$ kJ]

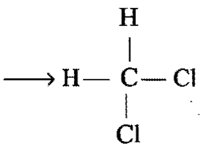
50. Calculate the enthalpy change for the reaction,

$$H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$$

given that, bond energies of H—H, Cl—Cl and H—Cl are 436, 243 and 432 kJ mol^{-1}.

[**Ans.** -185 kJ mol^{-1}]

51. Use the bond energy data and calculate the enthalpy change for:



$$2C(g) + 2H(g) + 2Cl(g) \longrightarrow H-\overset{\displaystyle H}{\underset{\displaystyle Cl}{C}}-Cl$$

The bond energies of C—H and C—Cl are 413 and 328 kJ mol^{-1} respectively.

[**Ans.** -1482 kJ mol^{-1}]

52. Calculate the heat of formation of ammonia from the following data:

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

The bond energies of N$\equiv$N, H—H and N—H bonds are 226, 104 and 93 kcal respectively.

[**Ans.** -10 kcal]

53. Use the following bond dissociation energies to compute the C—H bond energy in methane:

(i) $CH_4(g) \longrightarrow CH_3(g) + H(g); \quad \Delta H = 475 \text{ kJ mol}^{-1}$

(ii) $CH_3(g) \longrightarrow CH_2(g) + H(g); \quad \Delta H = 470 \text{ kJ mol}^{-1}$

(iii) $CH_2(g) \longrightarrow CH(g) + H(g); \quad \Delta H = 416 \text{ kJ mol}^{-1}$

(iv) $CH(g) \longrightarrow C(g) + H(g); \quad \Delta H = 335 \text{ kJ mol}^{-1}$

[**Ans.** 424 kJ mol^{-1}]

54. Calculate ΔH_f° for chloride ion from the following data:

$$\frac{1}{2} H_2(g) + \frac{1}{2} Cl_2(g) \longrightarrow HCl(g); \quad \Delta H = -92.4 \text{ kJ mol}^{-1}$$

$$HCl(g) + nH_2O \longrightarrow H^+(aq.) + Cl^-(aq.);$$

$$\Delta H = -74.8 \text{ kJ mol}^{-1}$$

$$\Delta H^\circ_{f\,(H^+\,aq.)} = 0.0 \text{ kJ mol}^{-1}$$

(IIT 1992)

[**Hint:** Required equation is

$$\frac{1}{2} Cl_2(g) + nH_2O \longrightarrow Cl^+(aq.); \; \Delta H = ?$$

Adding both equations.

$$\frac{1}{2} H_2(g) + \frac{1}{2} Cl_2(g) + nH_2O \longrightarrow H^+(aq.) + Cl^-(aq.);$$

$$\Delta H = -167.2$$

$$\frac{1}{2} H_2(g) \longrightarrow H^+(aq.); \quad \Delta H = 0$$

So, $\frac{1}{2} Cl_2(g) + nH_2O \longrightarrow Cl^-(aq.); \quad \Delta H = -167.2 \text{ kJ mol}^{-1}$]

55. The heat of ionisation of formic acid is 1.5 kJ/mol. 9.2 g formic acid on reaction with 7 g ammonium hydroxide gives 10.8 kJ of heat. Calculate the heat of ionisation of ammonium hydroxide. (1 cal = 4.2 J)

[**Ans.** 2.04 kJ/mol]

56. Assuming that 50% of the heat of useful, how many kg of water at 15°C can be heated to 95.0°C by burning 200 litre of methane measured at NTP? The heat of combustion of methane is 211 kcal mol^{-1}.

[**Ans.** 11.76 kg]

57. The standard potential for the reaction,

$$Ag^+(aq.) + Fe^{2+}(aq.) \longrightarrow Fe^{3+}(aq.) + Ag(s)$$

is 0.028 V. What is the standard free energy change for this reaction?

[**Ans.** -2.702 kJ mol^{-1}]

58. Calculate the theoretical maximum efficiency of a heat engine operating between 373 K and 173 K.

[Ans. 0.536 or 53.6%]

59. The standard free energy of formation in the gaseous state of methanol, dimethyl ether and water are – 38.7, – 27.3 and –54.6 kcal respectively. Is the transformation of methanol to dimethyl ether and water in gaseous state possible?

$$2CH_3OH \longrightarrow CH_3OCH_3 + H_2O$$

[Hint: ΔG° for the transformation

$$= \Sigma\, \Delta G^\circ_{\text{(products)}} - \Sigma\, \Delta G^\circ_{\text{(reactants)}}$$

$=$ – ve (the transformation is possible)]

60. Ethanol boils at 78.4° C and standard enthalpy of vaporization of ethanol is 42.4 kJ mol^{-1}. Calculate the entropy of vaporization of ethanol.

[Ans. 120.9 J K^{-1} mol^{-1}]

61. The following data is known about the melting of KCl:

$$\Delta H = 7.25 \text{ kJ mol}^{-1} \text{ and } \Delta S = +\,0.007 \text{ J K}^{-1} \text{ mol}^{-1}$$

Calculate its melting point.

[Ans. 1035.7 K]

[Hint: At melting point $\Delta G = 0$]

62. For the reaction,

$$Ag_2O \rightleftharpoons 2Ag(s) + \frac{1}{2} O_2(g)$$

Calculate the temperature at which free energy change is zero. At a temperature lower than this, predict whether the forward or the reverse reaction will be favoured. Give reason.

($\Delta H = +\,30.56$ kJ and $\Delta S = +\,0.066 \text{ kJ K}^{-1} \text{ mol}^{-1}$ at one atmosphere)

[Hint: Calculate T by applying the formula

$$\Delta G = \Delta H - T\,\Delta S \text{ and } \Delta G = 0.$$

Then find the value of ΔG at lower temperature than T. The value of ΔG comes positive; hence, the reverse reaction will be favoured. At temperature higher than T, the reaction is spontaneous.]

63. Calculate the boiling point of the liquid if its entropy of vaporization is 110 J K^{-1} mol^{-1} and the enthalpy of vaporization is 40.85 kJ mol^{-1}.

[Ans. 371.36 K]

64. Using S° values, calculate the entropy of the reaction,

$$SO_2(g) + \frac{1}{2} O_2(g) \longrightarrow SO_3(g)$$

The S° values for SO_2, O_2 and SO_3 are 248.5, 205.0 and 256.2 J K^{-1} mol^{-1}.

[Ans. $= -\,94.2 \text{ J K}^{-1} \text{ mol}^{-1}$]

[Hint: $\Delta S^\circ_{\text{reaction}} = \Sigma\, S^\circ_{\text{products}} - \Sigma\, S^\circ_{\text{reactants}}$]

65. Calculate the entropy change for the following reaction:

$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

$$S^\circ \quad 92.9 \qquad\qquad 39.7 \qquad 213.6 \text{ J K}^{-1} \text{ mol}^{-1}$$

[Ans. $+160.4 \text{ J K}^{-1} \text{ mol}^{-1}$]

66. Compute the value of ΔS at 298 K for the reaction,

$$H_2(g) + {}^1\!/_2 O_2(g) \longrightarrow H_2O(g)$$

given that, $\Delta G = -\,228.6$ kJ and $\Delta H = -\,241.8$ kJ.

[Ans $-\,44.3 \text{ J K}^{-1}$]

67. An engine operating between 150° C and 25° C takes 500 J heat from a high temperature reservoir. Assuming there is no frictional loss, calculate the work that can be done by the engine.

[Ans. 148 J]

68. At 300 K, the standard enthalpies of formation of $C_6H_5COOH(s)$, $CO_2(g)$ and $H_2O(l)$ are –408, –393 and –286 kJ mol^{-1} respectively. Calculate the heat of combustion of benzoic acid at (i) constant pressure and (ii) constant volume. ($R = 8.31 \text{ J mol}^{-1}\text{K}^{-1}$) **(IIT 1995)**

[Ans. (i) $\Delta H = -\,3201 \text{ kJ mol}^{-1}$;
(ii) $\Delta E = -\,3199.75 \text{ kJ mol}^{-1}$]

69. For the reaction,

$$Br_2(l) + Cl_2(g) \longrightarrow 2BrCl(g)$$

$\Delta H = 29.37 \text{ kJ mol}^{-1}$ and $\Delta S = 104 \text{ J K}^{-1} \text{ mol}^{-1}$. Find the temperature above which the reaction would become spontaneous.

[Ans. Above 282.4 K]

70. For the synthesis of ammonia,

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

Calculate ΔH°, ΔS° and ΔG° at 300 K using the following data:

Species	N_2	H_2	NH_3
ΔH°_f / (kJ mol^{-1})	0	0	– 46.2
S°/(J K^{-1} mol^{-1})	191.5	130.6	192.5

[Ans. $\Delta H^\circ = -\,92.4 \text{ kJ mol}^{-1}$, $\Delta S^\circ = -\,198.3 \text{ J K}^{-1} \text{ mol}^{-1}$
$\Delta G^\circ = -\,32.91 \text{ kJ mol}^{-1}$]

71. How much heat is required to change 15.6 g of benzene from liquid into vapour at its boiling point of 80° C? Entropy of vaporization of benzene is 87 J K^{-1} mol^{-1}.

[Ans. 6142.2 J]

72. Calculate the standard free energy change for the combustion of glucose at 298 K, using the given data.

$$C_6H_{12}O_6 + 6O_2 \longrightarrow 6CO_2 + 6H_2O$$

$$\Delta H^\circ = -\,2820 \text{ kJ mol}^{-1}, \Delta S^\circ = 210 \text{ J K}^{-1} \text{ mol}^{-1}.$$

[Ans. $\Delta G^\circ = -\,2882.58 \text{ kJ mol}^{-1}$]

73. The specific heat at constant volume for a gas is 0.075 cal/g and at constant pressure it is 0.125 cal/g. Calculate:
(i) the molecular weight of gas,
(ii) atomicity of gas.

[Hint: (i) $C_P - C_V = \dfrac{R}{M}$ where, M = molecular weight of gas

$$0.125 - 0.075 = \frac{1.987}{M}$$

$$M = 39.74 \approx 40$$

(ii) $$\frac{C_P}{C_V} = \gamma$$

$$\therefore \quad \gamma = \frac{0.125}{0.075} = 1.66$$

$\therefore$ 1.66 value of γ shows that the gas is monoatomic.]

74. The polymerisation of ethylene to linear polyethylene is represented by the reaction,

$$nCH_2{=}CH_2 \longrightarrow -\!\!\left(-CH_2-CH_2-\right)\!\!-_n$$

where, n has a large integral value. Given that the average enthalpies of bond dissociation for $C{=}C$ and $C{-}C$ at 298 K are +590 and + 331 kJ mol^{-1} respectively, calculate the enthalpy of polymerisation per mole of ethylene at 298 K. **(IIT 1994)**

[**Hint:** $nCH_2{=}CH_2 \longrightarrow -\!\!\left(-CH_2-CH_2-\right)\!\!-_n$

There are equal number of C—H bonds on both sides but on reactant side there are $nC{=}C$ bonds and on product side $(2n+1)C{-}C$ bonds.

Enthalpy of polymerisation

$$= n\Delta H_{(C=C)} - (2n+1)\Delta H_{(C-C)}$$
$$= 590n - (2n+1)(331)$$
$$= 590n - 662n \qquad [2n+1 \rightarrow 2n \text{ as } n \text{ is very large}]$$
$$= -72n \text{ kJ}$$

Enthalpy of polymerisation per mole

$$= \frac{\Delta H}{n} = -\frac{72n}{n} = -72 \text{ kJ mol}^{-1}]$$

75. An athlete is given 100 g of glucose ($C_6H_{12}O_6$) of energy equivalent to 1560 kJ. He utilises 50% of this gained energy in the event. In order to avoid storage of energy in the body, calculate the mass of water he would need to perspire. The enthalpy of evaporation of water is 44 kJ mol^{-1}.

[**Hint:** Unused energy $= \frac{1560}{2} = 780$ kJ

Mass of water needed for perspiration $= 18 \times \frac{780}{44} = 318.96$ g]

76. Calculate the entropy of ideal mixing when 2 moles of N_2, 3 moles of H_2 and 2 moles of NH_3 are mixed at constant temperature, assuming no chemical reaction is occurring.

[**Ans.** 62.80 J K^{-1}]

[**Hint:** Use the relation,

$$\Delta S = -R\,\Sigma\, n_i \log_e x_i$$

when n_i = no. of moles of component

x_i = mole fraction of the component]

77. Calculate free energy change for the reaction:

$$H_2(g) + Cl_2(g) \rightarrow 2H{-}Cl(g)$$

by using the bond energy and entropy data.

Bond energies of H—H, Cl—Cl and H—Cl bonds are 435 kJ mol^{-1}, 240 kJ mol^{-1} and 430 kJ mol^{-1} respectively. Standard entropies of H_2, Cl_2 and HCl are 130.59, 222.95 and 186.68 J K^{-1} mol^{-1} respectively.

[**Ans.** 190.9 kJ]

[**Hint:** ΔG° can be calculated by using:

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$
$$\Delta H^\circ = \Sigma\,(BE)_{reactants} - \Sigma\,(BE)_{products}$$
$$= 435 + 240 - 2 \times 430 = -185 \text{ kJ}$$
$$\Delta S^\circ = \Sigma\, S^\circ_{products} - \Sigma\, S^\circ_{reactants}$$
$$= 2 \times 186.68 - 130.59 - 222.95$$
$$= 19.82 \text{ J K}^{-1} = 19.82 \times 10^{-3} \text{ kJ K}^{-1}$$
$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$
$$= -185 - 298 \times 19.82 \times 10^{-3} = -190.9 \text{ kJ}]$$

78. For the reaction,

$$4C\,(\text{graphite}) + 5H_2(g) \longrightarrow nC_4H_{10}(g);$$
$$\Delta H^\circ = -124.73 \text{ kJ mol}^{-1}$$
$$\Delta S^\circ = -365.8 \text{ J K}^{-1} \text{ mol}^{-1}$$

$$4C\,(\text{graphite}) + 5H_2(g) \longrightarrow iso\text{-}C_4H_{10}(g)$$
$$\Delta H^\circ = -131.6 \text{ kJ mol}^{-1}$$
$$\Delta S^\circ = -381.079 \text{ J K}^{-1} \text{ mol}^{-1}$$

Indicate whether *normal butane* can be spontaneously converted to *iso-butane* or not.

[**Ans.** Yes, $\Delta G^\circ = -2.32$ kJ]

[**Hint:** For nC_4H_{10},

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$
$$= -124.73 - 298(-365.8 \times 10^{-3}) = -15.72 \text{ kJ}$$

For *iso*-butane (*iso*-C_4H_{10}),

$$\Delta G^\circ = -131.6 - 298(-381.079 \times 10^{-3})$$
$$= -18.04 \text{ kJ}$$

For conversion of $nC_4H_{10} \longrightarrow iso\text{-}C_4H_{10}$,

$$\Delta G^\circ = -18.04 - (-15.72) = -2.32 \text{ kJ}$$

Negative value shows that the process is spontaneous.]

79. The temperature of a bomb calorimeter was found to rise by 1.617 K, when a current of 3.20 amp was passed for 27 sec from a 12 V source. Calculate the calorimeter constant.

[**Hint:** Energy absorbed by the calorimeter

$$= I \times t \times V = 3.2 \times 27 \times 12 = 1036.8 \text{ J}$$

Calorimeter constant (ms) can be calculated as,

$$q = ms\,\Delta t$$
$$1036.8 = ms \times 1.617$$
$$ms = 641.187 \text{ kJ}]$$

80. 1 mole of an ideal gas is allowed to expand isothermally at 27°C until its volume is tripled. Calculate ΔS_{sys} and ΔS_{univ} under the following conditions:

(a) the expansion is carried out reversibly.

(b) the expansion is a free expansion.

[**Ans.** (a) $\Delta S_{sys} = 9.135 \text{ J K}^{-1} \text{ mol}^{-1}$

$$\Delta S_{surr} = -9.135 \text{ J K}^{-1} \text{ mol}^{-1}$$
$$\Delta S_{univ} = 0$$

(b) $\Delta S_{univ} = \Delta S_{sys} = 9.135 \text{ J K}^{-1} \text{ mol}^{-1}$]

[**Hint:** (a) In isothermal reversible process:

$$\Delta S = \frac{q_{rev}}{T}$$
$$q = -W = 2.303RT \log\frac{V_2}{V_1}$$
$$= 2.303 \times 8.314 \times 300 \log 3 = 2740.6 \text{ J mol}^{-1}$$
$$\Delta S_{system} = \frac{q_{rev}}{T} = \frac{2740.6}{300} = 9.135 \text{ J K}^{-1} \text{ mol}^{-1}$$
$$\Delta S_{surr} = -\Delta S_{system} = -9.135 \text{ J K}^{-1} \text{ mol}^{-1}$$
$$\Delta S_{univ} = 0$$

(b) In case of free expansion:

$$\Delta S = 2.303nR \log\left(\frac{V_2}{V_1}\right) = 9.135 \text{ J K}^{-1} \text{ mol}^{-1}$$

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} = 9.135 \text{ J K}^{-1} \text{ mol}^{-1}$$
$$\Delta S_{\text{surr}} = 0]$$

81. One kilogram water at 0° C is brought into contact with a heat reservoir at 100° C. Find:

(a) change in entropy when temperature reaches to 100° C.
(b) what is the change in entropy of reservoir?
(c) change in entropy of universe.
(d) the nature of process.

[**Ans.** (a) 312 cal K^{-1}, (b) −268.1 cal K^{-1}, (c) 43.9 cal K^{-1} (d) spontaneous]

[**Hint:** (a) $\Delta S = 2.303 nC_P \log\left(\frac{T_2}{T_1}\right)$

$$= 2.303 \times \frac{1000}{18} \times 18 \log\left(\frac{373}{273}\right) = 312 \text{ cal K}^{-1}$$

(b) $\Delta S_{\text{reservoir}} = -\frac{\Delta Q}{T}$

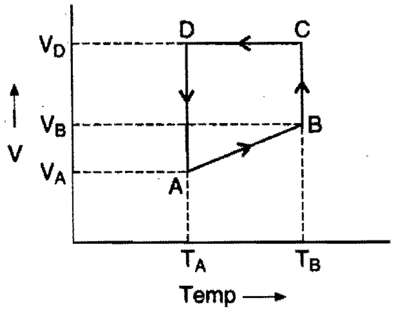
$$\Delta Q = ms\,\Delta t = 1000 \times 1 \times 100 = 10^5 \text{ cal}$$

$$\Delta S = \frac{-10^5}{373} = -268.1 \text{ cal K}^{-1}$$

(c) $\Delta S_{\text{universe}} = 312 - 268.1 = 43.9 \text{ cal K}^{-1}$

(d) $\Delta S > 0$, the process will be spontaneous.]

82. A monoatomic ideal gas of two moles is taken through a cyclic process starting from A as shown in figure. The volume ratios are $\frac{V_B}{V_A} = 2$ and $\frac{V_D}{V_A} = 4$. If the temperature T_A at A is 27°C. Calculate:



(a) the temperature of gas at B.
(b) heat absorbed or evolved in each process.
(c) total work done in cyclic process.

[**Hint:** $A \to B$: (It is isobaric process)

$$\frac{V_A}{T_A} = \frac{V_B}{T_B}$$

$$\therefore \quad T_B = \frac{V_B}{V_A} \times T_A = 2 \times 300 = 600 \text{ K}$$

$$q_{AB} = nC_P\,\Delta T = 2 \times \frac{5}{2} R\,\Delta T$$
$$= 2 \times \frac{5}{2} \times 2 \times 300 = 3000 \text{ cal}$$

$B \to C$: (Isothermal process)

$$\Delta U = 0$$

$$\therefore \quad q_{BC} = W = 2.303\, nRT \log\left(\frac{V_C}{V_B}\right)$$
$$= 2.303 \times 2 \times 2 \times 600 \log\frac{4}{2}$$
$$= 1.663 \times 10^3 \text{ cal}$$

$C \to D$: (Isochoric process)

$$q_{CD} = nC_V\,\Delta T = 2 \times \frac{3}{2} \times 2\,(-300) = -1800 \text{ cal}$$

$D \to A$: (Isothermal process)

$$q_{DA} = 2.303 nRT_A \log\frac{V_A}{V_D}$$
$$= 2.303 \times 2 \times 2 \times 300 \log\frac{1}{4}$$
$$= -1.663 \times 10^3 \text{ cal}$$

Total heat change $= 3000 + 1.663 \times 10^3 - 1800 - 1.663 \times 10^3$
$= 1200$ cal

Work done = − 1200 cal]

83. The reaction, $SOCl_2 + H_2O \longrightarrow SO_2 + 2HCl$ is endothermic by 49.4 kJ and exoergonic by 50.8 kJ. What is the factor that makes the reaction to be spontaneous? Calculate the entropy change at 298 K.

[**Ans.** $\Delta S^\circ = 0.3362 \text{ kJ K}^{-1}$]

[**Hint:** Exoergonic means $\Delta G^\circ = -$ ve.

$\Delta G^\circ = -50.8$ kJ,
$\Delta H^\circ = 49.4$ kJ

Substitute these values in $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ to calculate entropy.

$$\Delta S^\circ = \frac{\Delta H^\circ - \Delta G^\circ}{T} = \frac{49.4 - (-50.8)}{298}$$
$$= 0.3362 \text{ kJ K}^{-1}]$$

84. What amount of ice will remain when 52 g ice is added to 100 g of water at 40° C?
Specific heat of water is 1 cal/g and latent heat of fusion of ice is 80 cal/g.

[**Ans.** 2 g ice]

[**Hint:** At the stage of thermal equilibrium at 0° C,
Heat lost by water = Heat absorbed by ice to melt.

$$ms\,\Delta T = mL$$
$$100 \times 1 \times 40 = m \times 80$$
$$m = 50 \text{ g}$$

Remaining ice = 52 − 50 = 2 g]

85. Calculate the ΔH_f° of $C_6H_{12}O_6(s)$ from the following data:

$\Delta H_{\text{comb}}\,[C_6H_{12}O_6(s)] = -2816$ kJ / mol
ΔH_f° of $CO_2(g) = -393.5$ kJ / mol
ΔH_f° of $H_2O(l) = -285.9$ kJ / mol [BCECE 2006]

[**Ans.** −1260 kJ/mol]

86. A liquid freezes into solid ($\Delta H = -500 \text{ J mol}^{-1}$) at 100 K and 1 atm. Find the values of:

(i) Gibbs free energy change
(ii) entropy change. [CBSE (Mains) 2006]

[**Hint:** Liquid $\rightleftharpoons$ Solid

(i) $\Delta G = 0$, at equilibrium

(ii) $\Delta S = \frac{\Delta H}{T} = \frac{-500}{100} = -5 \text{ J K}^{-1} \text{ mol}^{-1}$]

OBJECTIVE QUESTIONS

Set-1: Questions with single correct answer

1. Thermodynamics is concerned with:
   (a) total energy of a system
   (b) energy changes in a system
   (c) rate of a chemical change
   (d) mass changes in nuclear reactions
2. An isolated system is that system in which: [PET (MP) 1993]
   (a) there is no exchange of energy with the surroundings
   (b) there is exchange of mass and energy with the surroundings
   (c) there is no exchange of energy and mass with the surroundings
   (d) there is exchange of mass with the surroundings
3. Identify the intensive property from the following:
   (a) volume (b) mass
   (c) enthalpy (d) temperature
4. Which one of the following is an extensive property? [Comed (Karnataka) 2008]
   (a) Enthalpy (b) Concentration
   (c) Density (d) Viscosity
5. For an adiabatic process, which of the following relations is correct? (CPMT 1990)
   (a) $\Delta E = 0$ (b) $P\,\Delta V = 0$ (c) $q = 0$ (d) $q = +w$
6. Which one is true from the following for isobaric process ? [CET (Gujarat) 2008]
   (a) $\Delta P = 0$ (b) $\Delta q = 0$
   (c) $\Delta H = 0$ (d) $\Delta E = 0$
7. For an ideal gas, the value of $\left(\frac{dE}{dV}\right)_T$ is: [PET (MP) 1993]
   (a) positive (b) zero
   (c) negative (d) interchangeable
8. A process, in which pressure remains constant, is called:
   (a) isochoric process (b) isothermal process
   (c) adiabatic process (d) isobaric process
9. A process in which volume remains constant, is called:
   (a) isochoric process (b) isothermal process
   (c) adiabatic process (d) isobaric process
10. For a cyclic process, the condition is:
   (a) $\Delta E = 0$ (b) $\Delta H = 0$
   (c) $\Delta E > 0$ and $\Delta H > 0$ (d) both $\Delta E = 0$ and $\Delta H = 0$
11. Which one of the following is a state property?
   (a) Heat (b) Work
   (c) Internal energy (d) Potential energy
12. Internal energy of a system of molecules is determined by taking into consideration its:
   (a) kinetic energy
   (b) vibrational energy
   (c) rotational energy
   (d) all kinds of energies present in the molecules
13. A thermodynamic quantity is that:
   (a) which is used in thermochemistry
   (b) which obeys all laws of thermodynamics
   (c) quantity whose value depends only upon the state of the system
   (d) quantity which is used in measuring thermal change
14. Thermodynamic equilibrium involves: [CET (Pb.) 1991]
   (a) chemical equilibrium (b) thermal equilibrium
   (c) mechanical equilibrium (d) all the three
15. For the reaction of one mole zinc dust with one mole sulphuric acid in a bomb calorimeter, ΔU and w correspond to: (AIIMS 2005)
   (a) $\Delta U < 0, w = 0$ (b) $\Delta U < 0, w < 0$
   (c) $\Delta U > 0, w = 0$ (d) $\Delta U > 0, w > 0$
   [Hint: In bomb calorimeter, $w = 0, \Delta U = q(-\text{ve})$]
16. A system is provided with 50 joules of heat and the work done on the system is 10 joules. What is the change in internal energy of the system in joules? [EAMCET (Engg.) 2010]
   (a) 60 (b) 40 (c) 50 (d) 10
17. During an isothermal expansion of an ideal gas, its: (CBSE 1991)
   (a) internal energy increases
   (b) enthalpy decreases
   (c) enthalpy remains unaffected
   (d) enthalpy reduces to zero
18. The work done in ergs for a reversible expansion of one mole of an ideal gas from a volume of 10 litre to 20 litre at 25° C is: [CMC (Vellore) 1991]
   (a) $2.303 \times 8.31 \times 10^7 \times 298 \log 2$
   (b) $2.303 \times 0.0821 \times 298 \log 2$
   (c) $2.303 \times 0.0821 \times 298 \log 0.5$
   (d) $2.303 \times 2 \times 298 \log 2$
19. When an ideal gas is compressed adiabatically and reversibly, the final temperature is:
   (a) higher than the initial temperature
   (b) lower than the initial temperature
   (c) the same as initial temperature
   (d) dependent upon the rate of compression
20. Adiabatic reversible expansion of a gas is represented by:
   (a) $\left(\frac{T_1}{T_2}\right)^{\gamma} = \left(\frac{P_2}{P_1}\right)^{1-\gamma}$ (b) $\left(\frac{T_1}{T_2}\right) = \left(\frac{P_1}{P_2}\right)^{1-\gamma}$
   (c) $\left(\frac{T_1}{T_2}\right)^{\gamma} = \left(\frac{P_2}{P_1}\right)^{\gamma-1}$ (d) all are correct
21. Total energy change for a reversible isothermal cycle is:
   (a) always positive (b) zero
   (c) always negative (d) always 100 kJ per degree
22. "Heat energy cannot be completely transformed into work without producing some change somewhere", is the statement of:

(a) Hess's law
(b) first law of thermodynamics
(c) Kirchhoff's law
(d) second law of thermodynamics

23. The heat content of the system is called:
(a) internal energy (b) enthalpy
(c) free energy (d) entropy

24. If one mole of ammonia and one mole of hydrogen chloride are mixed in a closed container to form ammonium chloride gas, then : **(KCET 2008)**
(a) $\Delta H < \Delta U$
(b) $\Delta H > \Delta U$
(c) $\Delta H = \Delta U$
(d) there is no relationship between ΔH and ΔU

25. An exothermic reaction is one in which the reacting substances:
(a) have same energy as products
(b) have less energy than the products
(c) have more energy than the products
(d) are at higher temperature than the products

26. In endothermic reactions, the reactants:
(a) have more energy than products
(b) have as much energy as the products
(c) are at lower temperature than products
(d) have less energy than the products

27. Identify the reaction in which the heat liberated corresponds to the heat of formation (ΔH): **(EAMCET 2006)**
(a) C (diamond) + $O_2(g) \rightarrow CO_2(g)$ + heat
(b) $2H_2(g) + O_2(g) \rightarrow 2H_2O(g)$ + heat
(c) C (diamond) + $2H_2(g) \rightarrow CH_4(g)$ + heat
(d) S (rhombic) + $O_2(g) \rightarrow SO_2(g)$ + heat

28. In an exothermic reaction, ΔH is:
(a) positive (b) negative
(c) zero (d) may be positive or negative

29. Evaporation of water is:
(a) a process in which neither heat is evolved nor absorbed
(b) a process accompanied by chemical reaction
(c) an exothermic change
(d) an endothermic change

30. An endothermic reaction is one in which:
(a) heat is converted into electricity
(b) heat is absorbed
(c) heat is evolved
(d) heat changes to mechanical work

31. If total enthalpy of reactants and products is H_R and H_P respectively, then for exothermic reaction:
(a) $H_R = H_P$ (b) $H_R < H_P$
(c) $H_R > H_P$ (d) $H_R - H_P = 0$

32. Calculate the work done when 1 mol of an ideal gas is compressed reversibly from 1 bar to 4 bar at a constant temperature of 300 K : **(DPMT 2009)**
(a) 4.01 kJ (b) –8.02 kJ
(c) 18.02 kJ (d) –14.01 kJ

[**Hint :** $w = 2.303\, nRT \log\left(\frac{P_2}{P_1}\right)$

$= 2.303 \times 1 \times 8.314 \times 300 \log \frac{4}{1}$

$= 3458.3\text{ J} = 3.458\text{ kJ}$]

33. Under which of the following conditions is the relation, $\Delta H = \Delta E + P\,\Delta V$ valid for a closed system?
(a) Constant pressure
(b) Constant temperature
(c) Constant temperature and pressure
(d) Constant temperature, pressure and composition

34. Which of the following is an endothermic reaction?
(a) $2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$
(b) $N_2(g) + O_2(g) \longrightarrow 2NO(g)$
(c) $NaOH(aq.) + HCl(aq.) \longrightarrow NaCl(aq.) + H_2O(l)$
(d) $C_2H_5OH(aq.) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(l)$

35. Which of the following reactions is endothermic?
(a) $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$
(b) $Fe(s) + S(s) \longrightarrow FeS(s)$
(c) $NaOH(aq.) + HCl(aq.) \longrightarrow NaCl(aq.) + H_2O(l)$
(d) $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$

36. The formation of water from $H_2(g)$ and $O_2(g)$ is an exothermic process because:
(a) the chemical energy of $H_2(g)$ and $O_2(g)$ is more than that of water
(b) the chemical energy of $H_2(g)$ and $O_2(g)$ is less than that of water
(c) the temperature of $H_2(g)$ and $O_2(g)$ is higher than that of water
(d) the temperature of $H_2(g)$ and $O_2(g)$ is lower than that of water

37. Which one of the following reactions is an exothermic reaction?
(a) $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$
(b) $N_2(g) + O_2(g) \longrightarrow 2NO(g)$
(c) $2HgO(s) \longrightarrow 2Hg(s) + O_2(g)$
(d) $C(s) + O_2(g) \longrightarrow CO_2(g)$

38. Which one of the following is not applicable for a thermochemical equation?
(a) It tells about physical state of reactants and products
(b) It tells whether the reaction is spontaneous
(c) It tells whether the reaction is exothermic or endothermic
(d) It tells about the allotropic form (if any) of the reactants

39. The enthalpies of all elements in their standard state at 25° C and one atmospheric pressure are:
(a) same (b) always positive
(c) always negative (d) zero

40. The heat of reaction does not depend upon:
(a) physical state of the reactants and products
(b) whether the reaction has been carried at constant pressure or constant volume
(c) the manner by which the reaction has been carried
(d) the temperature at which the reaction has been carried

41. The value of $\Delta H - \Delta U$ for the following reaction at 27°C will be:

$$2NH_3(g) \longrightarrow N_2(g) + 3H_2(g)$$

[AMU (Medical) 2007]
(a) $8.314 \times 273 \times (-2)$ (b) $8.314 \times 300 \times (-2)$
(c) $8.314 \times 273 \times 2$ (d) $8.314 \times 300 \times 2$

42. Since, the enthalpy of the elements in their standard states is taken to be zero, the heat of formation (ΔH_f) of compounds:
(a) is always negative (b) is always positive
(c) is zero (d) may be positive or negative

43. The difference between heats of reaction at constant pressure and constant volume for the reaction,
$2C_6H_6(l) + 15O_2(g) \longrightarrow 12CO_2(g) + 6H_2O(l)$ at 25° C in kJ is: **(IIT 1991)**
(a) +7.43 (b) +3.72 (c) −7.43 (d) −3.72

44. For a gaseous reaction, $A(g) + 3B(g) \rightarrow 3C(g) + 3D(g)$, ΔE is 17 kcal at 27°C. Assuming $R = 2\,\text{cal K}^{-1}\,\text{mol}^{-1}$, the value of ΔH for the above reaction is:
(a) 15.8 kcal (b) 18.2 kcal
(c) 20.0 kcal (d) 16.4 kcal

45. Which of the following statements is correct for the reaction, $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$ at constant temperature and pressure?
(a) $\Delta H = \Delta E$ (b) $\Delta H < \Delta E$
(c) $\Delta H > \Delta E$ (d) None of these

46. For the reaction, $Ag_2O(s) \longrightarrow 2Ag(s) + \frac{1}{2}O_2(g)$ which one of the following is true?
(a) $\Delta H = \Delta E$ (b) $\Delta H < \Delta E$
(c) $\Delta H > \Delta E$ (d) $\Delta H = \frac{1}{2}\Delta E$

47. Thermochemistry is the study of relationship between heat energy and:
(a) chemical energy (b) activation energy
(c) friction energy (d) none of these

48. Assume each reaction is carried out in an open container. For which reaction will $\Delta H = \Delta U$? **[CBSE (Med.) 2006]**
(a) $H_2(g) + Br_2(g) \longrightarrow 2HBr(g)$
(b) $C(s) + 2H_2O(g) \longrightarrow 2H_2(g) + CO_2(g)$
(c) $PCl_5(g) \longrightarrow PCl_3(g) + Cl_2(g)$
(d) $2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$

49. The enthalpy change in the reaction, $2CO + O_2 \longrightarrow 2CO_2$ is termed as:
(a) enthalpy of reaction (b) enthalpy of fusion
(c) enthalpy of formation (d) enthalpy of combustion

50. Reaction, $H_2(g) + I_2(g) \longrightarrow 2HI$; $\Delta H = 12.40$ kcal
According to this, heat of formation of HI will be: **[PET (MP) 1990]**
(a) 12.40 kcal (b) −12.4 kcal
(c) − 6.20 kcal (d) 6.20 kcal

51. For the reactions,
(i) $H_2(g) + Cl_2(g) = 2HCl(g) + x$ kJ
(ii) $H_2(g) + Cl_2(g) = 2HCl(l) + y$ kJ
which one of the following statements is correct? **[PET (MP) 2007]**
(a) $x > y$ (b) $x < y$ (c) $x - y = 0$ (d) $x = y$

52. For the reactions,
(i) $H_2(g) + Cl_2(g) = 2HCl(g) + x$ kJ
(ii) $2HCl(g) = H_2(g) + Cl_2(g) - y$ kJ
which one of the following statements is correct?
(a) $x - y > 0$ (b) $x - y < 0$
(c) $x - y = 0$ (d) None of these

53. According to the equation,
$$C_6H_6(l) + \frac{15}{2}O_2(g) \longrightarrow 6CO_2(g) + 3H_2O(l);$$
$$\Delta H = -3264.4\ \text{kJ mol}^{-1}$$
the energy evolved when 7.8 g benzene is burnt in air will be: **[PET (MP) 1990]**
(a) 163.22 kJ (b) 32.64 kJ (c) 3.264 kJ (d) 326.4 kJ

54. $\Delta H_{f\,(x)}, \Delta H_{f\,(y)}, \Delta H_{f\,(R)}$ and $\Delta H_{f\,(S)}$ denote the enthalpies of formation of x, y, R and S respectively. The enthalpy of the reaction, $x + y \longrightarrow R + S$ is given by:
(a) $\Delta H_{f\,(x)} + \Delta H_{f\,(y)}$
(b) $\Delta H_{f\,(R)} + \Delta H_{f\,(S)}$
(c) $\Delta H_{f\,(x)} + \Delta H_{f\,(y)} - \Delta H_{f\,(R)} - \Delta H_{f\,(S)}$
(d) $\Delta H_{f\,(R)} + \Delta H_{f\,(S)} - \Delta H_{f\,(x)} - \Delta H_{f\,(y)}$

55. The enthalpy change for the reaction,
$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(g)$ is called:
(a) enthalpy of formation (b) enthalpy of combustion
(c) enthalpy of vaporisation (d) enthalpy of sublimation

56. The heat of combustion of methane is −880 kJ mol^{-1}. If 3.2 g of methane is burnt .... of heat is evolved.
(a) 88 kJ (b) 264 kJ (c) 176 kJ (d) 440 kJ

57. The enthalpy change for the reaction,
$$2C_{(graphite)} + 3H_2(g) \longrightarrow C_2H_6(g)$$
is called:
(a) enthalpy of formation (b) enthalpy of combustion
(c) enthalpy of hydrogenation (d) enthalpy of vaporisation

58. The enthalpy of formation of water from hydrogen and oxygen is − 286.0 kJ mol^{-1}. The enthalpy of decomposition of water into hydrogen and oxygen is ...... kJ mol^{-1}:
(a) − 286.0 (b) − 143.0 (c) 286.0 (d) 143.0

59. The heat of combustion of $C_{(graphite)}$ is −393.5 kJ mol^{-1}. The heat of formation of CO_2 from graphite is ..... kJ mol^{-1}:
(a) 393.5 (b) −393.5 (c) −787.0 (d) 787.0

60. The enthalpies of formation of organic compounds are conveniently determined from their:
(a) boiling points
(b) melting points
(c) enthalpies of neutralization
(d) enthalpies of combustion

61. ΔH combustion of a compound is always:
(a) positive (b) negative (c) zero (d) uncertain

62. The apparatus used for measuring the heat changes of a reaction is called:
(a) a thermometer (b) a colorimeter
(c) a calorimeter (d) none of these

63. The heat of neutralization of any strong acid and strong base is always constant and $\Delta H = -57.3$ kJ. This is because: **[Comed (Karnataka) 2008]**
(a) both the acid and base undergo complete ionization.
(b) during neutralization, salt and water are formed.
(c) 1 mole of water is formed from H^+ and OH^- ions.
(d) the reaction is exothermic.

64. The enthalpy of neutralization of oxalic acid by a strong base is -25.4 k cal mol^{-1}. The enthalpy of neutralization of strong acid and strong base is -13.7 kcal eq^{-1}. The enthalpy of dissociation of oxalic acid is: (DPMT 2009)
(a) 1 kcal mol^{-1} (b) 2 kcal mol^{-1}
(c) 18.55 kcal mol^{-1} (d) 11.7 kcal mol^{-1}
[Hint : Oxalic acid is dibasic acid hence expected heat of neutralization will be $(2 \times -13.7 \text{ kcal})$.
The dissociation energy of oxalic acid $= 2 \times 13.7 - 25.4$
$= 2 \text{ kcal mol}^{-1}$]

65. The amount of heat liberated when one mole of NH_4OH reacts with one mole of HCl is: (IIT 1990)
(a) 13.7 kcal (b) more than 13.7 kcal
(c) less than 13.67 kcal (d) cannot be predicted

66. Heat of neutralisation for the reaction,
$$NaOH + HCl \longrightarrow NaCl + H_2O$$
is 57.1 kJ mol^{-1}. The heat released when 0.25 mole of NaOH is titrated against 0.25 mole of HCl will be:
(a) 22.5 kJ (b) 57.1 kJ
(c) 28.6 kJ (d) 14.3 kJ

67. If $H^+ + OH^- = H_2O + 13.7 \text{ kcal}$, then heat of complete neutralisation of one gram mole of H_2SO_4 with strong base will be: [PMT (MP) 1990]
(a) 13.7 kcal (b) 27.4 kcal
(c) 6.85 kcal (d) 3.425 kcal

68. In which of the following neutralization reactions, the heat of neutralization will be highest?
(a) HCl and NaOH (b) CH_3COOH and NaOH
(c) CH_3COOH and NH_4OH (d) HCl and NH_4OH

69. "The enthalpy of formation of a compound is equal in magnitude but of opposite sign to the enthalpy of decomposition of that compound under the same conditions." This law was presented by:
(a) Hess (b) Le Chatelier
(c) Kirchhoff (d) Lavoisier and Laplace

70. "The change of enthalpy of a chemical reaction is the same whether the reaction takes place in one step or in several steps". This law was presented by:
(a) Hess (b) Le Chatelier
(c) van't Hoff (d) Kirchhoff

71. The enthalpy change in a reaction does not depend on the:
(a) conditions under which the reaction is carried out
(b) initial and final enthalpies of the reactants and products
(c) state of reactants and products
(d) number of intermediate steps to convert reactants to products

72. Hess's law deals with:
(a) changes in heat of reaction
(b) rate of reaction
(c) equilibrium constant
(d) influence of pressure on volume of a gas

73. From the thermochemical reactions,
$$C_{(\text{graphite})} + \frac{1}{2}O_2 \longrightarrow CO; \quad \Delta H = -110.5 \text{ kJ}$$
$$CO + \frac{1}{2}O_2 \longrightarrow CO_2; \ \Delta H = -283.2 \text{ kJ}$$
the heat of reaction of $C_{(\text{graphite})} + O_2 \longrightarrow CO_2$ is:
(a) +393.7 kJ (b) −393.7 kJ (c) −172.7 kJ (d) +172.7 kJ

74. If $H_2 + \frac{1}{2}O_2 \longrightarrow H_2O; \quad \Delta H = -68.09 \text{ kcal}$
$$K + H_2O + \text{water} \longrightarrow KOH(aq.) + \frac{1}{2}H_2; \ \Delta H = -48.0 \text{ kcal}$$
$$KOH + \text{water} \longrightarrow KOH(aq.); \quad \Delta H = -14.0 \text{ kcal}$$
the heat of formation of KOH is:
(a) $-68.39 + 48 - 14.0$ (b) $-68.39 - 48.0 + 14.0$
(c) $+68.39 - 48.0 + 14.0$ (d) $+68.39 + 48.0 - 14.0$

75. The enthalpies of combustion of $C_{(\text{graphite})}$ and $C_{(\text{diamond})}$ are −393.5 and −395.4 kJ/mol respectively. The enthalpy of conversion of $C_{(\text{graphite})}$ to $C_{(\text{diamond})}$ in kJ/mol is:
(a) −1.9 (b) −788.9
(c) 1.9 (d) 788.9

76. The heat of combustion of yellow phosphorus and red phosphorus are −9.91 kJ and −8.78 kJ respectively. The heat of transition of yellow phosphorus to red phosphorus is: [CEE (Bihar) 1992]
(a) −18.69 kJ (b) +1.13 kJ
(c) +18.69 kJ (d) −1.13 kJ

77. What will be the heat of formation of methane, if the heat of combustion of carbon is '$-x$' kJ, heat of formation of water is '$-y$' kJ and heat of combustion of methane is '$-z$' kJ? (AIIMS 2008)
(a) $(-x - y + z)$ kJ (b) $(-z - x + 2y)$ kJ
(c) $(-x - 2y - z)$ kJ (d) $(-x - 2y + z)$ kJ

78. Given,
$$C(s) + O_2(g) \longrightarrow CO_2(g) + 94.2 \text{ kcal}$$
$$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) + 68.3 \text{ kcal}$$
$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l) + 210.8 \text{ kcal}$$
The heat of formation of methane in kcal will be: [PET (MP) 1990]
(a) 45.9 (b) 47.8 (c) 20.0 (d) 47.3

79. On combustion carbon forms two oxides CO and CO_2, heat of formation of CO_2 is −94.3 kcal and that of CO is −26.0 kcal. Heat of combustion of carbon is: [EAMCET (Med.) 2010]
(a) −26.0 kcal (b) − 68.3 kcal
(c) −94.3 kcal (d) −120.3 kcal

80. The heat of combustion of ethanol determined in a bomb calorimeter is −670.48 kcal mol^{-1} at 298 K. What is ΔE at 298 K for the reaction?
(a) −760 kcal mol^{-1} (b) − 670.48 kcal mol^{-1}
(c) +760 kcal mol^{-1} (d) + 670.48 kcal mol^{-1}

81. 1 calorie is equivalent to:
(a) 4.184 J (b) 41.84 J (c) 418.4 J (d) 0.4184 J

82. For an endothermic reaction, where ΔH represents the enthalpy of reaction, the minimum value for the energy of activation will be: [IIT 1991; PMT (MP) 1993]
(a) less than ΔH (b) zero
(c) equal to ΔH (d) more than ΔH

83. If $S + O_2 \longrightarrow SO_2;$ $\qquad \Delta H = -298.2 \text{ kJ}$

$SO_2 + \frac{1}{2}O_2 \longrightarrow SO_3;$ $\qquad \Delta H = -98.7 \text{ kJ}$

$SO_3 + H_2O \longrightarrow H_2SO_4;$ $\qquad \Delta H = -130.2 \text{ kJ}$

$H_2 + \frac{1}{2}O_2 \longrightarrow H_2O;$ $\qquad \Delta H = -227.3 \text{ kJ}$

the heat of formation of H_2SO_4 will be:

(a) –754.4 kJ (b) + 320.5 kJ (c) – 650.3 kJ (d) – 433.7 kJ

84. Which of the following units represents the largest amount of energy?

(a) Electron-volt (b) Erg
(c) Joule (d) Calorie

85. If ΔH_f° for $H_2O_2(l)$ and $H_2O(l)$ are –188 kJ mol^{-1} and –286 kJ mol^{-1}, what will be the enthalpy change of the reaction $2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$? |PMT (MP) 1992|

(a) 146 kJ mol^{-1} (b) –196 kJ mol^{-1}
(c) – 494 kJ mol^{-1} (d) –98 kJ mol^{-1}

86. The bond dissociation energies for Cl_2, I_2 and ICl are 242.3, 151 and 211.3 kJ/mol respectively. The enthalpy of sublimation of iodine is 62.8 kJ / mol. What is the standard enthalpy of formation of ICl(*g*)?

(a) – 211.3 kJ/mol (b) – 14.6 kJ/mol
(c) 16.8 kJ/mol (d) 33.5 kJ/mol

[**Hint:** $Cl_2(g) \longrightarrow 2Cl(g);$ $\qquad \Delta H_1 = 242.3 \text{ kJ/mol}$

$I_2(g) \longrightarrow 2I(g);$ $\qquad \Delta H_2 = 151 \text{ kJ/mol}$

$ICl(g) \longrightarrow I(g) + Cl(g);$ $\qquad \Delta H_3 = 211.3 \text{ kJ/mol}$

$I_2(s) \longrightarrow I_2(g);$ $\qquad \Delta H_4 = 62.8 \text{ kJ/mol}$

Required equation:

$$\frac{1}{2}I_2(s) + \frac{1}{2}Cl_2(g) \longrightarrow ICl(g); \quad \Delta H = ?$$

$$\Delta H = \frac{62.8 + 151 + 242.3}{2} - 211.3$$

$$= 16.75 \text{ kJ / mol}]$$

87. Standard heat of formation for CCl_4, H_2O, CO_2 and HCl at 298K are – 25.5, – 57.8, – 94.1 and – 22.1 kJ/ mol respectively. For the reaction,

$$CCl_4 + 2H_2O \longrightarrow CO_2 + 4HCl$$

what will be ΔH? (SCRA 2007)

(a) 36.4 kJ (b) 20.7 kJ (c) –20.7 kJ (d) – 41.4 kJ

88. Heat of combustion of CH_4, C_2H_6, C_2H_4 and C_2H_2 are –212.8, –373.0, –337.0 and –310.5 kcal respectively at the same temperature. The best fuel among these gases is:

(a) CH_4 (b) C_2H_6
(c) C_2H_4 (d) C_2H_2

89. Given, $C(s) + O_2(g) \longrightarrow CO_2(g);$ $\qquad \Delta H = -395 \text{ kJ}$

$S(s) + O_2(g) \longrightarrow SO_2(g);$ $\qquad \Delta H = -295 \text{ kJ}$

$CS_2(l) + 3O_2(g) \longrightarrow CO_2(g) + 2SO_2(g);$ $\Delta H = -1110 \text{ kJ}$

The heat of formation of $CS_2(l)$ is: |CEE (Bihar) 1992|

(a) 250 kJ (b) 62.5 kJ (c) 31.25 kJ (d) 125 kJ

90. The heats of combustion of rhombic and monoclinic sulphur are –70960 and –71030 calorie respectively. What will be the heat of conversion of rhombic sulphur to monoclinic sulphur?

(a) –70960 cal (b) –71030 cal
(c) 70 cal (d) –70 cal

91. The bond dissociation energy of C—H in CH_4 from the equation

$$C(g) + 4H(g) \longrightarrow CH_4(g); \qquad \Delta H = -397.8 \text{ kcal}$$

is:

(a) + 99.45 kcal (b) –99.45 kcal
(c) + 397.8 kcal (d) +198.9 kcal

92. The dissociation energy of CH_4 is 400 kcal mol^{-1} and that of ethane is 670 kcal mol^{-1}. The C—C bond energy is:

(a) 270 kcal (b) 70 kcal (c) 200 kcal (d) 240 kcal

93. Heat of reaction at constant volume is measured in the apparatus:

(a) bomb calorimeter (b) calorimeter
(c) pyknometer (d) pyrometer

94. When 10 mL of a strong acid is added to 10 mL of an alkali, the temperature rises by 5° C. If 100 mL of the same acid is mixed with 100 mL of the same base, the temperature rise would be:

(a) 5° C (b) 50°C
(c) 20°C (d) cannot be predicted

95. Energy required to dissociate 4 g of gaseous hydrogen into free gaseous atoms is 208 kcal at 25° C. The bond energy of H—H bond will be:

(a) 1.04 cal (b) 10.4 kcal
(c) 104 kcal (d) 1040 kcal

96. The heat of neutralisation of strong base and strong acid is 57.0 kJ. The heat released when 0.5 mole of HNO_3 solution is added to 0.20 mole of NaOH solution is: (KCET 1993)

(a) 57.0 kJ (b) 28.5 kJ
(c) 11.40 kJ (d) 34.9 kJ

97. The enthalpy of combustion of cyclohexane, cyclohexene and H_2 are respectively –3920, –3800 and –241 kJ mol^{-1}. The heat of hydrogenation of cyclohexene is: (AIIMS 2007)

(a) –121 kJ mol^{-1} (b) 121 kJ mol^{-1}
(c) –242 kJ mol^{-1} (d) 242 kJ mol^{-1}

98. If $C(s) + O_2(g) \longrightarrow CO_2(g);$ $\qquad \Delta H = r$

and $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g);$ $\qquad \Delta H = s$

then the heat of formation of CO is:

(a) $r + s$ (b) $r - s$ (c) $s - r$ (d) $r \times s$

99. Given that, heat of neutralisation of strong acid and strong base is 57.1 kJ. Calculate the heat produced when 0.25 mole of HCl is neutralised with 0.25 mole of NaOH in aqueous solution: (CPMT 1990)

(a) 22.5 kJ (b) 57 kJ
(c) 14.275 kJ (d) 28.55 kJ

100. Which one of the following values of ΔH° represents that the product is least stable?

(a) – 94.0 kcal mol^{-1} (b) –231.6 kcal mol^{-1}
(c) +21.4 kcal mol^{-1} (d) + 64.8 kcal mol^{-1}

101. The value of ΔH_{O-H} is 109 kcal mol^{-1}. The formation of one mole of water in gaseous state from H(*g*) and O(*g*) is accompanied by: (CBSE 1990)

(a) 218 kcal (b) –109 kcal
(c) –218 kcal (d) unpredictable

102. Heat of neutralisation of a strong dibasic acid in dilute solution by NaOH is nearly:
(a) –27.4 kcal/eq
(b) –13.7 kcal/eq
(c) +13.7 kcal/eq
(d) –13.7 kcal/mol

103. The enthalpy changes at 298 K in successive breaking of O—H bonds of water are

$$H_2O(g) \longrightarrow H(g) + OH(g); \quad \Delta H = 498 \text{ kJ mol}^{-1}$$

and $$OH(g) \longrightarrow H(g) + O(g); \quad \Delta H = 428 \text{ kJ mol}^{-1}$$

The bond enthalpy of O—H bond is:
(a) 498 kJ mol^{-1}
(b) 428 kJ mol^{-1}
(c) 70 kJ mol^{-1}
(d) 463 kJ mol^{-1}

104. ΔH and ΔE for the reaction, $S(s) + \frac{3}{2}O_2(g) \longrightarrow SO_3(g)$ are related as:
(a) $\Delta H = \Delta E - 0.5RT$
(b) $\Delta H = \Delta E - 1.5RT$
(c) $\Delta H = \Delta E + RT$
(d) $\Delta H = \Delta E + 1.5RT$

105. A spontaneous change is one in which the system suffers: **(VITEEE 2008)**
(a) an increase in internal energy
(b) lowering in entropy
(c) lowering in free energy
(d) no energy change

106. The free energy change for a reversible reaction at equilibrium is:
(a) zero
(b) positive
(c) negative
(d) none of these

107. In the evaporation of water, the entropy:
(a) decreases
(b) increases
(c) does not change
(d) sometimes increases, sometimes decreases

108. In which of the following change entropy decreases?
(a) Crystallisation of sucrose from solution
(b) Dissolving sucrose in water
(c) Melting of ice
(d) Vaporisation of camphor

109. For the precipitation reaction of Ag^+ ions with NaCl which of the following statements is true?
(a) ΔH is zero for the reaction
(b) ΔG is zero for the reaction
(c) ΔG is negative for the reaction
(d) ΔG should be equal to ΔH

110. If enthalpy of vaporisation of water is 186.5 kJ/mol, the entropy of its vaporisation will be:
(a) 0.5
(b) 1.0
(c) 1.5
(d) 2.0

111. A reaction is non-spontaneous when: **[AMU (Medical) 2006]**
(a) ΔH is +ve, ΔS is –ve
(b) both ΔH and ΔS are –ve
(c) ΔH is –ve and ΔS is +ve
(d) none of the above

112. Standard entropies of X_2, Y_2 and XY_3 are 60, 40 and 50 $JK^{-1}mol^{-1}$ respectively. For the reaction:

$$\frac{1}{2}X_2 + \frac{3}{2}Y_2 \rightleftharpoons XY_3; \quad \Delta H = -30 \text{ kJ}$$

to be at equilibrium, the temperature should be : **[CBSE (PMT) 2010]**
(a) 750 K
(b) 1000 K
(c) 1250 K
(d) 500 K

[**Hint :** $\Delta S = \Sigma S_{\text{Products}} - \Sigma S_{\text{Reactants}}$

$$= 50 - \left[\frac{1}{2} \times 60 + \frac{3}{2} \times 40\right]$$

$$= 50 - (30 + 60) = -40 \text{ JK}^{-1} \text{ mol}^{-1}$$

At equilibrium, $\Delta G = \Delta H - T\Delta S = 0$

i.e., $\Delta H = T\Delta S$

$$T = \frac{\Delta H}{\Delta S} = \frac{-30 \times 1000}{-40} = 750 \text{ K}$$]

113. 'At absolute zero the entropy of a perfect crystal is zero.' This statement corresponds to which law of thermodynamics?
(a) First law
(b) Second law
(c) Third law
(d) None of these

114. Unit of entropy is: **[PMT (Punjab) 2007]**
(a) $J K^{-1} mol^{-1}$
(b) $J mol^{-1}$
(c) $J^{-1} K^{-1} mol^{-1}$
(d) $J K mol^{-1}$

115. Given that $\Delta H_f(H) = 218$ kJ/mol, express the H—H bond energy in kcal/mol: **(EAMCET 2009)**
(a) 52.15
(b) 911
(c) 109
(d) 5.2153

116. For which reaction from the following, ΔS will be maximum?
(a) $Ca(s) + \frac{1}{2}O_2(g) \longrightarrow CaO(s)$
(b) $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$
(c) $C(s) + O_2(g) \longrightarrow CO_2(g)$
(d) $N_2(g) + O_2(g) \longrightarrow 2NO(g)$

117. A particular reaction at 27° C for which $\Delta H > 0$ and $\Delta S > 0$ is found to be non-spontaneous. The reaction may proceed spontaneously if:
(a) the temperature is decreased
(b) the temperature is kept constant
(c) the temperature is increased
(d) it is carried in open vessel at 27° C

118. The least random state of water system is:
(a) ice
(b) liquid water
(c) steam
(d) randomness is same in all

119. Although the dissolution of ammonium chloride in water is an endothermic reaction, even then it is spontaneous because:
(a) ΔH is positive, ΔS is –ve
(b) ΔH is +ve, ΔS is zero
(c) ΔH is positive, $T\,\Delta S < \Delta H$
(d) ΔH is +ve, ΔS is positive and $\Delta H < T\,\Delta S$

120. For an exothermic reaction to be spontaneous:
(a) temperature must be high
(b) temperature must be zero
(c) temperature may have any magnitude
(d) temperature must be low

121. For the reversible process, the value of ΔS is given by the expression:
(a) $\frac{q_{\text{rev}}}{T}$
(b) $T - q_{\text{rev}}$
(c) $q_{\text{rev}} \times T$
(d) $q_{\text{rev}} - T$

122. In an electrochemical cell, if E° is the emf of the cell involving n mole of electrons, then ΔG° is:
(a) $\Delta G^\circ = nFE^\circ$ (b) $\Delta G^\circ = -nFE^\circ$
(c) $E^\circ = nF\,\Delta G^\circ$ (d) $\Delta G^\circ = nF/E^\circ$

123. The correct relation between equilibrium constant (K), standard free energy (ΔG°) and temperature (T) is: **[CET (J&K) 2006]**
(a) $\Delta G^\circ = RT \ln K$ (b) $K = e^{-\Delta G^\circ/2.303\,RT}$
(c) $\Delta G^\circ = -RT \log K$ (d) $K = 10^{-\Delta G^\circ/2.303\,RT}$
(e) $\Delta G^\circ = R \ln K$

124. The value of entropy in the universe is:
(a) constant (b) decreasing
(c) increasing (d) zero

125. Which of the following thermodynamic relation is correct? **[JEE (WB) 2010]**
(a) $dG = VdP - SdT$ (b) $dU = PdV + TdS$
(c) $dH = -VdP + TdS$ (d) $dG = VdP + SdT$

[**Hint :** $dG = dH - TdS - SdT$
$(G = H - TS)$
$dH = dU + PdV + VdP$
$(H = U + PV)$
and $dU = TdS - PdV$
$\therefore$ $dG = (TdS - PdV) + PdV + VdP - TdS - SdT$
$dG = VdP - SdT$]

126. If enthalpies of formation for $C_2H_4(g)$, $CO_2(g)$ and $H_2O(l)$ at 25°C and 1 atm pressure be 52, –394 and –286 kJ mol^{-1} respectively, enthalpy of combustion of $C_2H_4(g)$ will be: **(CBSE 1995)**
(a) +141.2 kJ mol^{-1} (b) +1412 kJ mol^{-1}
(c) –141.2 kJ mol^{-1} (d) –1412 kJ mol^{-1}

127. Identify the correct statement regarding entropy: **(CBSE 1998)**
(a) at absolute zero, the entropy of a perfectly crystalline substance is + ve.
(b) at absolute zero, the entropy of a perfectly crystalline substance is zero.
(c) at 0°C the entropy of a perfectly crystalline substance is taken to be zero.
(d) at absolute zero of temperature the entropy of all crystalline substances is taken to be zero.

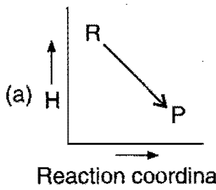
128. The enthalpy and entropy change for a chemical reaction are -2.5×10^{-3} cal and 7.4 cal deg^{-1} respectively. Predict whether the nature of reaction at 298 K is: **(AFMC 1998)**
(a) spontaneous (b) reversible
(c) irreversible (d) non-spontaneous

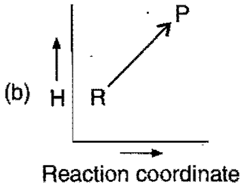
129. One mole of an ideal gas at 300 K is expanded isothermally from an initial volume of 1 litre to 10 litre. The ΔE for this process is: ($R = 2$ cal K^{-1} mol^{-1}) **(CBSE 1998)**
(a) 163.7 cal (b) 1381.1 cal
(c) 9 litre-atm (d) zero

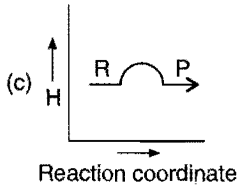
130. The latent heat of vaporisation of a liquid at 500 K and 1 atm pressure is 10 kcal/mol. What will be the change in internal energy (ΔE) of 3 moles of liquid at the same temperature? **(CBSE 1998)**
(a) 13.0 kcal (b) –13.0 kcal
(c) 27.0 kcal (d) –27.0 kcal

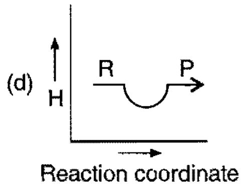
131. The enthalpy change of a reaction does not depend on: **(AIIMS 1997)**
(a) state of reactants and products
(b) nature of reactants and products
(c) different intermediate reactions
(d) initial and final enthalpy change of reaction

132. Which plot represents an exothermic reaction?









133. $S + \frac{3}{2}O_2 \longrightarrow SO_3 + 2x$ kcal;
$SO_2 + \frac{1}{2}O_2 \longrightarrow SO_3 + y$ kcal
The heat of formation of SO_2 is: **[AIIMS 1997; PET (Kerala) 2008]**
(a) $y - 2x$ (b) $2x + y$ (c) $x + y$ (d) $2x/y$

134. Given,
$NH_3(g) + 3Cl_2(g) \rightleftharpoons NCl_3(g) + 3HCl(g)$; $-\Delta H_1$
$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$; $-\Delta H_2$
$H_2(g) + Cl_2(g) \rightleftharpoons 2HCl(g)$; ΔH_3
The heat of formation of $NCl_3(g)$ in terms of ΔH_1, ΔH_2 and ΔH_3 is: **(EAMCET 1998)**
(a) $\Delta H_f = -\Delta H_1 + \frac{1}{2}\Delta H_2 - \frac{3}{2}\Delta H_3$
(b) $\Delta H_f = \Delta H_1 + \frac{1}{2}\Delta H_2 - \frac{3}{2}\Delta H_3$
(c) $\Delta H_f = \Delta H_1 - \frac{1}{2}\Delta H_2 - \frac{3}{2}\Delta H_3$
(d) none of the above

135. The word 'standard' in standard molar enthalpy change implies:
(a) temperature 298 K
(b) pressure 1 atm
(c) temperature 298 K and pressure 1 atm
(d) all temperatures and all pressures

136. The heat of formation (ΔH_f°) of $H_2O(l)$ is equal to:
(a) zero
(b) molar heat of combustion of $H_2(l)$
(c) molar heat of combustion of $H_2(g)$
(d) sum of heat of formation of $H_2O(g)$ and $O_2(g)$

137. An example of extensive property is:
(a) temperature (b) internal energy
(c) viscosity (d) molar heat capacity

138. For a diatomic molecule AB, the electronegativity difference between A and $B = 0.2028\sqrt{\Delta}$ [where, Δ = bond energy of

AB – geometric mean of the bond energies of A_2 and B_2]. The electronegativities of fluorine and chlorine are 4.0 and 3.0 respectively and the bond energies are of F—F: 38 kcal mol^{-1} and of Cl—Cl: 58 kcal mol^{-1}. The bond energy of Cl—F is:

(a) ~ 71 kcal/mol (b) ~ 61 kcal/mol
(c) ~ 48 kcal/mol (d) ~ 75 kcal/mol

139. The value of $\Delta H°$ for the reaction $Cu^+(g) + I^-(g) \rightarrow CuI(g)$ is – 446 kJ mol^{-1}. If the ionisation energy of Cu(g) is 745 kJ mol^{-1} and the electron affinity of I(g) is –295 kJ mol^{-1}, then the value of $\Delta H°$ for the formation of one mole of CuI(g) from Cu(g) and I(g) is:

(a) – 446 kJ (b) 450 kJ (c) 594 kJ (d) 4 kJ

140. If the enthalpy change for the reaction,
$CH_4(g) + Cl_2(g) \rightarrow CH_3Cl(g) + HCl(g)$; $\Delta H = -25$ kcal,
Bond energy of C—H is 20 kcal mol^{-1} greater than the bond energy of C—Cl and bond energies of H—H and H—Cl are same in magnitude, then for the reaction $H_2(g) + Cl_2(g) \rightarrow 2HCl(g)$, ΔH = ?

(a) –22.5 kcal/mol (b) –20.5 kcal/mol
(c) –32.5 kcal/mol (d) –12.5 kcal/mol

141. The standard heat of formation of sodium ions in aqueous solution from the following data:

Heat of formation of NaOH($aq.$) at 25° C = – 470.7 kJ
Heat of formation of OH^-($aq.$) at 25° C = – 228.8 kJ

is:

(a) –251.9 kJ (b) 241.9 kJ (c) – 241.9 kJ (d) 251.9 kJ

142. AB, A_2 and B_2 are diatomic molecules. If the bond enthalpies of A_2, AB and B_2 are in the ratio 1 : 1 : 0.5 and the enthalpy of formation of AB from A_2 and B_2 is –100 kJ mol^{-1}, what is the bond enthalpy of A_2?

(a) 400 kJ mol^{-1} (b) 200 kJ mol^{-1}
(c) 100 kJ mol^{-1} (d) 300 kJ mol^{-1}

143. The lattice energy of solid NaCl is 180 kcal per mol. The dissolution of the solid in water in the form of ions is endothermic to the extent of 1 kcal per mol. If the solvation energies of Na^+ and Cl^- ions are in the ratio 6 : 5, what is the enthalpy of hydration of sodium ion?

(a) – 85.6 kcal/mol (b) – 97.5 kcal/mol
(c) 82.6 kcal/mol (d) +100 kcal/mol

144. Which one of the following statements is false? **[IIT (Screening) 2000, 01]**

(a) Work is a state function
(b) Temperature is a state function
(c) Work appears at the boundary of the system
(d) Change in the state is completely defined when the initial and final states are specified

145. $\Delta G°$ for the reaction $x + y \rightleftharpoons z$ is – 4.606 kcal. The value of equilibrium constant of the reaction at 227° C is: **(IIT 1999)**

(a) 100 (b) 10 (c) 2 (d) 0.01
(R = 2.0 cal K^{-1} mol^{-1})

[Hint: $\Delta G° = -RT \times 2.303 \times \log K$]

146. The enthalpy of solution of $BaCl_2$ (s) and $BaCl_2 \cdot 2H_2O(s)$ are –20.6 and 8.8 kJ mol^{-1}, respectively. The enthalpy change for the reaction is: **(IIT 1998)**

(a) 29.8 kJ (b) –11.8 kJ
(c) –20.6 kJ (d) –29.4 kJ

147. For the reaction,

$$A(g) + 2B(g) \longrightarrow 2C(g) + 3D(g)$$

the value of ΔH at 27° C is 19.0 kcal. The value of ΔE for the reaction would be: (Given, R = 2.0 cal K^{-1} mol^{-1}): **(IIT 1998)**

(a) 20.8 kcal (b) 19.8 kcal (c) 18.8 kcal (d) 17.8 kcal

148. In thermodynamics, a process is called reversible when: **[IIT (Screening) 2000, 01]**

(a) surroundings and system change into each other
(b) there is no boundary between system and surroundings
(c) the surroundings are always in equilibrium with the system
(d) the system changes into the surroundings spontaneously

149. The heat liberated when 1.89 g of benzoic acid is burnt in a bomb calorimeter at 25°C increases the temperature of 18.94 kg of water by 0.632°C. If the specific heat of water at 25°C is 0.998 cal $g^{-1}deg^{-1}$, the value of heat of combustion of benzoic acid is: **(AFMC 2010)**

(a) 881.1 kcal (b) 771.4 kcal
(c) 981.1 kcal (d) 871.2 kcal

[Hint: Heat liberated by 1.89 g of benzoic acid,

$$q = ms\Delta T$$
$$= 18940 \times 0.998 \times 0.632$$
$$= 11946.14 \text{ cal}$$

Heat liberated by the combustion of
1 mol benzoic acid, *i.e.*,
122 g benzoic acid

$$= \frac{11946.14}{1.89} \times 122 = 771126.5 \text{ cal}$$
$$= 771.12 \text{ kcal mol}^{-1}]$$

150. One mole of a non-ideal gas undergoes a change state (2 atm, 3 L, 95 K) to (4 atm, 5 L, 245 K) with a change of internal energy, ΔU = 30 L atm. The change in enthalpy (ΔH) of the process in L atm.: **[IIT (S) 2002]**

(a) 40.0 (b) 42.3
(c) 44.0
(d) not defined, because pressure is not constant

151. Which of the following reactions defines $\Delta H_f°$? **[IIT (S) 2003]**

(a) $C_{(diamond)} + O_2(g) \longrightarrow CO_2(g)$
(b) $\frac{1}{2}H_2(g) + \frac{1}{2}F_2(g) \longrightarrow HF(g)$
(c) $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$
(d) $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$

152. If the enthalpies of formation of Al_2O_3 and Cr_2O_3 are –1596 kJ and –1134 kJ respectively, then the value of ΔH for the reaction;

$2Al + Cr_2O_3 \longrightarrow 2Cr + Al_2O_3$ is: **(AIIMS 2004)**

(a) –462 kJ (b) –1365 kJ
(c) –2530 kJ (d) +2530 kJ

153. Which of the following is true for spontaneous process? **[PMT (Himachal) 2006]**

(a) $\Delta G > 0$ (b) $\Delta G < 0$ (c) $\Delta G = 0$ (d) $\Delta G = T\,\Delta S$

154. Considering entropy(s) as a thermodynamic parameter, the criterion for the spontaneity of any process is: **[CBSE (PMT) 2004]**

(a) $\Delta S_{\text{system}} + \Delta S_{\text{surroundings}} > 0$
(b) $\Delta S_{\text{system}} - \Delta S_{\text{surroundings}} > 0$
(c) $\Delta S_{\text{system}} > 0$ only
(d) $\Delta S_{\text{surroundings}} > 0$ only

155. An ideal gas expands in volume from $1 \times 10^{-3}\ \text{m}^3$ to $1 \times 10^{-2}\ \text{m}^3$ at 300 K against a constant pressure of $1 \times 10^5\ \text{Nm}^{-2}$. The work done is: **(AIEEE 2004)**

(a) −900 J (b) −900 kJ
(c) 270 kJ (d) +900 kJ

156. What is the value of internal energy change (ΔU) at 27°C of a gaseous reaction $2A_2(g) + 5B_2(g) \longrightarrow 2A_2B_5(g)$ (whose heat change at constant pressure is −50700 J)? $R = 8.314\ \text{JK}^{-1}\ \text{mol}^{-1}$ **(SCRA 2009)**

(a) −50700 J (b) −63171 J
(c) −38229 J (d) +38229 J

[**Hint:** $\Delta H = \Delta U + \Delta n_g RT$

$-50700 = \Delta U + (-5) \times 8.314 \times 300$

$\Delta U = -38229$ J]

157. Two mole of an ideal gas is expanded isothermally and reversibly from 1 litre to 10 litre at 300 K. The enthalpy change (in kJ) for the process is: **[IIT (S) 2004]**

(a) 11.4 kJ (b) −11.4 kJ (c) 0 kJ (d) 4.8 kJ

158. The enthalpy of vaporization of a liquid is 30 kJ mol^{-1} and entropy of vaporization is 75 J $\text{mol}^{-1}\ \text{K}^{-1}$. The boiling point of the liquid at 1 atm is: **[IIT (S) 2004]**

(a) 250 K (b) 400 K (c) 450 K (d) 600 K

159. The sublimation energy of $I_2(s)$ is 57.3 kJ/mol and the enthalpy of fusion is 15.5 kJ/mol. The enthalpy of vaporisation of I_2 is: **(DCE 2005)**

(a) 41.8 kJ/mol (b) − 41.8 kJ/mol
(c) 72.8 kJ/mol (d) − 72.8 kJ/mol

[**Hint:** $\Delta H_{\text{sublimation}} = \Delta H_{\text{fusion}} + \Delta H_{\text{vaporisation}}$]

160. ΔH and ΔS for a reaction are +30.558 kJ mol^{-1} and 0.066 kJ $\text{K}^{-1}\ \text{mol}^{-1}$ at 1 atm pressure. The temperature at which free energy change is zero and the nature of the reaction below this temperature is: **[PET (Kerala) 2005]**

(a) 483 K, spontaneous (b) 443 K, non-spontaneous
(c) 443 K, spontaneous (d) 463 K, non-spontaneous
(e) 463 K, spontaneous

161. What would be the amount of heat released when an aqueous solution containing 0.5 mole of HNO_3 is mixed with 0.3 mole of OH^- (enthalpy of neutralisation is −57.1 kJ)? **[PET (Kerala) 2005]**

(a) 28.5 kJ (b) 17.1 kJ (c) 45.7 kJ (d) 1.7 kJ
(e) 2.85 kJ

[**Hint:** 0.3 mole OH^- ion will be completely neutralised,

$\therefore \quad \Delta H = -57.1 \times 0.3 = -17.13$ kJ]

162. A process in which the system does not exchange heat with the surroundings is known as: **[CET (J&K) 2005]**

(a) isothermal (b) isobaric (c) isochoric (d) adiabatic

163. The entropy of a crystalline substance at absolute zero on the basis of third law of thermodynamics should be taken as: **[CET (J&K) 2005]**

(a) 100 (b) 50
(c) zero (d) different for different substances

164. Which of the following expressions is correct? **[JEE (Orissa) 2005]**

(a) $\Delta G^\circ = -nFE^\circ$ (b) $\Delta G^\circ = +nFE^\circ$
(c) $\Delta G^\circ = -2.303RTnFE^\circ_{\text{cell}}$ (d) $\Delta G^\circ = -nF \log K_c$

165. Consider the reaction, $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$; carried out at constant temperature and pressure. If ΔH and ΔU are enthalpy change and internal energy change respectively, which of the following expressions is true? **(AIEEE 2005)**

(a) $\Delta H = 0$ (b) $\Delta H = \Delta U$
(c) $\Delta H < \Delta U$ (d) $\Delta H > \Delta U$

[**Hint:** $\Delta H = \Delta U + \Delta nRT, \Delta n = 2 - 4 = -2$

$\therefore \quad \Delta H < \Delta U$]

166. The absolute enthalpy of neutralisation of the reaction,

$$\text{MgO}(s) + 2\text{HCl}(aq.) \longrightarrow \text{MgCl}_2(aq.) + \text{H}_2\text{O}(l)$$

will be: **[CBSE-PMT (Pre) 2005]**

(a) −57.33 kJ mol^{-1}
(b) greater than −57.33 kJ mol^{-1}
(c) less than −57.33 kJ mol^{-1}
(d) 57.33 kJ mol^{-1}

[**Hint:** Since, MgO is an oxide of a weak base, hence its neutralisation will evolve the heat less than 57.33 kJ mol^{-1}]

167. The entropy values (in J $\text{K}^{-1}\ \text{mol}^{-1}$) of $H_2(g) = 130.6$, $Cl_2(g) = 223$ and $\text{HCl}(g) = 186.7$ at 298 K and 1 atm pressure are given. Then entropy change for the reaction,

$$H_2(g) + Cl_2(g) \longrightarrow 2\text{HCl}(g)$$

is: **[BHU (Pre) 2005]**

(a) + 540.3 (b) + 727.3 (c) − 166.9 (d) + 19.8

168. A mixture of 2 mole of $\text{CO}(g)$ and one mole of O_2, in a closed vessel, is ignited to convert the carbon monoxide to carbon dioxide. If ΔH and ΔU are enthalpy and internal energy change, then: **(KCET 2005)**

(a) $\Delta H > \Delta U$
(b) $\Delta H < \Delta U$
(c) $\Delta H = \Delta U$
(d) the relationship depends on the capacity of the vessel

169. Consider the following reactions at 1000°C:

A. $\text{Zn}(s) + \frac{1}{2}O_2(g) \longrightarrow \text{ZnO}(s); \quad \Delta G^\circ = -360\ \text{kJ mol}^{-1}$

B. $\text{C (graphite)} + \frac{1}{2}O_2(g) \longrightarrow \text{CO}(g); \quad \Delta G^\circ = -460\ \text{kJ/mol}$

Choose the correct statement at 1000°C: **[PMT (Kerala) 2006]**

(a) zinc can be oxidised by carbon monoxide.
(b) ZnO can be reduced by graphite.
(c) both (a) and (b) are true.
(d) both (a) and (b) are false.
(e) carbon monoxide can be reduced by zinc.

170. Which one of the following equations does not correctly represent the first law of thermodynamics for the given process? **[PET (Kerala) 2006]**

(a) Isothermal process : $q = -w$
(b) Cyclic process : $q = -w$
(c) Isochoric process : $\Delta U = q$
(d) Adiabatic process : $\Delta U = -w$
(e) Expansion of gas into vacuum : $\Delta U = q$

[**Hint:** In adiabatic process : $q = 0$

$\therefore$ From $\Delta U = q - w$

Work is done by the system,

$\Delta U = -w$ for adiabatic process]

171. The enthalpy and entropy changes for the reaction:

$$Br_2(l) + Cl_2(g) \rightleftharpoons 2BrCl(g)$$

are 30 kJ mol^{-1} and 105 J K^{-1} mol^{-1} respectively. The temperature at which the reaction will be in equilibrium is: **[CBSE (Med.) 2006]**

(a) 285.7 K (b) 273 K (c) 450 K (d) 300 K

172. $(\Delta H - \Delta U)$ for the formation of carbon monoxide (CO) from its element at 298 K is: $(R = 8.314\ J\ K^{-1}\ mol^{-1})$ **(AIEEE 2006)**

(a) −1238.78 J mol^{-1} (b) 1238.78 J mol^{-1}
(c) −2477.57 J mol^{-1} (d) 2477.57 J mol^{-1}

[**Hint:** $C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g)$ $\Delta n_g = 1 - \frac{1}{2} = \frac{1}{2}$

$$\Delta H - \Delta U = \Delta nRT$$
$$= \frac{1}{2} \times 8.314 \times 298 = 1238.786\ J\ mol^{-1}]$$

173. For a phase change:

$$\underset{0°\,C,\,1\,bar}{H_2O(l) \rightleftharpoons H_2O(s)}$$

(AIIMS 2006)

(a) $\Delta G = 0$ (b) $\Delta S = 0$
(c) $\Delta H = 0$ (d) $\Delta U = 0$

174. We can drive any thermodynamically forbidden reaction in the desired direction by coupling with: **[PET (Kerala) 2006]**

(a) highly exothermic reaction
(b) highly endothermic reaction
(c) highly exergonic reaction
(d) highly endergonic reaction
(e) reaction with large positive ΔS values

175. Given that, bond energies of H — H and Cl — Cl are 430 kJ/mol and 240 kJ/mol respectively. ΔH_f for HCl is − 90 kJ/ mol. Bond enthalpy of HCl is: **[CBSE (Med.) 2007]**

(a) 380 kJ mol^{-1} (b) 425 kJ mol^{-1}
(c) 245 kJ mol^{-1} (d) 290 kJ mol^{-1}

176. The amount of heat released, when 20 mL of 0.5 M NaOH is mixed with 100 mL of 0.1 M HCl, is x kJ. The heat of neutralization (in kJ mol^{-1}) is: **[BHU (Mains) 2007]**

(a) $-100x$ (b) $-50x$ (c) $+100x$ (d) $+50x$

[**Hint:** Number of moles of NaOH $= \frac{MV}{1000} = \frac{0.5 \times 20}{1000} = 0.01$

$$\text{Number of moles of HCl} = \frac{MV}{1000} = \frac{0.1 \times 100}{1000} = 0.01$$

$$\text{Heat of neutralization} = \frac{-x}{0.01} = -100x\,]$$

177. In the conversion of limestone to lime,

$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

the values of $\Delta H°$ and $\Delta S°$ are $+179.1\ kJ\ mol^{-1}$ and 160.2 JK^{-1} mol^{-1} respectively at 298 K and 1 bar. Assuming that, $\Delta H°$ and $\Delta S°$ do not change with temperature; temperature above which conversion of limestone to lime will be spontaneous is: **(AIEEE 2007)**

(a) 1118 K (b) 1008 K (c) 1200 K (d) 845 K

178. Assuming that, water vapour is an ideal gas, the internal energy change (ΔU) when 1 mol of water is vaporised at 1 bar pressure and 100°C, (given: molar enthalpy of vaporisation of water at 1 bar and 373K = 41 kJ mol^{-1} and $R = 8.3\ J\ K^{-1}\ mol^{-1}$) will be: **(AIEEE 2007)**

(a) 41.00 kJ mol^{-1} (b) 4.100 kJ mol^{-1}
(c) 3.7904 kJ mol^{-1} (d) 37.904 kJ mol^{-1}

[**Hint:** $\Delta U = \Delta H - \Delta nRT$

$$= 41000 - 1 \times 8.314 \times 373$$
$$= 37898.878\ J\ mol^{-1}$$
$$= 37.9\ kJ\ mol^{-1}\,]$$

179. For the process,

$$H_2O(l)\ (1\ bar, 373K) \longrightarrow H_2O(g)\ (1\ bar, 373K).$$

The correct set of thermodynamic parameters is: **(IIT 2007)**

(a) $\Delta G = 0, \Delta S = +ve$ (b) $\Delta G = 0, \Delta S = -ve$
(c) $\Delta G = +ve, \Delta S = 0$ (d) $\Delta G = -ve, \Delta S = +ve$

180. For the reaction,

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g); \quad \Delta H° = -573.2\ kJ$$

The heat of decomposition of water per mol is: **(MHT-CET 2007)**

(a) 286.6 kJ (b) 573.2 kJ (c) − 28.66 kJ (d) zero

181. The free energy change $\Delta G = 0$, when: **[CET (J&K) 2007]**

(a) the reactants are completely consumed
(b) a catalyst is added
(c) the system is at equilibrium
(d) the reactants are initially mixed

182. In a closed container, a liquid is stirred with a paddle to increase the temperature, which of the following is true? **[PMT (Pb.) 2007]**

(a) $\Delta U = \Delta W \neq 0, q = 0$ (b) $\Delta U = W = 0, q \neq 0$
(c) $\Delta U = 0, W = q \neq 0$ (d) $W = 0, \Delta U = q \neq 0$

183. For the gas phase reaction,

$$PCl_5\,(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

Which of the following conditions are correct ? **[CBSE-PMT (Pre) 2008]**

(a) $\Delta H < 0, \Delta S < 0$ (b) $\Delta H > 0$ and $\Delta S < 0$
(c) $\Delta H = 0, \Delta S < 0$ (d) $\Delta H > 0$ and $\Delta S > 0$

184. Which of the following is correct ? **[BHU (Screening) 2008]**

(a) $C_V = \left(\frac{\partial U}{\partial T}\right)_P$ (b) $C_P = \left(\frac{\partial H}{\partial T}\right)_V$

(c) $C_P - C_V = R$ (d) $\left(\frac{\partial U}{\partial V}\right)_t = \frac{-a}{V^2}$

(Internal pressure in van dar Waals' equation)

185. Which of the following represents total kinetic energy of one mole of gas? **[JEE (Orissa) 2008]**

(a) $\frac{1}{2}RT$ (b) $\frac{3}{2}RT$ (c) $(C_P - C_V)RT$ (d) $\frac{2}{3}RT$

186. Standard entropy of X_2, Y_2 and XY_3 are 60, 40 and 50 $\mathrm{JK^{-1}\ mol^{-1}}$ respectively. For the reaction :

$$\frac{1}{2}X_2+\frac{3}{2}Y_2 \longrightarrow XY_3, \qquad \Delta H=-30\ \mathrm{kJ},$$

to be at equilibrium, the temperature will be : **(AIEEE 2008)**

(a) 1000K (b) 1250K (c) 500K (d) 750K

[**Hint :** $\frac{1}{2}X_2+\frac{3}{2}Y_2 \rightarrow XY_3$

$$\Delta S^\circ_{\text{Reaction}}=\Delta S^\circ_{XY_3}-\frac{1}{2}\Delta S^\circ_{X_2}-\frac{3}{2}\Delta S^\circ_{Y_2}$$

$$=50-\frac{1}{2}\times 60-\frac{3}{2}\times 40=-40\ \mathrm{JK^{-1}\ mol^{-1}}$$

$\Delta G=\Delta H-T\,\Delta S=0$ at equilibrium.

$$\therefore \quad T=\frac{\Delta H}{\Delta S}=\frac{-30\times 1000}{40}=750\ \mathrm{K}\ ]$$

187. 4.48 L of an ideal gas at S.T.P requires 12 calories to raise its temperature by 15C° at constant volume. The C_P of the gas is : **[PMT (Kerala) 2009]**

(a) 3 cal (b) 4 cal (c) 7 cal (d) 6 cal
(e) 9 cal

[**Hint :** $C_V=\dfrac{\Delta U}{n\,\Delta T}$, $\quad n=\dfrac{4.48}{2.24}=0.2$

$$=\frac{12}{0.2\times 15}=4\ \text{cal}$$

$C_P=C_V+R=4+2=6$ cal]

188. On the basis of following thermochemical data : $[\Delta_f G^\circ\,\mathrm{H^+}(aq)=0]$

$$\mathrm{H_2O}(l)\longrightarrow \mathrm{H^+}(aq)+\mathrm{OH^-}(aq)\ ;\quad \Delta H=57.32\ \mathrm{kJ}$$

$$\mathrm{H_2}(g)+\frac{1}{2}\mathrm{O_2}(g)\longrightarrow \mathrm{H_2O}(l)\quad ;\quad \Delta H=-286.2\ \mathrm{kJ}$$

The value of enthalpy of formation of $\mathrm{OH^-}$ ion at 25°C is: **(AIEEE 2009)**

(a) −22.88 kJ (b) −228.88 kJ
(c) +228.88 kJ (d) −343.52 kJ

[**Hint :** The equation for the formation of $\mathrm{OH^-}(aq)$ is:

$$\mathrm{H_2}(g)+\frac{1}{2}\mathrm{O_2}(g)\longrightarrow \mathrm{H^+}(aq)+\mathrm{OH^-}(aq)$$

It is obtained by adding the two given equations :

$\Delta H=57.32+(-286.2)=-228.88$ kJ]

189. The values of ΔH and ΔS for the reaction, C(graphite) + $\mathrm{CO_2}(g)\longrightarrow 2\mathrm{CO}(g)$ are 170 kJ and 170 $\mathrm{JK^{-1}}$ respectively. This reaction will be spontaneous at : **[CBSE (PMT) Pre 2009]**

(a) 510 K (b) 710 K (c) 910 K (d) 1110 K

[**Hint :** $\Delta G=\Delta H-T\Delta S$, ΔG should be negative for spontaneous process.

$$\therefore \quad \Delta H-T\Delta S<0$$

$$\Delta H<T\Delta S$$

$$\text{or} \quad T>\frac{\Delta H}{\Delta S},\quad T>\frac{170\times 1000}{170}$$

$T>1000$ K]

190. In which reaction, there will be increase in entropy? **(DCE 2009)**

(a) $\mathrm{Na}(s)+\mathrm{H_2O}(l)\longrightarrow \mathrm{NaOH}(aq)+\frac{1}{2}\mathrm{H_2}(g)\uparrow$

(b) $\mathrm{Ag^+}(aq)+\mathrm{Cl^-}(aq)\longrightarrow \mathrm{AgCl}(s)$

(c) $\mathrm{H_2}(g)+\frac{1}{2}\mathrm{O_2}(g)\longrightarrow \mathrm{H_2O}(l)$

(d) $\mathrm{Cu^{2+}}(aq)+4\mathrm{NH_3}(g)\longrightarrow [\mathrm{Cu(NH_3)_4}]^{2+}_{(aq.)}$

191. The species which by definition has zero standard molar enthalpy of formation at 298 K is: **(IIT 2010)**

(a) $\mathrm{Br_2}(g)$ (b) $\mathrm{Cl_2}(g)$
(c) $\mathrm{H_2O}(g)$ (d) $\mathrm{CH_4}(g)$

192. The standard enthalpy of formation of $\mathrm{NH_3}$ is −46 kJ $\mathrm{mol^{-1}}$. If the enthalpy of formation of $\mathrm{H_2}$ from its atoms is −436 kJ $\mathrm{mol^{-1}}$ and that of $\mathrm{N_2}$ is −712 kJ $\mathrm{mol^{-1}}$, the average bond enthalpy of N—H bond in $\mathrm{NH_3}$ is: **(AIEEE 2010)**

(a) + 1056 kJ $\mathrm{mol^{-1}}$ (b) −1102 kJ $\mathrm{mol^{-1}}$
(c) −964 kJ $\mathrm{mol^{-1}}$ (d) +352 kJ $\mathrm{mol^{-1}}$

[**Hint :** $\frac{1}{2}(\mathrm{N\equiv N})+\frac{3}{2}(\mathrm{H-H})\longrightarrow \mathrm{H-N}\begin{matrix}\diagup\mathrm{H}\\ \diagdown\mathrm{H}\end{matrix}$

$\Delta H=-46$ kJ $\mathrm{mol^{-1}}$

BE $(\mathrm{N\equiv N})=-712$ kJ $\mathrm{mol^{-1}}$

BE $(\mathrm{H-H})=-436$ kJ $\mathrm{mol^{-1}}$

Let B.E. of $(\mathrm{N-H})=x$ kJ $\mathrm{mol^{-1}}$

$$\Delta H=\Sigma(\mathrm{B.E.})_{\text{Reactants}}-\Sigma(\mathrm{B.E.})_{\text{Products}}$$

$$-46=\left[\frac{1}{2}(712)+\frac{3}{2}(436)\right]-3x$$

$x=352$ kJ $\mathrm{mol^{-1}}$]

193. A 1 g sample of substance A at 100°C is added to 100 mL of $\mathrm{H_2O}$ at 25°C. Using separate 100 mL portion of $\mathrm{H_2O}$, the procedure is repeated with substance B and then with substance C. How will the final temperatures of the water compare?

Substance	Specific heat
A	0.6 $\mathrm{J\,g^{-1}\,{}^\circ C^{-1}}$
B	0.4 $\mathrm{J\,g^{-1}\,{}^\circ C^{-1}}$
C	0.2 $\mathrm{J\,g^{-1}\,{}^\circ C^{-1}}$

(DUMET 2010)

(a) $T_C>T_B>T_A$ (b) $T_B>T_A>T_C$
(c) $T_A>T_B>T_C$ (d) $T_A=T_B=T_C$

[**Hint :** $q=ms\Delta T$

$$s\propto\frac{1}{\Delta T}$$

Higher is the temperature of given solution, lesser is the temperature difference, so higher is the specific heat. Order of specific heat is $A>B>C$. Hence order of temperature will be :

$T_A>T_B>T_C$]

194. For vaporisation of water at 1 atmospheric pressure, the values of ΔH and ΔS are 40.63 kJ $\mathrm{mol^{-1}}$ and 108.8 J $\mathrm{K^{-1}mol^{-1}}$ respectively. The temperature when Gibbs free energy change (ΔG) for transformation will be zero, is: **[CBSE (PMT) 2010]**

(a) 273.4 K (b) 393.4 K
(c) 373.4 K (d) 293.4 K

[**Hint :** $\Delta G=\Delta H-T\Delta S$

$0=40.63\times 1000-T\times 108.8$

$T=373.4$ K]

Set-2: The questions given below may have more than one correct answers

1. Which is intensive property?
(a) Mass (b) Mass/volume
(c) Volume (d) Volume/mass

2. Which is an irreversible process?
(a) Mixing of two gases by diffusion
(b) Evaporation of water at 373 K and 1 atm pressure
(c) Dissolution of NaCl in water
(d) All of the above

3. One mole of anhydrous $MgCl_2$ dissolves in water and liberates 25 cal/mol of heat. $\Delta H_{\text{hydration}}$ of $MgCl_2 = -30$ cal/mol. Heat of dissolution of $MgCl_2 \cdot H_2O$ is:
(a) +5 cal/mol (b) –5 cal/mol
(c) 55 cal/mol (d) –55 cal/mol

4. Following enthalpy changes are given:
$\alpha\text{-}D$ glucose$(s) \longrightarrow \alpha\text{-}D$ glucose$(aq.)$; $\Delta H = 10.72$ kJ
$\beta\text{-}D$ glucose$(s) \longrightarrow \beta\text{-}D$ glucose$(aq.)$; $\Delta H = 4.68$ kJ
$\alpha\text{-}D$ glucose$(s) \longrightarrow \beta\text{-}D$ glucose$(aq.)$; $\Delta H = 1.16$ kJ
Calculate the enthalpy change in,
$\alpha\text{-}D$ glucose$(s) \longrightarrow \beta\text{-}D$ glucose(s)
(a) 14.24 kJ (b) 16.56 kJ (c) –7.2 kJ (d) 4.88 kJ

5. If x and y are arbitrary extensive variables, then:
(a) $(x+y)$ is an extensive variable
(b) x/y is an intensive variable
(c) dx/dy is an intensive variable
(d) both (b) and (c)

6. If x and y are arbitrary intensive variables, then:
(a) xy is an intensive variable
(b) x/y is an intensive variable
(c) $(x+y)$ is an extensive property
(d) dx/dy is an intensive property

7. $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)$; $\Delta H = x$
$H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l)$; $\Delta H = y$
Heat of vaporization of water is:
(a) $x+y$ (b) $x-y$ (c) $y-x$ (d) $-(x+y)$

8. Which is correct about ΔG?
(a) $\Delta G = \Delta H - T\,\Delta S$ (b) At equilibrium, $\Delta G^\circ = 0$
(c) At eq. $\Delta G = -RT \log K$ (d) $\Delta G = \Delta G^\circ + RT \log K$

9. Dissociation of sodium azide is given by,
$$NaN_3 \longrightarrow Na + 3/2N_2;$$
ΔH for this is:
(a) $\frac{3}{2}\Delta H^\circ_{f\,(N_2)} - \Delta H^\circ_{f\,(NaN_3)}$
(b) $-\Delta H^\circ_{f\,(NaN_3)}$
(c) $\Delta H^\circ_{f\,(NaN_3)} - [\Delta H^\circ_{f\,(Na)} + \frac{3}{2}\Delta H^\circ_{f\,(N_2)}]$
(d) $\Delta H^\circ_{f\,(Na)} + \frac{3}{2}\Delta H^\circ_{f\,(N_2)} - \Delta H^\circ_{f\,(NaN_3)}$

10. The lattice energy of KCl is 202 kcal/mol. When KCl is dissolved in water 2 kcal/mol is absorbed. If the sol energies of K^+ and Cl^- are in the ratio 2 : 3; then $\Delta H_{\text{hydration}}$ of K^+ is:
(a) –80 kJ/mol (b) –120 kJ/mol
(c) –150 kJ/mol (d) 133.3 kJ/mol

11. Which is a correct relationship?
(a) $\left[\frac{dH}{dT}\right]_P - \left[\frac{dE}{dT}\right]_T = (+\text{ve})$
(b) $\left[\frac{dE}{dV}\right]_T = 0$ (for ideal gas)
(c) $\left[\frac{dV}{dT}\right]_P = \frac{nR}{P}$ (for ideal gas)
(d) All of the above

12. The standard Gibbs free energy ΔG° is related to equilibrium constant K_P as:
(a) $K_P = -RT \log \Delta G^\circ$ (b) $K_P = [e/RT]^{\Delta G^\circ}$
(c) $K_P = -\Delta G^\circ/RT$ (d) $K_P = e^{-\Delta G^\circ/RT}$

13. For the two equations given below:
$$H_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow H_2O(l) + x_1 \text{ kJ}$$
$$H_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow H_2O(g) + x_2 \text{ kJ}$$
Select the correct answer:
(a) $x_1 > x_2$ (b) $x_2 > x_1$
(c) $x_1 = x_2$ (d) $x_1 + x_2 = 0$

14. $\Delta E = 0$, for which process?
(a) Cyclic process (b) Isothermal expansion
(c) Isochoric process (d) Adiabatic process

15. For a reaction to be spontaneous in neither direction, which of the following is/are correct regarding the closed system? **[BHU (Mains) 2007]**
(1) $(\Delta G)_{T,P} = 0$ (2) $(\Delta G)_{T,P} < 0$
(3) $(\Delta S)_{U,V} = 0$ (4) $(\Delta S)_{U,V} > 0$
Codes:
(a) 1, 2 and 3 are correct (b) 1 and 2 are correct
(c) 2 and 4 are correct (d) 1 and 3 are correct

Assertion-Reason TYPE QUESTIONS

Set-1

The questions given below consist of an '**Assertion**' **(A)** and the '**Reason**' **(R).** Use the following keys to choose the appropriate answer:

(a) If both (A) and (R) are correct and (R) is the correct explanation for (A).
(b) If both (A) and (R) are correct but (R) is not the correct explanation for (A).
(c) If (A) is correct but (R) is incorrect.
(d) If (A) is incorrect but (R) is correct.

1. (A) The endothermic reactions are favoured at lower temperature and the exothermic reactions are favoured at higher temperature.
(R) When a system in equilibrium is disturbed by changing the temperature, it will tend to adjust itself so as to overcome the effect of the change.

2. (A) $C_P - C_V = R$ for an ideal gas.
(R) $\left[\frac{\partial E}{\partial V}\right]_T = 0$ for an ideal gas.

3. (A) When hydrogen gas at high pressure and room temperature expands adiabatically into a region of low pressure, there is a decrease in temperature.
(R) Hydrogen gas at room temperature is above its inversion temperature.

4. (A) The thermodynamic factor which determines the spontaneity of a process is the free energy. For a process to be spontaneous the free energy must be –ve.
(R) The change in free energy is related to the change in enthalpy and change in entropy. The change in entropy for a process must always be positive if it is spontaneous.

5. (A) The Joules-Thomson coefficient for an ideal gas is zero.
(R) There are no intermolecular attractive forces in an ideal gas.

6. (A) As temperature increases, heat of reaction also increases for exothermic as well as endothermic reactions.
(R) $\Delta H_{\text{reaction}}$ varies according to the relation:

$$\frac{\Delta H_2 - \Delta H_1}{T_2 - T_1} = \Delta C_P$$

7. (A) All exothermic reactions are spontaneous at room temperature.
(R) $\Delta G = -$ ve for above reactions and for spontaneous reactions $\Delta G = -$ ve.

8. (A) Efficiency of a reversible engine is 100% (maximum) when the temperature of sink is $-273°C$.
(R) Efficiency of engine, $\eta = \frac{T_2 - T_1}{T_2}$.

Set-2

The questions given below consist of statements '**Assertion**' **(A)** and '**Reason**' **(R).**

(a) If both (A) and (R) are correct and (R) is the correct reason for (A).
(b) If both (A) and (R) are correct but (R) is not the correct explanation for (A).
(c) If (A) is true but (R) is false.
(d) If both (A) and (R) are false.

1. (A) Enthalpy of graphite is lower than that of diamond.
(R) Entropy of graphite is lower than that of diamond. **(AIIMS 1994)**

2. (A) The enthalpy of formation of gaseous oxygen molecules at 298 K and under a pressure of one atm is zero.
(R) The entropy of formation of gaseous oxygen molecules under the same condition is zero. **(AIIMS 1996)**

3. (A) Heat of neutralization for both HNO_3 and HCl with NaOH is 53.7 kJ per mol.
(R) NaOH is a strong electrolyte/base. **(AIIMS 1997)**

4. (A) Decrease in free energy causes spontaneous reaction.
(R) Spontaneous reactions are invariably exothermic. **(AIIMS 1997)**

5. (A) Many endothermic reactions that are not spontaneous at room temperature become spontaneous at high temperature.
(R) Entropy of the system increases with increase in temperature. **(AIIMS 1998)**

6. (A) The enthalpy of formation of $H_2O(l)$ is greater than that of $H_2O(g)$.
(R) Enthalpy change is negative for the condensation reaction

$$H_2O(g) \longrightarrow H_2O(l)$$

7. (A) For a particular reaction, heat of combustion at constant pressure (q_P) is always greater than that at constant volume (q_V).
(R) Combustion reactions are invariably accomplished by increase in number of moles. **(AIIMS 1998)**

8. (A) The enthalpy of both graphite and diamond is taken to be zero, being elementary substances.
(R) The enthalpy of formation of an elementary substance in any state is taken as zero.

9. (A) Heat of neutralization of perchloric acid, $HClO_4$, with NaOH is same as that of HCl with NaOH.
(R) Both HCl and $HClO_4$ are strong acids.

10. (A) Heat of ionization of water is equal to the heat of neutralization of a strong acid with a strong base.
(R) Water ionizes to a very small extent while H^+ ions from acid combine very rapidly with OH^- from base to form H_2O.

11. (A) Enthalpy of formation of HCl is equal to the bond energy of HCl.

(R) Enthalpy of formation and bond energy both involve formation of one mole of HCl from the elements.

12. (A) Pressure, volume and temperature are all extensive properties.

(R) Extensive properties depend upon the amount and nature of the substance.

13. (A) When a gas at high pressure expands against vacuum, the work done is maximum.

(R) Work done in expansion depends upon the pressure inside the gas and increase in volume.

14. (A) When a real gas is allowed to expand adiabatically through a fine hole from a region of high pressure to a region of low pressure, the temperature of the gas falls.

(R) Work is done at the cost of internal energy of the gas.

15. (A) Internal energy change in a cyclic process is zero.

(R) Internal energy is a state function.

16. (A) An exothermic process, non-spontaneous at high temperature, may become spontaneous at low temperature.

(R) With decrease in temperature, randomness (entropy) decrease.

17. (A) There is no reaction known for which ΔG is positive, yet it is spontaneous.

(R) For photochemical reaction, ΔG is negative.

18. (A) A reaction which is spontaneous and accompanied by decrease of randomness must be exothermic.

(R) All exothermic reactions are accompanied by decrease of randomness.

19. (A) Molar entropy of vaporization of water is different from ethanol.

(R) Water is more polar than methanol.

20. (A) Heat of neutralization for both HNO_3 and HCl with NaOH is 53.7 kJ/mol.

(R) NaOH is a strong electrolyte/base.

21. (A) In the following reaction:

$$C(s) + O_2(g) \longrightarrow CO_2(g); \qquad \Delta H = \Delta U - RT$$

(R) ΔH is related to ΔU by the equation,

$$\Delta H = \Delta U - \Delta n_g RT$$

22. (A) Enthalpy of graphite is lower than that of diamond.

(R) Entropy of graphite is greater than that of diamond.

23. (A) For a reaction

$$2NH_3(g) \longrightarrow N_2(g) + 3H_2(g); \qquad \Delta H > \Delta E$$

(R) Enthalpy change is always greater than internal energy change. **(AIIMS 2008)**

Answers : OBJECTIVE QUESTIONS

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS *for* IIT ASPIRANTS

The following questions contain single correct option :

1. In which of the following pairs, both properties are intensive?
(a) Pressure, temperature (b) Density, volume
(c) Temperature, density (d) Pressure, volume

2. Although the dissolution of ammonium chloride (NH_4Cl) in water is an endothermic reaction, even then it is spontaneous because:
(a) $\Delta S = -$ ve (b) $\Delta S =$ zero
(c) $T\,\Delta S < \Delta H$ (d) $\Delta S = +$ ve and $\Delta H < T\,\Delta S$

3. The S—S bond energy is if $\Delta H^\circ_f(E_t - S - E_t) = -147$ kJ/mol; $\Delta H^\circ_f(E_t - S - S - E_t) = -202$ kJ/mol and $\Delta H^\circ_f S(g) = +223$ kJ/mol:
(a) 168 kJ (b) 126 kJ (c) 278 kJ (d) 572 kJ

[**Hint:**

$$C_2H_5 — S — C_2H_5 + S(s) \longrightarrow C_2H_5 — S — S — C_2H_5$$

$$\Delta H_{\text{reaction}} = \Sigma\Delta H^\circ_{f\,(\text{products})} - \Sigma\Delta H^\circ_{f\,(\text{reactants})}$$
$$= (-202) - (-147) = -55 \text{ kJ}$$
$$\Delta H_{\text{reaction}} = \Sigma\,(\text{BE})_{\text{reactants}} - \Sigma(\text{BE})_{\text{products}}$$

$-55 =$ Heat of sublimation or enthalpy of atomisation of sulphur $-$ BE(S — S)

$-55 = 223 -$ BE(S — S)

BE(S — S) $= 223 + 55 = 278$ kJ

(Common bonds of reactants and products are rejected.)]

4. Standard enthalpies of formation of O_3, CO_2, NH_3 and HI are 142.2, –393.2, – 46.2 and +25.9 kJ mol^{-1} respectively. The order of their increasing stabilities will be:
(a) O_3, CO_2, NH_3, HI (b) CO_2, NH_3, HI, O_3
(c) O_3, HI, NH_3, CO_2 (d) NH_3, HI, CO_2, O_3

[**Hint:** (i) Exothermic compounds are more stable than endothermic compounds.
(ii) Greater is the amount of heat evolved in the formation of a compound, more will be its stability.]

5. Combustion of octane takes place in an automobile engine. The homogeneous equation of combustion is:

$$C_8H_{18}(g) + \frac{25}{2}O_2(g) \longrightarrow 8CO_2(g) + 9H_2O(g)$$

The signs of ΔH, ΔS and ΔG for the reaction will be:
(a) +ve, –ve, +ve (b) –ve, +ve, –ve
(c) –ve, +ve, +ve (d) +ve, +ve, –ve

6. Which among the following represents the reaction of formation of the product?
(a) $C_{(\text{diamond})} + O_2(g) \longrightarrow CO_2(g)$
(b) $S_{(\text{monoclinic})} + O_2(g) \longrightarrow SO_2(g)$
(c) $2N_2(g) + O_2(g) \longrightarrow 2N_2O(g)$
(d) None of the above

7. How much energy must be supplied to change 36 g of ice at 0° C to water at room temperature 25°C?

Data for water	
$\Delta H^\circ_{\text{fusion}}$	6.01 kJ/mol
$C_{p\,\text{liquid}}$	4.18 J K^{-1} g^{-1}

(a) 12 kJ (b) 16 kJ (c) 19 kJ (d) 22 kJ

[**Hint:** $\Delta H = \Delta H_{\text{fusion}}$ of two moles $+ ms\,\Delta T$
$= 6.01 \times 2 + 36 \times 4.18 \times 25 \times 10^{-3}$
≈ 16 kJ]

8. A large positive value of ΔG° corresponds to which of these?
(a) Small positive K (b) Small negative K
(c) Large positive K (d) Large negative K

9. Consider the values for ΔH° (in kJ mol^{-1}) and for ΔS° (in J mol^{-1} K^{-1}) given for four different reactions. For which reaction will ΔG° increase the most (becoming more positive) when the temperature is increased from 0°C to 25°C?
(a) $\Delta H^\circ = 50, \Delta S^\circ = 50$ (b) $\Delta H^\circ = 90, \Delta S^\circ = 20$
(c) $\Delta H^\circ = -20, \Delta S^\circ = -50$ (d) $\Delta H^\circ = -90, \Delta S^\circ = -20$

[**Hint:** Use the relation, $\Delta G^\circ = \Delta H^\circ - T\,\Delta S^\circ$]

10.
$$Fe_2O_3(s) + \frac{3}{2}C(s) \longrightarrow \frac{3}{2}CO_2(g) + 2Fe(s); \quad \Delta H^\circ = +234.1 \text{ kJ}$$
$$C(s) + O_2(g) \longrightarrow CO_2(g); \quad \Delta H^\circ = -393.5 \text{ kJ}$$

Use these equations and ΔH° values to calculate ΔH° for this reaction:

$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$$

(a) –1648.7 kJ (b) –1255.3 kJ
(c) –1021.2 kJ (d) –129.4 kJ

[**Hint:** $2Fe(s) + \frac{3}{2}CO_2(g) \longrightarrow Fe_2O_3(s) + \frac{3}{2}C(s)$ ...(i)
($\Delta H^\circ = -234.1$ kJ)
$C(s) + O_2(g) \longrightarrow CO_2(g)$ ($\Delta H^\circ = -393.5$ kJ) ...(ii)
Multiplying eq. (i) by 2 and eq. (ii) by 3 and on adding both equations, we get:
$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$;
$\Delta H^\circ = (-234.1 \times 2) + (-3 \times 393.5)$
$= -1648.7$ kJ]

11. Consider this equation and the associated value for ΔH°:

$$2H_2(g) + 2Cl_2(g) \longrightarrow 4HCl(g); \quad \Delta H^\circ = -92.3 \text{ kJ}$$

Which statement about this information is incorrect?
(a) If the equation is reversed, the ΔH° value equals + 92.3 kJ
(b) The four HCl bonds are stronger than four bonds in H_2 and Cl_2
(c) The ΔH° value will be –92.3 kJ if HCl is produced as a liquid
(d) 23.1 kJ of heat will be evolved when 1 mole of HCl(g) is produced

12. If the internal energy of an ideal gas decreases by the same amount as the work done by the system, the process is:
(a) cyclic (b) isothermal (c) adiabatic (d) isolated

13. The enthalpy of neutralization of a strong acid by a strong base is –57.32 kJ mol^{-1}. The enthalpy of formation of water is –285.84 kJ mol^{-1}. The enthalpy of formation of hydroxyl ion is:
(a) +228.52 kJ mol^{-1} (b) –114.26 kJ mol^{-1}
(c) –228.52 kJ mol^{-1} (d) +114.2 kJ mol^{-1}

[**Hint:** The process of neutralization is:

$H^+(aq.) + OH^-(aq.) \longrightarrow H_2O(l); \Delta H^\circ = -57.32\ \text{kJ mol}^{-1}$

$\Delta H_{\text{reaction}} = \Sigma$ Heat of formation of products − Σ Heat of formation of reactants

$$= \Delta H^\circ_{f\,H_2O(l)} - [\Delta H^\circ_{f\,H^+(aq.)} + \Delta H^\circ_{f\,OH^-(aq.)}]$$

$$-57.32 = -285.84 - (0 + x)$$

$$x = -285.84 + 57.32$$

$$= -228.52\ \text{kJ}]$$

14. For which process will ΔH° and ΔG° be expected to be most similar?

(a) $2Al(s) + Fe_2O_3(s) \longrightarrow 2Fe(s) + Al_2O_3(s)$

(b) $2Na(s) + 2H_2O(l) \longrightarrow 2NaOH(aq.) + H_2(g)$

(c) $2NO_2(g) \longrightarrow N_2O_4(g)$

(d) $2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$

[**Hint:** (a) In this reaction, $\Delta S^\circ \approx 0$

$\therefore \quad \Delta G^\circ = \Delta H^\circ - T\,\Delta S^\circ$

$\Delta G^\circ \approx \Delta H^\circ$]

15. For a particular reaction, $\Delta H^\circ = -38.3$ kJ and $\Delta S^\circ = -113$ $\text{J K}^{-1}\ \text{mol}^{-1}$. This reaction is:

(a) spontaneous at all temperatures

(b) non-spontaneous at all temperatures

(c) spontaneous at temperatures below 66°C

(d) spontaneous at temperatures above 66°C

[**Hint:** $\Delta G = \Delta H - T\,\Delta S$

For spontaneous process, $\Delta G < 0$.

$$\therefore \quad \Delta H - T\,\Delta S < 0$$

$$\frac{\Delta H}{\Delta S} < T$$

$$\frac{-38.3 \times 1000}{-113} < T$$

i.e., $T > 338.93$ K, *i.e.*, 66° C]

16. Which halogen in its standard state has the greatest absolute entropy per mole?

(a) $F_2(g)$ (b) $Cl_2(g)$ (c) $Br_2(l)$ (d) $I_2(s)$

17. For which of these processes is the value of ΔS negative?

I. Sugar is dissolved in water.

II. Steam condenses on a surface.

III. $CaCO_3$ is decomposed into CaO and CO_2.

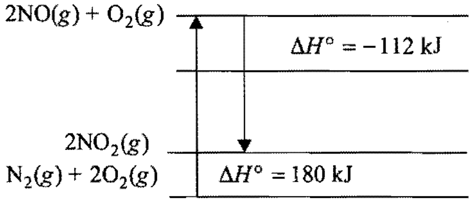
(a) I only (b) II only

(c) I and III only (d) II and III only

18. When solid NH_4NO_3 is dissolved in water at 25°C, the temperature of the solution decreases. What is true about the signs of ΔH and ΔS for this process?

	ΔH	ΔS
(a)	−	+
(b)	−	−
(c)	+	+
(d)	+	−

19. The diagram below shows the heat of reaction between N_2, O_2, NO and NO_2:



Which of the following statements pertaining to the formation of NO and NO_2 are correct?

1. The standard heat of formation of NO_2 is 68 kJ mol^{-1}.
2. NO_2 is formed faster than NO at higher temperature.
3. The oxidation reaction of nitrogen to NO_2 is endothermic.
4. These two reactions often take place in troposphere and causes green house effect.
5. These two reactions often take place and are responsible for city smog.

(a) 1 and 2 (b) 1 and 3 (c) 1 and 4 (d) 3 and 4

(e) 3 and 5

20. The enthalpy changes for two reactions are given by the equations:

$$2Cr(s) + 1\frac{1}{2}O_2(g) \longrightarrow Cr_2O_3(s); \quad \Delta H = -1130\ \text{kJ}$$

$$C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g); \quad \Delta H = -110\ \text{kJ}$$

What is the enthalpy change, in kJ, for the reaction?

$$3C(s) + Cr_2O_3(s) \longrightarrow 2Cr(s) + 3CO(g)$$

(a) −1460 kJ (b) −800 kJ (c) +800 kJ (d) +1020 kJ

(e) +1460 kJ

[**Hint:** The given equations can be written as:

$$Cr_2O_3(s) \longrightarrow 2Cr(s) + \frac{3}{2}O_2(g); \quad \Delta H = +1130\ \text{kJ}$$

$$3C(s) + \frac{3}{2}O_2(g) \longrightarrow 3CO(g); \quad \Delta H = -330\ \text{kJ}$$

Adding the above equations, we get:

$$Cr_2O_3(s) + 3C(s) \longrightarrow 2Cr(s) + 3CO(g); \quad \Delta H = +800\ \text{kJ}]$$

21. The enthalpy change at 298 K for decomposition is given in the following two steps:

Step I: $H_2O(g) \longrightarrow H(g) + OH(g); \quad \Delta H = 498\ \text{kJ mol}^{-1}$

Step II: $OH(g) \longrightarrow H(g) + O(g); \quad \Delta H = 428\ \text{kJ mol}^{-1}$

The bond enthalpy of the O—H bond is:

(a) 498 kJ mol^{-1} (b) 463 kJ mol^{-1}

(c) 428 kJ mol^{-1} (d) 70 kJ mol^{-1}

22. Consider the following two reactions:

(i) Propene + $H_2 \longrightarrow$ Propane; ΔH_1

(ii) Cyclopropane + $H_2 \longrightarrow$ Propane; ΔH_2

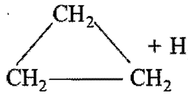
Then, $\Delta H_2 - \Delta H_1$ will be:

(a) 0 (b) $2BE_{C-C} - BE_{C=C}$

(c) $BE_{C=C}$ (d) $2BE_{C=C} - BE_{C-C}$

[**Hint:** $CH_3-CH=CH_2 + H_2 \longrightarrow CH_3-CH_2-CH_3$;

$$\Delta H_1 = (BE_{C=C} + BE_{H-H}) - (2BE_{C-H} + BE_{C-C})$$



$+ H_2 \longrightarrow CH_3-CH_2-CH_3$;

$$\Delta H_2 = (BE_{C-C} + BE_{H-H}) - (2 \times BE_{C-H})$$

$$\Delta H_2 - \Delta H_1 = 2BE_{C-C} - BE_{C=C}\ ]$$

23. Under which circumstances would the free energy change for a reaction be relatively temperature independent?
(a) ΔH° is negative
(b) ΔH° is positive
(c) ΔS° has a large positive value
(d) ΔS° has a small magnitude

24. Use the free energy change, $\Delta G^\circ = +63.3\,\text{kJ}$, for this reaction, to calculate the K_{sp} of $Ag_2CO_3(s)$ in water at 25°C :

$$Ag_2CO_3(s) \rightleftharpoons Ag^+(aq.) + CO_3^{2-}(aq.)$$

(a) 3.2×10^{-26} (b) 8×10^{-12} (c) 2.9×10^{-3} (d) 7.9×10^{-2}

25. Which statement(s) is/are true?
1. S° values for all elements in their states are positive.
2. S° values for all aqueous ions are positive.
3. ΔS° values for all spontaneous reactions are positive.

(a) 1 only (b) 1 and 2 only
(c) 2 and 3 only (d) All of these

26. The enthalpy of a reaction does not depend upon:
(a) the intermediate reaction steps
(b) the temperature of initial and final state of the reaction
(c) the physical states of reactants and products
(d) use of different reactants for the formation of the same product

27. When a solution of 500 mL of 2 M KOH is added to 500 mL of 2 M HCl, then the rise in temperature T_1 is noted. When the same experiment is repeated by mixing 250 mL of each solution, the rise in temperature T_2 is noted:
(a) $T_1 = T_2$ (b) $T_1 = 2T_2$ (c) $T_2 = 2T_1$ (d) $T_1 = 4T_2$

28. The heat of combustion of solid benzoic acid at constant volume is −321.30 kJ at 27°C. The heat of combustion at constant pressure is:
(a) $-321.30 - 300R$ (b) $-321.30 + 300R$
(c) $-321.30 - 150R$ (d) $-321.30 + 900R$

[Hint:

$$C_6H_5COOH(s) + \frac{15}{2}O_2(g) \longrightarrow 7CO_2(g) + 3H_2O(l),$$

$$\Delta n = 7 - \frac{15}{2} = -\frac{1}{2}$$

$$\Delta H = \Delta U + \Delta nRT$$

$$= -321.30 - \frac{1}{2} \times R \times 300 = -321.30 - 150R]$$

29. $A \longrightarrow B;$ $\Delta U = 40\ \text{kJ mol}^{-1}$

If the system goes from A to B by a reversible path and returns to state A by an irreversible path, what would be the net change in internal energy?
(a) More than 40 kJ (b) Zero
(c) Less than 40 kJ (d) 40 kJ

30. For the process, $NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$:
(a) $\Delta H = +\text{ve}, \Delta S = +\text{ve}$ (b) $\Delta H = -\text{ve}, \Delta S = +\text{ve}$
(c) $\Delta H = +\text{ve}, \Delta U = -\text{ve}$ (d) $\Delta H = -\text{ve}, \Delta S = -\text{ve}$

31. Match the thermodynamic properties **(List-I)** with their relation **(List-II):**

List-I	**List-II**
A. Free energy change (ΔG°)	(i) $RT \log_e K$
B. Entropy change ΔS°	(ii) $-nFE$
C. ΔH° enthalpy change of a reaction in standard state	(iii) $RT^2\left(\frac{d \ln K}{dT}\right)_P$
D. Standard free energy change (ΔG°)	(iv) $-\left\{\frac{d\,\Delta G}{dT}\right\}_P$

Select the correct answer:

Codes:	A	B	C	D
(a)	(i)	(ii)	(iii)	(iv)
(b)	(ii)	(iv)	(iii)	(i)
(c)	(iv)	(ii)	(iii)	(i)
(d)	(i)	(ii)	(iv)	(iii)

32. An ideal gas is allowed to expand under adiabatic conditions. The zero value is of:
(a) ΔT (b) ΔS
(c) ΔG (d) none of these

33. Match the physical changes in **List-I** with their relations given in **List-II:**

List-I	**List-II**
A. ΔG	(i) $\Delta U + P\Delta V$
B. ΔH	(ii) $-nFE$
C. ΔS°	(iii) $-RT \log_e K$
D. ΔG°	(iv) $nR \log_e\left(\frac{V_2}{V_1}\right)$

Select the correct answer from the given codes:

Codes:	A	B	C	D
(a)	(ii)	(i)	(iv)	(iii)
(b)	(i)	(ii)	(iii)	(iv)
(c)	(iv)	(iii)	(ii)	(i)
(d)	(i)	(ii)	(iv)	(iii)

34. Given the following data:

Substance	**ΔH°(kJ/mol)**	**S°(J/mol K)**	**ΔG°(kJ/mol)**
FeO(s)	−266.3	57.49	−245.12
C (Graphite)	0	5.74	0
Fe(s)	0	27.28	0
CO(g)	−110.5	197.6	−137.15

Determine at what temperature the following reaction is spontaneous?

$$FeO(s) + C\,(\text{Graphite}) \longrightarrow Fe(s) + CO(g)$$

(a) 298 K
(b) 668 K
(c) 966 K
(d) ΔG° is +ve, hence the reaction will never be spontaneous.

[Hint: $\Delta H_{\text{reaction}} = \Sigma\{\Delta H^\circ_{f\,Fe(s)} + \Delta H^\circ_{f\,CO(g)}\}$

$$-\{\Delta H^\circ_{f\,FeO(s)} + \Delta H^\circ_{f\,C(\text{graphite})}\}$$

$$= (0 - 110.5) - (-266.3 + 0) = 155.8\ \text{kJ mol}^{-1}$$

$$\Delta S_{\text{reaction}} = \Sigma[S^\circ_{Fe(s)} + S^\circ_{CO(g)}] - [S^\circ_{FeO(s)} + S^\circ_{C(\text{graphite})}]$$

$$= (27.28 + 197.6) - (57.49 + 5.74)$$

$$= 161.65\ \text{JK}^{-1}\ \text{mol}^{-1}$$

For spontaneous reaction, $T > \frac{\Delta H}{\Delta S}$; $T > \frac{155.8 \times 1000}{161.65}$

$\therefore \quad T > 966$ K]

35. Which of the following equations has/have enthalpy changes equal to ΔH_{comb} C?

I. $C(s) + O_2(g) \longrightarrow CO_2(g)$

II. $C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g)$

III. $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$

(a) I and II (b) I, II and III
(c) I and III (d) I only

36. The enthalpy change of which reaction corresponds to ΔH_f° for $Na_2CO_3(s)$ at 298 K?

(a) $2Na(s) + C(s) + \frac{3}{2}O_2(g) \longrightarrow Na_2CO_3(s)$
(b) $Na_2O(s) + CO_2(g) \longrightarrow Na_2CO_3(s)$
(c) $2Na^+(aq.) + CO_3^{2-}(aq.) \longrightarrow Na_2CO_3(s)$
(d) $2Na^+(aq.) + 2OH^-(aq.) + CO_2(aq.) \rightarrow Na_2CO_3(s) + H_2O$

37. Enthalpy is equal to: **(VITEEE 2007)**

(a) $T^2\left[\frac{\partial(G/T)}{\partial T}\right]_P$ (b) $-T^2\left[\frac{\partial(G/T)}{\partial T}\right]_P$

(c) $T^2\left[\frac{\partial(G/T)}{\partial T}\right]_V$ (d) $-T^2\left[\frac{\partial(G/T)}{\partial T}\right]_V$

[**Hint:**

$$G = H - TS \qquad \text{...(i)}$$

$$G = U + PV - TS$$

$$\Delta G = \Delta U + P\Delta V + V\Delta P - T\Delta S - S\Delta T$$

From the first and second laws,

$$T\Delta S = \Delta U + P\Delta V$$

$$\therefore \quad \Delta G = V\Delta P - S\Delta T$$

At constant pressure, $\Delta P = 0$

$$\frac{\Delta G}{\Delta T} = -S \qquad \text{...(ii)}$$

From eqs. (i) and (ii),

$$G = H + T\frac{\Delta G}{\Delta T}$$

OR

$$G = H + T\left(\frac{\partial G}{\partial T}\right)_P$$

$$-\frac{H}{T^2} = -\frac{G}{T^2} + \frac{1}{T}\left(\frac{\partial G}{\partial T}\right)_P$$

$$= \left[\frac{\partial(G/T)}{\partial T}\right]_P$$

$$H = -T^2\left[\frac{\partial(G/T)}{\partial T}\right]_P$$]

38. When a bomb calorimeter is used to determine the heat of reaction, which property of the system under investigation is most likely to remain constant?

(a) Number of molecules (b) Pressure
(c) Temperature (d) Volume

39. For the reaction shown, which is closest to the value of ΔH?

$$2Cr^{3+}(aq.) + 3Ni(s) \longrightarrow 2Cr(s) + 3Ni^{2+}(aq.)$$

ΔH_f°	(kJ mol^{-1})
$Cr^{3+}(aq.)$	−143
$Ni^{2+}(aq.)$	−54

(a) 124 kJ (b) 89 kJ
(c) −89 kJ (d) −124 kJ

40. An ice cube at 0.00°C is placed in 200 g of distilled water at 25° C. The final temperature after the ice is completely melted is 5°C. What is the mass of the ice cube?
($\Delta H_{\text{fus}} = 340$ J g^{-1}, $C_p = 4.18$ J g^{-1}°C^{-1})

(a) 23.6 g (b) 46.3 g
(c) 50.0 g (d) 800 g

41. Which reaction occurs with the greatest increase in entropy?

(a) $2H_2O(l) \longrightarrow 2H_2(g) + O_2(g)$
(b) $2NO(g) \longrightarrow N_2(g) + O_2(g)$
(c) $C(s) + O_2(g) \longrightarrow CO_2(g)$
(d) $Br_2(g) + Cl_2(g) \longrightarrow 2BrCl(g)$

42. The bond dissociation energies for single covalent bonds formed between carbon and A, B, C, D and E atoms are:

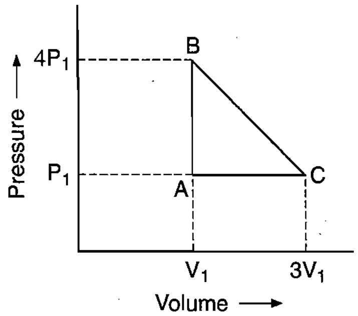
	Bond	Bond energy (kcal mol^{-1})
(i)	C—A	240
(ii)	C—B	382
(iii)	C—D	276
(iv)	C—E	486

This indicates that the smallest atom is:

(a) A (b) B (c) C (d) E

[**Hint:** C—E bond has highest bond energy; it means that the covalent bond C—E will be strongest. Smaller is the size of atom, stronger is the covalent bond.]

43. An ideal gas is taken around the cycle $ABCA$ as:



(a) $12P_1V_1$ (b) $6P_1V_1$ (c) $3P_1V_1$ (d) P_1V_1

[**Hint:** Work done in the cyclic process

$= \text{Area bounded } (ABCA)$

$= \frac{1}{2} \times AC \times AB$

$= \frac{1}{2} \times 2V_1 \times 3P_1 = 3P_1V_1$]

44. One gram mole of graphite and diamond were burnt to form CO_2 gas.

$$C_{(\text{graphite})} + O_2(g) \longrightarrow CO_2(g); \quad \Delta H^\circ = -399.5 \text{ kJ}$$

$$C_{(\text{diamond})} + O_2(g) \longrightarrow CO_2(g); \quad \Delta H^\circ = -395.4 \text{ kJ}$$

(a) graphite is more stable than diamond
(b) diamond is more stable than graphite
(c) graphite has greater affinity with oxygen
(d) diamond has greater affinity with oxygen

[**Hint:** Thermal stability of one isotope is directly proportional to the heat of combustion.]

45. Which among the following is not an exact differential?
(a) Q (dQ = heat absorbed)
(b) U (dU = change in internal energy)
(c) S (dS = entropy change)
(d) G (dG = Gibbs free energy change)

[**Hint:** Heat 'Q' is a path dependent function, hence its exact differentiation is not possible; however, internal energy, entropy and Gibbs free energy are state functions, hence can be differentiated exactly.]

46. A gas expands adiabatically at constant pressure such that:

$$T \propto \frac{1}{\sqrt{V}}$$

The value of γ, *i.e.*, (C_P / C_V) of the gas will be:
(a) 1.30 (b) 1.50 (c) 1.70 (d) 2

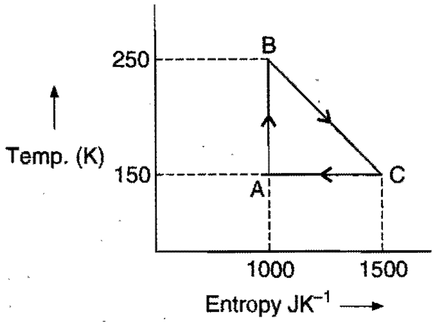
[**Hint:**
$$T \propto \frac{1}{\sqrt{V}}$$
$$TV^{1/2} = \text{constant}$$
For adiabatic process, $TV^{1/2} = TV^{\gamma - 1}$ = constant
$$\therefore \quad \gamma - 1 = \frac{1}{2}, \quad \gamma = \frac{3}{2}]$$

47.
$$2\text{Zn} + \text{O}_2 \longrightarrow 2\text{ZnO}; \quad \Delta G^\circ = -616 \text{ J} \quad \ldots \text{(i)}$$
$$2\text{Zn} + \text{S} \longrightarrow 2\text{ZnS}; \quad \Delta G^\circ = -293 \text{ J} \quad \ldots \text{(ii)}$$
$$2\text{S} + 2\text{O}_2 \longrightarrow 2\text{SO}_2(g); \quad \Delta G^\circ = -408 \text{ J} \quad \ldots \text{(iii)}$$

ΔG° for the following reaction:
$$2\text{ZnS} + 3\text{O}_2 \longrightarrow 2\text{ZnO} + 2\text{SO}_2$$
would be:
(a) −731 J (b) −1317 J (c) +731 J (d) +1317 J

[**Hint:** $\Delta G^\circ = 2\Delta G^\circ_{\text{ZnO}} + 2\Delta G^\circ_{\text{SO}_2} - 2\Delta G^\circ_{\text{ZnS}}$
$$= [-616 - 408] - [-293]$$
$$= -1024 + 293$$
$$= -731 \text{ J}]$$

48. The efficiency of the reversible cycle shown in the figure will be:
(a) 33.33% (b) 56% (c) 66% (d) 25%



[**Hint:** Efficiency of cycle $= \dfrac{\text{Area of closed cycle}}{\text{Area under the curve}} \times 100$

$$= \frac{\frac{1}{2} \times (1500 - 1000) \times (250 - 150)}{\frac{1}{2} \times (1500 - 1000) \times (250 - 150) + (1500 - 1000) \times (150 - 0)} \times 100$$
$$= \frac{\frac{1}{2} \times 500 \times 100}{\frac{1}{2} \times 500 \times 100 + 500 \times 150} \times 100$$
$$= \frac{500 \times 50 \times 100}{500 \times 50 + 500 \times 150} = 25]$$

49. In Haber's process of ammonia manufacture:
$$\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g);$$
$\Delta H^\circ_{25^\circ\text{C}} = -92.2$ kJ

Molecules	$\text{N}_2(g)$	$\text{H}_2(g)$	$\text{NH}_3(g)$
C_P J K^{-1} mol^{-1}	29.1	28.8	35.1

If C_P is independent of temperature, then reaction at 100°C as compared to that of 25°C will be:
(a) more endothermic (b) less endothermic
(c) more exothermic (d) less exothermic

[**Hint:** Use: $\dfrac{\Delta H_2 - \Delta H_1}{T_2 - T_1} = \Delta C_P$]

50. Consider the following statements:
I. Change in enthalpy is always smaller than change in internal energy.
II. The variation in enthalpy of a reaction with temperature is given by Kirchhoff's equation.
III. The entropy change in reversible adiabatic process is equal to zero.

Select the correct answer:
(a) I and II (b) II and III
(c) III and I (d) all are correct

51. In C_2H_4, energy of formation of (C=C) and (C—C) are −145 kJ/mol and −80 kJ/mol respectively. What is the enthalpy change when ethylene polymerises to form polythene? **[JEE (Orissa) 2006]**
(a) +650 kJ/mol (b) +65 kJ/mol
(c) −650 kJ mol^{-1} (d) −65 kJ mol^{-1}

[**Hint:** Polymerisation of ethene may be given as:
$$n\text{CH}_2{=}\text{CH}_2 \longrightarrow \text{-(}\text{CH}_2{-}\text{CH}_2\text{)-}_n$$
$$\Delta H = \Sigma(\text{BE})_{\text{reaetants}} - \Sigma(\text{BE})_{\text{products}}$$
$$= (+145) - (+80) = +65 \text{ kJ/mol}]$$

[**Note:** C—H bonds are common in both reactants and products.]

52. If 150 kJ of energy is needed for muscular work to walk a distance of 1 km, then how much of glucose one has to consume to walk a distance of 5 km, provided only 30% of energy is available for muscular work. The enthalpy of combustion of glucose is 3000 kJ mol^{-1}: **[PMT (Kerala) 2007]**
(a) 75 g (b) 30 g (c) 180 g (d) 150 g
(e) 45 g

53. The value of $\log_{10} K$ for a reaction $A \rightleftharpoons B$ is:
(Given, $\Delta_r H^\circ_{298\text{K}} = -54.07$ kJ mol^{-1},
$\Delta_r S^\circ_{298\text{K}} = 10$ JK^{-1} mol^{-1} and $R = 8.314$ J K^{-1} mol^{-1};
$2.303 \times 8.314 \times 298 = 5705$) **(IIT 2007)**
(a) 5 (b) 10 (c) 95 (d) 100

[**Hint:** $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$

$= -54.07 \times 1000 - 298 \times 10$

$= -57050$ J

$\Delta G^\circ = -2.303\, RT \log_{10} K$

$-57050 = -5705 \log_{10} K$

$\log_{10} K = 10$]

54. The lattice enthalpy and hydration enthalpy of four compounds are given below :

Compound	Lattice enthalpy (kJ/mol)	Hydration enthalpy (kJ/mol)
P	+ 780	− 920
Q	+ 1012	− 812
R	+ 828	− 878
S	+ 632	− 600

The pair of compounds which is soluble in water is : **[PET (Kerala) 2008]**

(a) P and Q (b) Q and R (c) R and S (d) Q and S
(e) P and R

[**Hint :** For solubility of ionic compounds, hydration energy must be greater than lattice energy.]

Following questions may have more than one correct options :

1. Which of the following are correct about irreversible isothermal expansion of ideal gas ?

(a) $W = -q$ (b) $\Delta U = 0$
(c) $\Delta T = 0$ (d) $W = -nRT \ln \dfrac{P_1}{P_2}$

2. The work done during adiabatic expansion or compression of an ideal gas is given by :

(a) $n\, C_V\, \Delta T$ (b) $\dfrac{nR}{(\gamma - 1)}(T_2 - T_1)$
(c) $-nR\, P_{\text{ext}} \left[\dfrac{T_2P_1 - T_1P_2}{P_1P_2}\right]$ (d) $-2.303\, RT \log \dfrac{V_2}{V_1}$

3. For an ideal gas $\left(\dfrac{C_{Pm}}{C_{Vm}} = \gamma\right)$; of molar mass M, its specific heat capacity at constant volume is :

(a) $\dfrac{\gamma R}{(\gamma - 1)M}$ (b) $\dfrac{\gamma}{M(\gamma - 1)}$ (c) $\dfrac{M}{R(\gamma - 1)}$ (d) $\dfrac{\gamma RM}{\gamma - 1}$

[**Hint :** $\dfrac{C_{Pm}}{C_{Vm}} = \gamma,\ C_{Pm} - C_{Vm} = R$

$C_{Vm} = \dfrac{R}{\gamma - 1}$ and $C_{Pm} = \dfrac{R\gamma}{\gamma - 1}$

$\dfrac{\gamma}{\gamma - 1} = C_{Vm} \times M$

$C_{Vm} = \dfrac{x}{M(\gamma - 1)}$]

Answers

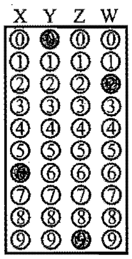
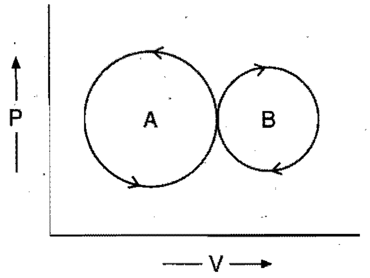
Integer Answer TYPE QUESTIONS

This section contains 11 questions. The answer to each of the questions is a single digit integer, ranging from 0 to 9. If the correct answers to question numbers X, Y, Z and W (say) are 6, 0, 9 and 2 respectively, then the correct darkening of bubbles will look like the given figure :



1. A bubble of 8 moles of helium is submerged at certain depth in water. The temperature of water increases by 30°C. How much heat is added approximately to helium (in kJ) during expansion?
2. For a liquid, enthalpy of fusion is 1.435 kcal mol^{-1} and molar entropy change is 5.26 cal $\text{mol}^{-1}\ \text{K}^{-1}$. The freezing point of liquid in celcius will be :
3. For the reaction, $\text{Ag}_2\text{O}(s) \rightleftharpoons 2\text{Ag}(s) + \frac{1}{2}\text{O}_2(g)$

   $\Delta H, \Delta S$ and T are 40.63 kJ mol^{-1}, 108.8 J $\text{K}^{-1}\ \text{mol}^{-1}$ and 373.4 K respectively. Free energy change ΔG of the reaction will be:
4. Standard Gibbs Free energy change $\Delta G°$ for a reaction is zero. The value of equilibrium constant of the reaction will be:
5. $\Delta G°$ for the reaction $x + y \rightleftharpoons z$ is -4.606 kcal. The value of equilibrium constant of the reaction at 227°C is $(x \times 10^2)$. The value of 'x' is :
6. 4.48 L of an ideal gas at STP requires 12 cal to raise the temperature by 15°C at constant volume. The C_P of the gas is .... cal.
7.



In the present graph, the area of circle A and B are 25 unit and 20 unit respectively. Work done will be .... unit.

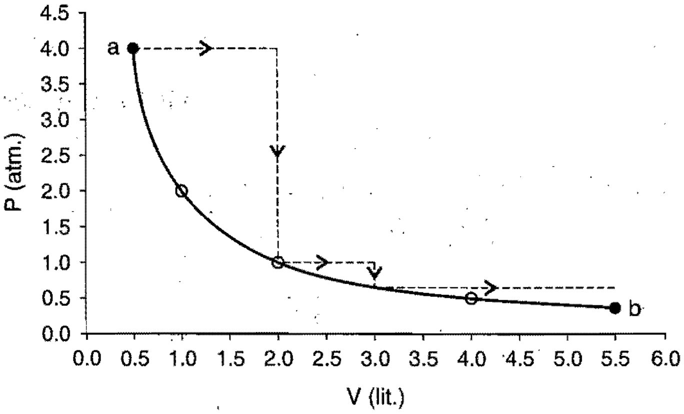
8. For the reaction,

   $$\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g)$$

   Heat of reaction at constant volume exceeds the heat of reaction at constant pressure by the value of xRT. The value of x is :
9. Gas (A_x) has the ratio of specific heat, equal to 1.66. The value of x will be :
10. For a liquid the vapour pressure is given by :

    $$\log_{10} P = \frac{-400}{T} + 10$$

    Vapour pressure of the liquid is 10^x mm Hg. The value of x will be :
11. One mole of an ideal gas is taken from a to b along two paths denoted by the solid and the dashed lines as shown in the graph below. If the work done along the solid line path is w_s and that along the dotted line path is w_d, then the integer closest to the ratio w_d / w_s is:



(IIT 2010)

[**Hint :** w_d = work done along dotted line

$$= \Sigma P\Delta V$$

$$= 4 \times 1.5 + 1 \times 1 + 2.5 \times \frac{2}{3} = 8.65 \text{ L atm}$$

w_s = It is reversible isothermal process

$$= 2.303 nRT \log\left(\frac{V_2}{V_1}\right)$$

$$= 2.303 \times (PV) \log\left(\frac{V_2}{V_1}\right)$$

$$= 2.303 \times 2 \log\frac{5.5}{0.5} = 4.79 \text{ L atm}$$

$$\frac{w_d}{w_s} = \frac{8.65}{4.79} \approx 2 \text{]}$$

LINKED COMPREHENSION TYPE QUESTIONS

• Passage 1

Chemical reactions are invariably associated with the transfer of energy either in the form of heat or light. In the laboratory, heat changes in physical and chemical processes are measured with an instrument called calorimeter. Heat change in the process is calculated as:

$$q = ms\,\Delta T; \quad s = \text{Specific heat}$$
$$= c\Delta T; \quad c = \text{Heat capacity}$$

Heat of reaction at constant volume is measured using bomb calorimeter.

$$q_V = \Delta U = \text{Internal energy change}$$

Heat of reaction at constant pressure is measured using simple or water calorimeter.

$$q_P = \Delta H$$
$$q_P = q_V + P\,\Delta V$$
$$\Delta H = \Delta U + \Delta nRT$$

The amount of energy released during a chemical change depends on the physical state of reactants and products, the condition of pressure, temperature and volume at which the reaction is carried out. The variation of heat of reaction with temperature and pressure is given by Kirchhoff's equation:

$$\frac{\Delta H_2 - \Delta H_1}{T_2 - T_1} = \Delta C_P \quad ; \quad \frac{\Delta U_2 - \Delta U_1}{T_2 - T_1} = \Delta C_V$$

(At constant pressure) *(At constant volume)*

Answer the following questions:

1. Match the **List-I** with **List-II** and select the answer from the given codes:

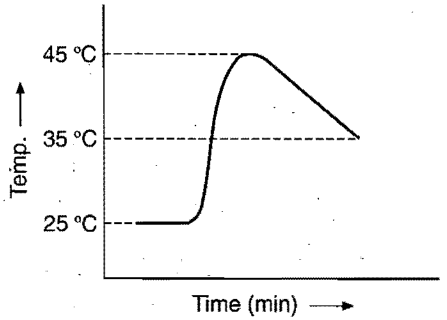
List-I	List-II
A. $C(s) + O_2(g) \longrightarrow CO_2(g)$	1. $\Delta H = \Delta U + RT$
B. $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$	2. $\Delta H = \Delta U$
C. $NH_4HS(s) \longrightarrow NH_3(g) + H_2S(g)$	3. $\Delta H = \Delta U - 2RT$
D. $PCl_5(g) \longrightarrow PCl_3(g) + Cl_2(g)$	4. $\Delta H = \Delta U + 2RT$
E. $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$	5. $\Delta H = \Delta U - RT$

Codes:	A	B	C	D	E
(a)	1	2	3	4	5
(b)	5	2	3	4	1
(c)	1	3	4	2	5
(d)	2	3	4	1	5

2. The heat capacity of a bomb calorimeter is 500 J/K. When 0.1 g of methane was burnt in this calorimeter, the temperature rose by 2°C. The value of ΔU per mole will be:
(a) +1 kJ (b) −1 kJ (c) +160 kJ (d) −160 kJ

3. For which reaction will $\Delta H = \Delta U$? Assume each reaction is carried out in an open container:
(a) $2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$
(b) $H_2(g) + Br_2(g) \longrightarrow 2HBr(g)$
(c) $C(s) + 2H_2O(g) \longrightarrow 2H_2(g) + CO_2(g)$
(d) $PCl_5(g) \longrightarrow PCl_3(g) + Cl_2(g)$

4. What value of ΔT should be used for the calorimetry experiment that gives the following graphical results?



(a) 10°C (b) 25°C (c) 20°C (d) 35°C

5. The enthalpy of fusion of ice is 6.02 kJ mol^{-1}. The heat capacity of water is 4.18 J g^{-1} C^{-1}. What is the smallest number of ice cubes at 0°C, each containing one mole of water, that are needed to cool 500 g of liquid water from 20°C to 0°C?
(a) 1 (b) 7 (c) 14 (d) 125
[**Hint:** Heat released to cool 500 g water from 20°C to 0°C,
$$q = ms\,\Delta T$$
$$= 500 \times 4.18 \times 20 = 41800\ \text{J} = 41.8\ \text{kJ}$$
Number of moles of water (ice) that will melt to absorb 41.8 kJ
$$= \frac{41.8}{6.02} \approx 7$$
∴ Number of cubes of ice that will melt = 7]

6. The enthalpy change (ΔH) for the reaction,
$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$
is −92.38 kJ at 298 K. The internal energy change ΔU at 298 K is: **(AIIMS 2006)**
(a) −92.38 kJ (b) −87.42 kJ (c) −97.34 kJ (d) −89.9 kJ
[**Hint:** $\Delta n_g = 2 - 4 = -2$
$$\Delta H = \Delta U + \Delta n_g RT$$
$$\Delta U = \Delta H - \Delta n_g RT$$
$$= -92.38 \times 1000 - (-2) \times 8.314 \times 298$$
$$= -87424\ \text{J} = -87.424\ \text{kJ}]$$

7. The specific heat of I_2 in vapour and solid state are 0.031 and 0.055 cal/g respectively. The heat of sublimation of iodine at 200°C is 6.096 kcal mol^{-1}. The heat of sublimation of iodine at 250°C will be:
(a) 3.8 kcal mol^{-1} (b) 4.8 kcal mol^{-1}
(c) 2.28 kcal mol^{-1} (d) 5.8 kcal mol^{-1}
[**Hint:** $I_2(s) \rightleftharpoons I_2(g)$
$$\Delta C_P = (0.031 - 0.055) \times 10^{-3} \times 254$$
$$\frac{\Delta H_2 - \Delta H_1}{T_2 - T_1} = \Delta C_P$$
$$\frac{\Delta H_2 - 6.096}{50} = (0.031 - 0.055) \times 10^{-3} \times 254$$
$$\Delta H_2 = 5.79\ \text{kcal mol}^{-1}]$$

• Passage 2

In a chemical reaction, the bonds of reactants are decomposed and new bonds of products are formed. The amount of energy required to break a particular bond in a gaseous molecule under standard conditions homolytically is called the standard bond dissociation enthalpy of that bond (ΔH°_{A-B}).

Bond energies can be used to obtain an approximate value for a reaction enthalpy of a gas phase reaction if the appropriate enthalpies of formation are not available.

$$\Delta H^{\circ}_{\text{reaction}} = \Sigma \textit{ Bond energy of bonds, broken in the reactants}$$
$$- \Sigma \textit{ Bond energy of bonds, formed in the products}$$

Bond energy depends on three factors:

(*a*) *Greater is the bond length, lesser is the bond energy.*
(*b*) *Bond energy increases with the bond multiplicity.*
(*c*) *Bond energy increases with the electronegativity difference between the bonding atoms.*

Answer the following questions:

1. Arrange N—H, O—H and F—H bonds in the decreasing order of bond energy:
(a) F—H > O—H > N—H (b) O—H > N—H > F—H
(c) N—H > O—H > F—H (d) F—H > N—H > O—H

2. X_2 represents halogen molecule. Bond energy of different halogen molecules will lie in following sequences:
(a) $F_2 > Cl_2 > Br_2 > I_2$ (b) $Cl_2 > Br_2 > F_2 > I_2$
(c) $I_2 > Cl_2 > Br_2 > I_2$ (d) $Br_2 > F_2 > I_2 > Cl_2$
[**Hint:** Bond energy of F_2 is surprisingly low due to strong repulsion between the lone pairs of two fluorine atoms.]

3. Which among the following sequences is correct about the bond energy of C—C, C=C and C≡C bonds?
(a) $C\equiv C > C=C > C-C$ (b) $C\equiv C < C=C < C-C$
(c) $C=C > C\equiv C > C-C$ (d) $C\equiv C > C-C > C=C$

4. In CH_4 molecule, which of the following statements is correct about the C—H bond energy?
(a) All C—H bonds of methane have same energy
(b) Average of all C—H bond energies is considered
(c) Fourth C—H bond requires highest energy to break
(d) None of the above

5. Use the bond energies to estimate ΔH for this reaction:

$$H_2(g) + O_2(g) \longrightarrow H_2O_2(g)$$

Bond	Bond energy
H—H	436 kJ mol^{-1}
O—O	142 kJ mol^{-1}
O=O	499 kJ mol^{-1}
H—O	460 kJ mol^{-1}

(a) −127 kJ (b) −209 kJ (c) −484 kJ (d) −841 kJ

6. The heat of formation of NO from its elements is +90 kJ mol^{-1}. What is the approximate bond dissociation energy of the bond in NO?

$$BE_{N\equiv N} = 941 \text{ kJ mol}^{-1} \quad BE_{O=O} = 499 \text{ kJ mol}^{-1}$$

(a) 630 kJ mol^{-1} (b) 720 kJ mol^{-1}
(c) 760 kJ mol^{-1} (d) 810 kJ mol^{-1}

• Passage 3

The change in Gibbs free energy (ΔG) *of the system alone provides a criterion for the spontaneity of a process at constant temperature and pressure. A change in the free energy of a system at constant temperature and pressure will be:*

$$\Delta G_{system} = \Delta H_{system} - T\,\Delta S_{system}$$

At constant temperature and pressure:

$$\Delta G_{system} < 0 \,(\textit{spontaneous})$$
$$\Delta G_{system} = 0 \,(\textit{equilibrium})$$
$$\Delta G_{system} > 0 \,(\textit{non-spontaneous})$$

Free energy is related to the equilibrium constant, as:

$$\Delta G^{\circ} = 2.303RT \log_{10} K_e$$

Answer the following questions:

1. The free energy for a reaction having $\Delta H = 31400$ cal, $\Delta S = 32 \text{ cal K}^{-1} \text{ mol}^{-1}$ at 1000°C is: **[JEE (Orissa) 2005]**
(a) −9336 cal (b) −7386 cal (c) −1936 cal (d) +9336 cal

2. For a spontaneous reaction ΔG, equilibrium 'K' and E°_{cell} will be respectively: **(AIEEE 2005)**
(a) −ve, > 1, +ve (b) +ve, > 1, −ve
(c) −ve, < 1, −ve (d) −ve, > 1, −ve

3. For a system in equilibrium, $\Delta G = 0$, under conditions of constant........: **(KCET 2005)**
(a) temperature and pressure (b) temperature and volume
(c) pressure and volume (d) energy and volume

4. If both ΔH and ΔS are negative, the reaction will be spontaneous:
(a) at high temperature (b) at low temperature
(c) at all temperatures (d) at absolute zero

5. A reaction has positive values of ΔH and ΔS. From this you can deduce that the reaction:
(a) must be spontaneous at any temperature
(b) cannot be spontaneous at any temperature
(c) will be spontaneous only at low temperature
(d) will be spontaneous only at high temperature

6. For a reaction to be spontaneous at all temperatures:
(a) ΔG − ve, ΔH + ve and ΔS + ve
(b) ΔG + ve, ΔH − ve and ΔS + ve
(c) ΔG − ve, ΔH − ve and ΔS − ve
(d) ΔG − ve, ΔH − ve and ΔS + ve

3 *moles of* CO_2 *gas expands isothermally against external pressure of* 1 *bar. Volume increases from* 10 *L to* 30 *L respectively. The system is in thermal contact of surroundings at temperature* 15°C. *Entropy change in isothermal process is:*

$$\Delta S = 2.303\, nR \log\left(\frac{V_2}{V_1}\right)$$

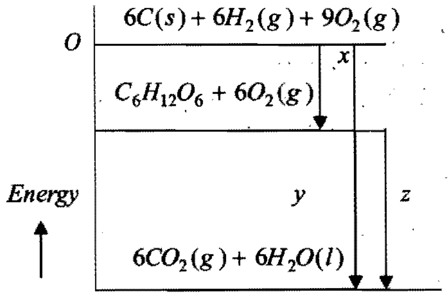
Answer the following questions:

7. If CO_2 behaves like an ideal gas, then entropy change of system (ΔS_{system}) will be:
(a) +27.4 J K^{-1} (b) 9.1 J K^{-1}
(c) −27.4 J K^{-1} (d) −9.1 J K^{-1}

8. Select the correct relation:
(a) $\Delta S_{\text{system}} > 0, \Delta S_{\text{surr.}} = 0$ (b) $\Delta S_{\text{surr.}} < 0, \Delta S_{\text{system}} > 0$
(c) $\Delta S_{\text{system}} = 0, \Delta S_{\text{surr.}} = 0$ (d) $\Delta S_{\text{surr.}} > 0, \Delta S_{\text{system}} < 0$

• Passage 4

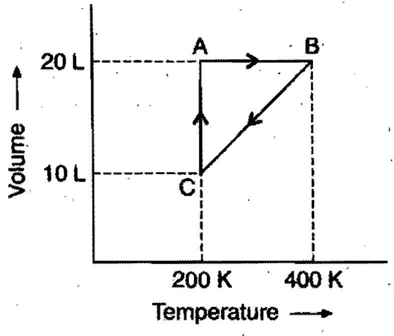
Consider the following energy level diagram:



Answer the following questions on the basis of the given diagram:

1. The heat of formation of glucose is:
   (a) $-x$ (b) $-y$ (c) $x - y$ (d) $-x + z$
2. In the given diagram z refers to:
   (a) $6 \times \Delta H^\circ_{f\,CO_2}$ (b) $\Delta H^\circ_{f\,C_6H_{12}O_6}$
   (c) $\Delta H^\circ_{\text{combustion } C_6H_{12}O_6}$ (d) $\Delta H^\circ_{\text{combustion } C(s)} + \Delta H^\circ_{f\,H_2O(l)}$
3. The quantity y is equal to:
   (a) $\Delta H_{\text{combustion } C(s)} + \Delta H_{\text{combustion } H_2(g)}$
   (b) $x + z$
   (c) $x - z$
   (d) $\Delta H_{f\,CO_2} + \Delta H_{H_2O}$
4. Select the incorrect statement(s):
   (a) combustion of glucose is exothermic process
   (b) standard state of glucose is $C_6H_{12}O_6(s)$
   (c) heat of formation of glucose = Heat of combustion of glucose
   (d) $x + y = z$

• Passage 5



Graph for one mole gas

Answer the following questions based on the above diagram:

1. Process, $A \longrightarrow B$ represents:
   (a) isobaric (b) isochoric (c) isothermal (d) adiabatic
2. The pressure at C is:
   (a) 3.284 atm (b) 1.642 atm (c) 0.0821 atm (d) 0.821 atm
3. Work done in the process $C \longrightarrow A$ is:
   (a) zero (b) 8.21 L atm
   (c) 16.2 L atm (d) unpredictable
4. The process which occurs in going from, $B \longrightarrow C$ is:
   (a) isothermal (b) adiabatic (c) isobaric (d) isochoric
5. The pressures at A and B in the atmosphere are respectively:
   (a) 0.821 and 1.642 (b) 1.642 and 0.821
   (c) 1 and 2 (d) 0.082 and 0.164

• Passage 6

The thermodynamic property that measures the extent of molecular disorder is called entropy. The direction of a spontaneous process for which the energy is constant is always the one that increases the molecular disorder. Entropy change of phase transformation can be calculated using Trouton's formula $\left(\Delta S = \dfrac{\Delta H}{T}\right)$. *In the reversible adiabatic process, however, ΔS will be zero. The rise in temperature in isobaric and isochoric conditions is found to increase the randomness or entropy of the system.*

$$\Delta S = 2.303C\ log\ (T_1 / T_2)$$
$$C = C_P\ or\ C_V$$

Answer the following questions:

1. The entropy change in an adiabatic process is:
   (a) zero
   (b) always positive
   (c) always negative
   (d) sometimes positive and sometimes negative
2. If, water in an insulated vessel at $-10°C$, suddenly freezes, the entropy change of the system will be:
   (a) $+10\ J\ K^{-1}\ mol^{-1}$
   (b) $-10\ J\ K^{-1}\ mol^{-1}$
   (c) zero
   (d) equal to that of surroundings
3. The melting point of a solid is 300 K and its latent heat of fusion is 600 cal mol^{-1}. The entropy change for the fusion of 1 mole of the solid (in cal K^{-1}) at the same temperature would be:
   (a) 200 (b) 2 (c) 0.2 (d) 20
4. For which of the following cases $\Delta S = \dfrac{\Delta H}{T}$?
   (a) A process for which $\Delta C_P = 0$ but $\Delta C_V = 0$
   (b) An adiabatic process
   (c) An isobaric or isothermal process
   (d) An isothermal reversible phase transition process
5. When 1 mol of an ideal gas is compressed to half of its volume, its temperature becomes double; then the change in entropy (ΔS) would be:
   (a) $C_V\ \ln 2$ (b) $C_P\ \ln 2$
   (c) $C_V\ R\ \ln 2$ (d) $(C_V - R)\ln 2 \times C_P$

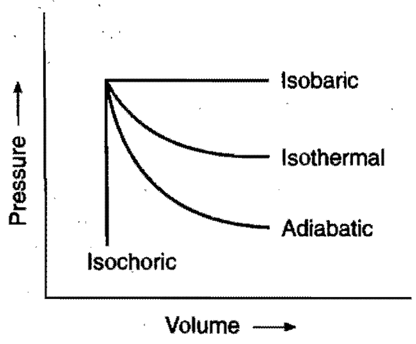
   [Hint: $\Delta S = 2.303 C_P \log_{10}\left(\dfrac{V_1}{V_2}\right)$

   $= C_P \ln\left(\dfrac{V_1}{V_2}\right) = C_P \ln_e\left(\dfrac{1}{1/2}\right)$

   $= C_P \ln_e 2$]

• Passage 7

The pressure-volume behaviour of various thermodynamic processes is shown in graphs:



Work is the mode of transference of energy. If the system involves gaseous substance and there is difference of pressure between system and surroundings, such a work is referred to as pressure-volume work ($w_{PV} = -P_{ext}\,\Delta V$)*. It has been observed that reversible work done by the system is the maximum obtainable work.*

$$w_{rev} > w_{irr}$$

The works of isothermal and adiabatic processes are different from each other.

$$w_{isothermal\ reversible} = 2.303nRT\log_{10}\left(\frac{V_2}{V_1}\right) = 2.303nRT\log_{10}\left(\frac{P_1}{P_2}\right)$$

$$w_{adiabatic\ reversible} = C_V(T_1 - T_2)$$

Answer the following questions:

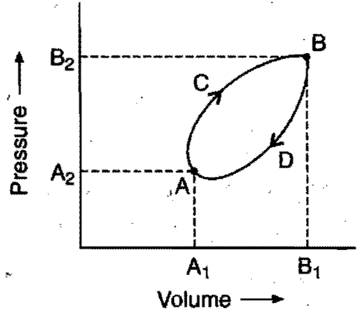
1. If w_1, w_2, w_3 and w_4 are work done in isothermal, adiabatic, isobaric and isochoric reversible processes, then the correct sequence (for expansion) would be:

   (a) $w_1 > w_2 > w_3 > w_4$ (b) $w_3 > w_2 > w_1 > w_4$

   (c) $w_3 > w_2 > w_4 > w_1$ (d) $w_3 > w_1 > w_2 > w_4$

   [**Hint:** w = Work done = Area under curve.]

2. A thermodynamic system goes in acyclic process as represented in the following P-V diagram:



The net work done during the com[illegible] cycle is given by the area:

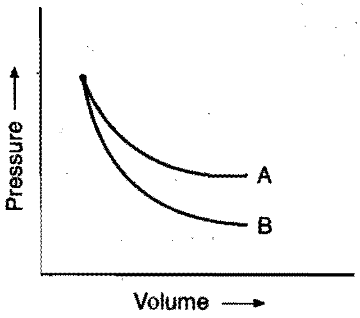
(a) cycle $ACBDA$

(b) AA_1B_1BDA

(c) AA_2B_2B

(d) half of area bounded by curve

3. $P-V$ plots for two gases during adiabatic processes are given in the given figure:



Plot A and plot B should correspond to:

(a) He and O_2 (b) He and Ar (c) O_2 and He (d) O_2 and F_2

[**Hint:** Slope of the adiabatic curve $\propto \gamma$

Slope of B > Slope of A

He ($\gamma = 1.66$); O_2 ($\gamma = 1.44$)

Thus, correct answer will be (c).]

4. The q value and work done in isothermal reversible expansion of one mole of an ideal gas from initial pressure of 1 bar to final pressure of 0.1 bar at constant temperature 273 K are:

   (a) 5.22 kJ, –5.22 kJ (b) –5.22 kJ, 5.22 kJ

   (c) 5.22 kJ, 5.22 kJ (d) –5.22 kJ, –5.22 kJ

   [**Hint:** $w = -2.303nRT\log\left(\frac{P_1}{P_2}\right)$

   $= -2.303 \times 1 \times 8.314 \times 273\log\left(\frac{1}{0.1}\right)$

   $= -5.227$ kJ

   $q = -w = +5.227$ kJ for isothermal process]

5. Calculate work done when 1 mole of an ideal gas is expanded reversibly from 20 L to 40 L at a constant temperature of 300 K.

   (a) 7.78 kJ (b) –1.73 kJ (c) 11.73 kJ (d) – 4.78 kJ

SELF ASSESSMENT

ASSIGNMENT NO. 7

SECTION-I

Straight Objective Type Questions

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. Reaction of silica with mineral acids may be given as:

$SiO_2 + 4HF \longrightarrow SiF_4 + 2H_2O; \quad \Delta H = -10.17$ kcal

$SiO_2 + 4HCl \longrightarrow SiCl_4 + 2H_2O; \quad \Delta H = +36.7$ kcal

which among the following is correct?

(a) HF and HCl both will react with silica

(b) Only HF will react with silica

(c) Only HCl will react with silica

(d) Neither HF nor HCl will react with silica

[**Hint:** Exothermic reactions are spontaneous]

2. In Mayer's relation,

$$C_P - C_V = R$$

'R' stands for:

(a) translational kinetic energy of 1 mol gas

(b) rotational kinetic energy of 1 mol gas

(c) vibrational kinetic energy of 1 mol gas

(d) work done to increase the temperature of 1 mol gas by one degree

[**Hint:** $PV = RT$ (For 1 mol gas) ...(i)

$P(V + \Delta V) = R(T + 1)$ ...(ii)

From eqs. (i) and (ii)

$P\Delta V = R$

i.e., $W = R$ (work done)]

3. For an ideal gas, the Joule-Thomson coefficient is:

(a) zero (b) positive

(c) negative (d) depends on atomicity of gas

4. Entropy change in reversible adiabatic process is:

(a) infinite (b) zero

(c) equal to $C_V \Delta T$ (d) equal to $nR \ln \left(\frac{V_2}{V_1}\right)$

5. For a process to be in equilibrium, it is necessary that:

(a) $\Delta S_{\text{system}} = \Delta S_{\text{surr.}}$ (b) $\Delta S_{\text{system}} = -\Delta S_{\text{surr.}}$

(c) $\Delta S_{\text{system}} = 0$ (d) $\Delta S_{\text{surr.}} = 0$

6. Predict the sign of ΔS for each of the following processes, which occur at constant temperature:

I. The volume of 2 mol of $O_2(g)$ increases from 44L to 54L

II. The pressure of 2 mol of $O_2(g)$ increases from 1 atm to 1.2 atm.

	I	II
(a)	$\Delta S = -$ ve	$\Delta S = -$ ve
(b)	$\Delta S = -$ ve	$\Delta S = +$ ve
(c)	$\Delta S = +$ ve	$\Delta S = -$ ve
(d)	$\Delta S = +$ ve	$\Delta S = +$ ve

7. Which of the following statements must be true for the entropy of a pure solid to be zero?

I. The temperature must be zero kelvin

II. The solid must be perfectly crystalline

III. The solid must be an element

IV. The solid must be ionic

(a) I (b) I and II

(c) I, II and III (d) All are correct

8. Which of the following statements is correct?

(a) Slope of adiabatic $P-V$ curve is smaller than that in isothermal one

(b) Slope of adiabatic $P-V$ curve will be same as that in isothermal one

(c) Slope of adiabatic $P-V$ curve will be larger than in isothermal one

(d) Slope of adiabatic $P-V$ curve will be zero

9. $\left(\frac{\partial H}{\partial P}\right)_T$ for an ideal gas is equal to:

(a) zero (b) $\frac{\Delta VRT}{P}$ (c) $\frac{P\Delta V}{T}$ (d) $nR\Delta T$

10. A refrigerator is used to remove heat from enclosure at 0° C at the rate of 600 watt. If the surroundings temperature is 30° C, calculate the power needed:
(a) 303 watt (b) 11000 watt
(c) 65.9 watt (d) 110 watt

SECTION-II

Multiple Answers Type Objective Questions

11. ΔU will be zero for which processes?
(a) Cyclic process (b) Isothermal expansion
(c) Isochoric process (d) Adiabatic process

12. If x and y are two intensive variables then:
(a) xy is an intensive variable
(b) $\frac{x}{y}$ is an intensive variable
(c) $(x + y)$ is an intensive variable
(d) $\frac{dx}{dy}$ is an extensive property

13. Which of the following expressions is/are correct for an adiabatic process?
(a) $\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{\gamma - 1}$ (b) $\frac{P_2}{P_1} = \left(\frac{T_1}{T_2}\right)^{\gamma - 1/\gamma}$
(c) $P_2V_2^{\gamma} = P_1V_1^{\gamma}$ (d) $P_1V_1^{\gamma - 1} = P_2V_2^{\gamma - 1}$

14. Select the state functions among the following:
(a) temperature (b) entropy
(c) work (d) enthalpy

15. Select the correct expressions among the following:
(a) $\frac{\Delta G - \Delta H}{T} = \left(\frac{\partial \Delta G}{\partial T}\right)_P$ (b) $\frac{\Delta G - \Delta H}{T} = \left[\frac{\partial(\Delta G)}{\partial T}\right]_V$
(c) $\frac{\Delta S}{nF} = \left(\frac{\partial E_{\text{cell}}}{\partial T}\right)_P$ (d) $\left(\frac{\partial T}{\partial P}\right)_H = -\left(\frac{\partial H}{\partial P}\right)_{T/C_P}$

16. Which of the following are correct for an ideal gas?
(a) $\left(\frac{\partial U}{\partial V}\right)_T = 0$ (b) $\left(\frac{\partial H}{\partial P}\right)_T = 0$
(c) $\left(\frac{\partial T}{\partial P}\right)_H = 0$ (d) $\left(\frac{\partial P}{\partial T}\right)_V = 0$

17. The Clausius-Clapeyron equation may be given as:
(a) $\log_{10}\left(\frac{P_2}{P_1}\right) = \frac{\Delta H_{\text{vap}}}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$
(b) $\frac{dP}{dT} = \frac{\Delta S}{\Delta V}$
(c) $\frac{dP}{dT} = \frac{q}{T\Delta V}$
(d) $\frac{dP}{dT} = \frac{\Delta V}{\Delta S}$

18. Which of the following is/are not state function?
(a) q (b) $q - w$
(c) $\frac{q}{w}$ (d) $q + w$

SECTION-III

Assertion-Reason Type Questions

This section contains 5 questions. Each question contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; statement-2 is true; statement-2 is a correct explanation for statement-1.
(b) Statement-1 is true; statement-2 is true; statement-2 is not a correct explanation for statement-1.
(c) Statement-1 is true; statement-2 is false.
(d) Statement-1 is false; statement-2 is true.

19. **Statement-1:** Most of the combustion reactions are exothermic.

Because

Statement-2: Products are more stable than reactants in exothermic process.

20. **Statement-1:** There is no exchange in internal energy in a cyclic process.

Because

Statement-2: In a cyclic process, the system returns to original state in a number of steps.

21. **Statement-1:** The value of enthalpy of neutralization of weak acid and strong base is always numerically less than 57.1 kJ.

Because

Statement-2: All the OH^- ions furnished by 1 gram equivalent of strong base are not completely neutralized.

22. **Statement-1:** Heat of solution is positive when $Na_2SO_4 \cdot 10H_2O$ is dissolved in water but it is negative when anhydrous $CuSO_4$ is dissolved in water.

Because

Statement-2: Molar masses of $Na_2SO_4.10H_2O$ and $CuSO_4$ are different.

23. **Statement-1:** The extensive property of a single pure substance depends upon the number of moles of the substance present.

Because

Statement-2: Any extensive property expressed per mole becomes intensive.

SECTION-IV

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

If the correct matches are (a-p,s); (b-q,r); (c-p,q) and (d-s); then correct bubbled 4 × 4 matrix should be as follows:

	p	q	r	s
a	●	○ q	○ r	●
b	○ p	●	●	○ s
c	●	●	○ r	○ s
d	○ p	○ q	○ r	●

24. Match the List-I with List-II:

List-I	List-II
(a) $\left(\frac{\partial T}{\partial P}\right)_H$	(p) V
(b) $\left(\frac{\partial G}{\partial P}\right)_T$	(q) T
(c) $\left(\frac{\partial H}{\partial S}\right)_P$	(r) $-S$
(d) $\left(\frac{\partial G}{\partial T}\right)_P$	(s) μ_{jT}

25. Match the List-I with List-II and select the correct answer from the given codes:

List-I (Thermodynamic properties)	List-II (Expression)
(I) ΔG	(A) $-RT \log_e K$
(II) $\Delta H°$	(B) $RT^2\left(\frac{d \ln K}{dT}\right)_P$
(III) ΔS	(C) nFE
(IV) $\Delta G°$	(D) $-\left[\frac{\partial \Delta G}{\partial T}\right]_P$

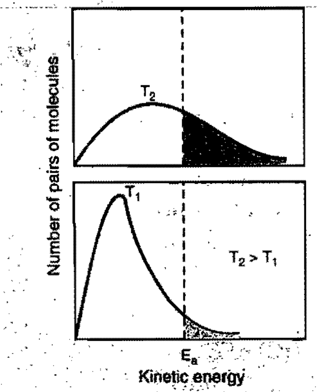
Codes:
(a) I-C, II-B, III-D, IV-A
(b) I-B, II-C, III-D, IV-A
(c) I-A, II-B, III-C, IV-D
(d) I-D, II-A, III-B, IV-C

26. Match the List-I with List-II:

List-I	List-II
(a) Perfectly crystalline solid	(p) $\Delta U = 0$
(b) Reversible reaction at equilibrium	(q) T = constant
(c) Isothermal process	(r) $\lim\limits_{T \to 0K} S \to 0$
(d) $\left(\frac{\partial G}{\partial P}\right) = -S$	(s) $\Delta S_{\text{universe}} = 0$

Answers

1. (b) 2. (d) 3. (a) 4. (b) 5. (b) 6. (c) 7. (b) 8. (c)
9. (a) 10. (c) 11. (a, b) 12. (a, b, d) 13. (a, c) 14. (a, b, d) 15. (a, c, d) 16. (a, b, c)
17. (a, b, c) 18. (a, b, c) 19. (a) 20. (a) 21. (c) 22. (c) 23. (b)
24. (a-s) (b-p) (c-q) (d-r) 25. (a) 26. (a-r) (b-s) (c-p, q) (d-q)



CHAPTER 8

CHEMICAL KINETICS

8.1 INTRODUCTION

Thermodynamics deals with the feasibility of a chemical change. The free energy change, ΔG, of a reaction helps us to understand whether the reaction will occur or not. Even though there may be decrease in free energy but reactants do not always form the products instantaneously and actual rate of the reaction may vary from extremely slow to very fast. Thermodynamics is concerned only with initial and final states of reacting systems but offers no explanation about the various stages through which the reactants pass to reach the final state. This leads to following questions concerning chemical changes.

(i) How fast do the chemical reactions go?

(ii) How can the speed of the reaction change?

(iii) What intermediate steps, the reactants follow to reach the final state of products, *i.e.*, the mechanism of the reaction.

The branch of physical chemistry which deals with the rate at which the chemical reactions occur, the mechanism by which the chemical reactions take place and the influence of various factors such as concentration, temperature, pressure, catalyst, etc., on the reaction rates, is called the **chemical kinetics.**

Different chemical reactions occur at different rates. On the basis of rates, the chemical reactions are broadly divided into three categories:

(a) Very fast or instantaneous reactions: These reactions are so fast that they occur as soon as the reactants are brought together. Generally, these reactions involve ionic species and thus known as ionic reactions. These reactions take about 10^{-14} to 10^{-16} seconds for completion. It is almost impossible to determine the rates of these reactions. Some such examples are:

(i) Precipitation of AgCl when solutions of silver nitrate and sodium chloride are mixed.

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$$

(ii) Precipitation of $BaSO_4$ when solutions of barium chloride and sulphuric acid are mixed.

$$BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl$$

(iii) Neutralisation of an acid with a base when their aqueous solutions are mixed.

$$\underset{\text{Acid}}{HCl} + \underset{\text{Base}}{NaOH} \longrightarrow \underset{\text{Salt}}{NaCl} + H_2O$$

(b) Very slow reactions: There are certain reactions which are extremely slow. They may take months together to show any measurable change at room temperature. It is also difficult to study the kinetics of such reactions.

Some examples are:

(i) Reaction between hydrogen and oxygen at room temperature.

$$2H_2 + O_2 \xrightarrow{\text{Room temperature}} 2H_2O \text{ (Very slow reaction)}$$

(ii) Reaction of atmospheric H_2S on basic lead acetate.

White basic lead acetate paint $\xrightarrow[H_2S]{\text{Atmospheric}}$ Blackening of paint occurs very slowly (due to formation of PbS.)

(iii) Reaction between carbon and oxygen.

$$C + O_2 \xrightarrow{\text{Room temperature}} CO_2$$

Carbon and oxygen are thermodynamically less stable than CO_2 at 298 K, yet coke does not spontaneously catch fire in air and remains unreacted even for years.

(iv) Reaction between carbon monoxide and hydrogen.

$$CO + 2H_2 \xrightarrow{\text{Room temperature}} CH_3OH$$

The reaction is thermodynamically feasible at 298 K but in actual practice the reaction proceeds infinitesimally slowly.

(v) Rusting of iron occurs very slowly.

(c) Moderate reactions: Between the above two extremes, there are a number of reactions which take place at moderate and measurable rates at room temperature and it is these reactions which are studied in chemical kinetics. Mostly these reactions are molecular in nature. Some common examples of such type are given below:

(i) Decomposition of hydrogen peroxide.

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$

(ii) Decomposition of nitrogen pentoxide.

$$2N_2O_5 \longrightarrow 2N_2O_4 + O_2$$

(iii) Hydrolysis of an ester.

$$\underset{\text{Ester}}{CH_3COOC_2H_5} + NaOH \longrightarrow \underset{\text{Sodium acetate}}{CH_3COONa} + C_2H_5OH$$

(iv) Inversion of cane sugar in aqueous solution.

$$\underset{\text{Cane sugar}}{C_{12}H_{22}O_{11}} + H_2O \longrightarrow \underset{\text{Glucose}}{C_6H_{12}O_6} + \underset{\text{Fructose}}{C_6H_{12}O_6}$$

(v) Reaction between nitrogen dioxide and carbon monoxide.

$$NO_2 + CO \longrightarrow NO + CO_2$$

(vi) Reaction between ferric chloride and stannous chloride.

$$2FeCl_3(aq.) + SnCl_2(aq.) \longrightarrow 2FeCl_2(aq.) + SnCl_4(aq.)$$

(vii) Decolourisation of acidified potassium permanganate with sodium oxalate.

(viii) Reaction between nitric oxide and chlorine.

$$NO + Cl_2 \longrightarrow NOCl_2$$

The chemical reactions can be slowed down or speeded up by changing conditions under which they occur. For example, very slow reaction, $CO + 2H_2 \longrightarrow CH_3OH$, can be speeded up by maintaining temperature around 400°C, pressure about 300 atmospheres and using a catalyst containing ZnO and Cr_2O_3. The decay of food articles can be slowed down by preserving them in refrigerators. There are two principal reasons for studying chemical kinetics.

(i) To predict the rate of a particular reaction under specified conditions: The conditions can be adjusted to make the reaction to go at a desired rate, either rapidly or slowly or moderately. The field of chemical kinetics is useful in industry as the conditions for maximum yields of industrial products can be ascertained.

(ii) To predict the mechanism of the reaction: The intelligent guess regarding various elementary processes responsible for the formation of products can be made which should be consistent with experimental data.

8.2 RATE OF REACTION (Average and Instantaneous Rate)

We are all familiar with processes in which something changes with time. Rate is usually expressed as the ratio of the amount of change in some quantity to the time required to produce that change.

$$\text{Rate} = \frac{\text{Change in some quantity}}{\text{Time taken for the change}} = \frac{\Delta X}{\Delta t}$$

The term ΔX means $X_{\text{final}} - X_{\text{initial}}$ and Δt is the amount of time elapsed. For example, a car driver starts his journey at 9.0 a.m. with odometer reading x miles. At 11.0 a.m. he reaches his destination. The odometer reading at destination is y miles. The rate of his travel can be calculated as:

$$\text{Rate} = \frac{\Delta(\text{distance})}{\Delta(\text{time})} = \frac{\text{distance}_{(f)} - \text{distance}_{(in)}}{\text{time}_{(f)} - \text{time}_{(in)}}$$

$$= \frac{y-x}{11.0-9.0} = \frac{y-x}{2}\ \text{miles hr}^{-1}$$

The above example indicates that the car has been driven with uniform rate but actually it has been driven sometimes faster and sometimes slower depending upon the conditions of the road. Thus, the overall rate is an average rate and the rate at which the car was moving at any instant, *i.e.*, instantaneous rate was changeable.

The rate measured over a long time interval is called average rate and the rate measured for an infinitesimally small time interval is called instantaneous rate.

In a chemical change, reactants and products are involved. As the chemical reaction proceeds, the concentration of the reactants decreases, *i.e.*, reactants are consumed and the concentration of products increases, *i.e.*, products are produced. **The rate of reaction (average rate) is defined as the change of concentration of any one of its reactants (or products) per unit time.**

Average rate of reaction,

$$r_{\text{av}} = \frac{\text{Change of concentration of one of the reactants or products}}{\text{Time taken for the change}}$$

Consider a common hypothetical reaction,

$$A \to B$$

The average rate of reaction may be expressed either in terms of decrease in concentration of A (reactants) or in terms of increase in concentration of B (product).

$$\text{Average rate of reaction} = \frac{\text{Decrease in concentration of } A}{\text{Time taken}}$$

$$\text{or Average rate of reaction} = \frac{\text{Increase in concentration of } B}{\text{Time taken}}$$

The concentrations of reactants or products are expressed as number of moles per litre. The symbol for the molar concentration consists of the formula of the substance enclosed in bracket. The symbol $[A]$ stands for the molar concentration of A. The symbol $\Delta[A]$, therefore, stands for the change in molar concentration of A.

The rate of decrease or increase in the concentration of reactants or products may also be expressed in terms of change in their concentration during the time interval, Δt, as:

$$\text{Average rate of reaction} = -\frac{\Delta[A]}{\Delta t}$$

$$\text{or} \quad \text{Average rate of reaction} = +\frac{\Delta[B]}{\Delta t}$$

(A negative sign placed before a reaction rate symbol signifies a decrease in concentration of the reactant with increase of time and a positive sign before the rate symbol signifies that the concentration of the product increases with increase in time. The

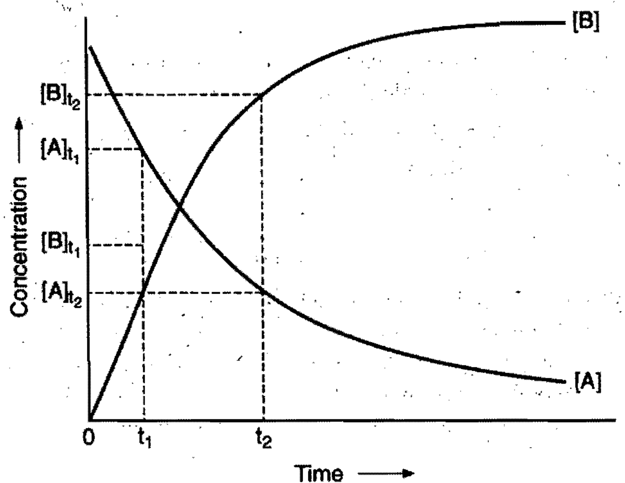


Fig. 8.1

concentration change may be positive or negative but the rate of reaction is always positive. The minus sign is always written when required but the plus sign is usually not mentioned.)

Figure 8.1 shows the change of concentrations of reactant (A) and product (B) as the chemical reaction $A \rightarrow B$ progresses with time. Let $[A]_{t_1}$ and $[A]_{t_2}$ be the concentrations of A at time t_1 and t_2, respectively.

$$\Delta[A] = [A]_{t_2} - [A]_{t_1}$$

and

$$\Delta t = t_2 - t_1$$

$$r_{\text{av}} = -\frac{\Delta[A]}{\Delta t} = -\frac{[A]_{t_2} - [A]_{t_1}}{t_2 - t_1}$$

Over the same time interval t_1 to t_2, the concentration of B changes from $[B]_{t_1}$ to $[B]_{t_2}$.

$$r'_{\text{av}} = \frac{\Delta[B]}{\Delta t} = \frac{[B]_{t_2} - [B]_{t_1}}{t_2 - t_1}$$

Since, one mole of A produces one mole of B, the rate of decrease in concentration of A should be equal to the rate of increase in concentration of B. Thus,

$$r_{\text{av}} = r'_{\text{av}}$$

$$-\frac{\Delta[A]}{\Delta t} = \frac{\Delta[B]}{\Delta t}$$

Reaction rate has the units of concentration or molarity divided by time. Therefore, the units of rate of reaction may be expressed as:

mole/litre sec (mol L^{-1} s^{-1})

or mole/litre min (mol L^{-1} min^{-1})

or mole/litre hour (mol L^{-1} h^{-1})

or mole/litre day (mol L^{-1} d^{-1})

or mole/litre year (mol L^{-1} y^{-1})

SOME SOLVED EXAMPLES

Example 1. *In a reaction, the concentration of a reactant* (A) *changes from* 0.200 *mol litre*$^{-1}$ *to* 0.150 *mol litre*$^{-1}$ *in* 10 *minutes. What is the average rate of reaction during this interval?*

Solution: $\Delta[A] = [A]_{\text{final}} - [A]_{\text{initial}}$

$$= [0.150 - 0.200] = -0.050 \text{ mol litre}^{-1}$$

$$\Delta t = 10 \text{ minutes}$$

$$\text{Average rate of reaction} = \frac{-\Delta[A]}{\Delta t} = \frac{-[-0.050]}{10}$$

$$= \frac{0.050}{10} = 0.005 \text{ mol litre}^{-1} \text{ min}^{-1}$$

Expression of Rate

Consider the following reaction between CO and NO_2:

$$CO + NO_2 \longrightarrow CO_2 + NO$$

The equation shows that when one mole of CO reacts with one mole of NO_2, one mole each of CO_2 and NO are formed. The average rate of reaction can be expressed either by decrease of concentration of any one of the reactants (CO or NO_2) or by the increase in concentration of any one of the products (CO_2 or NO):

Thus, $-\frac{\Delta[CO]}{\Delta t} = -\frac{\Delta[NO_2]}{\Delta t} = \frac{\Delta[CO_2]}{\Delta t} = \frac{\Delta[NO]}{\Delta t}$

However, for the reaction,

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$

it is observed that when 2 moles of H_2O_2 decompose, one mole of O_2 is formed in the same time interval. The rate of increase in the concentration of O_2, therefore, is half that of the disappearance of the concentration of H_2O_2 in the same time interval;

So, $\frac{\Delta[O_2]}{\Delta t} = -\frac{1}{2}\frac{\Delta[H_2O_2]}{\Delta t}$

In general, for a reaction,

$$n_1A + n_2B \longrightarrow m_1C + m_2D$$

the rate expression may be expressed as:

$$-\frac{1}{n_1}\frac{\Delta[A]}{\Delta t} = -\frac{1}{n_2}\frac{\Delta[B]}{\Delta t} = \frac{1}{m_1}\frac{\Delta[C]}{\Delta t} = \frac{1}{m_2}\frac{\Delta[D]}{\Delta t}$$

Thus, for the reaction,

$$H_2 + I_2 \rightleftharpoons 2HI$$

the rate may be expressed as:

$$-\frac{\Delta[H_2]}{\Delta t} = -\frac{\Delta[I_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[HI]}{\Delta t}$$

Note : In case of gaseous reaction, pressure may be taken in place of concentration. Thus, rate will have the unit of atm sec^{-1} or atm min^{-1}.

$$PV = nRT \quad \text{or} \quad P = \left[\frac{n}{V}\right]RT \quad \text{or} \quad P = CRT$$

$$\frac{\Delta[P]}{\Delta t} = \frac{\Delta[C]}{\Delta t} \cdot RT \quad \text{or} \quad \text{Rate in [atm/sec]} = \text{Rate in [molarity/sec]} \times RT$$

Similarly, for the decomposition of N_2O_5 in CCl_4 medium, the rate may be expressed as:

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

$$-\frac{1}{2}\frac{\Delta[N_2O_5]}{\Delta t} = \frac{1}{4}\frac{\Delta[NO_2]}{\Delta t} = \frac{\Delta[O_2]}{\Delta t}$$

Example 2. *Decomposition of N_2O_5 is expressed by the equation,*

$$N_2O_5 \longrightarrow 2NO_2 + \tfrac{1}{2}O_2$$

If during a certain time interval, the rate of decomposition of N_2O_5 is 1.8×10^{-3} mol litre^{-1} min^{-1}, what will be the rates of formation of NO_2 and O_2 during the same interval?

Solution: The rate expression for the decomposition of N_2O_5 is:

$$-\frac{\Delta[N_2O_5]}{\Delta t} = \frac{1}{2}\frac{\Delta[NO_2]}{\Delta t} = 2\cdot\frac{\Delta[O_2]}{\Delta t}$$

So, $$\frac{\Delta[NO_2]}{\Delta t} = 2\frac{\Delta[N_2O_5]}{\Delta t} = 2 \times 1.8 \times 10^{-3}$$

$$= 3.6 \times 10^{-3} \text{ mol litre}^{-1} \text{ min}^{-1}$$

and $$\frac{\Delta[O_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[N_2O_5]}{\Delta t} = \frac{1}{2} \times 1.8 \times 10^{-3}$$

$$= 0.9 \times 10^{-3} \text{ mol litre}^{-1} \text{ min}^{-1}$$

(Rate is always positive and hence $-\frac{\Delta[N_2O_5]}{\Delta t}$ is taken positive.)

Instantaneous Rate

In chemical kinetics, the rate at any particular instant, *i.e.*, instantaneous rate rather than the average rate over a time interval has much more practical application and importance. It is defined as **the rate of change of concentration of any one of the reactants or products over a very small interval of time.**

If we take infinitesimal small interval of time dt, it may be assumed that the rate is uniform through this interval; then if dx is amount of substance A transformed to B during this interval, the rate of reaction at that instant is given as $-\frac{dx}{dt}$.

[In differential calculus, when Δt becomes very small and approaches zero, the ratio $\frac{\Delta[A]}{\Delta t}$ may be replaced by the derivative, $\frac{d[A]}{dt}$, *i.e.*,

$$r_{\text{inst}} = \lim_{\Delta t \to 0} -\frac{\Delta[A]}{\Delta t} = -\frac{d[A]}{dt}\Bigg]$$

On the other hand, if the rate of reaction is expressed in terms of the concentration of any of the products which goes on increasing, then rate of reaction at particular instant $= \frac{dx}{dt}$:

In general, for a reaction,

$$n_1A + n_2B \longrightarrow m_1C + m_2D$$

The instantaneous rate may be expressed as:

$$r_{\text{inst}} = -\frac{1}{n_1}\frac{d[A]}{dt} = -\frac{1}{n_2}\frac{d[B]}{dt} = \frac{1}{m_1}\frac{d[C]}{dt} = \frac{1}{m_2}\frac{d[D]}{dt}$$

Experimental Determination of Instantaneous Rate of Reaction

In order to determine changes in concentration of reactants or products, it is customary to take small portions of the reaction mixture at suitable intervals of time and freeze them rapidly to about 0°C as to stop the reaction. The concentration is then measured with the help of a suitable method. In several cases, concentration changes are measured by observing changes in certain physical properties which are proportional to it such as optical densities, electrical conductivity, optical rotation, etc. A curve is plotted between concentration and time. A tangent is drawn to the curve at the point corresponding to time interval 't'. The slope of this tangent gives the instantaneous rate of reaction. This is shown in Fig. 8.2 (a).

Instantaneous rate of reaction = Slope of curve

$$= \frac{\text{Intercept along ordinate}}{\text{Intercept along abscissa}} = \frac{\Delta x}{\Delta t}$$

Since, the concentrations of the reactants keep on decreasing with time, the rate of reaction correspondingly decreases with time. Thus, the rate of reaction will depend on the stage considered during progress of the reaction. The rate of reaction is maximum at the initial stage and decreases with time. Theoretically, infinite time would be required for a reaction to complete. But the reaction rate becomes so slow after a certain time that for all practical purposes, the reaction can be considered to be completed. It is evident from Fig. 8.2 (b) that the rate of reaction is varying from moment to moment.

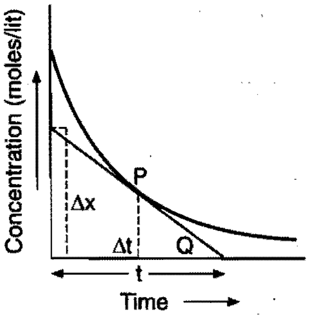

Fig. 8.2(a) Determination of rate of reaction

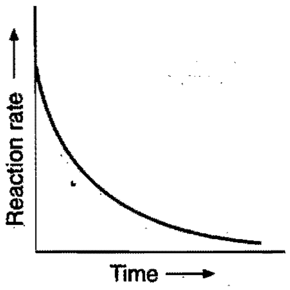

Fig. 8.2(b) Variation of rate

Reaction Life Time

It is defined as the time taken by a reaction to proceed to 98% of completion. The shorter the life time, the faster the reaction. Reaction life times are used to compare the various reactions. Reactions are also compared with half life periods. The half life period is defined as the time during which the concentration of a reactant is reduced to one-half of its initial value or the time in which half of the reaction is completed. It is generally denoted by $t_{1/2}$. The shorter the half life period, the faster is the reaction.

Example 3. *For each of the following reactions express the given rate of change of concentration of the reactant or product in terms of the rate of change of concentration of other reactants or products in that reaction :*

(a) $H_2O_2 + 2H^+ + 3I^- \longrightarrow I_3^- + 2H_2O$; $-\frac{d[I^-]}{dt} = ?$; $-\frac{d[H^+]}{dt} = ?$

(b) $16H^+ + 2MnO_4^- + 10I^- \longrightarrow 2Mn^{2+} + 8H_2O + 5I_2$; $-\frac{d[MnO_4^-]}{dt} = ?$

(c) $4NH_3 + 5O_2 \longrightarrow 4NO_2 + 6H_2O$; $-\frac{d[NH_3]}{dt} = ?$

Solution: We have,

(a) $H_2O_2 + 2H^+ + 3I^- \longrightarrow I_3^- + 2H_2O$

The equality in this case is:

$$-\frac{d[H_2O_2]}{dt} = -\frac{1}{2}\frac{d[H^+]}{dt} = -\frac{1}{3}\frac{d[I^-]}{dt} = \frac{d[I_3^-]}{dt} = \frac{1}{2}\frac{d[H_2O]}{dt}$$

$$\text{So,} -\frac{d[I^-]}{dt} = -3\frac{d[H_2O_2]}{dt} = -\frac{3}{2}\frac{d[H^+]}{dt} = 3\frac{d[I_3^-]}{dt} = \frac{3}{2}\frac{d[H_2O]}{dt}$$

$$\text{and} -\frac{d[H^+]}{dt} = -2\frac{d[H_2O_2]}{dt} = -\frac{2}{3}\frac{d[I^-]}{dt} = 2\frac{d[I_3^-]}{dt} = \frac{d[H_2O]}{dt}$$

(b) $16H^+ + 2MnO_4^- + 10I^- \rightarrow 2Mn^{2+} + 8H_2O + 5I_2$

The equality in this case is:

$$-\frac{1}{16}\frac{d[H^+]}{dt} = -\frac{1}{2}\frac{d[MnO_4^-]}{dt} = -\frac{1}{10}\frac{d[I^-]}{dt}$$
$$= \frac{1}{2}\frac{d[Mn^{2+}]}{dt} = \frac{1}{8}\frac{d[H_2O]}{dt} = \frac{1}{5}\frac{d[I_2]}{dt}$$

$$\text{So,} -\frac{d[MnO_4^-]}{dt} = -\frac{1}{8}\frac{d[H^+]}{dt} = -\frac{1}{5}\frac{d[I^-]}{dt}$$
$$= \frac{d[Mn^{2+}]}{dt} = \frac{1}{4}\frac{d[H_2O]}{dt} = \frac{2}{5}\frac{d[I_2]}{dt}$$

(c) $4NH_3 + 5O_2 \longrightarrow 4NO_2 + 6H_2O$

The equality in this case is:

$$-\frac{1}{4}\frac{d[NH_3]}{dt} = -\frac{1}{5}\frac{d[O_2]}{dt} = \frac{1}{4}\frac{d[NO_2]}{dt} = \frac{1}{6}\frac{d[H_2O]}{dt}$$

$$\text{So,} \quad -\frac{d[NH_3]}{dt} = -\frac{4}{5}\frac{d[O_2]}{dt} = \frac{d[NO_2]}{dt} = \frac{2}{3}\frac{d[H_2O]}{dt}$$

Example 4. *The following reaction was carried out in water:*

$$Cl_2 + 2I^- \longrightarrow I_2 + 2Cl^-$$

The initial concentration of I^- *was* $0.25\ mol\ L^{-1}$ *and the concentration after* 10 *minutes* $0.23\ mol\ L^{-1}$. *Calculate the rate of disappearance of* I^- *and appearance of* I_2.

Solution: $\Delta[I^-] = [I^-]_{final} - [I^-]_{initial}$

$$= 0.23 - 0.25 = -0.02\ \text{mol L}^{-1}$$

$$\Delta t = 10 - 0 = 10\ \text{min}$$

$$-\frac{\Delta[I^-]}{\Delta t} = -\frac{(-0.02)}{10} = 0.002\ \text{mol L}^{-1}\ \text{min}^{-1}$$

$$\text{Rate of appearance of } I_2 = -\frac{1}{2}\frac{\Delta[I^-]}{\Delta t} = \frac{0.002}{2}$$
$$= 0.001\ \text{mol L}^{-1}\ \text{min}^{-1}$$
$$= 1\times10^{-3}\ \text{mol L}^{-1}\ \text{min}^{-1}$$

Example 5. *The reaction between* $Cr_2O_7^{2-}$ *and* HNO_2 *in an acidic medium is:*

$$Cr_2O_7^{2-} + 5H^+ + 3HNO_2 \rightarrow 2Cr^{3+} + 3NO_3^- + 4H_2O$$

The rate of disappearance of $Cr_2O_7^{2-}$ *is found to be* $2.4\times10^{-4}\ mol\ L^{-1}\ s^{-1}$ *during a measured time interval. Find the rate of disappearance of* HNO_2 *and the rate of appearance of* Cr^{3+} *during this time interval.*

Solution: The equality in this case is:

$$-\frac{\Delta[Cr_2O_7^{2-}]}{\Delta t} = -\frac{1}{3}\frac{\Delta[HNO_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[Cr^{3+}]}{\Delta t}$$

It is given that,

$$-\frac{\Delta[Cr_2O_7^{2-}]}{\Delta t} = 2.4\times10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

$$\text{So,} \quad -\frac{\Delta[HNO_2]}{\Delta t} = 3\times2.4\times10^{-4} = 7.2\times10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

$$\text{and} \quad \frac{\Delta[Cr^{3+}]}{\Delta t} = 2\times2.4\times10^{-4} = 4.8\times10^{-4}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. For the reaction, $2N_2O_5 \longrightarrow 4NO_2 + O_2$ rate of reaction is: **(AIIMS 2006)**

(a) $\frac{1}{2}\frac{d}{dt}[N_2O_5]$ (b) $2\frac{d}{dt}[N_2O_5]$

(c) $\frac{1}{4}\frac{d}{dt}[NO_2]$ (d) $4\frac{d}{dt}[NO_2]$

[Ans. (c)]

[Hint: For the reaction:

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

$$-\frac{1}{2}\frac{d[N_2O_5]}{dt} = +\frac{1}{4}\frac{d[NO_2]}{dt} = \frac{d[O_2]}{dt} = \text{Rate}]$$

2. Observe the following reaction:

$$A(g) + 3B(g) \longrightarrow 2C(g)$$

The rate of this reaction $\left\{\frac{-d[A]}{dt}\right\}$ is 3×10^{-3} mol litre^{-1} min^{-1}. What is the value of $\frac{-d[B]}{dt}$ in mol litre^{-1} min^{-1}? **(EAMCET 2006)**

(a) 3×10^{-3} (b) 9×10^{-3} (c) 10^{-3} (d) 1.5×10^{-3}

[Ans. (b)]

[Hint: $\frac{-d[A]}{dt} = -\frac{1}{3}\frac{d[B]}{dt}$

$$\therefore \quad \frac{-d[B]}{dt} = 3\left\{\frac{-d[A]}{dt}\right\} = 3\times3\times10^{-3}$$
$$= 9\times10^{-3}\ \text{mol litre}^{-1}\ \text{min}^{-1}\ ]$$

3. For the reaction, $2A + B \longrightarrow 3C + D$, which of the following does not express the reaction rate? **[CBSE (Med.) 2006]**

(a) $\frac{-d[C]}{3\,dt}$ (b) $\frac{-d[B]}{dt}$ (c) $\frac{d[D]}{dt}$ (d) $\frac{-d[A]}{2\,dt}$

[Ans. (a)]

[Hint: $-\frac{1}{2}\frac{d[A]}{dt} = \frac{-d[B]}{dt} = +\frac{1}{3}\frac{d[C]}{dt} = +\frac{d[D]}{dt} = \text{Rate}$]

4. Consider the reaction, $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$. The equality relationship between $\frac{d[NH_3]}{dt}$ and $-\frac{d[H_2]}{dt}$ is: **[CBSE (Med.) 2006]**

(a) $\frac{d[NH_3]}{dt} = -\frac{1}{3}\frac{d[H_2]}{dt}$ (b) $+\frac{d[NH_3]}{dt} = -\frac{2}{3}\frac{d[H_2]}{dt}$

(c) $+\frac{d[NH_3]}{dt} = -\frac{3}{2}\frac{d[H_2]}{dt}$ (d) $\frac{d[NH_3]}{dt} = -\frac{d[H_2]}{dt}$

[Ans. (b)]

[Hint: $-\frac{1}{3}\frac{d[H_2]}{dt} = +\frac{1}{2}\frac{d[NH_3]}{dt}$]

5. For a reaction $\frac{1}{2}A \longrightarrow 2B$ rate of disappearance of A is related to the rate of appearance of B by the expression: **(AIEEE 2008)**

(a) $\frac{-d[A]}{dt} = 4\frac{d[B]}{dt}$ (b) $\frac{-d[A]}{dt} = \frac{1}{2}\frac{d[B]}{dt}$

(c) $\frac{-d[A]}{dt} = \frac{1}{4}\frac{d[B]}{dt}$ (d) $\frac{-d[A]}{dt} = +\frac{d[B]}{dt}$

[Ans. (c)]

[Hint: The reaction may be given as

$$A \longrightarrow 4B$$

$$\frac{-d[A]}{dt} = +\frac{1}{4}\frac{d[B]}{dt} = \text{Rate of reaction.}]$$

6. In a reaction of acidified hydrogen peroxide with potassium iodide, the concentration of iodine formed rises from 0 to 10^{-5} mol dm^{-3} in 10 seconds. What is the rate of reaction ? **[PET (Raj.) 2008]**

(a) 10^{-6} mol dm^{-3}s^{-1} (b) 10^{6} mol dm^{-3}s^{-1}

(c) 10^{-5} mol dm^{-3}s^{-1} (d) 10^{4} mol dm^{-3}s^{-1}

[Ans. (a)]

[Hint: The reaction is

$$2I^- + H_2O_2 + 2H^+ \longrightarrow I_2 + 2H_2O$$

$$\text{Rate} = +\frac{d[I_2]}{dt} = \frac{10^{-5}}{10} = 10^{-6}\ \text{mol dm}^{-3}\text{s}^{-1}]$$

8.3 LAW OF MASS ACTION (Guldberg and Waage, 1864)

This law relates rate of reaction with active mass or molar concentration of reactants.

"At a given temperature, the rate of a reaction at a particular instant is proportional to the product of the active masses of the reactants at that instant raised to powers which are numerically equal to the numbers of their respective molecules in the stoichiometric equation describing the reaction."

Active mass = molar concentration of the substance

$$= \frac{\text{number of gram moles of the substance}}{\text{volume in litres}}$$

$$= \frac{w/M}{V} = \frac{n}{V}$$

where, w = mass of substance and 'M' is the molecular mass in gram, 'n' is the number of gram moles and V is volume in litre.

Example 6. *4 g of hydrogen and 128 g of hydrogen iodide are present in a 2 litre flask. What are their active masses?*

Solution: Mass of hydrogen = 4 g

Mol. mass of hydrogen = 2

Volume of the flask = 2 litre

$$\text{Active mass of hydrogen} = \frac{4}{2 \times 2} = 1\ \text{mol L}^{-1}$$

Mass of HI = 128 g

Mol. mass of HI = 128

Volume of the flask = 2 litre

$$\text{Active mass of hydrogen iodide} = \frac{128}{128 \times 2} = 0.5\ \text{mol L}^{-1}$$

8.4 RATE CONSTANT

Consider a simple reaction $A \rightarrow B$.

If C_A is the molar concentration or active mass of A at a particular instant, then

$$\frac{dx}{dt} \propto C_A \text{ or } \frac{dx}{dt} = kC_A$$

where, k is a **proportionality constant,** called **velocity constant** or **rate constant** or **specific reaction rate.**

At a fixed temperature, if $C_A = 1$, then

$$\text{Rate} = \frac{dx}{dt} = k \quad \text{... (i)}$$

Let us consider a general reaction.

$$aA + bB \longrightarrow \text{Product}$$

$$\text{Rate} = \left(\frac{dx}{dt}\right) \propto [A]^a[B]^b$$

$$\text{Rate} = k[A]^a[B]^b \quad \text{...(ii)}$$

When $[A] = [B] = 1$ mol/litre, then

$$\text{Rate} = k$$

Rate of a reaction at unit concentration of reactants is called rate constant.

The value of rate constant depends on:

(i) Nature of reactant

(ii) Temperature

(iii) Catalyst

Unit of Rate Constant

Rate constant has different units for reactions of different order. General rule for rate of reaction may be given as:

$$\text{Unit of rate constant} = \left[\frac{1}{\text{unit of concentration}}\right]^{n-1} \times \text{time}^{-1}$$

$$= \left[\frac{1}{\text{mol / litre}}\right]^{n-1} \times \text{sec}^{-1}$$

$$= \left[\frac{\text{litre}}{\text{mol}}\right]^{n-1} \times \text{sec}^{-1}$$

where, n = order of reaction.

S. No.	Rate of reaction	Reaction rate constant
1.	It is the speed with which reactants are converted into products.	It is proportionality constant.
2.	It is measured as the rate of decrease of concentration of reactants or the rate of increase of concentration of products with time.	It is equal to the rate of reaction when the concentration of each of the reactants is unity.
3.	It depends upon the initial concentration of reactants.	It is independent of the initial concentration of the reactants. It has a constant value at fixed temperature.

8.5 COLLISION THEORY OF REACTION RATE (Arrhenius Theory of Reaction Rate)

(1) A chemical reaction takes place due to collision among reactant molecules. The number of collisions taking place per second per unit volume of the reaction mixture is known as **collision frequency (Z).** The value of collision frequency is very high, of the order of 10^{25} to 10^{28} in case of binary collisions.

(2) Every collision does not bring a chemical change. The collisions that actually produce the products are **effective collisions.** The effective collisions which bring chemical change are few in comparison to the total number of collisions. The collisions that do not form a product are **ineffective elastic collisions,** *i.e.*, molecules just collide and disperse in different directions with different velocities. For a collision to be effective, the following two barriers are to be cleared:

Energy Barrier

The minimum amount of energy which the colliding molecules must possess as to make the chemical reaction to occur, is known as threshold energy.

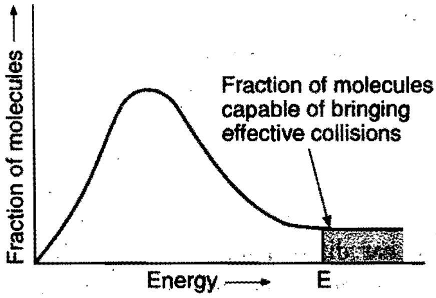

Fig. 8.3

In the graph (Fig. 8.3), 'E' corresponds to minimum or threshold energy for effective collision in a hypothetical reaction.

There is an energy barrier for each reaction. The reacting species must be provided with sufficient energy as to cross the energy barrier.

The minimum amount of energy required by reactant molecules to participate in a reaction is called activation energy.

Activation energy = threshold energy − average kinetic energy of reacting molecules

Threshold energy = initial potential energy of reactant molecules + activation energy.

A collision between high energy molecules overcomes the forces of repulsion and brings the formation of an unstable molecule cluster, called the **activated complex.** The life span of an activated complex is very small. Thus, the activated complex breaks either into reactants again or new substances, *i.e.*, products. The activation energy (E_a) depends upon the nature of chemical bonds undergoing rupture and is independent of enthalpies of reactants and products. The energy changes during exothermic and endothermic reactions *versus* the progress of the reaction are shown in Fig. 8.4.

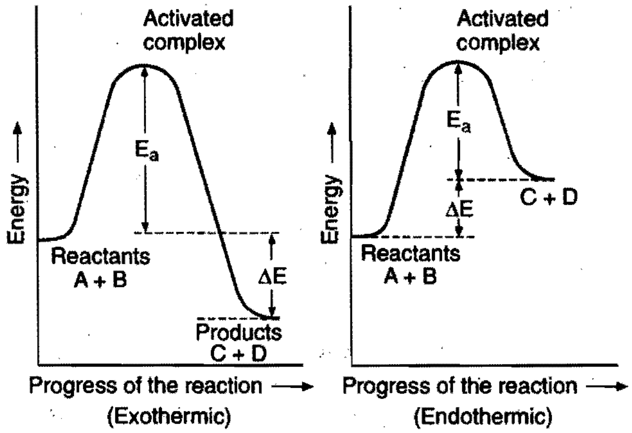

Fig. 8.4 Activation energy of exothermic and endothermic reaction

Thus, every chemical reaction whether exothermic or endothermic has an energy barrier which has to be overcome before reactants can be transformed into products. If the reactant molecules have sufficient energy, they can reach the peak of the energy barrier after collision and then they can go to the right side of the slope and consequently change into products. If the activation energy for a reaction is low, the fraction of effective collisions will be large and the reaction will be fast. On the other hand, if the activation energy is high, then fraction of effective collisions will be small and the reaction will be slow. When temperature is increased, the number of active molecules increases, *i.e.*, the number of effective collisions will increase and the rate of reaction will increase.

$$\text{Activation energy } E_a = E_{(\text{activated complex})} - E_{(\text{ground state})}$$

$$\Delta H = \text{activation energy of forward reaction} - \text{activation energy of backward reaction.}$$

Orientation Barrier

Energy alone does not determine the effectiveness of the collision. The reacting molecules must collide in proper manner if the reaction is to occur. This has been shown in Fig. 8.5.

Rate of reaction is directly proportional to the number of effective collisions.

$$\text{Rate} = -\frac{dx}{dt} = \text{collision frequency} \times \text{fraction of effective collisions}$$

$$= Z \times f$$

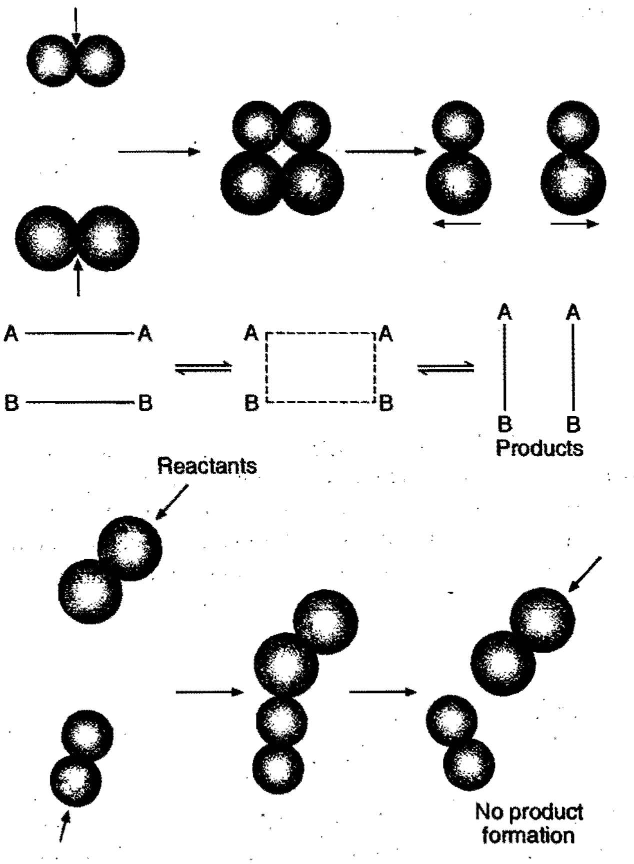

Fig. 8.5 Orientation of collisions

Factors Affecting Rate of Reaction

(i) Nature of the reactants

(a) Physical state of reactants: This has considerable effect over rate of reaction.

$$\underset{\text{Decreasing rate of reaction}}{\xrightarrow{\text{Gaseous state} > \text{Liquid state} > \text{Solid state}}}$$

Similarly, in a heterogeneous system, collision is not so effective as in homogeneous system. Thus, reactions in liquid phase or solution phase will be faster in comparison to heterogeneous conditions when same concentrations of the reactants are taken.

(b) Physical size of the reactants: Among the solids, rate increases with decrease in particle size. In powdered state rate of reaction is maximum because in powdered state, surface area is maximum.

(c) Chemical nature of reactants: Consider the following two reactions:

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g) \qquad \text{... (i)}$$

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O \qquad \text{... (ii)}$$

The first reaction is faster than the second because in the first reaction only $N{\equiv}O$ bond is to be broken whereas in the second reaction four (C—H) bonds are to be broken.

Similarly, consider another example of two similar reactions:

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g) \qquad \text{... (iii)}$$

$$2CO(g) + O_2(g) \longrightarrow 2CO_2(g) \qquad \text{... (iv)}$$

NO bond is weaker than CO bond, hence broken easily. Thus, reaction (iii) is faster than (iv).

(ii) Concentration of reactants

Let us consider the reaction:

$$A + B \longrightarrow C + D;$$

$$\text{Rate} = k\,[A][B]$$

Rate of the above reaction decreases with the passage of time because the concentration of reactants A and B will decrease as time passes on.

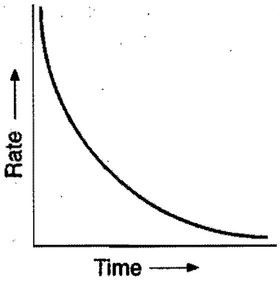

Fig. 8.6

Let us consider the following reversible reaction:

$$A + B \rightleftharpoons C + D$$

$$\text{Rate of forward reaction} = k_f\,[A][B]$$

$$\text{Rate of backward reaction} = k_b[C][D]$$

Rate of forward reaction decreases and that of backward reaction increases with passage of time. At equilibrium both the rates become equal.

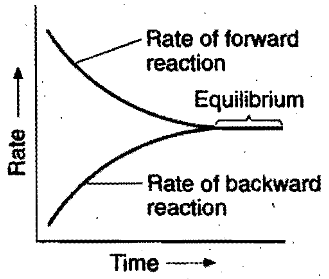

Fig. 8.7

(iii) Effect of temperature

The rate of reaction increases considerably with an increase in temperature. The rates of many reactions are approximately doubled or tripled for every 10°C rise in temperature. The temperature coefficient of a chemical reaction is defined as the ratio of the specific reaction rates of a reaction at two temperatures differing by 10°C.

$$\mu = \text{Temperature coefficient} = \frac{k_{t+10}}{k_t}$$

Let temperature coefficient of a reaction be 'μ' when temperature is raised from T_1 to T_2; then the ratio of rate constants or rate may be calculated as:

$$\frac{k_{T_2}}{k_{T_1}} = (\mu)^{(T_2 - T_1)/10} = \mu^{\Delta T/10}$$

$$\log_{10}\left(\frac{k_{T_2}}{k_{T_1}}\right) = \frac{\Delta T}{10}\log_{10}\mu$$

$$\frac{k_{T_2}}{k_{T_1}} = \text{antilog}\left[\frac{\Delta T}{10}\log_{10}\mu\right]$$

Its value lies generally between 2 and 3.

When the temperature is increased, heat energy is supplied which increases the kinetic energy of the reacting molecules. This will increase the number of collisions and ultimately the rate of reaction will be enhanced. Arrhenius suggested an equation which describes k as a function of temperature, *i.e.*,

$$k = Ae^{-E_a/RT}$$

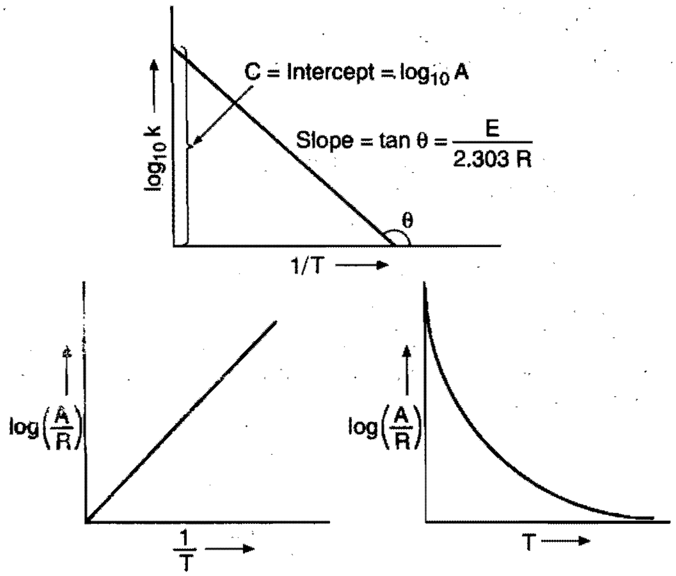

Fig. 8.8

where, $k \rightarrow$ rate constant

$A \rightarrow$ a constant (frequency factor)

$E_a \rightarrow$ energy of activation

At two temperatures T_1 and T_2, taking log of Arrhenius equation, we get

$$\log_e k_1 = \log A - \frac{E_a}{RT_1}\log_e e \quad \text{... (i)}$$

and

$$\log_e k_2 = \log A - \frac{E_a}{RT_2}\log_e e \quad \text{... (ii)}$$

Subtracting eq. (ii) from eq. (i) and converting the log to the base 10, we get

$$\log_{10}\frac{k_1}{k_2} = -\frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right] \text{ or } \log_{10}\frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1T_2}\right]$$

This equation can be used for calculation of energy of activation.

Logarithmic Arrhenius equation is:

$$\log_{10} k = \log_{10} A - \frac{E_a}{2.303R}\left[\frac{1}{T}\right]$$

$$Y = C + M\,X$$

It is the equation of straight line with negative slope. On plotting $\log_{10} k$ against $[1/T]$ we get a straight line as shown in Fig. 8.8. The graph gives two kinetic parameters.

The slope gives **activation energy** and intercept gives **frequency factor.**

The dependence of rate constant on temperature for two reactions is shown in the Fig. 8.9.

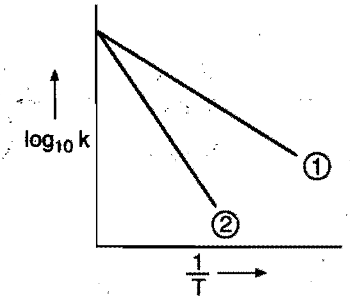

Fig. 8.9

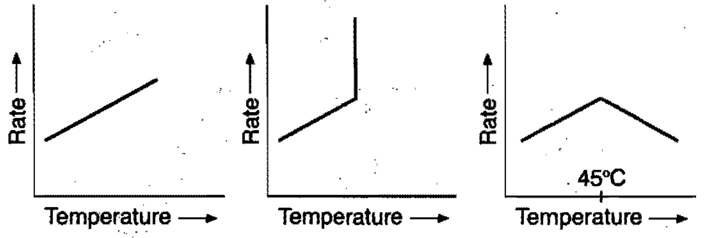
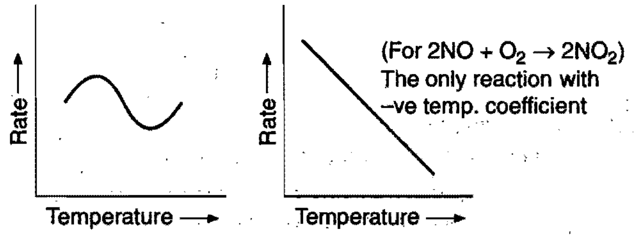
In the reaction (2), the modulus of slope is greater than that of reaction (1), hence reaction (2) has higher activation energy. The reaction (2) will be more sensitive to temperature change.

Reactions on the basis of influence of temperature are classified into five types. These are shown in the graphs.



(Normal reactions) (a) (Explosive reactions) (b) (Biological reactions) (c)



(Oxidation of carbon) (d) (e)

Fig. 8.10

(iv) Presence of a positive catalyst

The function of a positive catalyst is to lower down the activation energy. The greater the decrease in the activation energy caused by the catalyst, higher will be the reaction rate. In the presence of a catalyst, the reaction follows a path of lower activation energy. Under this condition, a large number of reacting molecules are able to cross over the energy barrier and thus the rate of reaction increases. Fig. 8.11 shows how the activation energy is lowered in presence of a catalyst.

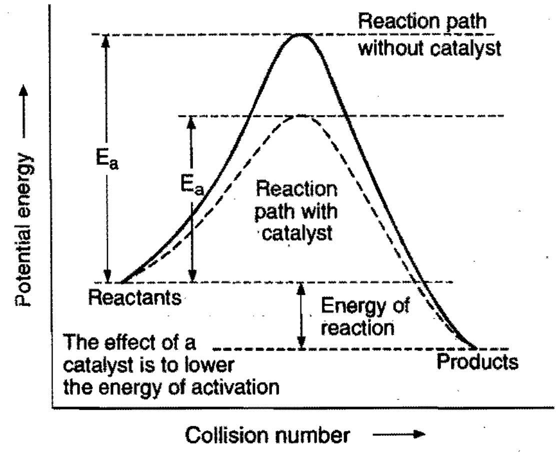


Fig. 8.11 A catalyst changes the reaction path (Positive catalyst)

(v) Presence of negative catalyst

A negative catalyst increases the activation energy of reaction by forming a new intermediate of high energy, *i.e.*, by changing the reaction mechanism.

Due to increased activation energy, some active molecules become inactive, therefore, rate of reaction decreases.

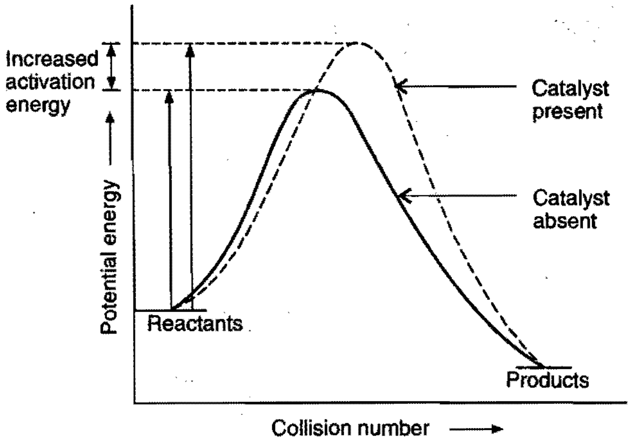

Fig. 8.12 Negative catalyst

Let 'p' denote presence of catalyst and 'a' denote absence of catalyst.

$$k_p = Ae^{-E_p/RT} \quad \text{... (i)}$$

$$k_a = Ae^{-E_a/RT} \quad \text{... (ii)}$$

Dividing eq. (i) by eq. (ii), we get

$$\frac{k_p}{k_a} = e^{(E_a - E_p)/RT} = e^{\Delta E/RT}$$

$$\frac{k_p}{k_a} = \text{antilog}\left[\frac{\Delta E}{2.303RT}\right]$$

SOME SOLVED EXAMPLES

Example 7. *The rate of a reaction triples when temperature changes from 20°C to 50°C. Calculate energy of activation for the reaction.* ($R = 8.314\ JK^{-1}\ mol^{-1}$)

Solution: The Arrhenius equation is,

$$\log_{10}\frac{k_2}{k_1} = \frac{E_a}{R \times 2.303}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

Given: $\frac{k_2}{k_1} = 3$; $R = 8.314\ \text{JK}^{-1}\ \text{mol}^{-1}$; $T_1 = 20 + 273 = 293\ \text{K}$

and $T_2 = 50 + 273 = 323\ \text{K}$

Substituting the given values in the Arrhenius equation,

$$\log_{10} 3 = \frac{E_a}{8.314 \times 2.303}\left[\frac{323 - 293}{323 \times 293}\right]$$

$$E_a = \frac{2.303 \times 8.314 \times 323 \times 293 \times 0.477}{30}$$

$$= 28811.8\ \text{J mol}^{-1}$$

$$= 28.8118\ \text{kJ mol}^{-1}$$

Example 8. *In Arrhenius equation for a certain reaction, the value of A and E_a (activation energy) are 4×10^{13} sec^{-1} and 98.6 kJ mol^{-1} respectively. At what temperature, the reaction will have specific rate constant 1.1×10^{-3} sec^{-1}?*

Solution: According to Arrhenius equation,

$$k = Ae^{-E_a/RT}$$

or $$\log_e k = \log_e A - \frac{E_a}{RT}\log_e e$$

or $$2.303 \log_{10} k = 2.303 \log_{10} A - \frac{E_a}{RT}$$

or $$2.303 \log (1.1 \times 10^{-3}) = 2.303 \log (4 \times 10^{13}) - \frac{98.6 \times 10^3}{8.314 \times T}$$

$$T = \frac{98.6 \times 10^3}{8.314 \times 2.303 \times 16.56}\ \text{K}$$

$$= 310.96\ \text{K}$$

Example 9. *The rate constant is given by Arrhenius equation,*

$$k = Ae^{-E_a/RT}$$

Calculate the ratio of the catalysed and uncatalysed rate constants at 25°C if the energy of activation of a catalysed reaction is 162 kJ and for the uncatalysed reaction the value is 350 kJ.

Solution: Let k_{ca} and k_{un} be the rate constants for catalysed and uncatalysed reactions.

$$2.303 \log_{10} k_{ca} = 2.303 \log_{10} A - \frac{162 \times 10^3}{RT} \quad \text{... (i)}$$

and $$2.303 \log_{10} k_{un} = 2.303 \log_{10} A - \frac{350 \times 10^3}{RT} \quad \text{... (ii)}$$

Subtracting eq. (ii) from eq. (i)

$$\log_{10} \frac{k_{ca}}{k_{un}} = \frac{10^3}{2.303RT}(350 - 162)$$

$$= \frac{188 \times 10^3}{2.303 \times 8.314 \times 298} = 32.95$$

$$\frac{k_{ca}}{k_{un}} = 8.88 \times 10^{32}$$

Example 10. *Calculate the rate constant of a reaction at 293 K when the energy of activation is 103 kJ mol $^{-1}$ and the rate constant at 273 K is 7.87×10^{-7} s $^{-1}$.*
($R = 8.314 \times 10^{-3}$ kJ mol $^{-1}$ K $^{-1}$)

Solution: The Arrhenius equation is,

$$\log_{10} \frac{k_2}{k_1} = \frac{E_a}{2.303R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

Given: $k_1 = 7.87 \times 10^{-7}\ \text{s}^{-1}$; $E_a = 103\ \text{kJ mol}^{-1}$;
$R = 8.314 \times 10^{-3}\ \text{kJ mol}^{-1}\ \text{K}^{-1}$;
$T_1 = 273$ K and $T_2 = 293$ K

Substituting the values in Arrhenius equation,

$$\log_{10} \frac{k_2}{7.87 \times 10^{-7}} = \frac{103 \times 20}{2.303 \times 8.314 \times 10^{-3} \times 293 \times 273}$$

$$= 1.345$$

$$\therefore k_2 = 1.74 \times 10^{-5}\ \text{s}^{-1}$$

Example 11. *At 407 K, the rate constant of a chemical reaction is 9.5×10^{-5} s $^{-1}$ and at 420 K, the rate constant is 1.9×10^{-4} s $^{-1}$. Calculate the frequency factor of the reaction.*

Solution: The Arrhenius equation is,

$$\log_{10} \frac{k_2}{k_1} = \frac{E_a}{2.303 \times R}\left[\frac{T_2 - T_1}{T_1 T_2}\right]$$

Given: $k_1 = 9.5 \times 10^{-5}\ \text{s}^{-1}$; $k_2 = 1.9 \times 10^{-4}\ \text{s}^{-1}$;
$R = 8.314\ \text{J mol}^{-1}\ \text{K}^{-1}$;
$T_1 = 407$ K and $T_2 = 420$ K

Substituting the values in Arrhenius equation

$$\log_{10} \frac{1.9 \times 10^{-4}}{9.5 \times 10^{-5}} = \frac{E_a}{2.303 \times 8.314}\left[\frac{420 - 407}{420 \times 407}\right]$$

$$E_a = 75782.3\ \text{J mol}^{-1}$$

Applying now $\log k_1 = \log A - \dfrac{E_a}{2.303RT_1}$

$$\log 9.5 \times 10^{-5} = \log A - \frac{75782.3}{2.303 \times 8.314 \times 407}$$

or $$\log \frac{A}{9.5 \times 10^{-5}} = \frac{75782.3}{2.303 \times 8.314 \times 407} = 9.7246$$

$$A = 5.04 \times 10^5\ \text{s}^{-1}$$

Example 12. *The energy of activation for a reaction is 100 kJ mol $^{-1}$. Presence of a catalyst lowers the energy of activation by 75%. What will be effect on rate of reaction at 20° C, other things being equal?*

Solution: The Arrhenius equation is,

$$k = Ae^{-E_a/RT}$$

In absence of catalyst, $k_1 = Ae^{-100/RT}$

In presence of catalyst, $k_2 = Ae^{-25/RT}$

So, $$\frac{k_2}{k_1} = e^{75/RT} \text{ or } 2.303 \log \frac{k_2}{k_1} = \frac{75}{RT}$$

or $$2.303 \log \frac{k_2}{k_1} = \frac{75}{8.314 \times 10^{-3} \times 293}$$

or $$\log \frac{k_2}{k_1} = \frac{75}{8.314 \times 10^{-3} \times 293 \times 2.303}$$

or $$\frac{k_2}{k_1} = 2.34 \times 10^{13}$$

As the things being equal in presence or absence of a catalyst,

$$\frac{k_2}{k_1} \text{ must be} = \frac{\text{rate in presence of catalyst}}{\text{rate in absence of catalyst}}$$

i.e., $$\frac{r_2}{r_1} = \frac{k_2}{k_1} = 2.34 \times 10^{13}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

7. For a reaction $E_a = 0$ and $k = 3.2 \times 10^4\ \text{s}^{-1}$ at 300 K. The value of k at 310 K would be:

(a) $6.4 \times 10^4\ \text{s}^{-1}$ (b) $3.2 \times 10^4\ \text{s}^{-1}$
(c) $3.2 \times 10^8\ \text{s}^{-1}$ (d) $3.2 \times 10^5\ \text{s}^{-1}$

[Ans. (b)]

[Hint: $k = Ae^{-E_a/RT}$
When $E_a = 0$, $k = A$ = constant
$\therefore$ $k_{310} = k_{300} = 3.2 \times 10^4\ \text{s}^{-1}$]

8. For a gaseous reaction, following data is given:

$$A \longrightarrow B, k_1 = 10^{15} e^{-2000/T}$$
$$C \longrightarrow D, k_2 = 10^{14} e^{-1000/T}$$

The temperature at which $k_1 = k_2$ is:

(a) 1000 K (b) 2000 K (c) 868.82 K (d) 434.2 K

[Ans. (d)]

[Hint: When $k_1 = k_2$,

$$10^{15} e^{-2000/T} = 10^{14} e^{-1000/T}$$
$$10 = e^{1000/T}$$
$$2.303 \log 10 = \frac{1000}{T}$$
$$T = 434.2\ \text{K}]$$

9. For $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g) + 22$ kcal, E_a for the reaction is 70 kcal. Hence, the activation energy for $2NH_3(g) \longrightarrow N_2(g) + 3H_2(g)$ is:
(a) 92 kcal (b) 70 kcal (c) 48 kcal (d) 22 kcal
[**Ans.** (a)]
[**Hint:**

$$\Delta H = E_f - E_b$$
$$-22 = 70 - E_b$$
$$E_b = 92 \text{ kcal}]$$

10. On introducing a catalyst at 500 K, the rate of a first order reaction increases by 1.718 times. The activation energy in the presence of a catalyst is 6.05 kJ mol^{-1}. The slope of the plot of $\ln k$ (sec^{-1}) against $1/T$ in the absence of catalyst is:
(a) +1 (b) −1 (c) +1000 (d) −1000
[**Ans.** (d)]
[**Hint:** $\dfrac{\text{Rate in presence of catalyst}}{\text{Rate in absence of catalyst}} = \text{Antilog}\left[\dfrac{+\Delta E}{2.303RT}\right]$.

$$1.718 = \text{Antilog}\, \frac{E_a - E_p}{2.303 \times 8.314 \times 500}$$
$$E_a - E_p = 2.25 \text{ kJ}$$
$$E_a = E_p + 2.25 = 6.05 + 2.25 = 8.30 \text{ kJ mol}^{-1}$$
$$= 8.3 \text{ kJ mol}^{-1}$$
$$\ln k = \ln A - \frac{E_a}{R} \times \frac{1}{T}$$
$$\text{Slope} = \frac{-E_a}{R} = \frac{-8.3 \times 1000}{8.3} = -1000]$$

11. For which of the following reactions k_{310}/k_{300} would be maximum?
(a) $A + B \longrightarrow C$; $E_a = 50$ kJ
(b) $X + Y \longrightarrow Z$; $E_a = 40$ kJ
(c) $P + Q \longrightarrow R$; $E_a = 60$ kJ
(d) $E + F \longrightarrow G$; $E_a = 100$ kJ
[**Ans.** (d)]
[**Hint:** Increase in rate constant is maximum for the reaction having maximum activation energy.]

12. The activation energy of exothermic reaction $A \longrightarrow B$ is 80 kJ mol^{-1}. The heat of reaction is 200 kJ mol^{-1}. The activation energy for the reaction $B \longrightarrow A$ (in kJ/mol) will be: **[PET (Kerala) 2007]**
(a) 80 (b) 120 (c) 40 (d) 200
(e) 280
[**Ans.** (e)]
[**Hint:**

$$\Delta H = E_f - E_b$$
$$-200 = 80 - E_b$$
$$E_b = 280 \text{ kJ/mol}]$$

13. Which equation is true to calculate the energy of activation, if the rate of reaction is doubled by increasing temperature from T_1 K to T_2 K? **[CET (Gujarat) 2008]**
(a) $\log_{10}\left(\dfrac{k_1}{k_2}\right) = \dfrac{E_a}{2.303\,R}\left[\dfrac{1}{T_1} - \dfrac{1}{T_2}\right]$
(b) $\log_{10}\left(\dfrac{k_2}{k_1}\right) = \dfrac{E_a}{2.303\,R}\left[\dfrac{1}{T_2} - \dfrac{1}{T_1}\right]$
(c) $\log_{10}\dfrac{1}{2} = \dfrac{E_a}{2.303}\left[\dfrac{1}{T_2} - \dfrac{1}{T_1}\right]$
(d) $\log_{10} 2 = \dfrac{E_a}{2.303\,R}\left[\dfrac{1}{T_1} - \dfrac{1}{T_2}\right]$
[**Ans.** (d)]
[**Hint:** We know, $\log\left(\dfrac{k_2}{k_1}\right) = \dfrac{E_a}{2.303\,R}\left[\dfrac{1}{T_1} - \dfrac{1}{T_2}\right]$

When reaction rate becomes double then $\dfrac{k_2}{k_1}$ will be equal to 2.

Then, $\log_{10} 2 = \dfrac{E_a}{2.303\,R}\left[\dfrac{1}{T_1} - \dfrac{1}{T_2}\right]$]

8.6 MOLECULARITY OF REACTION

In general, **molecularity of simple reactions is equal to the sum of the number of molecules of reactants involved in the balanced stoichiometric equation.**

OR

The molecularity of a reaction is the number of reactant molecules taking part in a single step of the reaction.

e.g.,
$PCl_5 \longrightarrow PCl_3 + Cl_2$ (Unimolecular)
$2HI \longrightarrow H_2 + I_2$ (Bimolecular)
$2SO_2 + O_2 \longrightarrow 2SO_3$ (Trimolecular)
$NO + O_3 \longrightarrow NO_2 + O_2$ (Bimolecular)
$2CO + O_2 \longrightarrow 2CO_2$ (Trimolecular)
$2FeCl_3 + SnCl_2 \longrightarrow SnCl_4 + 2FeCl_2$ (Trimolecular)

The minimum number of reacting particles (molecules, atoms or ions) that come together or collide in a rate determining step to form product or products is called the molecularity of a reaction.

For example, decomposition of H_2O_2 takes place in the following two steps:

$H_2O_2 \longrightarrow H_2O + \frac{1}{2}O_2$ (overall reaction)
Step 1: $H_2O_2 \longrightarrow H_2O + [O]$ (slow)
Step 2: $[O] + [O] \longrightarrow O_2$ (fast)

The slowest step is rate-determining. Thus, from step 1, reaction appears to be unimolecular.

Note: (i) Molecularity is a theoretical concept.
(ii) Molecularity cannot be zero, –ve, fractional, infinite and imaginary.
(iii) Molecularity cannot be greater than three because more than three molecules may not mutually collide with each other.

There are some chemical reactions whose molecularity appears to be more than three from stoichiometric equations, *e.g.*, in

$$4HBr + O_2 \longrightarrow 2H_2O + 2Br_2$$
$$2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

In the first reaction, molecularity seems to be '5' and in the second reaction molecularity seems to be '23'. Such reactions involve two or more steps; each step has its own molecularity not greater than three, *e.g.*, in first reaction,

$$HBr + O_2 \longrightarrow HOOBr$$
$$HOOBr + HBr \longrightarrow 2HOBr$$
$$[HOBr + HBr \longrightarrow H_2O + Br_2] \times 2$$
$$\overline{4HBr + O_2 \longrightarrow 2H_2O + Br_2}$$

Molecularity of each of the above steps is 2.

(a) Reaction between Br^- and H_2O_2 in acidic medium: The overall reaction is:

$$2Br^- + H_2O_2 + 2H^+ \longrightarrow Br_2 + 2H_2O$$

The proposed mechanism is:

$$Br^- + H_2O_2 + H^+ \longrightarrow HOBr + H_2O \quad \text{(slow)}$$
$$HOBr + H^+ + Br^- \longrightarrow Br_2 + H_2O \quad \text{(fast)}$$
$$\text{Rate} = k[Br^-][H_2O_2][H^+]$$

The reaction is trimolecular.

(b) Reaction between NO_2 and F_2: The overall reaction is:

$$2NO_2 + F_2 \longrightarrow 2NO_2F$$

The proposed mechanism is:

$$NO_2 + F_2 \longrightarrow NO_2F + F \quad \text{(slow)}$$
$$NO_2 + F \longrightarrow NO_2F \quad \text{(fast)}$$
$$\text{Rate} = k[NO_2][F_2]$$

The reaction is bimolecular.

(c) Decomposition of H_2O_2: The overall reaction is:

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$

The proposed mechanism is:

$$H_2O_2 \longrightarrow H_2O + O \quad \text{(slow)}$$
$$H_2O_2 + O \longrightarrow H_2O + O_2 \quad \text{(fast)}$$
$$\text{Rate} = k[H_2O_2]$$

The reaction is unimolecular.

8.7 ORDER OF REACTION

Let us consider a general reaction:

$$m_1 A + m_2 B + m_3 C \longrightarrow \text{Product}$$

Let active moles of 'A', 'B' and 'C' be 'α', 'β' and 'γ' respectively. Then, rate of reaction may be given as:

$$\text{Rate} = k[A]^{\alpha}[B]^{\beta}[C]^{\gamma}$$

Sum of powers of concentration terms involved in rate law expression is called order of reaction.

$$\alpha + \beta + \gamma = \text{order}$$

When $\alpha + \beta + \gamma = m_1 + m_2 + m_3$, then

Order of reaction = molecularity of reaction.

Order is an experimentally determined quantity. It may be equal to zero, positive, negative, fractional and greater than three. Infinite and imaginary values are not possible.

Examples:

(i) $$2H_2O_2 \longrightarrow 2H_2O + O_2$$

$$-\frac{dx}{dt} = k[H_2O_2]^2$$

(observed from law of mass action)

Step 1: $$H_2O_2 \longrightarrow H_2O + [O] \quad \text{(slow)}$$

Step 2: $$[O] + [O] \longrightarrow O_2 \quad \text{(fast)}$$

Actual rate $$-\frac{dx}{dt} = k[H_2O_2]$$

Thus, order of reaction is unity.

(ii) $$2NO_2 + F_2 \longrightarrow 2NO_2F$$

Rate law from law of mass action:

$$-\frac{dx}{dt} = k[NO_2]^2[F_2]$$

Experimentally observed rate law:

$$-\frac{dx}{dt} = k[NO_2][F_2]$$

Slowest step is $NO_2 + F_2 \longrightarrow NO_2F + [F]$

Thus, order of reaction = 1 + 1 = 2

(iii) $$CH_3CHO \longrightarrow CH_4 + CO$$

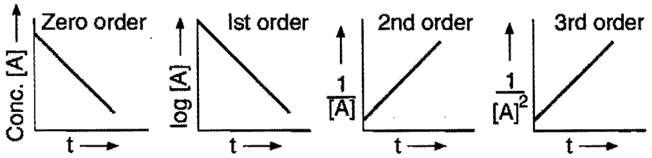
The rate equation derived from experimental data is found to be

$$-\frac{dx}{dt} = k[CH_3CHO]^{1.5}$$

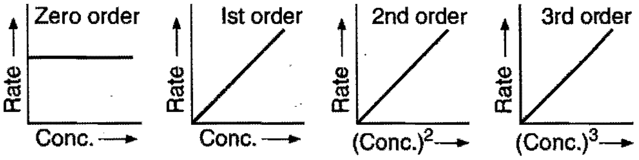
The order of reaction is 1.5.

Some typical linear plots for the reactions of different orders:

(a) Plots of rate *vs* concentrations [Rate = $k(\text{conc.})^n$]



(b) Plots from integrated rate equations:



From the study of the kinetics of many simple reactions, it is observed that for a large number of reactions, the molecularity and order are the same. Some examples are given below to justify this point.

1. Dissociation of N_2O_5,

$$N_2O_5 \longrightarrow N_2O_4 + \frac{1}{2}O_2$$

Order = 1, Molecularity = 1

2. Dissociation of H_2O_2,

$$H_2O_2 \longrightarrow H_2O + \frac{1}{2}O_2$$

Order = 1, Molecularity = 1

3. Dissociation of HI,

$$2HI \longrightarrow H_2 + I_2$$

Order = 2, Molecularity = 2

4. Formation of NO_2,

$$2NO + O_2 \longrightarrow 2NO_2$$

Order = 3, Molecularity = 3

8.8 PSEUDO-ORDER REACTION

Reactions whose actual order is different from that expected using rate law expression are called **pseudo-order reactions,** *e.g.*,

(i) $$RCl + H_2O \longrightarrow ROH + HCl$$

Expected rate law:

Rate = $k\,[RCl][H_2O]$ Expected order = 1 + 1 = 2

Actual rate law:

Rate = $k'\,[RCl]$; Actual order = 1

Water is taken in excess; therefore, its concentration may be taken constant. The reaction is, therefore, **pseudo first order.** Similarly, the acid catalysed hydrolysis of ester, *viz.*,

$$RCOOR' + H_2O \rightleftharpoons RCOOH + R'OH$$

follow first order kinetics:

$$\text{Rate} = k\,[RCOOR']$$

It is also a pseudo first order reaction.

The main differences between molecularity and order of reaction are given below:

Molecularity	Order of reaction
1. It is the total number of reacting species (molecules, atoms or ions) which bring the chemical change.	It is the sum of powers of molar concentrations of the reacting species in the rate equation of the reaction.
2. It is always a whole number.	It may be a whole number, zero, fractional, positive or negative.
3. It is a theoretical concept.	It is experimentally determined.
4. It is meaningful only for simple reactions or individual steps of a complex reaction. It is meaningless for overall complex reaction.	It is meant for the reaction and not for its individual steps.

Example 13. *The experimental data for the reaction,*

$$2A + B_2 \longrightarrow 2AB$$

is as follows:

Expt. No.	$[A]$ (*mol* L^{-1})	$[B_2]$ (*mol* L^{-1})	*Rate* (*mol* $L^{-1}\,s^{-1}$)
1.	0.50	0.50	1.6×10^{-4}
2.	0.50,	1.00	3.2×10^{-4}
3.	1.00	1.00	3.2×10^{-4}

Write the most probable equation for the rate of reaction giving reason for your answer. (IIT 1991)

Solution: From an examination of above data, it is clear that when the concentration of B_2 is doubled, the rate is doubled. Hence, the order of reaction with respect to B_2 is one.

Further, when concentration of A is doubled, the rate remains unaltered. So, order of reaction with respect to A is zero.

The probable rate law for the reaction will be

$$-\frac{dx}{dt} = k[B_2][A]^0 = k[B_2]$$

Alternatively, $\text{Rate} = k[B_2]^{\alpha}$

$$1.6 \times 10^{-4} = k[0.5]^{\alpha}$$

$$3.2 \times 10^{-4} = k[1]^{\alpha}$$

On dividing we get, $\alpha = 1$

$\therefore$ $\text{Rate} = k[A]^0[B_2]^1 = k[B_2]$

Example 14. *For the reaction,*

$$A + 2B \longrightarrow 2C$$

the following data were obtained:

Expt. No.	*Initial concentrations (mol L^{-1})*		*Initial reaction rates* (*mol* L^{-1} min^{-1})
	$[A]$	$[B]$	
1.	1.0	1.0	0.15
2.	2.0	1.0	0.30
3.	3.0	1.0	0.45
4.	1.0	2.0	0.15
5.	1.0	3.0	0.15

Write down the rate law for the reaction.

Solution: Let the rate law be

$$-\frac{dx}{dt} = k[A]^x[B]^y$$

By keeping the concentration of B constant in experiments (1), (2) and (3) and increasing the concentration uniformly, the rate also increases uniformly. Thus,

$$\text{Rate} \propto [A], \quad i.e., \quad x = 1$$

By keeping the concentration of A constant in experiments (1), (4) and (5) and increasing the concentration of B, the rate remains the same.

Hence, $y = 0$

The rate law is $-\dfrac{dx}{dt} = k[A]$

Alternative method:

From expt. (1), $k[1.0]^x[1.0]^y = 0.15$ ... (i)

From expt. (2), $k[2.0]^x[1.0]^y = 0.30$ ... (ii)

Dividing eq. (ii) by eq. (i),

$$\frac{[2.0]^x}{[1.0]^x} = \frac{0.30}{0.15} = 2$$

So, $x = 1$

From expt. (1), $k[1.0]^x[1.0]^y = 0.15$ ... (i)

From expt. (4), $k[1.0]^x[2.0]^y = 0.15$ ... (iii)

Dividing eq. (iii) by eq. (i),

$$\frac{[2.0]^y}{[1.0]^y} = 1$$

So, $y = 0$

Hence, the rate law is $-\frac{dx}{dt} = k[A]$

Example 15. *For the reaction,*

$$2NO + Cl_2 \longrightarrow 2NOCl$$

at 300K, following data are obtained:

Expt. No.	*Initial Concentration*		*Initial rate*
	[NO]	*[Cl₂]*	
1.	0.010	0.010	1.2×10^{-4}
2.	0.010	0.020	2.4×10^{-4}
3.	0.020	0.020	9.6×10^{-4}

Write rate law for the reaction. What is the order of the reaction? Also calculate the specific rate constant.

Solution: Let the rate law for the reaction be

$$\text{Rate} = k[\text{NO}]^x[\text{Cl}_2]^y$$

From expt. (1), $1.2 \times 10^{-4} = k[0.010]^x[0.010]^y$ ... (i)

From expt. (2), $2.4 \times 10^{-4} = k[0.010]^x[0.020]^y$ ... (ii)

Dividing eq. (ii) by eq. (i),

$$\frac{2.4 \times 10^{-4}}{1.2 \times 10^{-4}} = \frac{[0.020]^y}{[0.010]^y}$$

or $$2 = (2)^y$$

$$y = 1$$

From expt. (2), $2.4 \times 10^{-4} = k[0.010]^x[0.020]^y$ ... (ii)

From expt. (3), $9.6 \times 10^{-4} = k[0.020]^x[0.020]^y$ ... (iii)

Dividing eq. (iii) by eq. (ii),

$$\frac{9.6 \times 10^{-4}}{2.4 \times 10^{-4}} = \frac{[0.020]^x}{[0.010]^x}$$

or $$4 = 2^x$$

$$x = 2$$

Order of reaction $= x + y = 2 + 1 = 3$

Rate law for the reaction is

$$\text{Rate} = k[\text{NO}]^2[\text{Cl}_2]$$

Considering eq. (i) again,

$$1.2 \times 10^{-4} = k[0.010]^2[0.010]$$

$$k = \frac{1.2 \times 10^{-4}}{[0.010]^3} = 1.2 \times 10^2 \text{ mol}^{-2} \text{ L}^2 \text{ s}^{-1}$$

Example 16. *For the hypothetical reaction*

$$2A + B \rightarrow \text{Products}$$

the following data are obtained:

Expt. No.	*Initial conc. of (A) (mol L⁻¹)*	*Initial conc. of (B) (mol L⁻¹)*	*Initial rate mol L⁻¹ s⁻¹*
1.	0.10	0.20	3×10^2
2.	0.30	0.40	3.6×10^3
3.	0.30	0.80	1.44×10^4
4.	0.10	0.40	...
5.	0.20	0.60	...
6.	0.30	1.20	...

Find out how the rate of the reaction depends upon the concentration of A and B and fill in the blanks.

Solution: From expt. (2) and (3), it is clear that when concentration of A is kept constant and that of B is doubled, the rate increases four times. This shows that the reaction is of second order with respect to B.

Similarly, from expt. (1) and (2), it is observed that when concentration of A is increased three times and that of B two times, the rate becomes twelve times. Hence, the reaction is first order with respect to A.

Thus, the rate law for the reaction is:

$$\text{Rate} = k[A][B]^2$$

Fill in the blanks: Substituting the values of expt. (1) in the rate equation,

$$3 \times 10^2 = k[0.10][0.20]^2$$

or $$k = \frac{3 \times 10^2}{[0.10][0.20]^2} = 7.5 \times 10^4 \text{ L}^2 \text{ mol}^{-2} \text{ s}^{-1}$$

Expt. (4): $\text{Rate} = k[0.10][0.40]^2$

$$= 7.5 \times 10^4 \times 0.10 \times 0.40 \times 0.40$$

$$= 1.2 \times 10^3 \text{ mol L}^{-1} \text{ s}^{-1}$$

Expt. (5): $\text{Rate} = k[0.20][0.60]^2$

$$= 7.5 \times 10^4 \times 0.20 \times 0.60 \times 0.60$$

$$= 5.4 \times 10^3 \text{ mol L}^{-1} \text{ s}^{-1}$$

Expt. (6): $\text{Rate} = k[0.30][1.20]^2$

$$= 7.5 \times 10^4 \times 0.30 \times 1.20 \times 1.20$$

$$= 3.24 \times 10^4 \text{ mol L}^{-1} \text{ s}^{-1}$$

Example 17. *The table given below gives kinetic data for the following reaction at 298 K:*

$$OCl^- + I^- \rightarrow OI^- + Cl^-$$

Expt. No.	$[OCl^-]$ *mol dm*$^{-3}$	$[I^-]$ *mol dm*$^{-3}$	$[OH^-]$ *mol dm*$^{-3}$	$10^{-4} \times d[IO^-]/dt$ *mol dm*$^{-3}$*s*$^{-1}$
1.	0.0017	0.0017	1.0	1.75
2.	0.0034	0.0017	1.0	3.50
3.	0.0017	0.0034	1.0	3.50
4.	0.0017	0.0017	0.5	3.50

What is the rate law and what is the value of rate constant?

Solution: Let the rate law be $= k[OCl^-]^x[I^-]^y[OH^-]^z$

From expt. (1), $1.75 \times 10^{-4} = k[0.0017]^x[0.0017]^y[1.0]^z$ ...(i)

From expt. (2), $3.50 \times 10^{-4} = k[0.0034]^x[0.0017]^y[1.0]^z$ ...(ii)

Dividing eq. (ii) by eq. (i),

$$\frac{3.50 \times 10^{-4}}{1.75 \times 10^{-4}} = \frac{[0.0034]^x}{[0.0017]^x}$$

or $$2 = 2^x$$

or $$x = 1, \text{ i.e., first order w.r.t. } OCl^-$$

From expt. (1), $1.75 \times 10^{-4} = k[0.0017]^x[0.0017]^y[1.0]^z$ ...(i)

From expt. (3),

$$3.50 \times 10^{-4} = k[0.0017]^x[0.0034]^y[1.0]^z \quad \text{...(iii)}$$

Dividing eq. (iii) by eq. (i),

$$\frac{3.50 \times 10^{-4}}{1.75 \times 10^{-4}} = \frac{[0.0034]^y}{[0.0017]^y}$$

or $$2 = 2^y$$

or $$y = 1, \text{ i.e., first order w.r.t. } I^-$$

From expt. (1), $1.75 \times 10^{-4} = k[0.0017]^x[0.0017]^y[1.0]^z$ ...(i)

From expt. (4),

$$3.50 \times 10^{-4} = k[0.0017]^x[0.0017]^y[0.5]^z \quad \text{...(iv)}$$

Dividing eq. (i) by eq. (iv),

$$\frac{1.75 \times 10^{-4}}{3.50 \times 10^{-4}} = \frac{[1.0]^z}{[0.5]^z}$$

or $$\frac{1}{2} = 2^z$$

or $$2^{-1} = 2^z$$

$$z = -1, \text{ i.e., order w.r.t. } OH^- \text{ is } -1.$$

$$\text{Rate law} = \frac{k[OCl^-][I^-]}{[OH^-]}$$

From expt. (1) $$k = \frac{1.75 \times 10^{-4}[OH^-]}{[OCl^-][I^-]} = \frac{1.75 \times 10^{-4} \times 1.0}{0.0017 \times 0.0017}$$

$$= 60.55 \text{ s}^{-1}$$

Example 18. *The rate law for the reaction,*

$$2Cl_2O \longrightarrow 2Cl_2 + O_2$$

at 200°C is found to be: $\quad rate = k[Cl_2O]^2$.

(a) How would the rate change if $[Cl_2O]$ is reduced to one-third of its original value?

(b) How should the $[Cl_2O]$ be changed in order to double the rate?

(c) How would the rate change if $[Cl_2O]$ is raised to threefold of its original value?

Solution: (a) Rate equation for the reaction,

$$r = k[Cl_2O]^2$$

Let the new rate be r'; so, $r' = k\left[\frac{Cl_2O}{3}\right]^2 = \frac{1}{9}r$

(b) In order to have the rate $= 2r$, let the concentration of Cl_2O be x.

So, $$2r = kx^2 \quad \text{... (i)}$$

We know that, $$r = k[Cl_2O]^2 \quad \text{... (ii)}$$

Dividing eq. (i) by eq. (ii),

$$\frac{2r}{r} = \frac{kx^2}{k[Cl_2O]^2}$$

or $$2 = \frac{x^2}{[Cl_2O]^2}$$

or $$x^2 = 2[Cl_2O]^2$$

or $$x = \sqrt{2}[Cl_2O]$$

(c) New rate $= k[3Cl_2O]^2 = 9k[Cl_2O]^2 = 9r$

i.e., nine times of the original rate.

Example 19. *For a reaction in which A and B form C, the following data were obtained from three experiments:*

Expt. No.	*Initial conc. (mol L*$^{-1}$*)*		*Initial rate (mol L*$^{-1}$ *s*$^{-1}$*)*
	[A]	*[B]*	
1.	0.03	0.03	0.3×10^{-4}
2.	0.06	0.06	1.2×10^{-4}
3.	0.06	0.09	2.7×10^{-4}

What is the rate equation of the reaction and what is the value of rate constant?

Solution: Let the rate equation be $k[A]^x[B]^y$.

From expt. (1), $0.3 \times 10^{-4} = k[0.03]^x[0.03]^y$ ... (i)

From expt. (2), $1.2 \times 10^{-4} = k[0.06]^x[0.06]^y$ ... (ii)

$$\frac{1.2 \times 10^{-4}}{0.3 \times 10^{-4}} = \frac{[0.06]^x[0.06]^y}{[0.03]^x[0.03]^y}$$

$$= 2^x \times 2^y = 4 \quad \text{... (iii)}$$

Similarly, from expt. (1) and expt. (3),

$$2^x \times 3^y = 9 \qquad \text{... (iv)}$$

Solving eqs. (iii) and (iv),

$$x = 0, y = 2$$

Rate equation, $\text{Rate} = k[B]^2$

Considering eq. (i) again,

$$k = \frac{0.3 \times 10^{-4}}{[0.03]^2} = 3.33 \times 10^{-2} \text{ mol}^{-1} \text{ L s}^{-1}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

14. For the decomposition of HI at 1000 K ($2HI \longrightarrow H_2 + I_2$), the following data were obtained:

[HI], M	**Rate of decomposition of HI (mol L^{-1} s^{-1})**
0.1	2.75×10^{-8}
0.2	11×10^{-8}
0.3	24.75×10^{-8}

The order of reaction is:

(a) 1 (b) 2 (c) 0 (d) 1.5

[Ans. (b)]

[Hint: $\text{Rate} = k\,[\text{HI}]^n$

$$11 \times 10^{-8} = k\,[0.2]^n \qquad \text{... (i)}$$

$$2.75 \times 10^{-8} = k\,[0.1]^n \qquad \text{... (ii)}$$

Dividing eq. (i) by eq. (ii),

$$4 = 2^n, n = 2]$$

15. Consider a reaction, $A \longrightarrow B + C$. If the initial concentration of A was reduced from 2 M to 1 M in 1 hour and from 1 M to 0.25 M in 2 hours, the order of the reaction is:

(a) 1 (b) 0 (c) 2 (d) 3

[Ans. (a)]

[Hint: Half life of the given reaction is independent of initial concentration, hence, it is a first order reaction.

$$t_{1/2} \propto \frac{1}{a^{n-1}} \,]$$

16. The rate of a gaseous reaction is given by the expression $k\,[A]^2[B]^3$. The volume of the reaction vessel is suddenly reduced to one half of the initial volume. The reaction rate relative to the original rate will be:

(a) 1/24 (b) 1/32 (c) 32 (d) 24

[Ans. (c)]

[Hint: $\text{Rate} = k\,[A]^2[B]^3 \qquad \text{... (i)}$

When volume is halved, the concentration will become double.

$$\therefore \quad \text{Rate} = k\,[2A]^2[2B]^3$$

$$= 32k\,[A]^2[B]^3$$

$$= 32 \times \text{Original rate from (i)}]$$

17. For a chemical reaction, $A \longrightarrow B$, the rate of reaction increases by a factor of 1.837 when the concentration of A is increased by 1.5 times. The order of reaction with respect to A is:

(a) 1 (b) 1.5 (c) 2 (d) –1

[Ans. (b)]

[Hint: $\text{Rate} = k\,[A]^n \qquad \text{... (i)}$

$$1.837 \times \text{Rate} = k\,[1.5A]^n \qquad \text{... (ii)}$$

Dividing eq. (ii) by eq. (i),

$$1.837 = 1.5^n$$

$\therefore \quad n = 3/2$ (solving by logarithmic method)]

18. The rate of the reaction,

$$3A + 2B \longrightarrow \text{Products}$$

is given by the rate expression:

$$\text{Rate} = k\,[A][B]^2$$

If A is taken in excess, the order of the reaction would be:

(a) 3 (b) 2 (c) 1 (d) 5

[Ans. (b)]

[Hint: When A is taken in excess, its concentration will become constant; the rate law may, therefore, be given as:

$$\text{Rate} = k'[B]^2 \quad \text{Order} = 2]$$

19. For a reaction $A + B \longrightarrow C + D$, if the concentration of A is doubled without altering the concentration of B, the rate gets doubled. If the concentration of B is increased by nine times without altering the concentration of A, the rate gets tripled. The order of the reaction is: **(KCET 2006)**

(a) 2 (b) 1 (c) 3/2 (d) 4/3

[Ans. (c)]

[Hint: $\text{Rate} = k[A]^\alpha[B]^\beta \qquad \text{... (i)}$

$$2 \times \text{rate} = k[2A]^\alpha[B]^\beta \qquad \text{... (ii)}$$

$$3 \times \text{rate} = k[A]^\alpha[9B]^\beta \qquad \text{... (iii)}$$

From eqs. (i) and (ii), $\alpha = 1$

From eqs. (i) and (iii), $\beta = 1/2$

$$\text{Order} = \alpha + \beta = 1 + \frac{1}{2} = \frac{3}{2}\,]$$

20. Inversion of cane sugar in dilute acid is: **[CET (J&K) 2007]**

(a) bimolecular reaction

(b) pseudo-unimolecular reaction

(c) unimolecular reaction

(d) trimolecular reaction

[Ans. (b)]

[Hint: $C_{12}H_{22}O_{11} + H_2O \xrightarrow{H^+} C_6H_{12}O_6 + C_6H_{12}O_6$

$$\text{Rate} = k\,[C_{12}H_{22}O_{11}][H_2O]$$

When water is in excess, its concentration will be constant.

$$\therefore \quad \text{Rate} = k'[C_{12}H_{22}O_{11}]$$

The reaction is, therefore, pseudo first order or pseudo unimolecular reaction.]

21. The bromination of acetone that occurs in acid solution is represented by

$$CH_3COCH_3(aq.) + Br_2(aq.) \longrightarrow CH_3COCH_2Br\,(aq.) + H^+(aq.) + Br^-\,(aq.)$$

These kinetic data were obtained for given reaction concentrations:

Initial concentrations (M)			Initial rate of disappearance of Br_2, $M\,s^{-1}$
$[CH_3COCH_3]$	$[Br_2]$	$[H^+]$	
0.30	0.05	0.05	5.7×10^{-5}
0.30	0.10	0.05	5.7×10^{-5}
0.30	0.10	0.10	1.2×10^{-4}
0.40	0.05	0.20	3.1×10^{-4}

[CBSE (PMT) 2008]

Based on these data, rate equation is :

(a) Rate $= k[CH_3COCH_3][Br_2][H^+]^2$

(b) Rate $= k[CH_3COCH_3][Br_2][H^+]$

(c) Rate $= k[CH_3COCH_3][H^+]$

(d) Rate $= k[CH_3COCH_3][Br_2]$

[Ans. (c)]

[Hint : Rate $= k[CH_3COCH_3]^{\alpha}[Br_2]^{\beta}[H^+]^{\gamma}$

$$5.7\times10^{-5} = k[0.30]^{\alpha}[0.05]^{\beta}[0.05]^{\gamma} \quad ...(i)$$

$$5.7\times10^{-5} = k[0.30]^{\alpha}[0.10]^{\beta}[0.05]^{\gamma} \quad ...(ii)$$

$$1.2\times10^{-4} = k[0.30]^{\alpha}[0.10]^{\beta}[0.10]^{\gamma} \quad ...(iii)$$

$$3.1\times10^{-4} = k[0.40]^{\alpha}[0.05]^{\beta}[0.20]^{\gamma} \quad ...(iv)$$

Dividing eq. (i) by eq. (ii),

$$1 = \left[\frac{1}{2}\right]^{\beta}, \quad i.e., \quad \beta = 0$$

Dividing eq. (ii) by eq. (iii),

$$\frac{1}{2} = \left[\frac{1}{2}\right]^{\gamma}, \quad i.e., \quad \gamma = 1$$

Dividing eq. (i) by eq. (iv),

$$\frac{5.7\times10^{-5}}{3.1\times10^{-4}} = \left[\frac{3}{4}\right]^{\alpha}\times\left[\frac{1}{4}\right]^{1}$$

$$\alpha \simeq 1$$

Thus, rate law will be

rate $= k[CH_3COCH_3]^1[H^+]^1$]

8.9 REACTION MECHANISM

Knowledge about involved steps in a reaction, and to determine which step is slowest or rate determining, is called mechanism.

The intelligent guess depending on the observed rates of reactions about the series of steps (known as elementary processes) leading to the formation of products is called the reaction mechanism.

For illustration a few examples of reaction mechanisms are given below:

1. The reaction between H_2 and I_2 to form hydrogen iodide was originally postulated as a simple one step reaction.

$$H_2 + I_2 = 2HI$$

$$\text{Rate} = k[H_2][I_2]$$

But, the formation of HI has been explained on the basis of the following mechanism:

$$\begin{array}{lll} I_2 \longrightarrow 2I & \text{(fast)} & ...(i) \\ H_2 + I \longrightarrow H_2I & \text{(fast)} & ...(ii) \\ H_2I + I \longrightarrow 2HI & \text{(slow)} & ...(iii) \\ \hline \end{array}$$

$$\text{Overall reaction:} \quad H_2 + I_2 \longrightarrow 2HI$$

2. The reaction of NO and Br_2 is known to be of second order in NO and first order in Br_2.

$$2NO + Br_2 \longrightarrow 2NOBr$$

$$\text{Rate} = k[NO]^2[Br_2]$$

The likelihood of three molecules (2 molecules of NO and 1 molecule of Br_2) colliding simultaneously is far less than the likelihood that two molecules will collide.

The mechanism is believed to be as under:

$$\begin{array}{lll} NO + Br_2 \xrightarrow{k'} NOBr_2 & \text{(fast)} & ...(i) \\ NOBr_2 + NO \xrightarrow{k''} 2NOBr & \text{(slow)} & ...(ii) \\ \hline \end{array}$$

$$\text{Overall reaction: } 2NO + Br_2 \xrightarrow{k} 2NOBr$$

The rate determining step involves 1 molecule of NO and 1 molecule of $NOBr_2$. Thus, the expected rate expression should be

$$\text{Rate} = k''[NOBr_2][NO]$$

However, $NOBr_2$ is a reaction intermediate and its concentration at the beginning of second step cannot be directly measured.

Concentration of $NOBr_2$ will be equal to

$$[NOBr_2] = k'[NO][Br_2]$$

If this is substituted in the above equation, we get

$$\text{Rate} = k'k''[NO]^2[Br_2]$$

$$= k[NO]^2[Br_2]$$

3. Depletion of ozone takes place in the following steps:

Overall reaction:

$$2O_3 \longrightarrow 3O_2$$

Step 1: $O_3 \rightleftharpoons O_2 + [O]$ (fast)

(Equilibrium constant K_c)

Step 2: $O_3 + [O] \xrightarrow{k} 2O_2$ (slow)

$$\text{Rate} = k[O_3][O] \quad ...(i)$$

Nascent oxygen [O] is not present in overall reaction; thus it should be eliminated.

$$K_c = \frac{[O_2][O]}{[O_3]}; \; [O] = K_c\frac{[O_3]}{[O_2]} \quad ...(ii)$$

From eqs. (i) and (ii),

$$\text{Rate} = k[O_3]\cdot K_c\frac{[O_3]}{[O_2]}$$

$$= k\,K_c[O_3]^2[O_2]^{-1}$$

$$= K[O_3]^2[O_2]^{-1}$$

$$K = k\times K_c$$

$$\text{Order} = 2 - 1 = 1$$

8.10 REACTIONS OF VARIOUS ORDERS

(i) Zero order reactions

A reaction is said to be of zero order if its rate is independent of the concentration of the reactants, *i.e.*, the rate is proportional to the zeroth power of the concentration of the reactants.

For the reaction

$$A \longrightarrow \text{Products}$$

to be of zero order,

$$-\frac{dx}{dt} = k[A]^0 = k$$

Some photochemical reactions and a few heterogeneous reactions are zero order reactions. Such reactions are not common.

Examples:

1. Photochemical reaction between hydrogen and chlorine:

$$H_2(g) + Cl_2(g) \xrightarrow{h\nu} 2HCl(g)$$

This photochemical reaction is zero order reaction. The reaction is studied by placing H_2 and Cl_2 gases over water. The rate of reaction is studied by noting the rate at which water rises in the vessel due to dissolution of HCl formed. The rate of rise of water is the same as the rate of disappearance of H_2 and Cl_2, *i.e.*, the concentration of the gases per unit volume in the gaseous phase will not change with time, although the quantities will change.

2. Decomposition of N_2O on hot platinum surface:

$$N_2O \longrightarrow N_2 + \frac{1}{2}O_2$$

$$\text{Rate} \propto [N_2O]^0 = k[N_2O]^0 = k$$

or

$$\frac{d[N_2O]}{dt} = k$$

3. Decomposition of NH_3 in presence of molybdenum or tungsten is a zero order reaction.

$$2NH_3 \xrightarrow{[Mo]} N_2 + 3H_2$$

The surface of the catalyst is almost completely covered by NH_3 molecules. The adsorption of gas on the surface cannot change by increasing the pressure or concentration of NH_3. Thus, the concentration of gas phase remains constant although the product is formed. Therefore, this reaction shows zero order kinetics.

Other examples of zero order are:

4. Decomposition of HI on the gold surface.
5. Iodation of acetone in presence of H^+ ions,

$$CH_3COCH_3 + I_2 \xrightarrow{H^+} ICH_2COCH_3 + HI$$

The rate equation of this reaction does not include $[I_2]$ factor, *i.e.*,

$$-\frac{dx}{dt} = k[CH_3COCH_3][H^+]$$

Characteristics of zero order reaction

(a) The concentration of reactant decreases linearly with time.

$$[A]_t = [A]_0 - kt$$

(b) The time required for the reaction to be complete, *i.e.*, time at which $[A]$ is zero.

$$t_{\text{Completion}} = \frac{[A]_0}{k} = \frac{\text{Initial concentration}}{\text{Rate constant}}$$

(c) The units of k are mol L^{-1} time^{-1}.

(ii) First order reactions

A reaction is said to be of first order if its rate is determined by the change of one concentration term only.

Consider the reaction,

$$A \longrightarrow \text{Products}$$

Let a be the concentration of A at the start and after time t, the concentration becomes $(a-x)$, *i.e.*, x has been changed into products. The rate of reaction after time 't' is given by the expression

$$\frac{dx}{dt} = k(a-x)$$

or

$$\frac{dx}{(a-x)} = k\,dt$$

upon integration of above equation,

$$\int \frac{dx}{(a-x)} = k\int dt$$

or

$$-\log_e (a-x) = kt + c$$

where c is integration constant.

When $t = 0$, $x = 0$,

$$\therefore \quad c = -\log_e a$$

Putting the value of 'c',

$$-\log_e (a-x) = kt - \log_e a$$

or

$$\log_e a - \log_e (a-x) = kt$$

or

$$\log_e \frac{a}{(a-x)} = kt$$

or

$$k = \frac{2.303}{t}\log_{10}\frac{a}{(a-x)}$$

This is known as the kinetic equation for a reaction of the first order. The following two important conclusions are drawn from this equation:

(a) A change in concentration unit will not change the numerical value of *k*. Let the new unit be n times the first one.

So,

$$k = \frac{2.303}{t}\log_{10}\frac{na}{n(a-x)}$$

or

$$k = \frac{2.303}{t}\log_{10}\frac{a}{(a-x)}$$

Thus, for first order reactions, any quantity which is proportional to concentration can be used in place of concentration for evaluation of 'k'.

(b) The time taken for the completion of same fraction of change is independent of initial concentration. For example, for half change,

$$x = 0.5a \quad \text{and} \quad t = t_{1/2}$$

So,

$$k = \frac{2.303}{t_{1/2}}\log_{10}\frac{a}{0.5a} = \frac{2.303}{t_{1/2}}\log_{10} 2$$

$$= \frac{0.693}{t_{1/2}}$$

or $$t_{1/2} = \frac{0.693}{k}$$

Thus, $t_{1/2}$ is independent of initial concentration 'a'.

This time 't' in which the initial concentration becomes half is termed as **half life period.** Half life period of a first order reaction is independent of the initial concentration of the reactant.

Since, the velocity constant is independent of concentration and depends inversely on the time, the unit of k will be time^{-1}, *i.e.*, sec^{-1} or min^{-1} or hour^{-1}. The equation of the first order can also be written in the following form when initial concentration is not known:

$$k = \frac{2.303}{(t_2 - t_1)} \log_{10} \frac{(a - x_1)}{(a - x_2)}$$

$(a - x_1)$ is the concentration after time t_1 and $(a - x_2)$ the concentration after time t_2 when $t_2 > t_1$.

When the log of the concentration of the reactant at various intervals of time is plotted against the time intervals, a straight line is obtained (Fig. 8.13). The slope of this line gives the value 2.303/k, from which k can be evaluated.

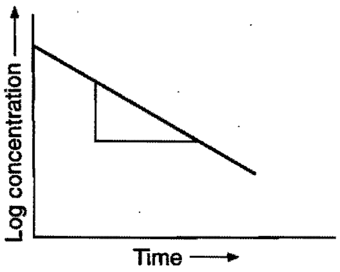


Fig. 8.13

Examples of first order reactions

1. Decomposition of H_2O_2 in aqueous solution.

$$H_2O_2 \longrightarrow H_2O + \frac{1}{2} O_2$$

2. Hydrolysis of methyl acetate in presence of mineral acids.

$$CH_3COOCH_3 + H_2O \xrightarrow{\text{Acid}} CH_3COOH + CH_3OH$$

3. Inversion of cane sugar in presence of mineral acids.

$$C_{12}H_{22}O_{11} + H_2O \xrightarrow{\text{Acid}} C_6H_{12}O_6 + C_6H_{12}O_6$$

4. Decomposition of ammonium nitrite in aqueous solution.

$$NH_4NO_2 \longrightarrow N_2 + 2H_2O$$

5. Hydrolysis of diazo derivatives.

$$C_6H_5N{=}NCl + H_2O \longrightarrow C_6H_5OH + N_2 + HCl$$

Note: In case of gases, pressure can be used in place of concentration.

First order growth kinetics

It is used for population growth and bacteria multiplication, *e.g.*,

Time	*Population*
0	a
dt	$(a + x)$

Growth rate is directly proportional to present population.

$$\frac{dx}{dt} \propto (a + x)$$

$$= k(a + x)$$

$$\frac{dx}{(a + x)} = k\,dt \qquad \text{... (i)}$$

It is a differential equation of first order and first degree in variable separable form. It may be solved on integration.

$$\int \frac{dx}{(a + x)} = k \int dt + c$$

$$\log_e (a + x) = kt + c \qquad \text{... (ii)}$$

Here, c = integration constant

At $t = 0$, $x = 0$

$\therefore$ $$\log_e a = k \times 0 + c$$

$$c = \log_e a \qquad \text{... (iii)}$$

Substituting the value of 'c' in eq. (ii), we get

$$\log_e (a + x) = kt + \log_e a$$

$$kt = -\log_e \frac{a}{(a + x)}$$

$$k = -\frac{2.303}{t} \log_{10} \left(\frac{a}{a + x}\right)$$

This is the kinetics for first order growth kinetics.

Note: (1) If volumes of reagents are given in volumetric analysis then we use the following equation to determine rate constant:

$$k = \frac{2.303}{t} \log_{10} \frac{V_\infty - V_0}{V_\infty - V_t}$$

where, V_0 = volume used at zero time,
V_t = volume used at time 't',
V_∞ = volume used at infinite time

Case I: When V_0 is not given, we use

$$k = \frac{2.303}{t} \log_{10} \frac{V_\infty}{V_\infty - V_t}$$

Case II: When V_∞ is not given, then

$$k = \frac{2.303}{t} \log_{10} \left(\frac{V_0}{V_t}\right)$$

(2) If information is given in terms of angle of rotation of optically active compounds, measured by polarimeter with respect to time, then

$$k = \frac{2.303}{t} \log_{10} \left\{\frac{r_\infty - r_0}{r_\infty - r_t}\right\}$$

where, r_0 = angle of rotation at zero time,
r_t = angle of rotation at time 't',
r_∞ = angle of rotation at infinite time

Case I: If r_0 is not given, then

$$k = \frac{2.303}{t}\log_{10}\left\{\frac{r_\infty}{r_\infty - r_t}\right\}$$

Case II: If r_∞ is not given, then

$$k = \frac{2.303}{t}\log_{10}\left\{\frac{r_0}{r_t}\right\}$$

(3) If pressure is given in gaseous reactions, then we use the following kinetic equation:

$$k = \frac{2.303}{t}\log_{10}\left\{\frac{p_0}{p_0 - x}\right\}$$

where, p_0 = pressure of reactant at initial stage,

$(p_0 - x)$ = pressure of such a reactant at 't' time.

Values of 'p_0' and 'x' can be calculated using the following examples:

	$A(g) \longrightarrow$	$B(g) +$	$C(g) +$	$D(g)$
At $t = 0$	p_0	0	0	0
Pressure after time 't'	$(p_0 - x)$	x	x	x
Pressure after a long time or infinite time	0	p_0	p_0	p_0

Case I: If total pressure of reaction mixture is given in place of pressure of reactant, then

$$p_t = (p_0 - x + x + x + x)$$

where, p_t = pressure of vessel at time 't'.

Case II: If pressure of vessel after a long time or infinite time is given, then

$$p_\infty = p_0 + p_0 + p_0$$

(iii) Second order reactions

A reaction is said to be of second order if its reaction rate is determined by the variation of two concentration terms.

The kinetics of second order reactions are given as follows:

(a) When concentrations of both reactants are equal or two molecules of the same reactant are involved in the change, *i.e.*,

$$A + B \longrightarrow \text{Products}$$

or

$$2A \longrightarrow \text{Products}$$

$$\frac{dx}{dt} = k(a - x)^2,$$

On solving this equation,

$$k = \frac{1}{t}\cdot\frac{x}{a(a - x)}$$

where, a = initial concentration of the reactant or reactants and
x = concentration of the reactant changed in time t.

(b) When the initial concentrations of the two reactants are different, *i.e.*,

$$A + B \longrightarrow \text{Products}$$

Initial conc. $\quad a \quad b$

$$\frac{dx}{dt} = k(a - x)(b - x)$$

$$k = \frac{2.303}{t(a - b)}\log_{10}\frac{b(a - x)}{a(b - x)}$$

$(a - x)$ and $(b - x)$ are the concentrations of A and B after time interval, t.

Characteristics of the second order reactions

(i) The value of k (velocity constant) depends on the unit of concentration. The unit of k is expressed as $(\text{mol/litre})^{-1}\ \text{time}^{-1}$ or litre $\text{mol}^{-1}\ \text{time}^{-1}$.

(ii) Half life period $(t_{1/2}) = \dfrac{1}{k}\cdot\dfrac{0.5a}{a \times 0.5a} = \dfrac{1}{ka}$

Thus, half life is inversely proportional to initial concentration.

(iii) Second order reaction conforms to the first order when one of the reactants is present in large excess.

Taking, $k = \dfrac{2.303}{t(a - b)}\log_{10}\dfrac{b(a - x)}{a(b - x)}$, if $a >>> b$ then

$$(a - x) \approx a \text{ and } (a - b) \approx a$$

Hence, $$k = \frac{2.303}{ta}\log_{10}\frac{ba}{a(b - x)}$$

or $$ka = k' = \frac{2.303}{t}\log_{10}\frac{b}{(b - x)}$$

(since, 'a' being very large, may be treated as constant after the change). Thus, the reaction follows first order kinetics with respect to the reactant taken relatively in small amount.

Examples of second order reactions

1. Hydrolysis of ester by an alkali (saponification).

$$CH_3COOC_2H_5 + NaOH \longrightarrow CH_3COONa + C_2H_5OH$$

2. The decomposition of NO_2 into NO and O_2.

$$2NO_2 \longrightarrow 2NO + O_2$$

3. Conversion of ozone into oxygen at 100°C.

$$2O_3 \longrightarrow 3O_2$$

4. Thermal decomposition of chlorine monoxide.

$$2Cl_2O \longrightarrow 2Cl_2 + O_2$$

(iv) Third order reactions

A reaction is said to be of third order if its rate is determined by the variation of three concentration terms.

When the concentration of all the three reactants is same or three molecules of the same reactant are involved, the rate expression is given as:

$$3A \longrightarrow \text{Products}$$

$$A + B + C \longrightarrow \text{Products}$$

$$\frac{dx}{dt} = k(a - x)^3$$

On solving this equation,

$$k = \frac{1}{t}\cdot\frac{x(2a - x)}{2a^2(a - x)^2}$$

Characteristics of third order reactions

1. Half life period

$$= \frac{1}{k}\cdot\frac{0.5a(2a - 0.5a)}{2a^2(0.5a)^2} = \frac{1}{k}\,\frac{0.5a \times 1.5a}{2a^2 \times 0.5a \times 0.5a}$$

$$= \frac{3}{2a^2k}$$

Thus, half life is inversely proportional to the square of initial concentration.

2. The change in the unit of concentration changes the numerical value of k.

3. The unit of k is expressed as $(\text{mol/litre})^{-2}\ \text{time}^{-1}$ or $\text{litre}^2\ \text{mol}^{-2}\ \text{time}^{-1}$.

Examples of third order reactions

1. Reaction between nitric oxide and oxygen.

$$2NO + O_2 \longrightarrow 2NO_2$$

2. Reaction between nitric oxide and chlorine.

$$2NO + Cl_2 \longrightarrow 2NOCl$$

3. Reduction of $FeCl_3$ by $SnCl_2$.

$$2FeCl_3 + SnCl_2 \longrightarrow SnCl_4 + 2FeCl_2$$

Expressions for rate constant for reactions of different orders:

Reaction	Order	Rate law eqn.	Expression for rate const.
$A \to$ Products	0	Rate $= k$	$k = \frac{1}{t}\left[[A]_0 - [A]\right]$
$A \to$ Products	1	Rate $= k[A]$	$k = \frac{2.303}{t}\log\frac{[A]_0}{[A]}$
$2A \to$ Products	2	Rate $= k[A]^2$	$k = \frac{1}{t}\left[\frac{1}{[A]} - \frac{1}{[A]_0}\right]$
$A + B \to$ Products	2	Rate $= k[A][B]$	$k = \frac{2.303}{t([A]_0 - [B]_0)}\log\frac{[B]_0[A]}{[A]_0[B]}$
$3A \to$ Products	3	Rate $= k[A]^3$	$k = \frac{1}{2t}\left[\frac{1}{[A]^2} - \frac{1}{[A]_0^2}\right]$

Parallel or Competing reaction

The reaction in which a substance reacts or decomposes in more than one way are called parallel or side reactions,

$$\begin{tikzcd} & B \\ A \arrow[ur, "k_1"] \arrow[dr, "k_2"'] & \\ & C \end{tikzcd}$$

$$\frac{-d[A]}{dt} = (k_1 + k_2)[A] = k_{av}[A]$$

$$k_1 = \text{fractional yield of } B \times k_{av}$$
$$k_2 = \text{fractional yield of } C \times k_{av}$$

If $k_1 >> k_2$ then,

$A \longrightarrow B$ main and
$A \longrightarrow C$ is side reaction

Let after a definite interval x mol/litre of B and y mol/litre of C are formed.

$$\frac{x}{y} = \frac{k_1}{k_2}$$

i.e.,
$$\frac{d[B]}{dt} \Big/ \frac{d[C]}{dt} = \frac{k_1}{k_2}$$

Variation of concentration A, B and C with time may be graphically represented as,

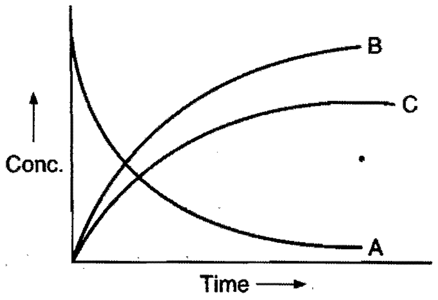

Fig. 8.14

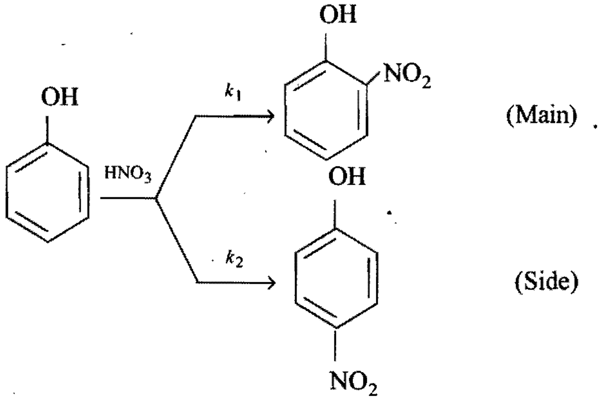
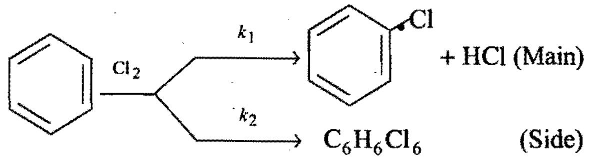
Examples:

(i)



(ii)



Consecutive reaction

This reaction is defined as that reaction which proceeds from reactants to final products through one or more intermediate stages. The overall reaction is a result of several successive or consecutive steps.

$$A \longrightarrow B \longrightarrow C \text{ and so on}$$

Examples: (i) Decomposition of ethylene oxide:

$$(CH_2)_2O \xrightarrow{k_1} CH_3CHO$$
$$CH_3CHO \xrightarrow{k_2} CO + CH_4$$

(ii) The pyrolysis of acetone:

$$(CH_3)_2CO \longrightarrow CH_4 + \underset{\text{Ketene}}{CH_2{=}C{=}O}$$

$$CH_2 = C = O \longrightarrow \frac{1}{2} C_2H_4 + CO$$

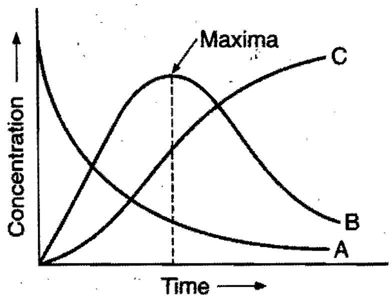


Fig. 8.15
Variation of concentration of various substances during the progress of reaction ($A \rightarrow B \rightarrow C$)

$$A \xrightarrow{k_1} B \xrightarrow{k_2} C$$

Let initially ($t = 0$), $[B] = 0$ and $k_1 < k_2$ then maximum concentration of $[B]$ may be calculated as,

$$[B]_{\max} = [A]_0 \left[\frac{k_1}{k_2}\right]^{k_2/k_1 - k_2}$$

where, $[A]_0$ = initial concentration of A

Time in which B attains maximum concentration may be given as,

$$t_{\max} = \frac{2.303}{k_2 - k_1} \log\left(\frac{k_2}{k_1}\right)$$

Concentration of $[B]$ after time 't' may be calculated as,

$$[B]_t = \frac{k_1 [A]_0}{k_2 - k_1}[e^{-k_1 t} - e^{-k_2 t}]$$

Activation energy diagram of a composite reaction involves more than one peaks and number of peaks indicate the number of different types of activated complexes involved. The number of valleys in the activation energy diagram indicates the number of different types of reactive intermediates involved.

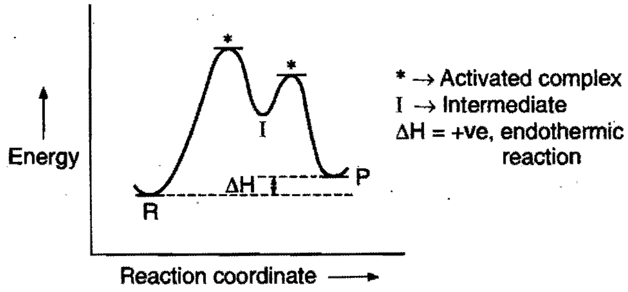

Fig. 8.16 Activation energy diagram of a two steps composite reaction

Energy Diagram of two Steps Reaction

Let us consider a reaction of the type :

$$A \xrightarrow{\text{Step 1}} B \xrightarrow{\text{Step 2}} C \quad \text{(Exothermic)}$$

These are two possibilities in this reaction

First possibility :

Step 1 $A \longrightarrow A^* \longrightarrow B$

Step 2 $B \longrightarrow B^* \longrightarrow C$

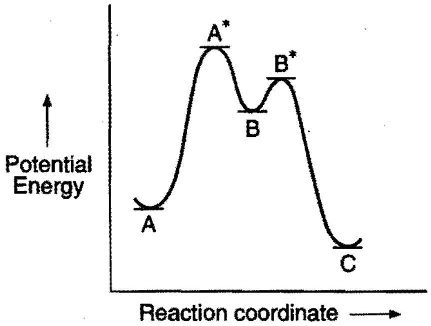

Fig. 8.17

Activation energy of **step 1** is greater than that of **step 2** thus **step 1** will be slow and rate determining.

Second possibility :

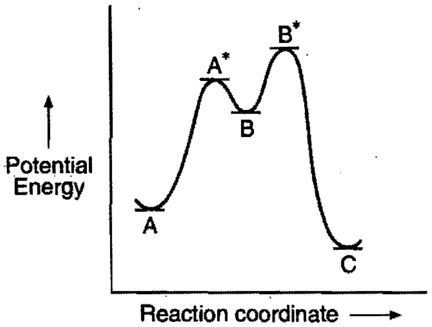

Fig. 8.18

Activation energy of **step 2** is greater than that of **step 1** hence **step 2** will be slow and rate determining

Reversible Reactions

The reactions in which the products of chemical change react together to form the original reactants, are called reversible reactions. These are also called opposing or counter reactions.

Let us consider a reversible reaction in which both forward and backward reactions are of first order.

$$A \underset{k_2}{\overset{k_1}{\rightleftharpoons}} B$$

Initial state ($t = 0$)	a	0
Conc. at time (t)	$a - x$	x
Equilibrium conc.	$(a - x_e)$	x_e

$$k_1 + k_2 = \frac{2.303}{t} \log_{10}\left\{\frac{x_e}{x_e - x}\right\}$$

8.11 METHODS FOR DETERMINATION OF ORDER OF A REACTION

The important methods used are the following:

1. Method of integration (Hit and trial method)

The most simple method is the one in which the quantities a, x and t are determined and substituted in the kinetic equations of various orders. The equation which gives the most constant value for the specific rate constant (k) for a series of time intervals is the one corresponding to the order of reaction. If all the reactants are at the same molar concentrations, the kinetic equations are:

$$k = \frac{2.303}{t} \log_{10} \frac{a}{(a-x)}, \text{ for first order reactions;}$$

$$k = \frac{1}{t}\left[\frac{1}{(a-x)} - \frac{1}{a}\right], \quad \text{for second order reactions;}$$

$$k = \frac{1}{2t}\left[\frac{1}{(a-x)^2} - \frac{1}{a^2}\right], \text{ for third order reactions.}$$

2. Graphical method

A graphical method based on the respective rate laws can also be used.

If the plot of $\log (a-x)$ *versus* 't' is a straight line, the reaction follows first order.

If the plot of $\frac{1}{(a-x)}$ *versus* 't' is a straight line, the reaction follows second order.

If the plot of $\frac{1}{(a-x)^2}$ *versus* 't' is a straight line, the reaction follows third order.

In general, for a reaction of nth order, a graph of $\frac{1}{(a-x)^{n-1}}$ *versus* 't' must be a straight line.

3. Half life method

A general expression for the half life, $(t_{1/2})$, is given by

$$t_{1/2} \propto \frac{1}{a^{n-1}}$$

where, 'n' is the order of the reaction.

Starting with two different initial concentrations a_1 and a_2 for the same reaction, the half lives are $(t_{1/2})_1$ and $(t_{1/2})_2$ respectively are determined. As we know that,

$$(t_{1/2})_1 \propto \frac{1}{a_1^{n-1}} \quad \text{... (i)}$$

and

$$(t_{1/2})_2 \propto \frac{1}{a_2^{n-1}} \quad \text{... (ii)}$$

Dividing eq. (i) by eq. (ii),

$$\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{a_2}{a_1}\right)^{n-1} \quad \text{... (iii)}$$

Taking logarithms on both sides,

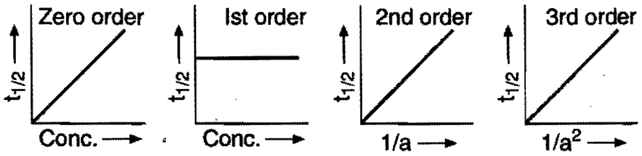
$$\log_{10} (t_{1/2})_1 - \log_{10} (t_{1/2})_2 = (n-1)[\log_{10} a_2 - \log_{10} a_1]$$

$$(n-1) = \frac{\log_{10} (t_{1/2})_1 - \log_{10} (t_{1/2})_2}{\log_{10} a_2 - \log_{10} a_1}$$

or

$$n = 1 + \frac{\log_{10} (t_{1/2})_1 - \log_{10} (t_{1/2})_2}{\log_{10} a_2 - \log_{10} a_1} \quad \text{... (iv)}$$

Plots of half lives *vs.* concentration $(t_{1/2} \propto a^{1-n})$:



This relation can be used to determine order of reaction 'n'.

4. van't Hoff differential method

As we know that, the rate of a reaction varies as the nth power of the concentration of the reactant where 'n' is the order of the reaction. Thus, for two different initial concentrations C_1 and C_2, equations can be written in the form

$$-\frac{dC_1}{dt} = kC_1^n \text{ and } -\frac{dC_2}{dt} = kC_2^n$$

Taking logarithms,

$$\log_{10}\left(-\frac{dC_1}{dt}\right) = \log_{10} k + n \log_{10} C_1 \quad \text{... (i)}$$

and

$$\log_{10}\left(-\frac{dC_2}{dt}\right) = \log_{10} k + n \log_{10} C_2 \quad \text{... (ii)}$$

Subtracting eq. (ii) from eq. (i),

$$\log_{10}\left(-\frac{dC_1}{dt}\right) - \log_{10}\left(\frac{-dC_2}{dt}\right) = n(\log_{10} C_1 - \log_{10} C_2)$$

or

$$n = \frac{\log_{10}\left(-\frac{dC_1}{dt}\right) - \log_{10}\left(-\frac{dC_2}{dt}\right)}{\log_{10} C_1 - \log_{10} C_2} \quad \text{... (iii)}$$

$-\frac{dC_1}{dt}$ and $-\frac{dC_2}{dt}$ are determined from concentration *vs.* time graphs and the value of 'n' can be determined.

SOME SOLVED EXAMPLES

Example 20. *Rate of a reaction $A + B \longrightarrow$ product, is given as a function of different initial concentrations of A and B.*

$[A]$ (*mol* L^{-1})	$[B]$ (*mol* L^{-1})	*Initial rate* (*mol* L^{-1} *min*$^{-1}$)
0.01	0.01	0.005
0.02	0.01	0.010
0.01	0.02	0.005

Determine the order of the reaction with respect to A and w.r.t. B. What is the half life of A in the reaction?

Solution: Let the rate of reaction be

$$\text{Rate} = k[A]^x[B]^y$$

From the data given, it is clear that by doubling the concentration of A, the rate also becomes double when B is kept constant. Thus, the rate is directly proportional to concentration of A.

$$\text{Rate} \propto [A], \quad i.e., \quad x = 1$$

Or the order of reaction w.r.t. A is 1.

When the concentration of A is kept constant and the concentration of B is doubled, the rate does not change, *i.e.*, $y = 0$; or the order of reaction w.r.t. B is zero.

Thus, reaction rate, $$-\frac{dx}{dt} = k[A]$$

Again $$k = \frac{0.005}{0.01} = 0.5\ \text{min}^{-1}$$

$$\text{Half life of } A = \frac{0.693}{k} = \frac{0.693}{0.5} = 1.386\ \text{min}$$

Example 21. *Thermal decomposition of a compound is of the first order. If 50% of a sample of the compound is decomposed in 120 minutes, how long will it take for 90% of the compound to decompose?*

Solution: Half life of reaction = 120 min

We know that,

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{120} = 5.77 \times 10^{-3}\ \text{min}^{-1}$$

Applying first order reaction equation,

$$t = \frac{2.303}{k}\log_{10}\frac{a}{a-x}$$

If $a = 100$, $x = 90$ or $(a - x) = 10$,

So, $$t = \frac{2.303}{5.77 \times 10^{-3}} \cdot \log_{10} 10 = \frac{2.303}{5.77 \times 10^{-3}} = 399\ \text{min}$$

Example 22. *The decomposition of Cl_2O_7 at 400 K in the gas phase to Cl_2 and O_2 is a first order reaction.*

(i) After 55 seconds at 400 K, the pressure of Cl_2O_7 falls from 0.062 to 0.044 atm. Calculate the rate constant.

(ii) Calculate the pressure of Cl_2O_7 after 100 seconds of decomposition at this temperature.

Solution: (i) As pressure ∝ concentration,

$$k = \frac{2.303}{t}\log_{10}\frac{P_i\ \text{(initial pressure)}}{P_t\ \text{(pressure after time } t)}$$

$$= \frac{2.303}{55}\log_{10}\frac{0.062}{0.044} = 6.2 \times 10^{-3}\ \text{s}^{-1}$$

(ii) Again applying the first order kinetic equation,

$$k = \frac{2.303}{t}\log_{10}\frac{P_i\ \text{(initial pressure)}}{P_t\ \text{(pressure after time } t)}$$

$$6.2 \times 10^{-3} = \frac{2.303}{100}\log_{10}\frac{0.062}{P_t}$$

or $$\frac{6.2 \times 10^{-3} \times 100}{2.303} = \log_{10} 0.062 - \log_{10}(P_t)$$

or $$0.2692 = \log_{10} 0.062 - \log_{10}(P_t)$$

or $$\log_{10}(P_t) = \log_{10} 0.062 - 0.2692$$

$$= (\bar{2}.7924 - 0.2692)$$

$$P_t = 0.033\ \text{atmosphere}$$

Pressure after 100 sec = 0.033 atm

Example 23. *The half life of a first order reaction is 60 min. How long will it take to consume 90% of the reactant?*

Solution: For the first order reaction

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{60} = 11.55 \times 10^{-3}\ \text{min}^{-1}$$

Applying first order kinetic equation,

$$t = \frac{2.303}{k}\log_{10}\frac{a}{(a-x)}$$

Given: $a = 100, x = 90$, *i.e.*, $(a - x) = (100 - 90) = 10$

Hence, $$t = \frac{2.303}{11.55 \times 10^{-3}} \cdot \log_{10} 10$$

$$= 199\ \text{min}$$

Example 24. *A first order reaction has a rate constant of $15 \times 10^{-3}\ s^{-1}$. How long will 5.0 g of this reactant take to reduce to 3.0 g?*

Solution: Applying first order kinetic equation,

$$t = \frac{2.303}{k}\log_{10}\frac{a}{(a-x)}$$

Given: $k = 15 \times 10^{-3}\ \text{sec}^{-1}, a = 5\ \text{g}, (a - x) = 3\ \text{g}$

So, $$t = \frac{2.303}{15 \times 10^{-3}}\log_{10}\frac{5}{3} = 34.07\ \text{sec}$$

Example 25. *Catalytic decomposition of nitrous oxide by gold at 900°C at an initial pressure of 200 mm was 50% in 53 minutes and 73% in 100 minutes.*

(a) What is the order of reaction?

(b) How much it will decompose in 100 minutes at the same temperature but at an initial pressure of 600 mm? **(IIT 1990)**

Solution: (a) Using first order kinetic equation and substituting given values,

In first case: $$k = \frac{2.303}{53}\log_{10}\frac{200}{200-100} = 0.0131\ \text{min}^{-1}$$

In second case: $$k = \frac{2.303}{100}\log_{10}\frac{200}{200-146} = 0.0131\ \text{min}^{-1}$$

As the values of k come out to be the same in both cases, the reaction is of first order.

(b) As in the first order reaction, the time required for the completion of same fraction is independent of initial concentration; the percentage decomposition in 100 minutes when the initial pressure is 600 mm will also be 73%.

Example 26. *A substance reacts according to the first order rate law and the specific reaction rate for the reaction is* $1\times 10^{-2}\ s^{-1}$. *If the initial concentration is* 1.0 *M.*

(*a*) *What is the initial rate?*

(*b*) *What is the reaction rate after* 1 *minute?*

Solution: (a) Initial rate of a first order reaction = kC

$$=1\times 10^{-2}\times 1.0=1\times 10^{-2}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

(b) Concentration after 60 seconds is calculated by applying first order kinetic equation,

$$k=\frac{2.303}{60}\log_{10}\frac{1}{(1-x)}$$

or
$$1\times 10^{-2}=\frac{2.303}{60}[-\log(1-x)]$$

or
$$\frac{60\times 10^{-2}}{2.303}=-\log(1-x)=0.2605$$

$$\log(1-x)=-0.2605$$
$$=\bar{1}.7395$$

$$(1-x)=\text{antilog of }(\bar{1}.7395)=0.5489\ \text{mol L}^{-1}$$

Rate of reaction after 1 minute $=k\times C$

$$=1\times 10^{-2}\times 0.5489$$
$$=5.489\times 10^{-3}\ \text{mol L}^{-1}\ \text{s}^{-1}$$

Example 27. *A first order reaction is 50% completed in* 30 *minutes at 27°C and in* 10 *minutes at 47°C. Calculate the reaction rate constant at 27°C and the energy of activation of the reaction in kJ mol*$^{-1}$.

Solution: For first order reaction $k=\dfrac{0.693}{t_{1/2}}$

At 27°C, $$k_{27°\text{C}}=\frac{0.693}{30}=0.0231\ \text{min}^{-1}$$

At 47°C, $$k_{47°\text{C}}=\frac{0.693}{10}=0.0693\ \text{min}^{-1}$$

Now applying the following equation:

$$\log_{10}\frac{k_1}{k_2}=\frac{-E_a}{2.303\times R}\cdot\left(\frac{T_2-T_1}{T_2\cdot T_1}\right)$$

or
$$\log_{10}\frac{0.0231}{0.0693}=\frac{-E_a}{2.303\times 8.314}\cdot\left(\frac{320-300}{320\times 300}\right)$$

or
$$-\log_{10}0.3333=\frac{E_a}{19.1471}\times\frac{20}{96000}$$

$$E_a=-\frac{19.1471\times 96000}{20}\times\log 0.3333$$
$$=-91906\times(-0.4772)$$
$$=43857\ \text{J mol}^{-1}=43.857\ \text{kJ mol}^{-1}$$

Example 28. *In Arrhenius equation for a certain reaction, the values of A and* E_a *(activation energy) are* 4×10^{13} *sec*$^{-1}$ *and* 98.6 *kJ mol*$^{-1}$ *respectively. If the reaction is of first order, at what temperature will its half life period be* 10 *minutes?*

(IIT 1990)

Solution: According to Arrhenius equation,

$$k=Ae^{-E_a/RT}$$

or
$$\log_e k=\log_e A-\frac{E_a}{RT}$$

or
$$2.303\log_{10}k=2.303\log_{10}A-\frac{E_a}{RT}$$

For a first order reaction $t_{1/2}=\dfrac{0.693}{k}$

So, $$k=\frac{0.693}{600}\ \text{sec}^{-1}\quad(t_{1/2}=10\ \text{min}=600\ \text{sec})$$
$$=1.1\times 10^{-3}\ \text{sec}^{-1}$$

Hence, $$\log(1.1\times 10^{-3})=\log(4\times 10^{13})-\frac{98.6\times 10^{3}}{2.303\times 8.314\times T}$$

$$T=310.95\ \text{K}$$

Example 29. *A second order reaction, in which both the reactants have same concentration, is* 20% *completed in* 500 *seconds. How much time it will take for* 60% *completion?*

Solution: The second order equation when both the reactants have same concentration is

$$k=\frac{1}{t}\cdot\frac{x}{a(a-x)}$$

If $a=100,\ x=20,\ t=500$ seconds.

So, $$k=\frac{1}{500}\times\frac{20}{100\times(100-20)}$$

When $a=100,\ x=60,\ t=?$

$$t=\frac{1}{k}\cdot\frac{60}{100\times 40}$$

Substituting the value of k,

$$t=\frac{500\times 100\times 80}{20}\times\frac{60}{100\times 40}$$

or $$t=3000\ \text{seconds}$$

Example 30. *A first order reaction is* 20% *complete in* 10 *minutes. Calculate the time taken for the reaction to go to* 80% *completion.*

Solution: Applying first order equation,

$$k=\frac{2.303}{t}\log_{10}\frac{100}{(100-20)}$$

$$=\frac{2.303}{10}\log_{10}\frac{100}{80}=0.0223\ \text{min}^{-1}$$

Again applying first order equation,

$$t = \frac{2.303}{k} \log_{10} \frac{100}{(100-80)}$$

$$= \frac{2.303}{0.0223} \log_{10} \frac{100}{20}$$

$$= 72.18 \text{ min}$$

Example 31. *The decomposition of dinitrogen pentoxide* (N_2O_5) *follows first order rate law. Calculate the rate constant from the given data:*

$t = 800\, sec \qquad [N_2O_5] = 1.45\, mol\, L^{-1} = [A_1]$

$t = 1600\, sec \qquad [N_2O_5] = 0.88\, mol\, L^{-1} = [A_2]$

Solution: Applying the formula,

$$k = \frac{2.303}{(t_2 - t_1)} \log_{10} \frac{[A_1]}{[A_2]}$$

$$= \frac{2.303}{(1600-800)} \log_{10} \frac{1.45}{0.88}$$

$$= \frac{2.303}{800} \times 0.2169 = 6.24 \times 10^{-4} \text{ sec}^{-1}$$

Example 32. *The decomposition of* N_2O_5 *according to the equation,*

$$N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$$

is a first order reaction. After 30 minutes from the start of the decomposition in a closed vessel, the total pressure developed is found to be 284.4 mm Hg and on completion, the total pressure is 584.5 mm Hg. Calculate the rate constant of the reaction.

(IIT 1991)

Solution: $2N_2O_5 \longrightarrow 4NO_2 + O_2$

On decomposition of 2 moles of N_2O_5, 4 moles of NO_2 and 1 mole of O_2 are produced. Thus, the total pressure after completion corresponds to 5 moles and initial pressure to 2 moles.

Initial pressure of N_2O_5, $p_0 = \frac{2}{5} \times 584.5 = 233.8$ mm Hg

After 30 minutes, the total pressure = 284.5 mm Hg

$$\underset{p_0 - 2p}{2N_2O_5} \longrightarrow \underset{4p}{4NO_2} + \underset{p}{O_2}$$

or $\quad p_0 + 3p = 284.5$

or $\quad 3p = 284.5 - 233.8 = 50.7$ mm Hg

or $\quad p = \frac{50.7}{3} = 16.9$ mm Hg

Pressure of N_2O_5 after 30 minutes $= 233.8 - (2 \times 16.9)$

$= 200$ mm Hg

$$k = \frac{2.303}{30} \log_{10} \frac{233.8}{200.0} = 5.2 \times 10^{-3} \text{ min}^{-1}$$

Example 33. *The gas phase decomposition of dimethyl ether follows first order kinetics.*

$$CH_3OCH_3(g) \longrightarrow CH_4(g) + H_2(g) + CO(g)$$

The reaction is carried out in a constant volume container at 500°C and has a half life of 14.5 minutes. Initially only dimethyl ether is present at a pressure of 0.40 atm. What is the total pressure after 12 minutes? Assume ideal gas behaviour.

(IIT 1993)

Solution: $k = \frac{0.693}{t_{1/2}} = \frac{0.693}{14.5} = 0.047793 \text{ min}^{-1}$

Let the pressure of dimethyl ether after 12 minutes be p atm. Applying first order equation,

$$k = \frac{2.303}{t} \log_{10} \frac{p_0}{p}$$

$$\log_{10} \frac{0.4}{p} = \frac{0.047793 \times 12}{2.303} = 0.2490$$

or $\quad \frac{0.4}{p} = 1.7743$

or $\quad p = \frac{0.4}{1.7743} = 0.2254$ atm

Decrease in pressure, $x = 0.4 - 0.2254 = 0.1746$ atm

$$\underset{p_0 - x}{CH_3OCH_3(g)} \longrightarrow \underset{x}{CH_4(g)} + \underset{x}{H_2(g)} + \underset{x}{CO(g)}$$

Total pressure $= p_0 + 2x$

$= 0.4 + 2 \times 0.1746$

$= 0.7492$ atm

Example 34. *The half life of first order decomposition of nitramide is 2.1 hours at 15°C.*

$$NH_2NO_2(aq.) \longrightarrow N_2O(g) + H_2O(l)$$

If 6.2 g of NH_2NO_2 *is allowed to decompose calculate (i) time taken for* NH_2NO_2 *to decompose 99% and (ii) the volume of dry* N_2O *produced at this point, measured at STP.* **(IIT 1994)**

Solution: (i) $k = \frac{0.693}{t_{1/2}} = \frac{0.693}{2.1} = 0.33 \text{ hr}^{-1}$

Applying kinetic equation of first order reaction,

$$k = \frac{2.303}{t} \log_{10} \frac{a}{(a-x)}$$

or $\quad t = \frac{2.303}{0.33} \log_{10} \frac{100}{(100-99)}$

$= 13.96$ hrs

(ii) No. of moles of NH_2NO_2 decomposed

$= 0.99 \times \frac{6.2}{62}$

$= 0.099$

No. of moles of N_2O formed = 0.099

Volume of N_2O at STP = 0.099 × 22400 mL

= 2217.6 mL

Example 35. *From the following data for the reaction between A and B:*

Expt. No.	$[A]$ ($mol\ L^{-1}$)	$[B]$ ($mol\ L^{-1}$)	Initial rate ($mol\ L^{-1}\ s^{-1}$)	
			300 K	**320 K**
(1)	2.5×10^{-4}	3.0×10^{-5}	5.0×10^{-4}	2.0×10^{-3}
(2)	5.0×10^{-4}	6.0×10^{-5}	4.0×10^{-3}	...
(3)	1.0×10^{-3}	6.0×10^{-5}	1.6×10^{-2}	...

Calculate the following:

(*i*) *The order of the reaction with respect to A and with respect to B,*

(*ii*) *The rate constant at 300K,*

(*iii*) *The energy of activation and*

(*iv*) *The pre-exponential factor.* (IIT 1994)

Solution: (i) Let the rate law be:

$$\text{Rate} = k[A]^x[B]^y$$

From expt. (1), $5.0\times10^{-4} = k[2.5\times10^{-4}]^x[3.0\times10^{-5}]^y$ ... (i)

From expt. (2), $4.0\times10^{-3} = k[5.0\times10^{-4}]^x[6.0\times10^{-5}]^y$ ... (ii)

Dividing eq. (ii) by eq. (i), $\dfrac{4.0\times10^{-3}}{5.0\times10^{-4}} = 2^x\cdot2^y = 8$

From expt. (3), $1.6\times10^{-2} = k[1.0\times10^{-3}]^x[6.0\times10^{-5}]^y$ ... (iii)

Dividing eq. (iii) by eq. (ii), $\dfrac{1.6\times10^{-2}}{4.0\times10^{-3}} = 2^x = 4$

or $x = 2$ and $y = 1$

Hence, order w.r.t. A is 2nd and order w.r.t. B is 1st.

(ii) $\text{Rate} = k\cdot[A]^2[B]$

From expt. (1), $5\times10^{-4} = k[2.5\times10^{-4}]^2[3.0\times10^{-5}]$

or $k = \dfrac{5\times10^{-4}}{[2.5\times10^{-4}]^2[3.0\times10^{-5}]} = 2.67\times10^8\ \text{L}^2\ \text{mol}^{-2}\ \text{s}^{-1}$

(iii) From Arrhenius equation,

$$\log_{10}\frac{2.0\times10^{-3}}{5.0\times10^{-4}} = \frac{E_a}{2.303\times8.314}\times\frac{20}{300\times320}$$

$$E_a = \frac{2.303\times8.314\times300\times320}{20}\times\log_{10}4$$

$$= 55.333\ \text{kJ mol}^{-1}$$

(iv) Applying $\log_{10}k = \log_{10}A - \dfrac{E_a}{2.303RT}$

$$\log_{10}\frac{A}{k} = \frac{55.333}{2.303\times8.314\times300} = 9.633$$

or $$\frac{A}{k} = 4.29\times10^9$$

or $$A = 4.29\times10^9\times2.67\times10^8$$

$$= 1.145\times10^{18}$$

Example 36. *At a certain temperature, the half change period for the catalytic decomposition of ammonia were found as follows:*

Pressure (Pascals):	6667	13333	26666
Half life period in hours:	3.52	1.92	1.0

Calculate the order of reaction.

Solution: $\dfrac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\dfrac{a_2}{a_1}\right)^{n-1}$ where, n is order of reaction

From the given data,

$$\frac{3.52}{1.92} = \left(\frac{13333}{6667}\right)^{n-1} \quad (a \propto \text{initial pressure})$$

$$= (2)^{n-1}$$

$$\log\frac{3.52}{1.92} = (n-1)\log 2$$

$$= 0.3010\times(n-1)$$

$$0.2632 = 0.3010\times(n-1)$$

$$n = 1.87 \approx 2$$

Similar calculations are made between first and third observations. n comes equal to $1.908\ (\approx 2)$.

Thus, the reaction is of second order.

Example 37. *On heating, arsine (AsH_3) decomposes as:*

$$2AsH_3(g) \longrightarrow 2As(s) + 3H_2(g)$$

The total pressure measured at constant temperature and constant volume varies with time as follows:

t (min)	0	5	7.5	10
p/mm Hg	760	836	866.4	896.8

Calculate the rate constant assuming the reaction to follow the first order rate law.

Solution: For first order, the rate equation is

Initially after time t

$$k = \frac{2.303}{t}\log\frac{[A]_0}{[A]} = \frac{2.303}{t}\log\frac{p_0}{p}$$

given, $p_0 = 760$ mm Hg.

The decomposition reaction is:

$$\begin{array}{ccccc} 2\text{AsH}_3(g) & \rightarrow & \text{As}(s) & + & 3\text{H}_2(g) \\ p_0 & & 0 & & 0 \\ p_0-2x & & & & 3x \end{array}$$

Total pressure, $p_t = p_0 - 2x + 3x = p_0 + x$

$$x = p_t - p_0$$

$$p_{\text{AsH}_3} = (p_0 - 2x) = p_0 - 2p_t + 2p_0 = 3p_0 - 2p_t$$

After 5 minutes, $p_{\text{AsH}_3} = (3 \times 760) - (2 \times 836)$

$$= 608 \text{ mm Hg}$$

$$k = \frac{2.303}{5} \log_{10} \frac{760}{608} = 0.0446 \text{ min}^{-1}$$

After 7.5 minutes, $p_{\text{AsH}_3} = (3 \times 760) - (2 \times 866.4)$

$$= 547.2 \text{ mm Hg}$$

$$k = \frac{2.303}{7.5} \log_{10} \frac{760}{547.2} = 0.0438 \text{ min}^{-1}$$

After 10 minutes, $p_{\text{AsH}_3} = (3 \times 760) - (2 \times 896.8)$

$$= 486.4 \text{ mm Hg}$$

$$k = \frac{2.303}{10} \log_{10} \frac{760}{486.4} = 0.0446 \text{ min}^{-1}$$

Example 38. *Cane sugar is gradually converted into dextrose and laevulose by dilute acid. The rate of inversion is observed by measuring the polarisation angle, at various times, when the following results are obtained:*

Time (min)	0	10	20	30	40	100	∞
Angle	32.4	28.8	25.5	22.4	19.6	−6.1	−14.1

Show that the reaction is of first order. Calculate the value of t, when the solution is optically inactive.

Solution: In case, the inversion of cane sugar is a first order change, then

$$k = \frac{2.303}{t} \log_{10} \frac{[A]_0}{[A]} = \frac{2.303}{t} \log_{10} \frac{r_0 - r_\infty}{r_t - r_\infty}$$

When, $t = 10$, $r_0 = 32.4$, $r_t = 28.8$, $r_\infty = -14.1$

$$k = \frac{2.303}{10} \log_{10} \frac{32.4 - (-14.1)}{28.8 - (-14.1)}$$

$$= \frac{2.303}{10} \log_{10} \frac{46.5}{42.9} = 0.008 \text{ min}^{-1}$$

When, $t = 20$, $r_0 = 32.4$, $r_t = 25.5$, $r_\infty = -14.1$

$$k = \frac{2.303}{20} \log_{10} \frac{32.4 - (-14.1)}{25.5 - (-14.1)} = \frac{2.303}{20} \log \frac{46.5}{39.6}$$

$$= 0.008 \text{ min}^{-1}$$

When, $t = 30$, $r_0 = 32.4$, $r_t = 22.4, r_\infty = -14.1$

$$k = \frac{2.303}{30} \log_{10} \frac{32.4 - (-14.1)}{22.4 - (-14.1)} = \frac{2.303}{30} \log_{10} \frac{46.5}{36.5}$$

$$= 0.008 \text{ min}^{-1}$$

Thus, the reaction is of first order as the value of k is constant.

The solution will be optically inactive when half of the cane sugar is inverted.

$$t_{1/2} = \frac{0.693}{k} = \frac{0.693}{0.008} = 86.6 \text{ min}$$

Example 39. *1 mL of methyl acetate was added to a flask containing 20 mL of N/20 HCl maintained at 25° C. 2 mL of the reaction mixture were withdrawn at different intervals and titrated with a standard alkali solution. The following results were obtained:*

Time (min)	0	75	119	183	∞
Alkali used (mL)	19.24	24.20	26.60	29.32	42.03

Show that the reaction follows first order kinetics.

Solution: In case the hydrolysis follows first order kinetics, then

$$k = \frac{2.303}{t} \log_{10} \frac{[A]_0}{[A]} = \frac{2.303}{t} \log_{10} \frac{V_\infty - V_0}{V_\infty - V_t}$$

When, $t = 75$ min, $V_\infty = 42.03$, $V_0 = 19.24$, $V_t = 24.20$

$$k = \frac{2.303}{75} \log_{10} \frac{(42.03 - 19.24)}{(42.03 - 24.20)} = \frac{2.303}{75} \log_{10} \frac{22.79}{17.83}$$

$$= 0.00327 \text{ min}^{-1}$$

$t = 119$ min, $V_\infty = 42.03$, $V_0 = 19.24$, $V_t = 26.60$

$$k = \frac{2.303}{119} \log_{10} \frac{(42.03 - 19.24)}{(42.03 - 26.60)} = \frac{2.303}{119} \log_{10} \frac{22.79}{15.43}$$

$$= 0.00327 \text{ min}^{-1}$$

Since, the values of k are constant, hence, it follows first order kinetics.

Example 40. *The gaseous decomposition of ozone*

$$2O_3 \rightarrow 3O_2$$

obeys the rate law $r = -\frac{d[O_3]}{dt} = \frac{k[O_3]^2}{[O_2]}$

Show that the following mechanism is consistent with the above rate law:

$$O_3 \overset{K_{eq}}{\rightleftharpoons} O_2 + O \qquad \textit{(fast)}$$

$$O + O_3 \xrightarrow{k_1} 2O_2 \qquad \textit{(slow)}$$

Solution: From the slow rate determining step

$$r = -\frac{d[\text{O}_3]}{dt} = k \qquad {}_3]$$

From the fast reaction,

$$K_{\text{eq}} = \frac{[\text{O}_2][}{[\text{O}_3}$$

or $$[\text{O}] = \frac{K_{\text{eq}}[\text{O}_3]}{[\text{O}_2]}$$

Substituting the value of [O] in the above expression

$$r = -\frac{d[\text{O}_3]}{dt} = \frac{k_1 K_{\text{eq}}[\text{O}_3]^2}{[\text{O}_2]} = \frac{k[\text{O}_3]^2}{[\text{O}_2]}$$

Example 41. *For the formation of phosgene from $CO(g)$ and chlorine,*

$$CO(g) + Cl_2(g) \longrightarrow COCl_2(g)$$

the experimentally determined rate equation is,

$$\frac{d[COCl_2]}{dt} = k[CO][Cl_2]^{3/2}$$

Is the following mechanism consistent with the rate equation?

(*i*) $Cl_2 \rightleftharpoons 2Cl$ *(fast)*

(*ii*) $Cl + CO \rightleftharpoons COCl$ *(fast)*

(*iii*) $COCl + Cl_2 \rightleftharpoons COCl_2 + Cl$ *(slow)*

Solution: Multiplying equation (ii) by 2 and adding (i), we get:

$$Cl_2 + 2CO \rightleftharpoons 2COCl$$

$$K = \frac{[COCl]^2}{[Cl_2][CO]^2}$$

$$[COCl] = (K)^{1/2}\,[Cl_2]^{1/2}[CO] \qquad \ldots(i)$$

Slowest step is rate determining, hence,

$$\text{Rate} = k[COCl][Cl_2] \qquad \ldots(ii)$$

From eqs. (i) and (ii), we get

$$\text{Rate} = kK^{1/2}[Cl_2]^{1/2}[Cl_2][CO]$$

$$\text{Rate} = k'[Cl_2]^{3/2}[CO]$$

Thus, rate law is in accordance with the mechanism.

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

22. A first order reaction has half life of 14.5 hrs. What percentage of the reactant will remain after 24 hrs?

(a) 18.3% (b) 31.8% (c) 45.5% (d) 68.2%

[Ans. (b)]

[Hint: $k = \frac{2.303}{t}\log\left(\frac{a}{a-x}\right)$

$$\frac{0.693}{14.5} = \frac{2.303}{24}\log\frac{100}{(a-x)}$$

On solving, $(a - x) = 31.8\%$]

23. Half life of a first order reaction is 10 min. What % of reaction will be completed in 100 min?

(a) 25% (b) 99.9% (c) 75% (d) 80%

[Ans. (b)]

[Hint: $\frac{0.693}{t_{1/2}} = \frac{2.303}{t}\log_{10}\left(\frac{a}{a-x}\right)$

$$\frac{0.693}{10} = \frac{2.303}{100}\log\left(\frac{100}{100-x}\right)$$

$x = 99.9\%$]

24. A certain zero order reaction has $k = 0.025\,M\,s^{-1}$ for the disappearance of A. What will be the concentration of A after 15 seconds if the initial concentration is 0.5 M?

(a) 0.5 M (b) 0.32 M (c) 0.12 M (d) 0.06 M

[Ans. (c)]

[Hint: $x = kt = 0.025 \times 15 = 0.375\,M$

Remaining conc. $= 0.5 - 0.375 = 0.125\,M$]

25. A first order reaction:

$$2N_2O(g) \longrightarrow 2N_2(g) + O_2(g)$$

has a rate constant of $1.3 \times 10^{-11}\,s^{-1}$ at 270°C and $4.5 \times 10^{-10}\,s^{-1}$ at 350°C. What is the activation energy for this reaction?

(a) 15 kJ (b) 30 kJ (c) 68 kJ (d) 120 kJ

[Ans. (d)]

[Hint: $\log\left(\frac{k_2}{k_1}\right) = \frac{E_a}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$

$$\log\left(\frac{4.5 \times 10^{-10}}{1.3 \times 10^{-11}}\right) = \frac{E_a}{2.303 \times 8.314 \times 10^{-3}}\left[\frac{1}{543} - \frac{1}{623}\right]$$

$E_a = 120$ kJ]

26. The reaction of O_3 with chlorine atom is given as:

$$O_3(g) + Cl(g) \longrightarrow O_2(g) + ClO(g); \quad k_1 = 5.2 \times 10^9\ \text{L mol}^{-1}\ \text{sec}^{-1}$$

$$ClO(g) + O(g) \longrightarrow Cl(g) + O_2(g); \quad k_2 = 2.6 \times 10^{10}\ \text{L mol}^{-1}\ \text{sec}^{-1}$$

Which of these values is closest to the rate constant of the overall reaction?

$$O_3(g) + O(g) \longrightarrow 2O_2(g)$$

(a) 5.2×10^9 (b) 2.6×10^{10}

(c) 3.1×10^{10} (d) 1.4×10^{20}

[Ans. (a)]

[Hint: Lowest value of k shows that the step is rate determining.]

27. If a first order reaction takes 32 minutes for 75% completion, then time required for 50% completion is: [AMU (Medical)

(a) 32 min (b) 16 min (c) 8 min (d) 4 min

[Ans. (b)]

[Hint: $k = \frac{2.303}{t}\log\left(\frac{a}{a-x}\right)$

When, $a = 100$, $x = 75$, $t = 32$

$$k = \frac{2.303}{32}\log_{10}\left(\frac{100}{25}\right) = 0.0433\ \text{min}^{-1}$$

Time for 50% completion $(t_{1/2}) = \frac{0.693}{k} = \frac{0.693}{0.0433} \approx 16$ min]

28. Rate constant of a reaction is 175 $\text{litre}^{-2}\ \text{mol}^{-2}\ \text{sec}^{-1}$. What is the order of reaction? [CET ([illegible])]

(a) First (b) Second (c) Third (d) Zero

[Ans. (c)]

[Hint: Unit of $k = \left[\frac{\text{litre}}{\text{mol}}\right]^{n-1} \times \text{sec}^{-1}$ ... (i)

Given unit of $k = \text{litre}^2\ \text{mol}^{-2}\ \text{sec}^{-1}$ ... (ii)

Comparing the unit of litre,

$$n - 1 = 2$$

$n = 3$]

29. The half life of a first order reaction having rate constant $k = 1.7 \times 10^{-5}\ \text{sec}^{-1}$ is: **(JIPMER 2006)**

(a) 12.1 hrs (b) 9.7 hrs (c) 11.3 hrs (d) 1.8 hrs

[Ans. (c)]

[Hint: $t_{1/2} = \frac{0.693}{k} = \frac{0.693}{1.7 \times 10^{-5}} = 40764$ sec $= 11.3$ hrs]

30. At 500 K, the half life period of a gaseous reaction at an initial pressure of 80 kPa is 350 sec. When the pressure is 40 kPa, the half life period is 175 sec; the order of the reaction is: **[PET (Kerala) 2007]**

(a) zero (b) one (c) two (d) three

(e) half

[Ans. (a)]

[Hint: $\dfrac{(t_{1/2})_1}{(t_{1/2})_2}=\left(\dfrac{p_2}{p_1}\right)^{n-1}$

$$\frac{350}{175}=\left(\frac{40}{80}\right)^{n-1}$$

$$2=\left(\frac{1}{2}\right)^{n-1}$$

$$n-1=-1$$

$n=0$ (zero order reaction)]

31. 90% of the first order reaction is completed in 70 minutes. The velocity constant of the reaction is: [Comed (Karnataka) 2008]
(a) 0.0329 (b) 0.329 (c) 3.29 (d) 0.0293
[Ans. (a)]

[Hint : $k=\dfrac{2.303}{t}\log\dfrac{a}{a-x}$

$$=\frac{2.303}{70}\log\frac{100}{100-90}$$

$=0.0329\ \text{min}^{-1}$]

32. The half life period of a first order reaction is 1 min 40 seconds. Calculate its rate constant. (VITEEE 2008)
(a) $6.93\times10^{-3}\ \text{min}^{-1}$ (b) $6.93\times10^{-3}\ \text{sec}^{-1}$
(c) 6.93×10^{-3} sec (d) 6.93×10^{3} sec
[Ans. (b)]
[Hint : $k=\dfrac{0.693}{t_{1/2}}=\dfrac{0.693}{100}=6.93\times10^{-3}\ \text{sec}^{-1}$]

MISCELLANEOUS NUMERICAL EXAMPLES

Example 1. *Ammonia and oxygen react at higher temperature as,*

$$4NH_3(g)+5O_2(g)\longrightarrow 4NO(g)+6H_2O(g)$$

in an experiment, the concentration of NO increases by 1.08×10^{-2} *mol litre*$^{-1}$ *in 3 seconds. Calculate:*

(*i*) *rate of reaction,* (*ii*) *rate of disappearance of ammonia,* (*iii*) *rate of formation of water.*

Solution:

(i) $\text{Rate}=-\dfrac{1}{4}\dfrac{d[NH_3]}{dt}=-\dfrac{1}{5}\dfrac{d[O_2]}{dt}=\dfrac{1}{4}\dfrac{d[NO]}{dt}=\dfrac{1}{6}\dfrac{d[H_2O]}{dt}$

$$\text{Rate}=\frac{1}{4}\times\frac{1.08\times10^{-2}}{3}=9\times10^{-4}\ \text{mol litre}^{-1}\ \text{sec}^{-1}$$

(ii) $\dfrac{-d[NH_3]}{dt}=4\times\text{rate}=4\times9\times10^{-4}$

$$=36\times10^{-4}\ \text{mol litre}^{-1}\ \text{sec}^{-1}$$

(iii) $\dfrac{d[H_2O]}{dt}=6\times\text{rate}=6\times9\times10^{-4}$

$$=54\times10^{-4}\ \text{mol litre}^{-1}\ \text{sec}^{-1}$$

Example 2. *Decomposition of* $N_2O_5(g)$ *into* $NO_2(g)$ *and* $O_2(g)$ *is a first order reaction. If initial concentration of* $N_2O_5(g)$, *i.e.,* $[N_2O_5]_0$ *is 0.03 mol litre*$^{-1}$, *what will be its concentration after 30 minutes? Rate constant of the reaction is* $1.35\times10^{-4}\ s^{-1}$.

Solution: $k=\dfrac{2.303}{t}\log_{10}\dfrac{[A_0]}{[A]}$

$$1.35\times10^{-4}=\frac{2.303}{30\times60}\log_{10}\frac{0.03}{[A]}$$

$$[A]=0.0235\ \text{mol litre}^{-1}$$

Example 3. *Rate constant for the decomposition of ethylene oxide into* CH_4 *and* CO *may be described by the equation,* $\log k\ (s^{-1})=14.34-\dfrac{1.25\times10^4}{T}$.

(*a*) *What is the energy of activation of this reaction?*
(*b*) *What is the value of k at 670 K?*

Solution: (a) We know that,

$$\log_{10}k=\log_{10}A-\frac{E}{2.303RT}\quad\text{... (i)}$$

$$\log_{10}k\ (\text{s}^{-1})=14.34-\frac{1.25\times10^4}{T}\quad\text{... (ii)}$$

Comparing eq. (i) and eq. (ii), we get

$$\frac{E}{2.303R}=1.25\times10^4$$

$$E=1.25\times10^4\times2.303\times8.314\times10^{-3}$$

$$E=239.339\ \text{kJ/mol}$$

(b) Substituting the value of T, *i.e.*, at 670 K, in equation (ii), we get,

$$\log k\ (\text{s}^{-1})=14.34-\frac{1.25\times10^4}{670}=-4.3167$$

$$k=4.82\times10^{-5}\ \text{s}^{-1}$$

Example 4. *A drug becomes ineffective after 30% decomposition. The original concentration of a sample was 5 mg/mL, which becomes 4.2 mg/mL during 20 months. Assuming the decomposition of first order, calculate the expiry time of the drug in months. What is the half life of the product?*

Solution: $k=\dfrac{2.303}{t}\log_{10}\left(\dfrac{a}{a-x}\right)=\dfrac{2.303}{20}\log_{10}\left(\dfrac{5}{4.2}\right)$

$$=0.00872\ \text{month}^{-1}$$

Expiry time 't' may be calculated as:

$$k=\frac{2.303}{t}\log_{10}\frac{a}{a-x}$$

$$0.00872=\frac{2.303}{t}\log_{10}\frac{100}{70}$$

$$t=40.9\approx41\ \text{month}$$

$$t_{1/2}=\frac{0.693}{0.00872}=79.4\ \text{month}$$

Example 5. *Two reactions of the same order have equal exponential factors but their activation energies differ by* 24.9 *kJ/mol. Calculate the ratio between the rate constants of these reactions at* $27°C$. $(R = 8.31 J\,K^{-1}\,mol^{-1})$ (Dhanbad 1990)

Solution: We know that,

$$\log_{10} k = \log_{10} A - \frac{E}{2.303RT}$$

So, $$\log_{10} k_2 = \log_{10} A - \frac{E_2}{2.303RT}$$

and $$\log_{10} k_1 = \log_{10} A - \frac{E_1}{2.303RT}$$

$$\log_{10}\left(\frac{k_2}{k_1}\right) = \frac{(E_1 - E_2)}{2.303RT}$$

$$\log_{10}\left(\frac{k_2}{k_1}\right) = \frac{24.9 \times 1000}{2.303 \times 8.314 \times 300}$$

$$\frac{k_2}{k_1} = 2.199 \times 10^4$$

Example 6. *Pseudo first order rate for the reaction,*

$$A + B \longrightarrow P$$

when studied in 0.1 *M of B is given by*

$$-\frac{d[A]}{dt} = k[A]$$

where, $k = 1.85 \times 10^4\ sec^{-1}$. *Calculate the value of second order rate constant.*

Solution: $$A + B \longrightarrow P$$

$$-\frac{d[A]}{dt} = k[A]$$

$$-\frac{d[A]}{dt} = 1.85 \times 10^4 \times [A] \qquad \text{... (i)}$$

Assuming the reaction to be of second order,

$$-\frac{d[A]}{dt} = k'[A][B]$$

$$-\frac{d[A]}{dt} = k'[A][0.1] \qquad \text{... (ii)}$$

Dividing eq. (i) by eq. (ii), we get

$$1 = \frac{1.85 \times 10^4}{k'[0.1]}$$

$$k' = 1.85 \times 10^5 \text{ litre mol}^{-1} \text{ sec}^{-1}$$

Example 7. *The time required for* 10% *completion of a first order reaction at* 298 *K is equal to that required for its* 25% *completion at* 308 *K. If the pre-exponential factor for the reaction is* $3.56 \times 10^9\ sec^{-1}$, *calculate its rate constant at* 318 *K and also the energy of activation.* (IIT 1997)

Solution: We know that,

$$k = \frac{2.303}{t} \log_{10}\left(\frac{a}{a-x}\right)$$

At 298 K, $x = 10, \quad a = 100,$

$$k_{298} = \frac{2.303}{t_1} \log_{10} \frac{100}{90} \qquad \text{... (i)}$$

At 308 K, $a = 100, x = 25, (a - x) = 75$

$$k_{308} = \frac{2.303}{t_2} \log_{10}\left(\frac{100}{75}\right) \qquad \text{... (ii)}$$

$t_1 = t_2$, dividing eq. (ii) by eq. (i)

$$\therefore \quad \frac{k_{308}}{k_{298}} = 2.73$$

$$\log \frac{k_{308}}{k_{298}} = \frac{E}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

$$\log 2.73 = \frac{E}{2.303 \times 8.314}\left(\frac{1}{308} - \frac{1}{298}\right)$$

$$E = 76.622 \text{ kJ/mol}$$

Similarly, we can solve for k_{318} which is equal to $9.22 \times 10^{-4}\ s^{-1}$.

Example 8. *The rate constant of a reaction is* $1.5 \times 10^7\ s^{-1}$ *at* $50°C$ *and* $4.5 \times 10^7\ s^{-1}$ *at* $100°C$. *Calculate the Arrhenius parameter A and* E_a. (IIT 1998)

Solution: $$\log_{10} \frac{k_2}{k_1} = \frac{E_a}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

$$\log_{10} \frac{4.5 \times 10^7}{1.5 \times 10^7} = \frac{E_a}{2.303 \times 8.314}\left(\frac{1}{323} - \frac{1}{373}\right)$$

$$E_a = 2.2 \times 10^4 \text{ J/mol}$$

We know that,

$$\log_{10} k = \log_{10} A - \frac{E_a}{2.303RT}$$

$$\log_{10}(1.5 \times 10^7) = \log_{10} A - \frac{2.2 \times 10^4}{2.303 \times 8.314 \times 323}$$

$$A = 5.42 \times 10^{10}\ s^{-1}$$

Example 9. *In hydrogenation reaction at* $25°C$, *it is observed that hydrogen gas pressure falls from* 2 *atm to* 1.2 *atm in* 50 *min. Calculate the rate of reaction in molarity per sec.* $(R = 0.0821\ litre-atm\ degree^{-1}\ mol^{-1})$

Solution: $$\text{Rate} = \frac{dP}{dt} = \frac{2 - 1.2}{50 \times 60}$$

$$= 2.666 \times 10^{-4} \text{ atm s}^{-1}$$

$$PV = nRT$$

$$\frac{P}{\text{sec}} = \left(\frac{n}{V}\right)\frac{RT}{\text{sec}}$$

$$\left[\frac{n}{V}\right]\frac{1}{\text{sec}}=\left[\frac{P}{\text{sec}}\right]\frac{1}{RT}$$

$$\text{Rate (molarity/sec)}=\frac{2.666\times10^{-4}}{0.0821\times298}$$

$$=1.09\times10^{-5}\ \text{mol litre}^{-1}\ \text{s}^{-1}$$

Example 10. *A drop of solution (volume 0.05 mL) contains 3×10^{-6} mole H^+ ions. If the rate of disappearance of the H^+ ions is 1×10^{7} mol litre^{-1} sec^{-1}, how long would it take for H^+ ions in the drop to disappear?*

Solution:

$$\text{Concentration of drop}=\frac{\text{mole}}{\text{volume in mL}}\times1000$$

$$=\frac{3\times10^{-6}}{0.05}\times1000=0.06\ \text{mol litre}^{-1}$$

$$\text{Rate of disappearance}=\frac{\text{conc. change}}{\text{time}}$$

$$1\times10^{7}=\frac{0.06}{\text{time}}$$

$$\text{Time}=6\times10^{-9}\ \text{sec}$$

Example 11. *A constant temperature and volume X decomposes as,*

$$2X(g)\longrightarrow3Y(g)+2Z(g)$$

P_X is the partial pressure of X.

Observation No.	*Time (min)*	*P_X (in mm Hg)*
1	0	800
2	100	400
3	200	200

(*i*) *What is the order of the reaction with respect to X?*
(*ii*) *Find the rate constant.*
(*iii*) *Find the time for 75% completion of the reaction.*
(*iv*) *Find the total pressure when pressure of X is 700 mm Hg.* **(IIT 2005)**

Solution: (i) Data shows that half life of the reaction is constant, *i.e.*, 100 min; hence, it is a first order reaction.

(ii) $k=\frac{0.693}{t_{1/2}}=\frac{0.693}{100}=6.93\times10^{-3}\ \text{min}^{-1}$

(iii) $t_{75\%}$, *i.e.*, $t_{3/4}=2\times t_{1/2}=2\times100=200$ min

(iv) $2X(g)\longrightarrow3Y(g)+2Z(g)$

$t=0$ 800 0 0

dt $800-2X$ $3X$ $2X$

$$\text{Total pressure}=800-2X+3X+2X=800+3X \quad ...(i)$$

$$800-2X=700$$

$$X=50$$

$\therefore$ Total pressure $=800+3\times50=950$ mm Hg

Example 12. *Suppose 50 bacteria are placed in a flask containing nutrients for the bacteria so that they can multiply.*

A study at 35° C gave the following results:

Time (minute)	0	15	30	45	60
Number of bacteria	50	100	200	400	800

Show that the rate of production of bacteria is of first order. How many bacteria will be there after 3 hours?

Solution: For bacterial growth,

$$k=-\frac{2.303}{t}\log_{10}\left(\frac{a}{a+x}\right)$$

At 15 minutes: $k=-\frac{2.303}{15}\log_{10}\left(\frac{50}{100}\right)$

$$=0.0462\ \text{min}^{-1}$$

At 30 minutes: $k=-\frac{2.303}{30}\log_{10}\left(\frac{50}{200}\right)$

$$=0.0462\ \text{min}^{-1}$$

At 45 minutes: $k=-\frac{2.303}{45}\log_{10}\left(\frac{50}{400}\right)=0.0462\ \text{min}^{-1}$

Same values of rate constants show that the process corresponds to first order.

Let there be '*n*' bacteria after 3 hrs.

$$k=-\frac{2.303}{t}\log_{10}\left(\frac{a}{a+x}\right)$$

$$0.0462=-\frac{2.303}{180}\log_{10}\frac{50}{n}$$

$$n=2.04\times10^{5}$$

Example 13. *A viral preparation was inactivated in a chemical bath. The inactivation process was found to be of first order in virus concentration, and at the beginning of the experiment 2.0% of the virus was found to be inactivated per minute. Evaluate 'k' for the inactivation process.*

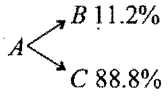
Solution: $a=100,\quad a-x=98,\quad t=60$ sec

$$k=\frac{2.303}{t}\log_{10}\left(\frac{a}{a-x}\right)$$

$$=\frac{2.303}{60}\log_{10}\left(\frac{100}{98}\right)=3.3\times10^{-4}\ \text{sec}^{-1}$$

Example 14. *Trans-1,2-dideuterocyclopropane (A) undergoes a first order decomposition. The observed rate constant at a certain temperature, measured in terms of disappearance of 'A' was 1.52×10^{-4} sec^{-1}. Analysis of products showed that the reaction followed two parallel paths, one leading to dideuteropropane (B) and the other to cis-1,2-dideutero-cyclopropane (C). (B) was found to constitute 11.2% of the reaction product, independently of extent of reaction. What is the order of reaction for each path and what is the value of the rate constant for the formation of each of the products?*

Solution:



In case of parallel path reaction,

$$k_B = k_A \times \text{fractional yield of } B$$
$$= 1.52 \times 10^{-4} \times 0.112 = 1.7 \times 10^{-5}\ \text{sec}^{-1}$$
$$k_C = k_A \times \text{fractional yield of } C$$
$$= 1.52 \times 10^{-4} \times 0.888 = 1.35 \times 10^{-4}\ \text{sec}^{-1}$$

The reaction will be first order for each individual path.

Example 15. *In milk, at* 37°C, *lactobacillus acidophilus has a generation time of about* 75 *minutes. Calculate the population relative to the initial value at* 30, 60, 75, 90 *and* 150 *minutes.*

Solution: For growth kinetics,

$$k = -\frac{2.303}{t}\log_{10}\left(\frac{a}{a+x}\right)$$
$$k = -\frac{2.303}{t}\log_{10}\left(\frac{N_0}{N}\right)$$

Generation time = 75 minutes; $a = 1,\ a + x = 2$

$$k = -\frac{2.303}{75}\log_{10}\left(\frac{1}{1+1}\right) = 0.00924\ \text{min}^{-1}$$

After 30 minutes,

$$k = \frac{-2.303}{t}\log_{10}\left(\frac{N_0}{N}\right)$$
$$0.00924 = -\frac{2.303}{30}\log_{10}\left(\frac{N_0}{N}\right)$$
$$\frac{N}{N_0} = 1.319 \approx 1.32$$

Similarly, we may calculate after 60, 75, 90 and 150 minutes.

Example 16. *Rate law for ozone layer depletion is,*

$$\frac{d[O_3]}{dt} = \frac{K[O_3]^2}{[O_2]}$$

Give the probable mechanism of reaction?

Solution: $O_3 \rightleftharpoons O_2 + O$ (fast reaction)

(equilibrium constant K_c)

$O_3 + O \longrightarrow 2O_2$ (slow reaction, rate constant k)

$$\text{Rate} = k[O_3][O] \qquad \dots \text{(i)}$$
$$K_c = \frac{[O_2][O]}{[O_3]} \text{ or } [O] = K_c\frac{[O_3]}{[O_2]},$$

putting the value in eq. (i)

From eq. (i),

$$\text{Rate} = k \cdot [O_3] \cdot K_c\frac{[O_3]}{[O_2]} = k \cdot K_c \cdot \frac{[O_3]^2}{[O_2]} = K \cdot \frac{[O_3]^2}{[O_2]}$$

Here, $K = k \times K_c$

Example 17. *In hypothetical reaction* $A_2 + B_2 \longrightarrow 2AB$, *follows the mechanism as given below:*

$$A_2 \rightleftharpoons A + A \qquad (\textit{fast reaction})$$
$$A + B_2 \longrightarrow AB + B \qquad (\textit{slow reaction})$$
$$A + B \longrightarrow AB \qquad (\textit{fast reaction})$$

Give the rate law and order of reaction.

Solution: Slowest step is rate determining.

$$\text{Rate} = k[A][B_2] \qquad \dots \text{(i)}$$

Here, $[A]$ should be eleminated.

$$K_c = \frac{[A][A]}{[A_2]} = \frac{[A]^2}{[A_2]}$$
$$[A] = K_c^{1/2}[A_2]^{1/2}$$

From eq. (i), $\text{Rate} = kK_c^{1/2}[A_2]^{1/2}[B_2]$

$$= K[A_2]^{1/2}[B_2]; \qquad [K = k \cdot K_c]$$
$$\text{Order} = 1 + 1/2 = 3/2$$

Example 18. *Calculate order of reaction from the following data:*

$$2NH_3 \longrightarrow N_2 + 3H_2\ (\textit{reaction})$$

Pressure (mm Hg)	50	100	200
Half lives (min)	3.52	1.82	0.93

Solution: We know that,

$$n = 1 + \frac{\log_{10}(t_{1/2})_1 - \log_{10}(t_{1/2})_2}{\log_{10}p_2 - \log_{10}p_1}$$
$$= 1 + \frac{\log_{10}3.52 - \log_{10}1.82}{\log_{10}100 - \log_{10}50}$$
$$= 1.95 \approx 2$$

Similarly, we may calculate for other set of conditions.

Example 19. *The chemical reaction between mercuric chloride and potassium oxalate proceeds as under:*

$$2HgCl_2 + K_2C_2O_4 \longrightarrow KCl + 2CO_2 + Hg_2Cl_2$$

the mass of Hg_2Cl_2 *precipitated from different solutions in a given time, at* 100°C *was as follows:*

Expt. No.	**$HgCl_2$ (mol L^{-1})**	**$K_2C_2O_4$ (mol L^{-1})**	**Time (minutes)**	**Hg_2Cl_2 precipitated (mole)**
(1)	0.0836	0.404	65	0.0068
(2)	0.0836	0.202	120	0.0031
(3)	0.0418	0.404	60	0.0032

From these data calculate order of the reaction.

Solution: $\text{Rate} = k[\text{HgCl}_2]^{\alpha}[\text{K}_2\text{C}_2\text{O}_4]^{\beta};$

$$\frac{0.0068}{65} = k[0.0836]^{\alpha}[0.404]^{\beta}; \qquad \dots \text{(i)}$$

$$\frac{0.0031}{120} = k[0.0836]^{\alpha}[0.202]^{\beta}; \qquad \ldots \text{(ii)}$$

$$\frac{0.0032}{60} = k[0.0418]^{\alpha}[0.404]^{\beta} \qquad \ldots \text{(iii)}$$

Dividing eq. (i) by eq. (ii), we get $4 = 2^{\beta}; \beta = 2$

Dividing eq. (i) by eq. (iii), we get $2 = 2^{\alpha}; \alpha = 1$

Thus, overall order $= \alpha + \beta = 3$

Example 20. *The rate constant of the reaction $A \rightarrow B$ is $k = 0.5$; the initial concentration of A being 1 mol/litre. Calculate the degree of conversion of substance 'A' within 1 hour if the reaction is of zeroth, first and second order. How does the degree of conversion depend on the order of reaction?*

Solution: Zero order:

$$x = kt$$

$$x = 0.5 \times 1 = 0.5$$

First order: $$k = \frac{2.303}{t}\log_{10}\frac{a}{a-x}$$

$k = 0.5$; $t = 1$ hr; $a = 1M$

$$0.5 = \frac{2.303}{1}\log_{10}\frac{1}{(1-x)}$$

$$x = 0.39$$

Second order: $$k = \frac{1}{t}\frac{x}{a(a-x)}$$

$$0.5 = \frac{1}{1}\cdot\frac{x}{1(1-x)}$$

$$x = 0.33$$

Example 21. *Two first order reactions proceed at 25° C at the same rate. The temperature coefficient of the rate of the first reaction is 2 and that of second reaction is 3. Find the ratio of the rates of these reactions at 75° C.*

Solution: For first order reaction, $r_1 = k[A]^1$

$\therefore \quad r_1/r_2 = k_1/k_2 =$ temperature coefficient

Let the rate of reaction for Ist at 25°C be R_1 and the rate of reaction for IInd at 25°C be R_2.

Also, $R_1 = R_2$

	Rates of reaction	
∴ At 25°C	R_1	R_2
35°C	$2R_1$	$3R_2$
45°C	$(2)^2R_1$	$(3)^2R_2$
55°C	$(2)^3R_1$	$(3)^3R_2$
65°C	$(2)^4R_1$	$(3)^4R_2$
75°C	$(2)^5R_1$	$(3)^5R_2$

$\therefore$ Temperature coefficient for 1st reaction $= \dfrac{k_{35}}{k_{25}} = \dfrac{R_{35}}{R_{25}} = 2$

i.e., for each 10°C rise in temperature, rate becomes 2 times.

Similarly, for 2nd reaction it becomes 3 times,

$\therefore$ At 75°C

$$\frac{\text{rate of reaction for 2nd}}{\text{rate of reaction for 1st}} = \frac{(3)^5 R_2}{(2)^5 R_1} = 7.5937 \; (\because R_1 = R_2)$$

Example 22. *The reaction, $A + OH^- \rightarrow$ Products, obeys rate law expression as:*

$$\frac{-d[A]}{dt} = k[A][OH^-]$$

If initial concentrations of $[A]$ and $[OH^-]$ are 0.002 M and 0.3 M respectively and if it takes 30 sec for 1% A to react at 25°C, calculate the rate constant for the reaction.

Solution:

	A	+	OH^-	$\rightarrow$ Products
$t = 0$	0.002		0.3	
$t = 30$	$\left[0.002 - \frac{0.002 \times 1}{100}\right]$		$\left[0.3 - \frac{0.002 \times 1}{100}\right]$	

Using $k = \dfrac{2.303}{t(a-b)}\log_{10}\dfrac{b(a-x)}{a(b-x)}$,

$$k = \frac{2.303}{30 \times (0.002 - 0.3)}\log_{10}\frac{0.3\left[0.002 - \frac{0.002 \times 1}{100}\right]}{0.002\left[0.3 - \frac{0.002 \times 1}{100}\right]}$$

$$k = 1.12 \times 10^{-3} \text{ litre mol}^{-1}\text{ s}^{-1}$$

Example 23. *A hydrogenation reaction is carried out at 500 K. If the same reaction is carried out in presence of a catalyst at the same rate, the temperature required is 400 K. Calculate the activation energy of the reaction if the catalyst lowers the activation barrier by 20 kJ mol^{-1}.* **(IIT 2000)**

Solution: Arrhenius equation may be given as,

$$k = Ae^{-E_a/RT}$$

Let k_{500} and k_{400} be the rate constants at temperatures 500 K and 400 K (in presence of catalyst) respectively. E_{500} and E_{400} be the activation energies at temperatures 500 K and 400 K respectively.

$$k_{500} = Ae^{-E_{500}/R \times 500} \qquad \ldots \text{(i)}$$

$$k_{400} = Ae^{-E_{400}/R \times 400} \qquad \ldots \text{(ii)}$$

Given, $k_{500} = k_{400}$ (same rates in presence and absence of a catalyst).

On comparing eq. (i) with eq. (ii),

$$\frac{E_{500}}{R \times 500} = \frac{E_{400}}{R \times 400}$$

or $$\frac{E_{500}}{5} = \frac{E_{400}}{4}$$

or $$E_{500} = \frac{E_{400}}{4} \times 5 \qquad \ldots \text{(iii)}$$

Given, $$E_{500} = E_{400} + 20$$

Substituting in eq. (iii),

$$E_{400} + 20 = E_{400} \times 1.25$$

or $$E_{400} = \frac{20}{0.25} = 80 \text{ kJ mol}^{-1}$$

So, $$E_{500} = 80 + 20 = 100 \text{ kJ mol}^{-1}$$

Example 24. *Some $PH_3(g)$ is introduced into a fask at 600°C containing an inert gas. PH_3 proceeds to decompose into $P_4(g)$ and $H_2(g)$ and the reaction goes to completion. Total pressure is given below as a function of time. Find the order of the reaction and calculate the rate constant,*

Time (sec)	0	60	120	∞
Pressure (mm Hg)	262.40	272.90	275.51	276.40

(IIT 2001)

Solution: $4PH_3(g) + \text{Inert gas} \longrightarrow P_4(g) + 6H_2(g) + \text{Inert gas}$

$t=0$	P	P_i	0	0	0
$t=t$	$(P-x)$	P_i	$x/4$	$6x/4$	P_i
$t=\infty$	0	P_i	$P/4$	$6P/4$	P_i

At $t=0$, $$262.40 = P + P_i \quad \ldots \text{(i)}$$

$t = 60$ sec $$272.90 = P_{PH_3(\text{left})} + P_{P_4(g)} + P_{H_2(g)} + P_i$$

$t = 120$ sec $$275.51 = P_{PH_3(\text{left})} + P_{P_4(g)} + P_{H_2(g)} + P_i$$

$t = \infty$ $$276.40 = P_{P_4(g)} + P_{H_2(g)} + P_i$$

$$276.40 = \frac{P}{4} + \frac{6P}{4} + P_i$$

$$276.40 \times 4 = 7P + 4P_i \quad \ldots \text{(ii)}$$

At $t = 0$, $$262.40 = P + P_i \quad \ldots \text{(iii)}$$

On solving eqs. (ii) and (iii), we get

$$P = 18.66 \text{ mm}, P_i = 243.74 \text{ mm}$$

At 60°C: $$272.90 = (P - x) + P_i + \frac{x}{4} + \frac{6x}{4}$$

$$272.90 = 18.66 - x + 243.74 + \frac{7x}{4}$$

$$x = 14 \text{ mm}$$

$$k = \frac{2.303}{t} \log\left(\frac{a}{a-x}\right) = \frac{2.303}{60} \log \frac{18.66}{18.66 - 14}$$

$$k = 2.32 \times 10^{-2} \text{ sec}$$

Similarly, at 120 sec $k = 2.30 \times 10^{-2}$ sec^{-1} (do yourself)

Since, ∵ values of '*k*' are same, hence the reaction belongs to first order.

Example 25. *For the given reaction, $A + B \longrightarrow$ Products following data were obtained:*

	$[A_0]$	$[B_0]$	R_0 *mol litre*$^{-1}$ *sec*$^{-1}$
1.	0.1 *M*	0.2 *M*	0.05
2.	0.2 *M*	0.2 *M*	0.10
3.	0.1 *M*	0.1 *M*	0.05

(*i*) *Write the rate law expression.*

(*ii*) *Find the rate constant.* **[IIT 2004 (Memory based)]**

Solution: Let order with respect to *A* and *B* are α and β respectively. Rate law expression may be given as,

$$\text{Rate} = k[A]^\alpha [B]^\beta$$

$$0.05 = k[0.1]^\alpha [0.2]^\beta \quad \ldots \text{(i)}$$

$$0.10 = k[0.2]^\alpha [0.2]^\beta \quad \ldots \text{(ii)}$$

$$0.05 = k[0.1]^\alpha [0.1]^\beta \quad \ldots \text{(iii)}$$

Dividing eq. (i) by eq. (ii), we get

$$\frac{1}{2} = \left[\frac{1}{2}\right]^\alpha, \quad i.e., \quad \alpha = 1$$

Dividing eq. (i) by eq. (iii), we get

$$1 = [2]^\beta, i.e., \beta = 0$$

∴ $$\text{Rate} = k[A]^1 [B]^0$$

Substituting the value of α and β in eq. (i), we get

$$0.05 = k[0.1]^1 [0.2]^0$$

$$k = 0.5 \text{ sec}^{-1}$$

Example 26. $A + 2B \longrightarrow 3C + 2D$

The rate of disappearance of B is 1×10^{-2} mol litre^{-1} sec^{-1}. What will be the (i) rate of the reaction and (ii) rate of change in concentration of A and C? **[CBSE (Mains) 2005]**

Solution: (i) $$\text{Rate} = -\frac{1}{2}\frac{d[B]}{dt}$$

$$= -\frac{1}{2}[-1 \times 10^{-2}]$$

$$= 0.5 \times 10^{-2} \text{ mol litre}^{-1} \text{ sec}^{-1}$$

(ii) $$-\frac{d[A]}{dt} = -\frac{1}{2}\left[\frac{d[B]}{dt}\right] = 0.5 \times 10^{-2} \text{ mol litre}^{-1} \text{ sec}^{-1}$$

$$\frac{1}{3}\frac{d[C]}{dt} = -\frac{1}{2}\frac{d[B]}{dt}$$

$$\frac{d[C]}{dt} = -\frac{3}{2} \times (-1 \times 10^{-2})$$

$$= 1.5 \times 10^{-2} \text{ mol litre}^{-1} \text{ sec}^{-1}$$

Example 27. *For the reaction, $A + B \longrightarrow$ Products, rate is given as, rate $= k[A][B]^2$.*

How will the rate change if volume of the reaction mixture is reduced to 1/3rd of its original volume? **(BCECE 2006)**

Solution: When volume is reduced to 1/3rd, then concentration will increase three times.

∴ $$r_1 = k[A][B]^2 \quad \ldots \text{(i)}$$

$$r_2 = k[3A][3B]^2 \quad \ldots \text{(ii)}$$

From eqs. (i) and (ii),

$$\frac{r_1}{r_2} = \frac{1}{27}$$

$$r_2 = 27r_1$$

∴ Rate will increase 27 times.

Example 28. *For first order reaction, if rate constant at* $17°C$ *is* $2.8 \times 10^{-5}\ s^{-1}$ *and at* $27°C$ *is* $2.8 \times 10^{-4}\ s^{-1}$.

(*i*) *Write the equation for calculation of activation energy.*

(*ii*) *Calculate the activation energy.*

($R = 8.3\ J\ mol^{-1}\ k^{-1}$) [AIPMT (Mains) 2008]

Solution. We know,

$$\log\left(\frac{k_2}{k_1}\right) = \frac{E_a}{2.303R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

$$\log\frac{2.8 \times 10^{-4}}{2.8 \times 10^{-5}} = \frac{E_a}{2.303 \times 8.3}\left[\frac{1}{290} - \frac{1}{300}\right]$$

$$E_a = \frac{2.303 \times 8.3 \times 290 \times 300}{10}$$

$$= 166299.6 \text{ J mol}^{-1}$$

$$= 166.3 \text{ kJ mol}^{-1}$$

SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. Chemical kinetics: It is the branch of chemistry which deals with the rates of reactions, the factors which influence it and the mechanism by which the reactions occur.

2. Rate of reaction: It is the speed with which the reactants are converted into products. It may be expressed in terms of rate of disappearance of any of the reactants or rate of appearance of any of the products.

The rate measured over a long time interval is called the average rate.

$$\text{Average rate of reaction} = -\frac{\text{Decrease in conc. of reactant}}{\text{Time taken}}$$

$$= +\frac{\text{Increase in conc. of product}}{\text{Time taken}}$$

A –ve sign signifies a decrease in concentration of the reactant and +ve sign indicates an increase in concentration of the product.

In general, for a reaction,

$$n_1 A + n_2 B + n_3 C + \ldots \rightarrow m_1 X + m_2 Y + m_3 Z + \ldots$$

$$-\frac{1}{n_1}\frac{\Delta A}{\Delta t} = -\frac{1}{n_2}\frac{\Delta B}{\Delta t} = -\frac{1}{n_3}\frac{\Delta C}{\Delta t} = \ldots$$

$$\frac{1}{m_1}\frac{\Delta X}{\Delta t} = \frac{1}{m_2}\cdot\frac{\Delta Y}{\Delta t} = \frac{1}{m_3}\frac{\Delta Z}{\Delta t} = \ldots$$

Average rate is not very useful as it does not remain constant throughout its life span. It is more appropriate to express instantaneous rate.

Rate of reaction with reference to a particular instant of time is called instantaneous rate of reaction. It is defined as the rate of change of concentration of any one of the reactant or product species over a small interval of time.

$$\text{Rate of reaction} = -\frac{dx}{dt} \text{ or } +\frac{dx}{dt}$$

Units of rate of reaction are conc. time^{-1}, *e.g.*, mol L^{-1}s^{-1} or mol L^{-1} hr^{-1}, etc.

3. Law of mass action: It was presented by Guldberg and Waage in 1864. At a given temperature, the rate of a reaction at a particular instant is proportional to the product of the active masses of the reactants at that instant raised to powers which are numerically equal to the numbers of their respective molecules in the stoichiometric equation describing the reaction. Consider the following general reaction,

$$m_1 A_1 + m_2 A_2 + m_3 A_3 + \ldots \longrightarrow \text{Products}$$

$$\text{Rate of reaction} \propto [A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3} \ldots$$

4. Rate constant: It is equal to rate of reaction when concentration of each reactant is unity, *i.e.*, one mole litre^{-1}. It is a constant for a particular reaction at a given temperature and also known as specific rate constant or specific reaction rate.

Consider a general reaction,

$$aA + bB + \ldots \longrightarrow \text{Products}$$

$$\frac{dx}{dt} = k[A]^a[B]^b \ldots$$

If $\quad C_A = C_B = 1 \quad \text{or} \quad [A] = [B] = 1$

Then, $\quad \dfrac{dx}{dt} = k$

5. Collision theory of reaction rate: A chemical reaction occurs when the existing bonds of the reactants are broken down and new bonds come into existence in the molecules of products. The basic requirement for a reaction to occur is that there should be physical contact between reacting species, *i.e.*, they must collide with one another. Effective collisions which bring chemical change are few inspite of large number of actual collisions. For a collision to be effective, the following two conditions must be satisfied:

(i) Reacting species must possess adequate energy to overcome the energy barrier.

(ii) Reacting molecules must be properly oriented at the time of collision.

The minimum amount of energy which the colliding particles must possess as to make the chemical reaction to occur is called threshold energy. The excess energy (over and above the average energy of the reacting species) required by the reacting species to undergo chemical reaction is called activation energy (E_a).

Activation energy = Threshold energy – Average kinetic energy of the reacting molecules

Every chemical reaction whether exothermic or endothermic has an energy barrier which has to be overcome before the reactants can be transformed into products. The reacting molecules must have sufficient energy as to cross this energy barrier. The effective collisions increase with increase of temperature, *i.e.*, rate of reaction increases with increase of temperature.

6. Factors influencing the reaction rate: The chief factors which influence the rates of reactions are:

(i) Nature of reactants: The reactants with weak bonds react quickly whereas the reactions involving reactants with strong bonds are slow. The molecular reactions are generally slow while ionic reactions are fast.

(ii) Concentration of reactants: The rate of reaction increases with increase in concentration of reactants as the number of collisions increases.

(iii) Catalyst: Positive catalysts increase the reaction rate by providing an alternative path involving lesser amount of activation energy.

(iv) Temperature: The rate of reaction increases with an increase in temperature. The number of effective collisions increases with increase of temperature. The rates of many reactions are approximately doubled or tripled for every 10° C rise in temperature. The temperature coefficient is defined as the ratio of specific reaction rates of a reaction at two temperatures differing by 10° C.

$$\text{Temp. coefficient} = \frac{k_{t+10}}{k_t} \text{ (value lies generally between 2 and 3)}$$

Arrhenius suggested an equation which describes k as a function of temperature, *i.e.*,

$$k = Ae^{-E_a/RT}$$

where, k = rate constant, A = a frequency factor (constant), E_a = energy of activation, R = gas constant and T = temperature.

At two temperatures T_1 and T_2,

$$\log_{10}\left(\frac{k_2}{k_1}\right) = \frac{E_a}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

7. Molecularity and order of reaction:

(i) Molecularity of reaction: The minimum number of reacting particles (molecules, atoms or ions) that come together or collide in a rate determining step to form product or products is called the molecularity of the reaction. The reactions are termed as unimolecular, bimolecular or trimolecular, etc., depending upon the number of reacting particles as 1, 2, 3, etc., in the rate determining step. Simultaneous collisions involving more than three molecules are very rare and hence reactions with molecularity more than three are also rare.

$NH_4NO_2 \rightarrow N_2 + 2H_2O$ (Unimolecular)

$NO + O_3 \rightarrow NO_2 + O_2$ (Bimolecular)

$2FeCl_3 + SnCl_2 \rightarrow 2FeCl_2 + SnCl_4$ (Trimolecular)

In simple reactions involving one step only, the molecularity is equal to the sum of number of molecules of the reactants involved in the balanced equation. There are number of reactions which are complex in nature and occur in several steps; the molecularity of such reactions is determined by the slowest step. Thus, molecularity depends upon the mechanism of the reaction.

(ii) Order of reaction: Rate equation or rate law is an experimentally determined mathematical expression relating the molar concentrations of the reactants to the actual reaction rate.

Consider a general reaction,

$$n_1A + n_2B + n_3C + \ldots \rightarrow \text{Products}$$

The rate law or rate equation is

$$\text{Rate} = -\frac{dx}{dt} = k[A]^x[B]^y[C]^z \ldots$$

Order of reaction is the sum of the exponents (powers) to which molar concentration terms are raised in the rate law.

Order of reaction = $(x + y + z + \ldots)$

The value of $(x + y + z + \ldots)$ usually ranges between 0 and 2 and even 3. It may have positive, negative, zero and fractional values. It is termed overall order. The reactions are classified as zero, first, second, third order according as $(x + y + z + \ldots)$ is zero, one, two or three respectively. The order can be expressed either in terms of the order of the specific reactant or in terms of overall order of the reaction.

The reactions which obey a first order rate equation, although they are not unimolecular, are said to be pseudo first order.

8. Reactions of various orders: In such reactions, the concentrations of various reactants except one remain practically constant during the course of reaction.

(i) Zero order reactions:. A reaction in which the rate is independent of the concentration of the reactant molecules, *i.e.*, the rate is proportional to the zeroth power of the concentration of the reactants.

$$-\frac{dx}{dt} = k[A]_0 = k$$

i.e., the reaction velocity remains constant throughout the progress of the reaction. The concentration decreases linearly with time.

$$[A]_t = [A]_0 - kt$$

$$t_{\text{completion}} = \frac{[A]_0}{k} = \frac{\text{Initial concentration}}{\text{Rate constant}}$$

The units of k are mol L^{-1} time^{-1}.

(ii) First order reactions: The rate depends upon the concentration of one reactant only.

$$-\frac{dx}{dt} = k[A]$$

$$k = \frac{2.303}{t}\log_{10}\frac{a}{(a-x)} = \frac{2.303}{t}\log_{10}\frac{[A]_0}{[A]_t}$$

t = time, a = initial concentration and $(a - x)$ = concentration at time t.

A change in concentration unit does not affect the numerical value of k. Thus, for first order reactions, any quantity which is proportional to concentration can be used in place of concentration in the integrated equation.

The time taken for the completion of same fraction of change is independent of initial concentration. When $x = 0.5a$ and $t = t_{1/2}$,

$$k = \frac{2.303}{t_{1/2}} \log_{10} \frac{a}{0.5a} = \frac{2.303}{t_{1/2}} \log_{10} 2 = \frac{0.693}{t_{1/2}}$$

$$t_{1/2} = \frac{0.693}{k}$$

Thus, $t_{1/2}$ is independent of initial concentration.

The equation of the first order can also be written in the following form when initial concentration is not known.

$$k = \frac{2.303}{(t_2 - t_1)} \log_{10} \frac{(a - x_1)}{(a - x_2)} = \frac{2.303}{(t_2 - t_1)} \log_{10} \frac{[A]_{t_1}}{[A]_{t_2}}$$

The unit of k is time^{-1}.

(iii) Second order reactions: Reaction rate depends upon the concentration of two reactants.

$$\frac{dx}{dt} = k[A][B] = k[A]^2$$

$$k = \frac{2.303}{t(a-b)} \log_{10} \frac{b(a-x)}{a(b-x)}$$

[$(a-x)$ and $(b-x)$ are the concentrations of A and B after time interval t.]

When concentrations of both the reactants are same,

$$k = \frac{1}{t} \cdot \frac{x}{a(a-x)}$$

(x is the concentration changed in time interval t)

Half life period, $t_{1/2} = \frac{1}{ka}$, *i.e.*, inversely proportional to initial concentration. The units of k are litre mol^{-1} time^{-1}.

(iv) Third order reactions: Expression for third order reactions of the type

$$3A \rightarrow \text{Products}$$

$$\frac{dx}{dt} = k[A]^3$$

$$k = \frac{1}{t} \cdot \frac{x(2a - x)}{2a^2 (a-x)^2}$$

The units of k are L^2 mol^{-2} time^{-1}.

9. Methods for the determination of order of a reaction:

(i) Initial rate method: A number of experiments are carried out by varying concentration of a reactant w.r.t. which the order is to be determined keeping the concentrations of all other reactants constant. The initial rate of the reaction at each concentration is determined by concentration-time curves. The order of the reactant is then calculated from the rates at various concentrations. The experiments are repeated with other reactants in a similar way. Likewise, the orders w.r.t. all reactants are determined. The overall order is the sum of the orders of all the reactants.

(ii) Integration method: The quantities a, x and t are determined and substituted in the kinetic equations of various orders. The equation which gives the most consistent values for the specific rate constant (k) for a series of time intervals is the one corresponding to order of reaction.

$k = \frac{2.303}{t} \log_{10} \frac{a}{(a-x)}$ for first order reactions

$k = \frac{1}{t} \cdot \left[\frac{a}{a(a-x)}\right]$ for second order reactions

Rate $= k$ for zero order reactions

(iii) Graphical method: If the plot of $\log(a-x)$ *versus* 't' is a straight line, the reaction follows first order.

If a plot of $\frac{1}{(a-x)}$ *versus* 't' is a straight line, the reaction follows second order.

If a plot of $\frac{1}{(a-x)^2}$ *versus* 't' is a straight line, the reaction follows third order.

(iv) Half life method: Starting with two different concentrations a_1 and a_2 for the same reaction, the half lives $(t_{1/2})_1$ and $(t_{1/2})_2$ are determined.

$$\frac{(t_{1/2})_1}{(t_{1/2})_2} = \left(\frac{a_2}{a_1}\right)^{n-1} \quad \text{or} \quad n = 1 + \frac{\log (t_{1/2})_1 - \log (t_{1/2})_2}{\log a_2 - \log a_1}$$

n is the order of reaction.

(v) van't Hoff differential method: For two different initial concentrations C_1 and C_2 equations can be written in the form

$$-\frac{dC_1}{dt} = kC_1^n \text{ and } -\frac{dC_2}{dt} = kC_2^n$$

Taking logarithms of two equations and then subtracting

$$n = \frac{\log\left(-\frac{dC_1}{dt}\right) - \log\left(-\frac{dC_2}{dt}\right)}{\log C_1 - \log C_2}$$

10. Mechanism: An intelligent guess depending upon the observed rates of reactions about the series of steps (known as elementary processes) leading to the formation of products is called the reaction mechanism. The overall reaction is the summation of all elementary steps. The slowest step is taken as the rate determining step.

Questions

1. **Matrix Matching Problems:**
(According to the new pattern of IIT Screening)

[A] Match the reactions of List-I with their orders in List-II:

List-I	**List-II**
(a) $C_{12}H_{22}O_{11} + H_2O \xrightarrow{H^+} C_6H_{12}O_6 + C_6H_{12}O_6$	(p) Pseudo first order
(b) $CH_3COOC_2H_5 \xrightarrow[H^+ \text{ or } OH^-]{HOH} CH_3COOH + C_2H_5OH$	(q) Zero order
(c) $H_2 + Cl_2 \xrightarrow{h\nu} 2HCl$	(r) Second order
(d) $CH_3Cl + OH^- \longrightarrow CH_3OH + Cl^-$	(s) First order

[B] Match the reactions in Column-I with the units of their rate constant in Column-II:

Column-I **(Reactions)**	**Column-II** **(Unit of k)**
(a) $SO_2Cl_2 \longrightarrow SO_2 + Cl_2$	(p) sec^{-1}
(b) $CH_3COOC_2H_5 + NaOH \longrightarrow CH_3COONa + C_2H_5OH$	(q) min^{-1}
(c) $2H_2O_2 \longrightarrow 2H_2O + O_2$	(r) $L\ mol^{-1}\ min^{-1}$
(d) $H_2O_2 + 2I^- + 2H^+ \longrightarrow 2H_2O + I_2$	(s) $L\ mol^{-1}\ s^{-1}$

[C] Match the kinetic equations of Column-I with the units of their rate constant in Column-II:

Column-I **(Kinetic equations)**	**Column-II** **(Units of rate constant)**
(a) $x = kt$	(p) sec^{-1}
(b) $k = \frac{2.303}{t}\log_{10}\left(\frac{a}{a-x}\right)$	(q) $L\ mol^{-1}\ sec^{-1}$
(c) $k = \frac{1}{t}\left[\frac{1}{(a-x)} - \frac{1}{a}\right]$	(r) $mol\ L^{-1}\ sec^{-1}$
(d) $k = \frac{2.303}{t(a-b)}\log\left[\frac{b(a-x)}{a(b-x)}\right]$	(s) $atm^{-1}\ sec^{-1}$

[D] Match the half lives in Column-I with the orders in Column-II:

Column-I **(Half life)**	**Column-II** **(Order)**
(a) $t_{1/2}$ = constant	(p) First order
(b) $t_{1/2} \propto a$	(q) Pseudo first order
(c) $t_{1/2} \propto \frac{1}{a}$	(r) Second order
(d) $t_{1/2} \propto p^{-1}$	(s) Zero order

where, a = Initial concentration of the reactant
p = Initial pressure of the reactant

[E] Match the reactions of List-I with the increase in rate when concentration is raised two times in List-II:

List-I **(Reactions)**	**List-II** **(Increase in rate when conc. of reactant is doubled)**
(a) $CH_3CHO \longrightarrow CH_4 + CO$	(p) 2 times
(b) $SO_2Cl_2 \longrightarrow SO_2 + Cl_2$	(q) $2^{1.5}$ times
(c) $2H_2O_2 \longrightarrow 2H_2O + O_2$	(r) 2 times in acid medium
(d) $CH_3COOC_2H_5 \xrightarrow{HOH} CH_3COOH + C_2H_5OH$	(s) 2^2 times in basic medium

[F] Match the List-I with Liwst-II and List-III:

List-I	**List-II**	**List-III**
(a) x is plotted against 't' in zero order reaction	(p) Slope= $-k/2.303$	(u) Intercept = 0
(b) $\log(a-x)$ is plotted against 't' in first order reaction	(q) Slope = $2k$	(v) Intercept $= 1/a$
(c) $(a-x)^{-1}$ is plotted against 't' in second order reaction	(r) Slope = $-k$ (when log is natural)	(w) Intercept $= 1/a^2$
(d) $(a-x)^2$ is plotted against 't' in second order reaction	(s) Slope = k	(x) Intercept $= \log_{10} a$

where, a = Initial concentration of reactant
x = Extent of reaction in time 't' sec

[G] Match the List-I with List-II:

List-I	**List-II**
(a) Molecularity	(p) 0
(b) Order	(q) 1/2
(c) Temperature coefficient	(r) Between 2 to 3
(d) Activation energy for participation of all reactant molecules	(s) 2

[H] Match the Column-I with Column-II:

Column-I **(Rate law)**	**Column-II** **(Order)**
(a) Rate = $k \times$ Intensity of light	(p) Second order
(b) Rate = $k[A]^1[B]^1$	(q) Zero order
(c) Rate = $k[A]^{3/2}[B]^{1/2}$	(r) First order when A is excess
(d) Rate = $k[A]^2[B]^1$	(s) Second order when B is excess

[I] Match the Column-I with Column-II:

Column-I	Column-II
(a) $t_{1/2} = \frac{0.693}{k}$	(p) Zero order
(b) $t_{1/2} = \frac{a}{2k}$	(q) First order
(c) $\tau = \frac{1}{k}$	(r) Average life
(d) $t_{3/4} = 2t_{1/2}$	(s) 75% completion
	(t) 25% completion

[J] Match the Column-I with Column-II:

Column-I	Column-II
(a) $t_{3/4} = \frac{3}{2} \times t_{1/2}$	(p) 99% completion
(b) $t_{3/4} = 2 \times t_{1/2}$	(q) Zero order
(c) $6.909/k$	(r) First order
(d) $2.303/k$	(s) 90% completion

Here, $t_{1/2}$ = half life
$t_{3/4}$ = 3/4th life
k = rate constant

[K] Match the Column-I with Column-II:

Column-I	Column-II
(a) First order reaction	(p) $C_0 = 0.1\,M$; $t_{1/2} = 25$ min $C_0 = 0.05\,M$; $t_{1/2} = 12.5$ min
(b) Second order reaction	(q) $C_0 = 0.1\,M$; $t_{1/2} = 12$ min $C_0 = 0.05\,M$; $t_{1/2} = 24$ min
(c) Zero order reaction	(r) Radioactive decay
(d) $t_{1/2}$ varies inversely to the concentration of the reactants	(s) $C_0 = 0.1\,M$; $t_{1/2} = 8$ min $C_0 = 0.05\,M$; $t_{1/2} = 8$ min

• PRACTICE PROBLEMS •

1. For the reaction $A \rightarrow B$, it was found that the concentration of B increased by 0.3 mol L^{-1} in 2 hours. What is the average rate of reaction?
[Ans. 0.15 mol L^{-1} hr^{-1}]

2. In the reaction $X \rightarrow Y$, the initial concentration of X is 2.5 mol L^{-1} and its concentration after 3 hours is 0.7 mol L^{-1}. What is the average rate of the reaction?
[Ans. 6.0×10^{-1} mol $L^{-1}hr^{-1}$]

3. For the reaction $2A + B \rightarrow C$, the rate of formation of C is 0.25 mol L^{-1} hr^{-1}. What is the rate of disappearance of A and B?
[Ans. 0.5 mol L^{-1} hr^{-1}; 0.25 mol L^{-1} hr^{-1}]

4. For each of the following reactions express the given rate of change of the concentration of the reactant or product in terms of the rate of change of concentration of the other reactants or products in that reaction.

(i) $N_2 + 3H_2 \rightarrow 2NH_3$; $-\frac{d[H_2]}{dt} = ?$

(ii) $H_2 + \frac{1}{2}O_2 \rightarrow H_2O$; $-\frac{d[O_2]}{dt} = ?$

(iii) $2NO + Cl_2 \rightarrow 2NOCl$; $\frac{d[NOCl]}{dt} = ?$

(iv) $CO + NO_2 \rightarrow CO_2 + NO$; $-\frac{d[NO_2]}{dt} = ?$

[Ans. (i) $-\frac{d[H_2]}{dt} = -3 \cdot \frac{d[N_2]}{dt} = +\frac{3}{2}\frac{d[NH_3]}{dt}$;

(ii) $-\frac{d[O_2]}{dt} = -\frac{1}{2}\frac{d[H_2]}{2 \cdot dt} = \frac{1}{2}\frac{d[H_2O]}{dt}$;

(iii) $\frac{d[NOCl]}{dt} = -\frac{d[NO]}{dt} = 2 \cdot \frac{d[Cl_2]}{dt}$

(iv) $-\frac{d[NO_2]}{dt} = -\frac{d[CO]}{dt} = \frac{d[CO_2]}{dt} = \frac{d[NO]}{dt}$]

5. When ammonia is treated with O_2 at elevated temperatures, the rate of disappearance of ammonia is found to be 3.5×10^{-2} mol dm^{-3} s^{-1} during a measured time interval. Calculate the rate of appearance of nitric oxide and water.
[Ans. $\frac{\Delta[NO]}{dt} = 3.5 \times 10^{-2}$ mol dm^{-3} s^{-1};
$\frac{\Delta[H_2O]}{dt} = 5.3 \times 10^{-2}$ mol dm^{-3} s^{-1}]

[**Hint:** Consider the following equation:

$$4NH_3 + 5O_2 \rightarrow 4NO + 6H_2O$$

The equality in this case is

$$-\frac{1}{4}\frac{\Delta[NH_3]}{dt} = \frac{1}{4}\frac{\Delta[NO]}{dt} = \frac{1}{6}\frac{\Delta[H_2O]}{dt}\ ]$$

6. In a reaction, $N_2O_5 \rightarrow 2NO_2 + \frac{1}{2}O_2$, the rate of disappearance of N_2O_5 is 6.5×10^{-3} mol L^{-1} s^{-1}. Compute the rates of formation of NO_2 and O_2.

[**Ans.** $\frac{d[NO_2]}{dt} = 1.25 \times 10^{-2}$ mol L^{-1} s^{-1};

$\frac{d[O_2]}{dt} = 3.125 \times 10^{-3}$ mol L^{-1} s^{-1}]

7. For the reaction,

$$2O_3 \rightleftharpoons 3O_2$$

$-\frac{\Delta[O_3]}{dt}$ was found to be 4.0×10^{-4} atm s^{-1}.

Determine the value of $\frac{\Delta[O_2]}{\Delta t}$ in atm s^{-1} during this period of time.

[**Ans.** 6.0×10^{-4} atm s^{-1}]

8. The following reaction was carried out at 44° C:

$$N_2O_5 \rightarrow 2NO_2 + \frac{1}{2}O_2$$

The concentration of NO_2 is 6.0×10^{-3} M after 10 minutes of the start of the reaction. Calculate the rate of production of NO_2 over the first ten minutes of the reaction.

[**Ans.** 6.0×10^{-4} mol L^{-1} min^{-1}]

9. The rate of a particular reaction doubles when temperature changes from 27°C to 37°C. Calculate the energy of activation for such reaction. ($R = 8.314$ J K^{-1} mol^{-1})

[**Ans.** 53.59 kJ mol^{-1}]

10. The rate constant of a reaction is 2×10^{-2} s^{-1} at 300 K and 8×10^{-2} s^{-1} at 340 K. Calculate the energy of activation of the reaction.

[**Ans.** 29.39 kJ mol^{-1}]

11. For a chemical reaction the energy of activation is 85 kJ mol^{-1}. If the frequency factor is 4.0×10^{9} L mol^{-1} s^{-1}, what is the rate constant at 400 K?

[**Ans.** $k = 3.19 \times 10^{-2}$ L mol^{-1}s^{-1}]

12. The energy of activation of a reaction is 140 kJ mol^{-1}. If its rate constant at 400 K is 2.0×10^{-6} s^{-1}, what is the value at 500 K?

[**Ans.** 9.06×10^{-3} s^{-1}]

13. Calculate the ratio of the catalysed and uncatalysed rate constant at 20°C if the energy of activation of a catalysed reaction is 20 kJ mol^{-1} and for the uncatalysed reaction is 75 kJ mol^{-1}.

[**Ans.** 6.4×10^{9}]

14. The decomposition of methyl iodide,

$$2CH_3I(g) \rightarrow C_2H_6(g) + I_2(g)$$

at 273° C has a rate constant of 2.418×10^{-5} s^{-1}. If activation energy for the reaction is +179.9 kJ mol^{-1}, what is the value of collision factor 'A' at 273° C?

[**Ans.** 3.9×10^{12} s^{-1}]

15. The reaction,

$$2N_2O_5 \rightarrow 2N_2O_4 + O_2$$

occurs in carbon tetrachloride. The rate constant is 2.35×10^{-4} sec^{-1} at 20° C and 9.15×10^{-4} sec^{-1} at 30° C. Calculate the activation energy of the reaction.

[**Ans.** 100.343 kJ mol^{-1}]

16. For the inversion of cane sugar,

$$C_{12}H_{22}O_{11} + H_2O \rightarrow C_6H_{12}O_6 + C_6H_{12}O_6,$$

the rate constant is 2.12×10^{-4} L mol^{-1} sec^{-1} at 27° C. The activation energy of the reaction is 1.07×10^{5} J mol^{-1}. What is the rate constant of the reaction at 37° C?

[**Ans.** 8.46 L mol^{-1} sec^{-1}]

17. From the data given below for the reaction $2A + B \rightarrow 3C$ at 298 K, find out the rate law expression for the reaction.

Expt. No.	[A] (mol L^{-1})	[B] (mol L^{-1})	Rate of formation of C
1.	0.10	0.10	4.0×10^{-4}
2.	0.30	0.30	1.2×10^{-3}
3.	0.10	0.30	4.0×10^{-4}
4.	0.20	0.40	8.0×10^{-4}

[**Ans.** Rate $= k[A]$]

18. What is the rate law expression for the reaction,

$$A + B \rightarrow C\ ?$$

The following data were collected from the experiments:

Expt. No.	Initial [A] (mol L^{-1})	Initial [B] (mol L^{-1})	Rate of formation of C
1.	0.10	0.10	4.0×10^{-4}
2.	0.20	0.20	3.2×10^{-3}
3.	0.10	0.20	1.6×10^{-3}

[**Ans.** Rate $= k[A][B]^2$]

19. The reaction,

$$2N_2O_5 \rightarrow 2NO_2 + O_2,$$

was studied and the following data were collected:

Expt. No.	[N_2O_5] (mol L^{-1})	Rate of disappearance of N_2O_5 (mol L^{-1} min^{-1})
1.	1.13×10^{-2}	34×10^{-5}
2.	0.84×10^{-2}	25×10^{-5}
3.	0.62×10^{-2}	18×10^{-5}

Determine (i) order the reaction (ii) the rate law and (iii) rate constant for the reaction.

[**Hint:** Let the rate law for the reaction be

$$\text{Rate} = k[N_2O_5]^x$$

$$34 \times 10^{-5} = k[1.13 \times 10^{-2}]^x$$

$$25\times10^{-5}=k[0.84\times10^{-2}]^x$$

or $$\frac{34\times10^{-5}}{25\times10^{-5}}=\frac{[1.13\times10^{-2}]^x}{[0.84\times10^{-2}]^x}$$

$$1.36=[1.345]^x$$

$$x=1$$

Order of the reaction is 1. Rate law = $k[N_2O_5]$

$$k=\frac{\text{Rate}}{[N_2O_5]}=\frac{34\times10^{-5}}{1.13\times10^{-2}}=30.08\times10^{-3}\ \text{min}^{-1}]$$

20. For the reaction,

$$2NO+2H_2\rightarrow N_2+2H_2O,$$

the following kinetic data were obtained:

Expt. No.	$[H_2]$ (mol L^{-1})	[NO] (mol L^{-1})	Rate of reaction (mol L^{-1} s^{-1})
1.	0.12	0.12	0.25×10^{-4}
2.	0.12	0.24	1.0×10^{-4}
3.	0.24	0.24	2.0×10^{-4}

Determine the rate law and the rate constant.

[**Ans.** Rate = $k[H_2][NO]^2$; $k=1.45\times10^{-2}$ L^2 mol^{-2} s^{-1}]

21. Fill in the blanks in the following table which treats reaction of a compound A with a compound B, that is of the first order with respect to A and zero order with respect to B:

Expt. No.	$[A]$ (mol L^{-1})	$[B]$ (mol L^{-1})	Initial rate (mol L^{-1} s^{-1})
1.	0.1	0.1	2.0×10^{-2}
2.	...	0.2	4.0×10^{-2}
3.	0.4	0.4	...
4.	...	0.2	2.0×10^{-2}

[**Ans.** (2) $[A]=0.2$ mol L^{-1}
(3) Rate = 8.0×10^{-2} mol L^{-1} s^{-1}
(4) $[A]=0.1$ mol L^{-1}]

22. The reaction $2NO+O_2\rightarrow2NO_2$, follows the rate law $=k[NO]^2[O_2]$. What is the order of the reaction? If $k=2.0\times10^{-6}$ mol^{-2} L^2 s^{-1}, what is the rate of the reaction when [NO] = 0.04 mol L^{-1} and $[O_2]=0.2$ mol L^{-1}?

[**Ans.** Order of the reaction = 3;
Rate = 6.4×10^{-10} mol L^{-1} s^{-1}]

23. From the following data of initial concentrations and rates, calculate the order of reaction $aA\rightarrow$ Products; and its rate constant.

$[A]$ mol L^{-1}	0.1	0.2	0.4
Rate mol L^{-1} s^{-1}	9×10^{-5}	36×10^{-5}	144×10^{-5}

[**Ans.** Order of reaction = 2;
Rate constant = 9.0×10^{-3} mol^{-1} L s^{-1}]

24. For a reaction $aA+bB\rightarrow mM+nN$, the rate of reaction is given as $k[A]^x[B]^y$.

Calculate the order of the reaction and the rate constant from the given initial concentrations and the corresponding rates.

$[A]$ mol L^{-1}	0.1	0.1	0.2
$[B]$ mol L^{-1}	0.2	0.4	0.2
Rate mol $L^{-1}s^{-1}$	4×10^4	16×10^4	8×10^4

[**Ans.** Order of the reaction = 3, $k=1.0\times10^7$ L^2 mol^{-2} s^{-1}]

25. The data given in the following table pertain to the reaction,

$$2A+B\rightarrow C.$$

Determine the form of the rate equation and the value of the rate constant.

Expt. No.	Initial concentration (mol L^{-1})		Initial rate (mol L^{-1} s^{-1})
	$[A]$	$[B]$	
1.	1×10^{-3}	1×10^{-3}	7×10^{-6}
2.	1×10^{-3}	2×10^{-3}	14×10^{-6}
3.	1×10^{-3}	3×10^{-3}	21×10^{-6}
4.	2×10^{-3}	3×10^{-3}	84×10^{-6}

[**Ans.** Rate = $k[A]^2[B]$; $k=7\times10^3$]

26. The following initial rate data were obtained for the reaction:

$$2NO(g)+Br_2(g)\rightarrow2NOBr(g)$$

Run	[NO]/M	$[Br_2]$/ M	Rate/M min^{-1}
1.	1.0	1.0	1.30×10^{-3}
2.	2.0	1.0	5.20×10^{-3}
3.	4.0	2.0	4.16×10^{-2}

Determine the reaction rate law and the value of the rate constant. **(Dhanbad 1992)**

[**Ans.** $-\frac{dx}{dt}=k[NO]^2[Br_2]$; $K=1.30\times10^{-3}$ mol^{-2} L^2 s^{-1}]

27. The data below are for the reaction of NO and Cl_2 to form NOCl at 295 K.

Expt. No.	$[Cl_2]$ (mol L^{-1})	[NO] (mol L^{-1})	Initial rate (mol L^{-1} s^{-1})
1.	0.05	0.05	1.0×10^{-3}
2.	0.15	0.05	3.0×10^{-3}
3.	0.05	0.15	9.0×10^{-3}

(a) What is the order w.r.t. NO and Cl_2 in the reaction?
(b) Write the rate expression.
(c) Calculate the rate constant.
(d) Determine the reaction rate when concentrations of Cl_2 and NO are 0.2 M and 0.4 M respectively. **(IIT 1993)**

[**Ans.** (a) Order w.r.t. NO = 2; order w.r.t. Cl_2 = 1
(b) Rate expression, $r=k[NO]^2[Cl_2]$
(c) $k=8.0$ L^2 mol^{-2} s^{-1}
(d) Rate = 0.256 mol L^{-1} s^{-1}]

28. In the hydrolysis of propyl acetate in presence of dilute HCl in aqueous solution, the following data were recorded:

Time from start (in minute)	60	350
% of ester decomposed	18.17	69.12

Calculate the rate constant of decomposition and time in which half of the ester was decomposed.

[**Ans.** 3.34×10^{-3} min^{-1}; 207.6 min]

29. In a first order reaction the concentration of the reactant is reduced to one-fourth of its initial value in 50 seconds. Calculate the rate constant of the reaction.

[**Ans.** 2.77×10^{-2} s^{-1}]

30. For a first order reaction, the rate constant is 0.1 s^{-1}. How much time will it take to reduce the concentration from initial value of 0.6 mol L^{-1} to 0.06 mol L^{-1}?

[**Ans.** 23.0 second]

31. A substance decomposes following first order reaction. If the half life period of the reaction is 35 minutes, what is the rate constant of this reaction?

[**Ans.** 1.98×10^{-2} min^{-1}]

32. For a certain first order reaction, it takes 5 minutes for the initial concentration of 0.6 mol L^{-1} to become 0.2 mol L^{-1}. What is the rate constant for this reaction? [log 3 = 0.4771].

[**Ans.** 0.2197 min^{-1}]

33. Find the two-thirds life ($t_{2/3}$) of a first order reaction in which $k = 5.48 \times 10^{-1}$ sec^{-1} (log 3 = 0.4771; log 2 = 0.3010).

[**Ans.** 2.005 s]

[**Hint:** $t_{2/3} = \dfrac{2.303}{k} \log_{10} \dfrac{a}{a - \frac{2}{3}a}$]

34. A first order reaction has a specific rate of 10^{-3} sec^{-1}. How much time will it take from 10 g of the reactant to reduce to 7.5 g (log 2 = 0.3010; log 4 = 0.6020 and log 6 = 0.7782)?

[**Ans.** 287.7 s]

35. In a reaction 5 g ethyl acetate is hydrolysed per litre in presence of dilute HCl in 300 min. If the reaction is of first order and initial concentration is 22 g per litre, calculate the rate constant for the reaction.

[**Ans.** $k = 8.59 \times 10^{-4}$ min^{-1}]

36. Calculate the half life of the reaction $A \to B$, when the initial concentration of A is 0.01 mol L^{-1} and initial rate is 0.00352 mol L^{-1} min^{-1}. The reaction is of the first order.

[**Ans.** 1.969 min]

[**Hint:** Evaluate k from $\dfrac{dx}{dt} = k[A]$]

37. In a reaction, $A \to B + C$, the following data were obtained:

t in seconds	0	900	1800
Concentration of A	50.8	19.7	7.62

Prove that it is a first order reaction.

[**Hint:** Calculate the value of k in both cases by using first order equation.]

38. The first order reaction has $k = 1.5 \times 10^{-6}$ per second at 200° C. If the reaction is allowed to run for 10 hours at the same temperature, what percentage of the initial concentration would have changed into the product? What is the half life period of this reaction?

[**Ans.** $t_{1/2} = 128.3$ hours; 5.27%]

39. A first order reaction is 20% completed in 10 minutes. Calculate (i) the specific rate constant of the reaction and (ii) the time taken for the reaction to go to 75% completion.

[**Ans.** $k = 2.232 \times 10^{-2}$ min^{-1}; $t = 62.12$ min]

40. The rate constant of a reaction with respect to reactant A is 6 min^{-1}. If we start with $[A] = 0.8$ mol L^{-1}, when would $[A]$ reach the value of 0.08 mol L^{-1}?

[**Ans.** 0.3838 min]

41. What will be the initial rate of a reaction if the rate constant is 10^{-3} min^{-1} and the concentration is 0.2 mol dm^{-3}? How much of the reactant will be converted into the product in 200 minutes? [illegible]

[**Ans.** Initial rate = 2×10^{-4} mol L^{-1} s^{-1}; 0.036 mol]

42. A substance A decomposes by the first order reaction. Starting initially with $[A] = 2.00\,M$, after 200 minutes $[A] = 0.25\,M$. For this reaction what is $t_{1/2}$ and k? [illegible]

[**Ans.** $t_{1/2} = 66.66$ min, $k = 0.01039$ min^{-1}]

43. The specific rate constant for the concentration of H_2 and I_2 to form HI is 0.0234 mol^{-1} L s^{-1} at 400° C and 750 mol^{-1} L s^{-1} at 500° C. Calculate the activation energy of the reaction.

[CEE (Bihar) [illegible]]

[**Ans.** 107.9 kcal]

44. For a certain reaction it takes 10 minutes for the initial concentration of 2.0 mol L^{-1} to become 1.0 mol L^{-1} and another 10 minutes to become 0.5 mol L^{-1}. Calculate the rate constant of the reaction. [illegible]

[**Ans.** 0.0693 min^{-1}]

45. The catalytic decomposition of H_2O_2 was studied by titrating it at different intervals with $KMnO_4$ and the following data were obtained:

t (seconds)	0	600	1200
V of $KMnO_4$ (mL)	22.8	13.8	8.3

Calculate the velocity constant for the reaction assuming it to be a first order reaction.

[**Ans.** 8.4×10^{-3} s^{-1}]

[**Hint:** Volume of $KMnO_4$ used $\propto$ concentration of H_2O_2

Hence, $k = \dfrac{2.303}{t} \log_{10} \dfrac{V_0}{V_t}$]

46. The half life of a first order reaction is 10 seconds. Calculate the time for completion of 99.9% of the reaction.

[**Ans.** 99.7 sec ≈ 100 sec]

47. A first order reaction is 40% complete after 8 min. How long will it take before it is 90% complete? What is the value of the rate constant?

[**Ans.** $k = 0.06386$ min^{-1}; $t = 36.06$ min]

48. The reaction $SO_2Cl_2 \to SO_2 + Cl_2$, is a first order gas reaction with $k = 2.2 \times 10^{-5}$ s^{-1} at 573 K. What per cent of SO_2Cl_2 is decomposed on heating at 573 K for 90 min?

[**Ans.** 11.2]

49. The decomposition of $AB(g) \rightarrow A(g) + B(g)$, is first order reaction with a rate constant $k = 4 \times 10^{-4}\ \text{s}^{-1}$ at 318 K. If AB has 26664.5 Pa pressure at the initial stage, what will be the partial pressure of AB after half an hour?

[**Ans.** 12981.7 Pa]

50. In the first order reaction $A(g) \rightarrow B(g) + C(g)$, the initial pressure of A is 11200 Pa and the total pressure at the end of 16 minutes is 14667 Pa. Calculate the half life period of reaction.

[**Ans.** 30 min]

51. It was found that a solution of cane sugar was hydrolysed to the extent of 25% in 1 hr. Calculate the time taken for the sugar to be 50% hydrolysed assuming that the reaction is of first order.

[**Ans.** 2.408 hours]

52. A reaction is 20% complete in 20 minutes. How long will it take for 80% completion if the order of reaction is (a) zero and (b) one?

[**Ans.** (a) 80 minutes (b) 144.27 minutes]

53. A second order reaction where $a = b$ is 20% completed in 500 seconds. How long will the reaction take to be 60% complete?

[**Hint:** Apply

$$k = \frac{x}{ta(a - x)} = \frac{20}{500\,[100 \times (100 - 20)]} = \frac{1}{200000}\ \text{mol}^{-1}\ \text{L s}^{-1}$$

$$t = \frac{60}{k \times 100 \times 40} = \frac{60 \times 200000}{100 \times 40} = 3000 \text{ seconds]}$$

54. At a certain temperature, the half life periods of a reaction at different initial pressures were as follows:

p (kPa)	100	66.67	33.33
t (min)	105	235	950

Find out the order of the reaction.

[**Ans.** 3]

55. The time for half change for a gaseous reaction was measured for various initial pressures and the following data were obtained:

p (kPa)	26.6	40	53.3
t (min)	150	99.8	75.3

Find out the order of the reaction.

[**Ans.** 2]

56. Show that for a first order reaction the time required for 99% completion is twice the time required for the completion of 90% of the reaction.

57. Show that for a first order reaction the time required to complete 99.9% of the reaction is 10 times that required for half the reaction.

58. Show that for a first order reaction, the time required for a 50% reaction is half that for 75% reaction.

59. The decomposition of an aqueous solution of ammonium nitrite was studied. The volume of nitrogen gas collected at different intervals of time was as follows:

Time (minutes)	10	15	20	∞
Vol. of N_2 (mL)	6.25	9.00	11.40	35.05

From the above data prove that the reaction is of the first order.

[**Hint:** $[A]_0 =$ volume of nitrogen at $\infty = 35.05$

$$[A]_t = V_\infty - V_t$$

when $t = 10$, $k = \dfrac{2.303}{10} \log \dfrac{35.05}{(35.05 - 6.25)} = 0.0196$

when $t = 15$, $k = 0.0198$

when $t = 20$, $k = 0.0196$]

60. Optical rotation of sucrose in 1 N HCl at various times was found as shown below:

Time (sec)	0	7.18	18.0	27.05	∞
Rotation (deg)	+ 24.09	+ 21.7	+ 17.7	+15.0	−10.74

Show that the inversion of sucrose is a first order reaction.

[**Hint:** Initial concentration, $[A]_0 = r_0 - r_\infty$

At time t, $[A]_t = r_t - r_\infty$

$$k = 11.8 \times 10^{-3}\ \text{s}^{-1}\,]$$

61. The rate law for the decomposition of gaseous N_2O_5

$$N_2O_5 \rightarrow 2NO_2 + \tfrac{1}{2}O_2$$

is observed to be:

$$-\frac{d[N_2O_5]}{dt} = k[N_2O_5]$$

A reaction mechanism which has been suggested to be consistent with this is:

$$N_2O_5 \overset{K}{\rightleftharpoons} NO_2 + NO_3 \qquad \text{(fast)}$$

$$NO_2 + NO_3 \xrightarrow{k_1} NO_2 + NO + O_2 \qquad \text{(slow)}$$

$$NO + NO_3 \xrightarrow{k_2} 2NO_2 \qquad \text{(fast)}$$

Show that the mechanism is consistent with the observed law.

[**Hint:** $r = k_1[NO_2][NO_3]$,

$$K = \frac{[NO_2][NO_3]}{[N_2O_5]} \quad \text{or} \quad [NO_3] = \frac{K[N_2O_5]}{[NO_2]}$$

$$r = k_1K[N_2O_5] = k[N_2O_5]\,]$$

62. Write the overall reaction and the rate law equation from the following elementary steps:

$$NO + Br_2 \rightleftharpoons NOBr_2$$

$$NOBr_2 + NO \rightarrow 2NOBr$$

[**Hint:** Adding both the steps, we get overall reaction,

$$2NO + Br_2 \rightarrow 2NOBr.$$

The second step is slow and, therefore, a rate determining step.

$$r = k'[NOBr_2][NO]$$

$$K = \frac{[NOBr_2]}{[NO][Br_2]} \quad \text{or} \quad [NOBr_2] = K[NO][Br_2]$$

$$r = k'K[NO]^2[Br_2]\,]$$

63. The reaction, $2NO + O_2 \rightarrow 2NO_2$ proceeds in two steps. If one elementary reaction is $NO + O_2 \rightarrow NO_3$, write the second elementary reaction. Write the rate law of the reaction.

[**Ans.** $NO + NO_3 \rightarrow 2NO_2$, rate $= k[NO]^2[O_2]$]

64. At 380° C, the half life period for the first order decomposition of H_2O_2 is 360 min. The energy of activation of the reaction is 200 kJ mol^{-1}. Calculate the time required for 75% decomposition at 450° C. **(IIT 1995)**

[**Ans.** 20.39 min]

65. Calculate the average rate of decomposition of N_2O_5 by the reaction,

$$2N_2O_5(g) \rightarrow 4NO_2(g) + O_2(g).$$

During the time interval from $t = 600$ s to $t = 1200$ s using the following data:

Time	$[N_2O_5]$
600 s	$1.24 \times 10^{-2}\ M$
1200 s	$0.93 \times 10^{-2}\ M$

[CEE (Bihar) 1995]

[**Ans.** $5.166 \times 10^{-6}\ M\ s^{-1}$]

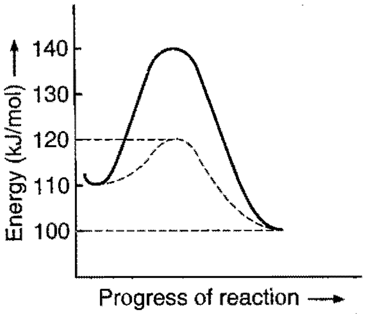
66. Consider the diagram for reaction:

$$A_2 + B_2 \rightleftharpoons 2AB$$

(a) Calculate the ΔH of the reaction.

(b) Calculate the energy of activation for forward and backward reaction.

(c) The dotted line curve is the path in the presence of a catalyst. What is the energy of activation for the forward and backward reactions in the presence of the catalyst?



What is the lowering in activation energy in the presence of the catalyst?

(d) Will the catalyst change the extent of the reaction?

[**Ans.** (a) $\Delta H = -10$ kJ / mol;

(b) $E_f = 30$ kJ / mol; $E_b = 40$ kJ / mol;

(c) $E_f = 10$ kJ / mol; $E_b = 20$ kJ / mol; 20 kJ / mol;

(d) no]

67. Temperature coefficient, $\mu = \dfrac{k_{35°C}}{k_{25°C}}$ of a reaction is 1.82. Calculate the energy of activation in calories. ($R = 1.987$ cal degree^{-1} mol^{-1}).

[**Ans.** 10.924 kcal/mol]

68. For first order gaseous reaction, log k when plotted against $\dfrac{1}{T}$ gives a straight line with a slope of -8000. Calculate the activation energy of the reaction.

[**Ans.** 36.6 kcal]

69. The rate at 27° C of a chemical reaction increases 1000 times when a suitable catalyst is introduced. Calculate the change in the energy of activation that the catalyst has brought in.

[**Ans.** 4118 cal]

70. Dehydration of tertiary butyl alcohol follows a first order reaction,

$$(CH_3)_3C{-}OH(g) \rightarrow (CH_3)_2C{=}CH_2(g) + H_2O(g)$$

the rate constant at 300° C is $2.27 \times 10^{-8}\ s^{-1}$. Calculate the rate constant at 400° C if the energy of activation for the reaction is 58 kcal.

[**Ans.** $4.392 \times 10^{-5}\ s^{-1}$]

71. Let us consider the following mechanism:

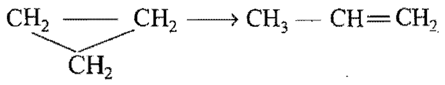
$$CH_3CN + H^+ \rightleftharpoons CH_3CNH^+ \qquad \text{(fast)}$$

$$CH_3CNH^+ + H_2O \rightarrow \text{Product} \qquad \text{(slow)}$$

What would be the rate law?

[**Ans.** Rate $= k[CH_3CN][H_2O][H^+]$]

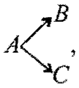
72. The thermal isomerization of cyclopropane occurs according to the equation:



The specific reaction rate constant for this reaction at 499° C was 5.95×10^{-4} sec^{-1}. What is the half life of the reaction? What fraction of the cyclopropane will remain after 1 hour at 499.5° C?

[**Ans.** 1165 s; 11.7%]

73. A substance 'A' was found to undergo two parallel first order reactions,



, i.e., $A \rightarrow B$ and $A \rightarrow C$,

with rate constants $1.26 \times 10^{-4}\ s^{-1}$ and $3.8 \times 10^{-5}\ s^{-1}$ respectively. What were the percentage distributions of B and C?

[**Ans.** 76.83% of B and 23.17% of C]

74. Two reactions proceed at 25° C at the same rate; the temperature coefficient of the rate of the first reaction is 2 and that of the second reaction is 2.5. Find the ratio of rates of these reactions at 95° C.

[**Ans.** 5 times]

75. The population of India in the year 1988 was 800 million. Growth rate is 25 per thousand per year. What will be the population in the year 2000 if the growth follows first order kinetics?

[**Ans.** 1075 million]

76. Half lives against initial pressure are given below. Calculate the order of the reaction.

p (mm)	750	500	250
t (min)	105	235	950

Find out the order of the reaction.

[**Ans.** 3]

77. For a given reaction at temperature T, the velocity constant k, is expressed as:

$$k = Ae^{-27000\,k'/T} \quad (k' = \text{Boltzmann constant})$$

Given, $R = 2$ cal K^{-1} mol^{-1}. Calculate the value of energy of activation. Comment on the results.

[**Ans.** $E = 18 \times 10^{-20}$ cal]

[**Hint:** Compare the equation with Arrhenius equation

$$k = Ae^{-E_a/RT} \qquad \text{... (i)}$$

$$k = Ae^{-27000k'/T} \qquad \text{... (ii)}$$

$$\frac{E_a}{RT} = \frac{27000k'}{T}$$

$$E_a = 27000Rk'$$

$$= 27000\,R \times \frac{R}{N} = \frac{27000 \times (2)^2}{6.023 \times 10^{23}}$$

$$= 18 \times 10^{-20} \text{ cal}$$

Activation energy is low, therefore reaction will be fast.]

78. If the activation energy of a reaction is 80.9 kJ mol^{-1}, calculate the fraction of molecules at 400°C which have enough energy to react to form the products.

[**Ans.** 5.257×10^{-7}]

[**Hint:** Fraction of total molecules which are active at a temperature is given as,

$$= \frac{k}{A} = e^{-E_a/RT}$$

$$\log \frac{k}{A} = \frac{-E_a}{2.303\,RT}$$

$$\frac{k}{A} = \text{antilog}\left(\frac{-E_a}{2.303RT}\right)$$

Substituting the values of E and T we can solve the problem.]

79. The following data were obtained for a given reaction at 300 K:

Reaction	**Energy of activation (kJ/mol)**
1. Uncatalysed	76
2. Catalysed	57

Calculate by what factor the rate of catalysed reaction is increased?

[**Ans.** 2000]

[**Hint:** Use: $\frac{k_p}{k_a} = \text{antilog}\left(\frac{\Delta E}{2.303RT}\right)$

k_p = rate constant in presence of catalyst

k_a = rate constant in absence of catalyst

$\Delta E = 76 - 57 = 19 \text{ kJ/mol}$]

80. The Arrhenius equations for *cis-trans* isomerization of but-2-ene ($CH_3-CH{=}CH-CH_3$) and but-2-ene, 1-nitrile ($CH_3-CH{=}CH-CN$) are,

$$k(\text{s}^{-1}) = 10^{13.8} \exp(-263.5 \text{ kJ mol}^{-1}/RT)$$

$$k^{-1}(\text{s}^{-1}) = 10^{11} \exp(-214.5 \text{ kJ mol}^{-1}/RT)$$

Calculate the temperature at which $k = k^{-1}$.

[**Ans.** 914 K]

81. The half life for a reaction between fixed concentration of reactants varies with temperature as follows:

t °C	520	533	555	574
$t_{1/2}$ sec	1288	813	562	477

Calculate the activation energy of this reaction.

[**Ans.** 86.47 kJ mol^{-1}]

[**Hint:** Use: $\log\left(\frac{k_2}{k_1}\right) = \frac{E}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$

$$k_2 = 0.693/t_2$$

$$k_1 = 0.693/t_1$$

$$\therefore \quad \log\left(\frac{t_1}{t_2}\right) = \frac{E}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)]$$

82. What percentage of reactant molecules will crossover the energy barrier at 325 K? Heat of reaction is 0.12 kcal and activation energy of backward reaction is 0.02 kcal.

[**Hint:** Activation energy of forward reaction = 0.12 − 0.02

= 0.10 kcal

Fraction of molecules which are active or which crossover the energy barrier $\left(\frac{k}{A}\right) = e^{-E/RT}$

$$\log_e\left(\frac{k}{A}\right) = -\frac{E}{RT}$$

$$\frac{k}{A} = \text{antilog}\left[\frac{-E}{2.303\,RT}\right]$$

$$= \text{antilog}\left[\frac{-0.10 \times 1000}{2.303 \times 2 \times 325}\right]$$

$$= \text{antilog}[-0.06680] = 0.8574$$

∴ Percentage of reactant molecules crossing over the barrier

$= 0.8574 \times 100 = 85.74$]

83. In a milk at 37°C Lactobacillus acidophillus has a generation time of about 75 minutes. Calculate the population relative to the initial value at 30, 60, 75, 90 and 150 minutes.

[**Ans.**

t_{min}	30	60	75	90
N/N_0	1.32	1.74	2	2.30]

[**Hint:** In the case of population growth we have to use growth kinetics.

$$-k = \frac{2.303}{t}\log\left(\frac{a}{a+x}\right)$$

a = initial population

x = growth in population in time 't'

Here, $N_0 = a$; $N = a + x$]

84. Two reactions of same order have equal pre-exponential factors but their activation energies differ by 41.9 J/mol. Calculate the ratios between rate constants of these reactions at 600 K.

[**Ans.** 0.002]

[**Hint:** Use the relation,

$$\log_{10} k = \log_{10} A - \frac{E}{2.303RT} \quad \text{... (i)}$$

$$\log_{10} k_1 = \log_{10} A - \frac{E_1}{2.303 \times 8.314 \times 600} \quad \text{... (ii)}$$

$$\log_{10} k_2 = \log_{10} A - \frac{E_2}{2.303 \times 8.314 \times 600} \quad \text{... (iii)}$$

$$E_1 - E_2 = 41.95/\text{mol} \quad \text{... (iv)}$$

Subtract eq. (iii) from eq. (ii) to determine the ratio.]

85. A decomposition reaction has following mechanism

$$2N_2O_5 \longrightarrow 4NO_2 + O_2 \quad \text{(overall)}$$

$$N_2O_5 \rightleftharpoons NO_2 + NO_3 \quad \text{(fast decomposition)}$$

$$NO_2 + NO_3 \longrightarrow NO + NO_2 + O_2 \quad \text{(slow)}$$

$$NO + NO_3 \longrightarrow 2NO_2 \quad \text{(fast)}$$

Determine rate law, is the mechanism corresponds to first order reaction.

[**Ans.** $\frac{-d[N_2O_5]}{dt} = \frac{2k_1k_3}{k_1 + k_3}[N_2O_5]$]

86. Rate constant of a reaction changes by 2% by 0.1°C rise in temperature at 25°C. The standard heat of reaction is 121.6 kJ mol^{-1}. Calculate E_a of reverse reaction.

[**Ans.** 24.7 kJ/mol]

[Hint: $\log\left(\frac{k_2}{k_1}\right) = \frac{E_a}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$

$$\log\frac{102}{100} = \frac{E}{2.303 \times 8.314}\left(\frac{1}{298} - \frac{1}{298.1}\right)$$

$$E = 1.463 \times 10^5 \text{ J/mol} = 146.3 \text{ kJ/mol}$$

$$\Delta H = E_f - E_b$$

$$121.6 = 146.3 - E_b$$

$E_b = 24.7$ kJ/mol]

87. Urea $(NH_2)_2CO$ can be prepared by heating ammonium cyanate NH_4OCN.

$$NH_4OCN \longrightarrow (NH_2)_2CO$$

The reaction may occur by the following mechanism:

$$NH_4^+ + OCN^- \underset{k-1}{\overset{k_1}{\rightleftharpoons}} NH_3 + HOCN \qquad \text{(fast, equilibrium)}$$

$$NH_3 + HOCN \xrightarrow{k_2} (NH_2)_2CO \qquad \text{(slow)}$$

What is rate law predicted by this mechanism?

[Ans. Rate $= \frac{k_2k_1}{k-1}[NH_4^+][OCN^-] = k[NH_4]^+[OCN^-]^-$]

88. For the reaction $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$, under certain conditions of pressure and temperature of the reactants, the rate of formation of NH_3 is 0.001 kg hr^{-1}. Calculate the rate of reaction for N_2 and H_2.

[Ans. 1.76×10^{-4} kg hr^{-1}]

[Hint: $-\frac{d[N_2]}{dt} = -\frac{1}{3}\frac{d[H_2]}{dt} = +\frac{1}{2}\frac{d[NH_3]}{dt}$

$$\frac{d[NH_3]}{dt} = 0.001 \text{ kg hr}^{-1} = \frac{0.001 \times 1000}{17} \text{ mol hr}^{-1}$$

$$= 0.058 \text{ mol hr}^{-1}$$

$$\frac{-d[N_2]}{dt} = \frac{1}{2} \times 0.058 \text{ mol hr}^{-1}$$

$$= 0.029 \text{ mol hr}^{-1}$$

$$= 0.029 \times 28 \times 10^{-3} \text{ kg hr}^{-1}$$

$$= 8.12 \times 10^{-4} \text{ kg hr}^{-1}$$

Similarly, $-\frac{d[H_2]}{dt} = 1.76 \times 10^{-4}$ kg hr^{-1}]

OBJECTIVE QUESTIONS

Set-1: Questions with single correct answer

1. Chemical kinetics, a branch of physical chemistry, deals with:
(a) heat changes in a reaction
(b) physical changes in a reaction
(c) rates of reactions
(d) structure of molecules

2. The rate at which a substance reacts depends upon its:
(a) atomic mass (b) equivalent mass
(c) molecular mass (d) active mass

3. The rate of a chemical reaction:
(a) increases as the reaction proceeds
(b) decreases as the reaction proceeds
(c) may increase or decrease during the reaction
(d) remains constant as the reaction proceeds

4. For the reaction, $N_2 + 3H_2 \longrightarrow 2NH_3$, rate is expressed as:
(a) $-3\frac{d[N_2]}{dt} = -\frac{d[H_2]}{dt} = \frac{3}{2}\frac{d[NH_3]}{dt}$
(b) $-\frac{d[N_2]}{dt} = -\frac{1}{3}\frac{d[H_2]}{dt} = \frac{1}{2}\frac{d[NH_3]}{dt}$
(c) $-\frac{d[N_2]}{dt} = -\frac{3d[H_2]}{dt} = \frac{2d[NH_3]}{dt}$
(d) $-\frac{d[N_2]}{dt} = -\frac{d[H_2]}{dt} = \frac{d[NH_3]}{dt}$

5. For the reaction, $2NO_2 \longrightarrow 2NO + O_2$, rate is expressed as:
(a) $-\frac{1}{2}\frac{d[NO_2]}{dt} = \frac{1}{2}\frac{d[NO]}{dt} = \frac{d[O_2]}{dt}$
(b) $-\frac{1}{2}\frac{d[NO_2]}{dt} = -\frac{1}{2}\frac{d[NO]}{dt} = \frac{d[O_2]}{dt}$
(c) $-\frac{2d[NO_2]}{dt} = \frac{2d[NO]}{dt} = \frac{d[O_2]}{dt}$
(d) $-\frac{d[NO_2]}{dt} = \frac{d[NO]}{dt} = \frac{d[O_2]}{dt}$

6. The rate of reaction that does not involve gases, is not dependent on:
(a) pressure (b) temperature
(c) concentration (d) catalyst

7. For the reaction, $A + B \longrightarrow 2C + D$, which one is the incorrect statement?
(a) Rate of disappearance of A = Rate of disappearance of B
(b) Rate of disappearance of A = Rate of appearance of D
(c) Rate of disappearance of B = 2 × rate of appearance of C
(d) Rate of disappearance of $B = \frac{1}{2} \times$ rate of appearance of C

8. In a reaction, $2A_2 + B_2 \longrightarrow 2A_2B$, the reactant A will disappear at:
(a) half the rate that B will decrease
(b) the same rate that B will decrease
(c) double the rate that A_2B will form
(d) twice the rate that B will decrease

9. In the reaction $3A \rightarrow 2B$, rate of reaction $+\frac{d[B]}{dt}$ is equal to: **[JEE (WB) 2008]**
(a) $-\frac{1}{3}\frac{d[A]}{dt}$ (b) $-\frac{2}{3}\frac{d[A]}{dt}$ (c) $+2\frac{d[A]}{dt}$ (d) $-\frac{3}{2}\frac{d[A]}{dt}$

10. For the reaction, $2NO \longrightarrow N_2 + O_2$, the expression $-\frac{1}{2}\frac{d[NO]}{dt}$ represents:

(a) the rate of formation of NO
(b) the average rate of the reaction
(c) the instantaneous rate of the reaction
(d) all of the above

11. The term $-\frac{dx}{dt}$ in the rate expression refers to the:
(a) instantaneous rate of reaction
(b) average rate of reaction
(c) increase in the concentration of reactants
(d) concentration of reactants

12. According to collision theory of reaction rates:
(a) every collision between reactant molecules leads to a chemical reaction
(b) rate of reaction is proportional to the velocity of the molecules
(c) rate of reaction is proportional to the average energy of the molecules
(d) rate of reaction is proportional to the number of collisions per second

13. According to collision theory:
(a) all collisions are sufficiently violent
(b) all collisions are responsible for product formation
(c) all collisions are effective
(d) only a fraction of collisions are effective which have enough energy to form products

14. Which of the following has been used to explain the subject of chemical kinetics?
(a) Collision theory of bimolecular reactions
(b) The activated complex theory
(c) Arrhenius equation
(d) All of the above

15. The activation energy for a chemical reaction depends upon:
(a) temperature
(b) nature of reacting species
(c) concentration of the reacting species
(d) collision frequency

16. In a reaction, the threshold energy is equal to:
(a) activation energy + normal energy of reactants
(b) activation energy – normal energy of reactants
(c) normal energy of reactants – activation energy
(d) average kinetic energy of molecules of reactants

17. The influence of temperature on the rate of reaction is determined by:
(a) Nernst's equation (b) Gibbs-Helmholtz equation
(c) Arrhenius equation (d) van't Hoff equation

18. According to the collision theory of reaction rates, the rate of reaction increases with temperature due to:
(a) greater number of collisions
(b) higher velocity of reacting molecules
(c) greater number of molecules having the activation energy
(d) decrease in the activation energy

19. The temperature coefficient of a reaction is:
(a) ratio of rate constants at two temperatures differing by 1°C
(b) ratio of rate constants at temperature 35°C and 25°C
(c) ratio of rate constants at temperature 30°C and 25°C
(d) specific reaction rate at 25°

20. In general, with every 10°C rise in temperature, the rate of reaction becomes approximately ....
(a) ten times (b) double
(c) half (d) one tenth

21. Activation energy of the reaction is:
(a) the energy released during the reaction
(b) the energy evolved when activated complex is formed
(c) minimum amount of energy needed to overcome the potential barrier
(d) the energy needed to form one mole of the product

22. The temperature coefficient of most of the reactions lies between:
(a) 2 and 3 (b) 1 and 2
(c) 2 and 4 (d) 3 and 4

23. According to Arrhenius equation, rate constant of a chemical reaction is equal to:
(a) $Ae^{-E_a/RT}$ (b) $Ae^{E_a/RT}$
(c) Ae^{RT/E_a} (d) Ae^{-RT/E_a}

24. The correct expression for Arrheniu[illegible] the effect of temperature on the rate constant is ($T_2 > T_1$): (DCE 2009)

(a) $\log_{10}\frac{k_2}{k_1}=\frac{E_a}{2.303R}\left[\frac{T_1T_2}{T_2-T_1}\right]$

(b) $\log_{10}\frac{k_2}{k_1}=\frac{R}{2.303E_a}\left[\frac{T_2-T_1}{T_1T_2}\right]$

(c) $\log_{10}\frac{k_2}{k_1}=\frac{E_a}{R}\left[\frac{T_2-T_1}{T_1T_2}\right]$

(d) $\log_{10}\frac{k_2}{k_1}=\frac{E_a}{2.303R}\left[\frac{T_2-T_1}{T_2T_1}\right]$

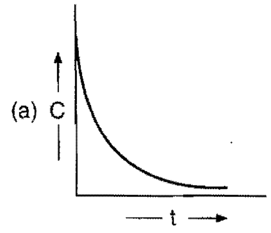
25. In order to react, a molecule, at the time of collision, must possess a certain amount of energy known as:
(a) free energy (b) kinetic energy
(c) threshold energy (d) internal energy

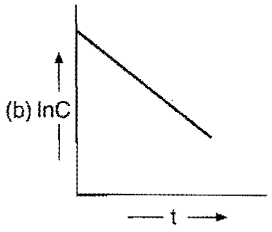
26. The activation energy of a reaction is zero. The rate constant of the reaction: [CET (Pb.) 1991]
(a) increases with increase of temperature
(b) decreases with decrease of temperature
(c) decreases with increase of temperature
(d) is nearly independent of temperature

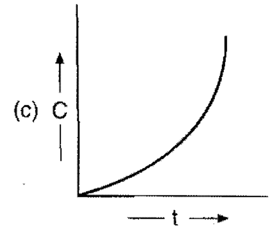
27. The activation energy of a reaction can be lowered by:
(a) using a positive catalyst
(b) increasing temperature
(c) decreasing temperature
(d) increasing concentration of the reactants

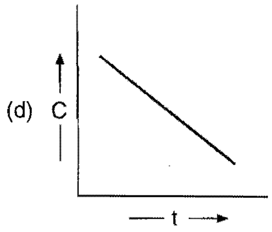
28. The activation energy for a hypothetical reaction $A \longrightarrow$ Product is 12.49 kcal/mol. If temperature is raised from 295 to 305, the rate of reaction increases by:
(a) 60% (b) 100%
(c) 50% (d) 20%

29. The plot between concentration versus time for a zero order reaction is represented by: [AMU (Engg.) 2009]









30. The rate of reaction increases with rise in temperature because of: **[Comed (Karnataka) 2008]**
(a) increase in the number of activated molecules
(b) increase in the activation energy
(c) decrease in the activation energy
(d) increase in the number of molecular collisions

31. Which of the following is a first order reaction?
(a) $2HI \longrightarrow H_2 + I_2$ (b) $2NO_2 \longrightarrow 2NO + O_2$
(c) $2NO + O_2 \longrightarrow 2NO_2$ (d) $NH_4NO_2 \longrightarrow N_2 + 2H_2O$

32. Which one of the following is not a first order reaction?
(a) $CH_3COOCH_3 + H_2O \xrightarrow{H^+} CH_3COOH + CH_3OH$
(b) $CH_3COOC_2H_5 + NaOH \longrightarrow CH_3COONa + C_2H_5OH$
(c) $2H_2O_2 \longrightarrow 2H_2O + O_2$
(d) $2N_2O_5 \longrightarrow 4NO_2 + O_2$

33. Rate expression of a chemical change is $-\dfrac{dx}{dt} = k[A]^2[B][C]^0$.
The order of reaction is:
(a) 3 (b) 2 (c) 1 (d) zero

34. For a reaction, $2A + B \longrightarrow C + D$, the concentration of B is kept constant and that of A is tripled the new rate of reaction will be:
(a) nine times (b) three times
(c) same (d) zero

35. The rate of the reaction, $A + B + C \longrightarrow$ Products, is given by

$$-\frac{d[A]}{dt} = k[A]^{1/2}[B]^{1/3}[C]^{1/4}$$

The order of the reaction is:
(a) 1/2 (b) 13/12
(c) 1 (d) 2

36. Which of the following rate laws has an overall order of 0.5 for the reaction involving substances x, y and z?
(a) Rate $= k[C_x][C_y][C_z]$
(b) Rate $= k[C_x]^{0.5}[C_y]^{0.5}[C_z]^{0.5}$
(c) Rate $= k[C_x]^{1.5}[C_y]^{-1}[C_z]^0$
(d) Rate $= k[C_x][C_y]^{-2}[C_z]^0$

37. If the rate of reaction between A and B is given by rate $= k[A][B]^2$, then the reaction is:
(a) first order in A (b) second order in B
(c) third order overall (d) all are correct

38. For the reaction $A \longrightarrow B$, the rate of reaction is quardrupled when the concentration of A is doubled; the rate of the reaction is $r = k[A]^n$; the value of n is:
(a) 1 (b) zero (c) 3 (d) 2

39. Select the rate law that corresponds to the data shown for the following reaction: $A + B \longrightarrow C$ **(CBSE 1994)**

Expt. No.	$[A]_0$	$[B]_0$	Initial rate
1.	0.012	0.035	0.10
2.	0.024	0.070	0.80
3.	0.024	0.035	0.10
4.	0.012	0.070	0.80

(a) rate $= k[B]^3$ (b) rate $= k[B]^4$
(c) rate $= k[A][B]^3$ (d) rate $= k[A]^2[B]^2$

40. For a chemical reaction, $A \longrightarrow E$, it is found that rate of reaction is doubled when the concentration of A is increased four times. The order of the reaction is:
(a) 1 (b) 2
(c) 1/2 (d) zero

41. The rate of reaction, $A + B \longrightarrow$ Products, is given by the equation, $r = k[A][B]$. If B is taken in large excess, the order of reaction would be: **(BIT 1992)**
(a) 2 (b) 1
(c) zero (d) unpredictable

42. The rate of reaction between A and B increases by a factor of 100, when the concentration of A is increased 10 folds. The order of reaction with respect to A is:
(a) 10 (b) 2 (c) 1 (d) 20

43. The rate law for the reaction,

$$RCl + NaOH(aq.) \longrightarrow ROH + NaCl$$

is given by, Rate $= k[RCl]$. The rate of reaction will be:
(a) unaffected by increasing temperature of the reaction
(b) doubled on doubling the concentration of NaOH
(c) halved on reducing the concentration of NaOH to one half
(d) halved on reducing the concentration of RCl to one half

44. A zero order reaction is one:
(a) in which reactants do not react
(b) in which one of the reactants is in large excess
(c) whose rate is uniform and not affected by time
(d) whose rate increases with time

45. The rates of a certain reaction at different time intervals are as follows:

Time (second)	0	10	20
Rate	1.8×10^{-2}	1.82×10^{-2}	1.79×10^{-2} mol L^{-1} s^{-1}

The reaction is of:
(a) zero order (b) first order
(c) second order (d) third order

46. For which of the following, the units of rate and rate constant of the reaction are identical?
(a) First order reaction (b) Zero order reaction
(c) Second order reaction (d) Fractional order reaction

47. The unit of rate constant for a zero order reaction is:
(a) mol time^{-1} (b) L time^{-1}
(c) mol L^{-1} time^{-1} (d) L mol^{-1} time^{-1}

48. For a zero order reaction: (EAMCET 1990)
(a) $t_{1/2} \propto a$ (b) $t_{1/2} \propto \frac{1}{a}$ (c) $t_{1/2} \propto a^2$ (d) $t_{1/2} \propto \frac{1}{a^2}$

49. The rate of the first order reaction, $A \longrightarrow$ Products, is 7.5×10^{-4} mol L^{-1} s^{-1}, when the concentration of A is 0.2 mol L^{-1}. The rate constant of the reaction is:
(a) 2.5×10^{-5} s^{-1} (b) 8.0×10^{-4} s^{-1}
(c) 6.0×10^{-4} s^{-1} (d) 3.75×10^{-3} s^{-1}

50. If the concentration is expressed in mole per litre and time in second, the units of rate constant for a first order reaction is:
(a) mol L^{-1} sec^{-1} (b) sec^{-1}
(c) mol L^{-1} (d) mol^{-1}

51. Which one of the following formula represents a first order reaction?
(a) $k = \frac{2.303}{t} \log \frac{[A]_t}{[A]_0}$ (b) $k = \frac{1}{t} \cdot \frac{x}{a(a-x)}$
(c) $k = \frac{2.303}{t} \log \frac{a}{a-x}$ (d) $k = \frac{2.303}{t} \log \frac{a}{x}$

52. 75% of a first order reaction was completed in 32 minute; when was 50% of the reaction completed?
(a) 4 min (b) 8 min (c) 24 min (d) 16 min

53. The first order rate constant for the decomposition of N_2O_5 is 6.2×10^{-4} s^{-1}. The half life period for this decomposition is: (MLNR 1991)
(a) 1117.7 s (b) 1117 s (c) 223.4 s (d) 160.9 s

54. The half life period of a first order reaction is:
(a) $\frac{0.693}{a}$ (b) $\frac{0.693}{k}$ (c) $\frac{0.693}{t}$ (d) $\frac{0.693}{ak}$

55. The specific rate constant of a first order reaction depends on:
(a) concentration of the reactants
(b) concentration of the products
(c) time
(d) temperature

56. For a given reaction of first order, it takes 20 minutes for the concentration to drop from 1.0 M to 0.6 M. The time required for the concentration to drop from 0.6 M to 0.36 M will be:
(a) more than 20 minutes (b) less than 20 minutes
(c) equal to 20 minutes (d) infinity

57. For the first order reaction $A \longrightarrow$ Product, the half life is 200 seconds. The rate constant of the reaction is:
(a) 3.46×10^{-2} s^{-1} (b) 3.46×10^{-3} s^{-1}
(c) 3.46×10^{-4} s^{-1} (d) 3.46×10^{-5} s^{-1}

58. The following data were obtained for the thermal decomposition of nitrous oxide on finely divided gold:

t (minutes)	0	20	40	60	80
Concentration of N_2O (mol L^{-1})	0.10	0.08	0.06	0.04	0.02

The order of reaction is:
(a) zero (b) 1 (c) 2 (d) 3

59. The following data are for the decomposition of ammonium nitrite in aqueous solution:

Vol. of N_2 in cm^3	6.25	9.0	11.42	13.65	35.02
Time (min)	10	15	20	25	∞

The order of reaction is:
(a) 3 (b) 2 (c) 1 (d) zero
[**Hint:** $a = 35.02, (a-x) = 35.02 - V_t$
Apply, $k = \frac{2.303}{t} \log \frac{35.02}{(35.02 - V_t)}$]

60. In the first order reaction, the concentration of reactant decreases from 1.0 M to 0.25 M in 20 minutes. The value of specific rate is:
(a) 69.32 (b) 6.932 (c) 0.6932 (d) 0.06932

61. The half life period of a first order reaction is 10 minutes. The time required for the concentration of the reactant to change from 0.08 M to 0.02 M is: (IIT 1990)
(a) 10 min (b) 20 min (c) 30 min (d) 40 min

62. The rate constant for the hydrolysis reaction of an ester by dilute acid is 0.6931×10^{-3} s^{-1}. The time required to change the concentration of ester from 0.04 M to 0.01 M is:
(a) 6931 sec (b) 4000 sec
(c) 2000 sec (d) 1000 sec

63. The rate of a gaseous reaction is given by the expression $k[A][B]$. If the volume of reaction vessel is suddenly reduced to one-fourth of the initial volume, the reaction rate relative to the original rate will be: (IIT 1992)
(a) 1/16 (b) 1/8 (c) 8 (d) 16

64. The velocity of a reaction is doubled for every 10°C rise in temperature. If the temperature is raised to 50°C, the reaction velocity increases by about:
(a) 12 times (b) 16 times (c) 32 times (d) 50 times

65. If the rate expression for a reaction is $\frac{dx}{dt} = k[A]^{1/2}[B]^{3/2}$, the overall order of the reaction is: [CEE (Bihar) 1992]
(a) 2 (b) 1/2 (c) 3/2 (d) 1

66. The rates of a certain reaction at different times are as follows:

Time (second)	0	10	20	30
Rate (mol L^{-1} s^{-1})	2.8×10^{-2}	2.78×10^{-2}	2.81×10^{-2}	2.79×10^{-2}

The reaction is of:
(a) third order (b) second order
(c) first order (d) zero order

67. The second order rate constant is usually expressed as:
(a) mol L^{-1} s^{-1} (b) mol^{-1} L^{-1} s^{-1}
(c) mol^{-1} L s^{-1} (d) mol L s^{-1}

68. The hydrolysis of ethyl acetate is a reaction of:

$$CH_3COOC_2H_5 + H_2O \xrightarrow{H^+} CH_3COOH + C_2H_5OH$$

(a) zero order (b) first order
(c) second order (d) third order

69. The inversion of cane sugar is represented by,

$$C_{12}H_{22}O_{11} + H_2O \longrightarrow C_6H_{12}O_6 + C_6H_{12}O_6$$

It is a reaction of: **[PMT (MP) 1993]**
(a) second order (b) unimolecular
(c) pseudo-unimolecular (d) zero order

70. In a second order reaction, the time needed for the initial concentration of the reactant to reduce to half that value is:
(a) independent of the initial concentration
(b) proportional to the initial concentration
(c) inversely proportional to initial concentration
(d) proportional to the square of the initial concentration

71. Which of the following statements regarding molecularity of the reaction is wrong?
(a) It may be either whole number or fractional
(b) It is calculated from the reaction mechanism
(c) It depends on the rate determining step
(d) It is number of molecules of reactants taking part in a single step chemical reaction

72. For the reaction, $H_2(g) + Br_2(g) \rightarrow 2HBr(g)$, the reaction rate is:

$$\text{rate} = k[H_2][Br_2]^{1/2}$$

Which one of the following statements is true for this reaction?
(a) The reaction is of second order
(b) The molecularity of the reaction is 3/2
(c) The unit of k is $\sec^{-1}$
(d) The molecularity of the reaction is two

73. Molecularity of the reaction:
(a) is always a whole number
(b) is never a whole number
(c) can have a fractional value
(d) can be zero

74. For a single step reaction, $A + 2B \longrightarrow$ Products, the molecularity is:
(a) zero (b) three (c) two (d) one

75. The hypothetical reaction, $A_2 + B_2 \longrightarrow 2AB$, follows the following mechanism:

$A_2 \longrightarrow A + A$ (fast)
$A + B_2 \longrightarrow AB + B$ (slow)
$A + B \longrightarrow AB$ (fast)

The order of the overall reaction is: **[PMT (Pb.) 1991]**
(a) zero (b) 1 (c) 2 (d) 3/2

76. The molecularity of a reaction is:
(a) same as its order
(b) different from order
(c) may be same or different as compared to order
(d) always zero

77. The chemical reaction, $2O_3 \longrightarrow 3O_2$ proceeds as follows:

$O_3 \longrightarrow O_2 + O$ (fast)
$O + O_3 \longrightarrow 2O_2$ (slow)

The rate law expression should be:
(a) $r = k[O_3]^2$ (b) $r = k[O_3]^2[O_2]^{-1}$
(c) $r = k[O_3][O_2]$ (d) $r = [O_3][O_2]^2$

[**Hint:** $r = k'[O_3][O] = \dfrac{k'k''[O_3][O_3]}{[O_2]} = k[O_3]^2[O_2]^{-1}$]

78. Time required to decompose half of the substance for nth order reaction is inversely proportional to:
(a) a^{n+1} (b) a^{n-1}
(c) a^{n-2} (d) a^n

79. What is the order of the reaction which obeys the expression $t_{1/2} = \dfrac{1}{ka}$?
(a) Zero (b) Third
(c) First (d) Second

80. The order of reaction can be deduced from:
(a) experiment (b) chemical equation
(c) rate constant (d) thermochemical equations

81. The order of a reaction may be determined by:
(a) differential method (b) initial rate method
(c) graphical method (d) all of these

82. A graph between time (t) and the substance consumed at any time is found to be a straight line passing through the origin. This indicates that the reaction is of:
(a) second order (b) first order
(c) zero order (d) fractional order

83. A plot of log $(a - x)$ against time 't' is a straight line. This indicates that the reaction is of:
(a) zero order (b) first order
(c) second order (d) third order

84. For the reaction $N_2O_5(g) \longrightarrow 2NO_2(g) + \frac{1}{2}O_2(g)$, the value of rate of disappearance of N_2O_5 is given as 6.25×10^{-3} mol $L^{-1}s^{-1}$. The rate of formation of NO_2 and O_2 is given respectively as: **[CBSE (PMT) 2010]**
(a) 6.25×10^{-3} mol $L^{-1}s^{-1}$ and 6.25×10^{-3} mol $L^{-1}s^{-1}$
(b) 1.25×10^{-2} mol $L^{-1}s^{-1}$ and 3.125×10^{-3} mol $L^{-1}s^{-1}$
(c) 6.25×10^{-3} mol $L^{-1}s^{-1}$ and 3.125×10^{-3} mol $L^{-1}s^{-1}$
(d) 1.25×10^{-2} mol $L^{-1}s^{-1}$ and 6.25×10^{-3} mol $L^{-1}s^{-1}$

[**Hint:** $\dfrac{-d[N_2O_5]}{dt} = +\dfrac{1}{2}\dfrac{d[N_2O_5]}{dt} = +2\dfrac{d[O_2]}{dt}$

$$\therefore \quad \frac{d[N_2O_5]}{dt} = 2\left\{\frac{-d[N_2O_5]}{dt}\right\} = 2 \times 6.25 \times 10^{-3}$$
$$= 1.25 \times 10^{-2} \text{mol } L^{-1}s^{-1}$$
$$\frac{d[O_2]}{dt} = \frac{1}{2}\left\{\frac{-d[N_2O_5]}{dt}\right\} = \frac{1}{2} \times 6.25 \times 10^{-3}$$
$$= 3.125 \times 10^{-3} \text{mol } L^{-1}s^{-1}$$]

85. The ratio of the time required for $\frac{3}{4}$th of the reaction of first order to complete to that required for half of the reaction:
(a) 4 : 3 (b) 3 : 2
(c) 2 : 1 (d) 1 : 2

86. In pseudo-unimolecular reactions:
(a) one of the reactants is present in large excess
(b) both the reactants have same concentration
(c) both the reactants are present in low concentration
(d) one of the reactants is less reactive

87. The reaction,

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g),$$

is first order with respect to N_2O_5. Which of the following graph, would yield a straight line?

(a) log ($p_{N_2O_5}$) *versus* time with −ve slope

(b) ($p_{N_2O_5}$)$^{-1}$ *versus* time

(c) ($p_{N_2O_5}$) *versus* time

(d) log ($p_{N_2O_5}$) *versus* time with +ve slope

88. Consider the following statements :

(i) increase in concentration of reactant increases the rate of a zero order reaction

(ii) rate constant k is equal to collision frequency 'A' if $E_a = 0$

(iii) rate constant k is equal to collision frequency A if $E_a = \infty$

(iv) $\log_e k$ *vs* T is a straight line

(v) $\log_e k$ *vs* $1/T$ is a straight line

Correct statement are : **[PMT (Kerala) 2010]**

(a) (i) and (iv) (b) (ii) and (v)

(c) (iii) and (iv) (d) (ii) and (iii)

(e) (i) and (v)

89. If we plot a graph between log k and $\frac{1}{T}$ by Arrhenius equation, the slope is: **[EAMCET (Engg.) 2010]**

(a) $-E_a/R$ (b) $+E_a/R$ (c) $-\frac{E_a}{2.303R}$ (d) $+\frac{E_a}{2.303R}$

90. The rate of the reaction,

$$CCl_3CHO + NO \longrightarrow CHCl_3 + NO + CO,$$

is given by the equation, rate $= k[CCl_3CHO][NO]$. If concentration is expressed in mol / litre, the units of k are: **[PMT (MP) 1993]**

(a) $mol^{-2}\ L^2\ s^{-1}$ (b) $mol\ L^{-1}\ s^{-1}$

(c) $L\ mol^{-1}\ s^{-1}$ (d) s^{-1}

91. In a reaction, $2A + B \longrightarrow A_2B$, the reactant A will disappear at: **[PMT (MP) 1993]**

(a) half the rate that B will decrease

(b) twice the rate that B will decrease

(c) the same rate that B will decrease

(d) the same rate that A_2B will form

92. The rate of the reaction, $2NO + O_2 \longrightarrow 2NO_2$, at 25°C is 0.028 mol $L^{-1}\ s^{-1}$. The experimental rate is given by

$$r = k[NO]^2[O_2]$$

If the initial concentrations of the reactants are $O_2 = 0.040$ mol L^{-1} and NO = 0.01 mol L^{-1}, the rate constant of the reaction is:

(a) $7.0 \times 10^{-2}\ L\ mol^{-1}\ s^{-1}$ (b) $7.0 \times 10^{-4}\ L^2\ mol^{-2}\ s^{-1}$

(c) $7.0 \times 10^{2}\ L^2\ mol^{-2}\ s^{-1}$ (d) $7.0 \times 10^{3}\ L^2\ mol^{-2}\ s^{-1}$

[Hint: $0.028 = k[0.01]^2[0.040]$]

93. For the reaction,

$$2NO + Cl_2 \longrightarrow 2NOCl,$$

the following mechanism has been proposed.

$$NO + Cl_2 \rightleftharpoons NOCl_2 \quad \text{(fast)}$$
$$NOCl_2 + NO \longrightarrow 2NOCl \quad \text{(slow)}$$

The rate law for the reaction is:

(a) rate $= k[NO]^2[Cl_2]$ (b) rate $= k[NO][Cl_2]^2$

(c) rate $= k[NOCl_2]$ (d) rate $= k[NOCl]^2$

[Hint:
rate $= k'[NO][NOCl_2] = k'K[NO][NO][Cl_2] = k[NO]^2[Cl_2]$]

94. The rate of a reaction can be increased in general by all the following factors except:

(a) by increasing the temperature

(b) using a suitable catalyst

(c) by increasing the concentration of reactants

(d) by an increase in activation energy

95. How will the rate $r = k[SO_2][O_2]$ of reaction,

$$2SO_2 + O_2 \longrightarrow 2SO_3,$$

change if the volume of the reaction vessel is tripled?

(a) It will be $\frac{1}{3}$rd of its initial value

(b) It will be 3 times of its initial value

(c) It will be 9 times of its initial value

(d) It will be $\frac{1}{9}$th of its initial value

96. Radioactive disintegration is an example of:

(a) zero order reaction (b) first order reaction

(c) second order reaction (d) third order reaction

97. In the formation of sulphur trioxide by the contact process, $2SO_2 + O_2 \rightleftharpoons 2SO_3$, the rate of reaction was measured as $-\frac{d[O_2]}{dt} = 3.0 \times 10^{-4}$ mol $L^{-1}\ s^{-1}$.

The rate of reaction expressed in terms of SO_3 will be:

(a) 3.0×10^{-4} mol $L^{-1}\ s^{-1}$ (b) 6.0×10^{-4} mol $L^{-1}\ s^{-1}$

(c) 1.5×10^{-4} mol $L^{-1}\ s^{-1}$ (d) 4.5×10^{-4} mol $L^{-1}\ s^{-1}$

98. The rate constant for a first order reaction is 6.909 min^{-1}. Therefore, the time required in minutes for the participation of 75% of the initial reactant is: **[PET (J&K) 2009]**

(a) $\frac{2}{3}\log 2$ (b) $\frac{2}{3}\log 4$ (c) $\frac{3}{2}\log 2$ (d) $\frac{3}{2}\log 4$

99. For the reaction,

$$A + 2B \longrightarrow C + D, \frac{d[A]}{dt} = k[A][B]^2$$

the expression for $\frac{d[B]}{dt}$ will be:

(a) $2k[A][B]^2$ (b) $\frac{1}{2}k[A][B]^2$

(c) $k[A][B]^2$ (d) $k[A][B/2]^2$

100. Which of the following statements is not correct for the reaction,

$$4A + B \longrightarrow 2C + 2D?$$

(a) The rate of appearance of C is one-half the rate of disappearance of B

(b) The rate of disappearance of B is one-fourth of the rate of disappearance of A

(c) The rate of formation of D is one-half of the rate of consumption of A

(d) The rates of formation of C and D are equal

101. The overall rate of a reaction is governed by:
(a) the rate of the fastest intermediate step
(b) the sum total of the rates of all the intermediate steps
(c) the average of the rates of all the intermediate steps
(d) the rate of the slowest intermediate step

102. The rate constant of a reaction does not depend upon:
(a) temperature
(b) activation energy
(c) catalyst
(d) concentration of reactants and products

103. The half-life period of a first order chemical reaction is 6.93 minutes. The time required for the completion of 99% of the chemical reaction will be : (log 2 = 0.301) (AIEEE 2009)
(a) 230.3 minutes (b) 23.03 minutes
(c) 46.06 minutes (d) 460.6 minutes

104. For the chemical reaction $x \longrightarrow y$, it is found that the rate of reaction increases 2.25 times when the concentration of x is increased 1.5 times. What is the order of reaction?
(a) One (b) Two (c) Three (d) Zero
[**Hint:** $r = k[x]^a$ and $2.25r = k[1.5x]^a$
So, $2.25 = (1.5)^a$ or $a = 2$]

105. The half life period of a reaction is constant for:
(a) zero order (b) first order
(c) second order (d) none of these

106. From different sets of data of $t_{1/2}$ at different initial concentrations say 'a' for a given reaction, the $[t_{1/2} \times a]$ is found to be constant. The order of reaction is:
(a) zero (b) 1 (c) 2 (d) 3

107. Diazonium salt decomposes as

$$C_6H_5N_2^+Cl^- \longrightarrow C_6H_5Cl + N_2.$$

At 0°C, the evolution of N_2 becomes two times faster when the initial concentration of the salt is doubled. Therefore, it is: (MLNR 1994)
(a) a first order reaction
(b) a second order reaction
(c) independent of the initial concentration of the salt
(d) a zero order reaction

108. For the reaction, $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$, under certain conditions of temperature and pressure of the reactants, the rate of formation of ammonia is 0.001 kg hr^{-1}. The rate of consumption of hydrogen under the same conditions is ...... kg hr^{-1}.
(a) 0.001 (b) 0.003 (c) 0.002 (d) 0.0015

109. The rate constant, the activation energy and the Arrhenius parameter of a chemical reaction at 25°C are $3.0 \times 10^{-4}\ s^{-1}$, 104.4 kJ mol^{-1} and $6.0 \times 10^{14}\ s^{-1}$ respectively. The value of rate constant at $T \longrightarrow \infty$ is: (IIT 1996)
(a) $2.0 \times 10^{18}\ s^{-1}$ (b) $6.0 \times 10^{14}\ s^{-1}$
(c) infinity (d) $3.6 \times 10^{30}\ s^{-1}$

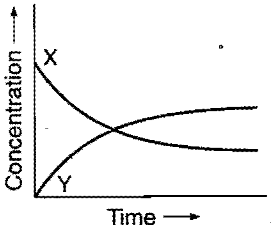
110. In the reaction

$$BrO_3^-(aq.) + 5Br^-(aq.) + 6H^+ \longrightarrow 3Br_2(l) + 3H_2O(l)$$

The rate of appearance of bromine (Br_2) is related to rate of disappearance of bromide ions as following: [CBSE (PMT) 2009]
(a) $\frac{d[Br_2]}{dt} = \frac{3}{5}\frac{d[Br^-]}{dt}$ (b) $\frac{d[Br_2]}{dt} = -\frac{3}{5}\frac{d[Br^-]}{dt}$
(c) $\frac{d[Br_2]}{dt} = -\frac{5}{3}\frac{d[Br^-]}{dt}$ (d) $\frac{d[Br_2]}{dt} = +\frac{5}{3}\frac{d[Br^-]}{dt}$

111. Given that k is the rate constant for some order of any reaction at temp. T, then the value of $\lim_{T \to \infty} \log k$, (where, A is the Arrhenius constant) is:
(a) $A/2.303$ (b) A (c) $2.303A$ (d) $\log A$

112. The curve depicts the change in concentration of species X and Y as a function of time. The point of intersection of the two curves represents:
(a) $t_{1/2}$
(b) $t_{3/4}$
(c) $t_{2/3}$
(d) data insufficient to predict



113. In gaseous reactions, important for the understanding of the upper atmosphere H_2O and O react bimolecularly to form two OH radicals. ΔH for this reaction is 72 kJ at 500 K and E_a is 77 kJ mol^{-1}; then E_a for the bimolecular recombination of two OH radicals to form H_2O and O is:
(a) 3 kJ mol^{-1} (b) 4 kJ mol^{-1}
(c) 5 kJ mol^{-1} (d) 7 kJ mol^{-1}

114. From the following data, the activation energy for the reaction (cal/mol) is:

$$H_2 + I_2 \longrightarrow 2HI$$

T (K)	$1/T$ (K^{-1})	log K
769	1.3×10^{-3}	2.9
667	1.5×10^{-3}	1.1

(a) 4×10^4 (b) 2×10^4
(c) 8×10^4 (d) 3×10^4

115. The hydrolysis of an ester was carried out separately with 0.05 N HCl and 0.05 N H_2SO_4. Which of the following will be true?
(a) $k_{HCl} > k_{H_2SO_4}$ (b) $k_{H_2SO_4} > k_{HCl}$
(c) $k_{H_2SO_4} = 2k_{HCl}$ (d) $k_{H_2SO_4} = k_{HCl}$

116. For an endothermic reaction, where, ΔH represents the enthalpy of the reaction in kJ/mol, the minimum value for the energy of activation will be:
(a) less than ΔH (b) zero
(c) more than ΔH (d) equal to ΔH

117. In the following first order competing reactions;

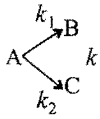
$$A + \text{Reagent} \longrightarrow \text{Product}$$
$$B + \text{Reagent} \longrightarrow \text{Product}$$

The ratio of k_1/k_2 if only 50% of B will have been reacted when 94% of A has been reacted is:
(a) 4.06 (b) 3.06
(c) 2.06 (d) 0.06

118. Two reactions $A \to$ Products and $B \to$ Products, have rate constants k_A and k_B at temperature T and activation energies E_A and E_B respectively. If $k_A > k_B$ and $E_A < E_B$ and assuming that A for both the reactions is same, then:

(a) at higher temperatures k_A will be greater than k_B
(b) at lower temperatures k_A and k_B will be close to each other in magnitude
(c) as temperature rises, k_A and k_B will be close to each other in magnitude
(d) at lower temperature $k_B > k_A$

119. A substance undergoes first order decomposition. The decomposition follows two parallel first order reactions as:



$k_1 = 1.26 \times 10^{-4}\ \text{s}^{-1}$ and $k_2 = 3.8 \times 10^{-5}\ \text{s}^{-1}$

The percentage distributions of B and C are:
(a) 80% B and 20% C (b) 76.83% B and 23.17% C
(c) 90% B and 10% C (d) 60% B and 40% C

120. Inversion of a sugar follows first order rate equation which can be followed by noting the change in rotation of the plane of polarisation of light in a polarimeter. If r_∞, r_t and r_0 are the rotations at $t = \infty$, $t = t$ and $t = 0$, then first order reaction can be written as:
(a) $k = \frac{1}{t}\log_e \frac{r_t - r_\infty}{r_0 - r_\infty}$ (b) $k = \frac{1}{t}\log_e \frac{r_0 - r_\infty}{r_t - r_0}$
(c) $k = \frac{1}{t}\log_e \frac{r_\infty - r_0}{r_\infty - r_t}$ (d) $k = \frac{1}{t}\log_e \frac{r_\infty - r_t}{r_\infty - r_0}$

121. Rate of a chemical reaction can be kept constant by: **(BHU 1993)**
(a) stirring the compounds
(b) keeping the temperature constant
(c) both (a) and (b)
(d) none of the above

122. The number of molecules of the reactants taking part in a single step of the reaction tells about: **(AMU 1992)**
(a) molecularity of the reaction
(b) mechanism of the reaction
(c) order of reaction
(d) all of the above

123. Number of moles of a substance present in 1 litre volume is known as: **[PMT (MP) 1993]**
(a) activity (b) molar concentration
(c) active mass (d) none of these

124. The inversion of cane sugar into glucose and fructose is:
(a) I order (b) II order (c) III order (d) zero order

125. The unit of rate constant obeying the rate expression $r = k[A]'[B]^{2/3}$ is:
(a) $\text{mol}^{-2/3}\ \text{litre}^{2/3}\ \text{time}^{-1}$ (b) $\text{mol}^{2/3}\ \text{litre}^{-2/3}\ \text{time}^{-1}$
(c) $\text{mol}^{-5/3}\ \text{litre}^{5/3}\ \text{time}^{-1}$ (d) none of these

126. For the reaction,

$$N_2O_5 \longrightarrow 2NO_2 + 1/2O_2,$$
$$-\frac{d[N_2O_5]}{dt} = k_1[N_2O_5]$$
$$\frac{d[NO_2]}{dt} = k_2[N_2O_5]$$
$$\frac{d[O_2]}{dt} = k_3[N_2O_5]$$

The relation in between k_1, k_2 and k_3 is:
(a) $2k_1 = k_2 = 4k_3$ (b) $k_1 = k_2 = k_3$
(c) $2k_1 = 4k_2 = k_3$ (d) none of these

127. The rate constant is numerically the same for three reactions of first, second and third order respectively. Which one is true for the rates of the three reactions if the concentration of the reactant is greater than 1 M?
(a) $r_1 = r_2 = r_3$ (b) $r_1 > r_2 > r_3$
(c) $r_1 < r_2 < r_3$ (d) All of these

128. In the Q.No. 127, if the concentration of the reactant is less than 1 M, then:
(a) $r_1 = r_2 = r_3$ (b) $r_1 > r_2 > r_3$
(c) $r_1 < r_2 < r_3$ (d) all of these

129. In the Q.No. 127, if the concentration of the reactant is 1 M, then:
(a) $r_1 = r_2 = r_3$ (b) $r_1 > r_2 > r_3$
(c) $r_1 < r_2 < r_3$ (d) all of these

130. For a first order reaction, $A \longrightarrow$ Product, the rate of reaction at $[A] = 0.2\,\text{mol L}^{-1}$ is $1.0 \times 10^{-2}\ \text{mol L}^{-1}\ \text{min}^{-1}$. The half life period for the reaction is: **(IIT 1999)**
(a) 832 s (b) 440 s (c) 416 s (d) 14 s

131. The rate constant of a first order reaction, $A \longrightarrow$ Products, is $60 \times 10^{-4}\ \text{min}^{-1}$. Its rate at $[A] = 0.01\,\text{mol L}^{-1}$ would be: **(IIT 1997)**
(a) $60 \times 10^{-6}\ \text{mol L}^{-1}\ \text{min}^{-1}$ (b) $36 \times 10^{-4}\ \text{mol L}^{-1}\ \text{min}^{-1}$
(c) $60 \times 10^{-2}\ \text{mol L}^{-1}\ \text{min}^{-1}$ (d) $36 \times 10^{-1}\ \text{mol L}^{-1}\ \text{min}^{-1}$

132. For a first order reaction, the half life is independent of: **(CBSE 1999)**
(a) initial concentration
(b) cube root of initial concentration
(c) first power of final concentration
(d) square root of final concentration

133. Activation energy of a chemical reaction can be determined by: **(CBSE 1998)**
(a) changing concentration of reactants
(b) evaluating rate constant at standard temperature
(c) evaluating rate constants at two different temperatures
(d) evaluating velocities of reaction at two different temperatures

134. The experimental data for the reaction $2A + B_2 \rightarrow 2AB$, is:

Expt. No.	**$[A]$**	**$[B_2]$**	**Rate (mol s^{-1})**
1.	0.50	0.50	1.6×10^{-4}
2.	0.50	1.00	3.2×10^{-4}
3.	1.0	1.00	3.2×10^{-4}

The rate equation for the above data is: **(CBSE 1997)**
(a) rate $= k[B_2]^2$ (b) rate $= k[B_2]$
(c) rate $= k[A]^2[B]^2$ (d) rate $= k[A]^2[B]$

135. For the reaction $A \rightarrow B$, the rate law is: rate $= k[A]$. Which of the following statements is incorrect? **[PMT (Pb.) 1998]**
(a) The reaction follows first order kinetics
(b) The $t_{1/2}$ of the reaction depends on initial concentration
(c) k is constant for the reaction at a constant temperature
(d) The rate law provides a simple way of predicting the concentration of reactants at any time after the start of the reaction

136. Cyclopropane rearranges to form propene:

$$\Delta \longrightarrow CH_3-CH=CH_2$$

This follows first order kinetics. The rate constant is $2.714 \times 10^{-3}\ \text{sec}^{-1}$. The initial concentration of cyclopropane is 0.29 M. What will be the concentration of cyclopropane after 100 sec? **[JEE (Orissa) 2009]**

(a) 0.035 M (b) 0.22 M
(c) 0.145 M (d) 0.0018 M

137. The rate constant for the reaction,

$$N_2O_5(g) \longrightarrow 2NO_2(g) + \frac{1}{2}O_2(g),$$

is $2.3 \times 10^{-2}\ \text{sec}^{-1}$. Which equation given below describes the change of $[N_2O_5]$ with time $[N_2O_5]_0$ and $[N_2O_5]_t$ correspond to concentration of N_2O_5 initially and time 't'? **(AIIMS 2004)**

(a) $[N_2O_5]_0 = [N_2O_5]_t\, e^{kt}$

(b) $\log_e \dfrac{[N_2O_5]_0}{[N_2O_5]_t} = kt$

(c) $\log_{10}[N_2O_5]_t = \log_{10}[N_2O_5]_0 - kt$

(d) $[N_2O_5]_t = [N_2O_5]_0 + kt$

138. The reaction, $X \longrightarrow Y$ (Product) follows first order kinetics. In 40 minutes, the concentration of X changes from 0.1 M to 0.025 M, then the rate of reaction when concentration of X is 0.01 M is: **[IIT (S) 2004]**

(a) $1.73 \times 10^{-4}\ M/\text{min}$ (b) $3.47 \times 10^{-5}\ M/\text{min}$
(c) $3.47 \times 10^{-4}\ M/\text{min}$ (d) $1.73 \times 10^{-5}\ M/\text{min}$

139. In a first order reaction, the concentration of the reactant, decreases from 0.8 M to 0.4 M in 15 minutes. The time taken for the concentration to change from 0.1 M to 0.025 M is:

(a) 30 min (b) 15 min (c) 7.5 min (d) 60 min

140. A substance undergoes first order decomposition. The decomposition follows two parallel first order reactions as;

$$A \begin{cases} \xrightarrow{k_1} B & k_1 = 1.26 \times 10^{-4}\ \text{sec}^{-1} \\ \xrightarrow{k_2} C & k_2 = 3.8 \times 10^{-5}\ \text{sec}^{-1} \end{cases}$$

The percentage distribution of B and C are: **[PMT (Kerala) 2004]**

(a) 75% B and 25% C (b) 80% B and 20% C
(c) 60% B and 40% C (d) 90% B and 10% C
(e) 76.83% B and 23.17% C

141. For a reaction $2NH_3 \longrightarrow N_2 + 3H_2$, it is observed that

$$\frac{-d(NH_3)}{dt} = k_1(NH_3), \frac{d(N_2)}{dt} = k_2(NH_3), \frac{d(H_2)}{dt} = k_3(NH_3).$$

What is the relation between k_1, k_2 and k_3?

(a) $k_1 = k_2 = k_3$ (b) $3k_1 = 6k_2 = 2k_3$
(c) $2k_1 = 3k_2 = 6k_3$ (d) $6k_1 = 3k_2 = 2k_3$

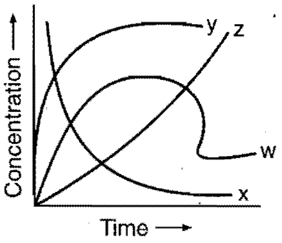
142. In Arrhenius equation $k = Ae^{-E_a/RT}$, factor $e^{-E_a/RT}$ is known as:

(a) frequency factor (b) activation factor
(c) pre-exponential factor (d) Boltzmann factor

143. Unit of frequency factor (A) is:

(a) moles/lit (b) moles/lit/sec
(c) depends upon order (d) no unit

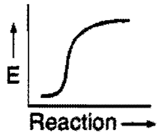
144. For the reaction $A + B \longrightarrow C + D$, the variation of the concentration of the products is given by the curve:



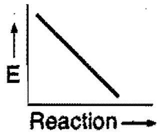
(a) x (b) y (c) z (d) w

145. Which graph shows zero activation energy?

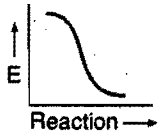
(a)



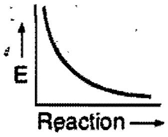
(b)



(c)



(d)



146. $E_{\text{Threshold}}$ can never be:

(a) $> E_R$ (b) $> E_P$
(c) $< E_P$ (d) $> E_R$ as well as $> E_P$

147. A reaction takes place in three steps; the rate constants are k_1, k_2 and k_3. The overall rate constant $k = \dfrac{k_1 k_3}{k_2}$. If energies of activation are 40, 30 and 20 kJ, the overall energy of activation is:

(a) 10 (b) 15 (c) 30 (d) 60

148. For hypothetical reaction $A \rightarrow B$ takes place according to

$$A \overset{k_1}{\rightleftharpoons} C, \quad A + C \xrightarrow{k_2} D\ \text{(slow)}$$

Rate law will be:

(a) $k_2[A][C]$ (b) $k_1k_2[A]$ (c) $k_1k_2[A]^2$ (d) $k_1k_2[A][C]$

149. If concentration of reactant is increased by 'm'; then k becomes:

(a) $e^{k/m}$ (b) k (c) k/m (d) mk

150. $aA + bB \longrightarrow P$; $dx/dt = k[A]^a \cdot [B]^b$. If conc. of A is doubled, rate is doubled. If B is doubled, rate becomes four times. Which is correct?

(a) $\dfrac{-d[A]}{dt} = \dfrac{-d[B]}{dt}$ (b) $\dfrac{-d[A]}{dt} = \dfrac{-2d[B]}{dt}$

(c) $\dfrac{-2d[A]}{dt} = \dfrac{-d[B]}{dt}$ (d) None of these

151. A drop of solution (volume 0.05 mL) contains 3×10^{-6} mole of H^+. If the rate constant of disappearance of H^+ is 10^7 mol litre^{-1} sec^{-1}, how long would it take for H^+ in the drop to disappear?

(a) 6×10^{-8} sec (b) 6×10^{-9} sec

(c) 6×10^{-10} sec (d) 6×10^{-12} sec

152. For the reaction, $H_2 + I_2 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} 2HI$. The rate law expression is:

(a) $\left[-\frac{1}{2}\frac{d[HI]}{dt}\right] = k_1[H_2][I_2]$

(b) $\left[-\frac{1}{2}\frac{d[HI]}{dt}\right] = \frac{k_1[HI]^2}{k_2[H_2][I_2]}$

(c) $\left[-\frac{1}{2}\frac{d[HI]}{dt}\right] = k_1[H_2][I_2] - k_2[HI]^2$

(d) $\left[-\frac{1}{2}\frac{d[HI]}{dt}\right] = k_1k_2[H_2][I_2]$

153. The chemical reaction, $2O_3 \rightarrow 3O_2$ proceeds as;

$O_3 \rightleftharpoons O_2 + O$ (fast), $O + O_3 \rightarrow 2O_2$ (slow)

The rate law expression will be:

(a) rate $= k[O][O_3]$ (b) rate $= k[O_3]^2$

(c) rate $= k[O_3]^2[O_2]^{-1}$ (d) can't be determined

154. For the reaction $NH_4^+ + OCN^- \longrightarrow NH_2CONH_2$, the probable mechanism is,

$NH_4^+ + OCN^- \rightleftharpoons NH_4OCN$ (fast)

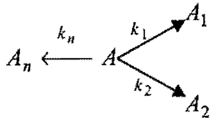
and $NH_4OCN \longrightarrow NH_2CONH_2$ (slow)

The rate law will be:

(a) rate $= k[NH_2CONH_2]$ (b) rate $= k[NH_4]^+[OCN]^-$

(c) rate $= k[NH_4OCN]$ (d) none of these

155. For a 1st order decomposition,



overall k will be given by:

(a) $k = k_1 + k_2 + \ldots + k_n$ (b) $k = (k_1 + k_2 + \ldots + k_n)/n$

(c) $k = k_1 \times k_2 \times \ldots \times k_n$ (d) none of these

156. For a reaction $A + 3B \rightarrow P$, Rate $= \frac{-d[A]}{dt}$, the expression for the rate of reaction in terms of change in the concentration of $B, \frac{-d[B]}{dt}$ will be :

(a) $k[A]^2[B]$ (b) $k[A]^2[3B]$

(c) $3k[A]^2[B]$ (d) $(\frac{1}{3})k[A]^2[B]$

157. Which of the following statements is correct?

(a) Rate of reaction $\propto \frac{1}{E_a}$

(b) At lower temp., increase in temp. causes more change in the value of k

(c) Both (a) and (b) are correct

(d) None is correct

158. For $X \rightarrow Y$; $k = 10^{10}e^{-500/T}$, and for $W \rightarrow Z$; $k = 10^{12}e^{-1000/T}$ at what temperature 'T' both reactions will have same value of k?

(a) 500 K (b) 1500 K

(c) $\frac{4.606}{500}$ K (d) $\frac{2.303}{5000}$ K

159. For a reversible reaction where the forward reaction is exothermic, which of the following statements is correct? **[JEE (WB) 2010]**

(a) The backward reaction has higher activation energy than the forward reaction

(b) The backward and the forward processes have same activation energy

(c) The backward reaction has lower activation energy

(d) No activation energy is required at all since energy is liberated in the process

160. For the reaction, $A + 3B \longrightarrow 2C + D$

which one of the following is not correct? **[EAMCET (Med.) 2010]**

(a) Rate of disappearance of A = Rate of formation of D

(b) Rate of formation of $C = \frac{2}{3} \times$ Rate of disappearance of B

(c) Rate of formation of $D = \frac{1}{3} \times$ Rate of disappearance of B

(d) Rate of disappearance of $A = 2 \times$ Rate of formation of C

161. $2A \longrightarrow B + C$, would be a zero order reaction when: **[CBSE (PMT) 2002]**

(a) the rate of reaction is proportional to square of concentration of 'A'

(b) the rate of reaction is same at any concentration of 'A'

(c) the rate remains unchanged at any concentration of 'B' and 'C'

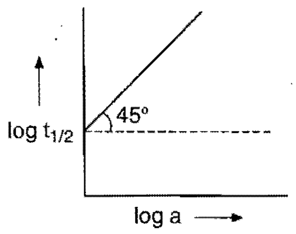
(d) the rate of reaction doubles if concentration of 'B' is increased to double

162. Units of rate constants for first and zero order reactions in terms of molarity M unit are respectively: **(AIEEE 2002)**

(a) sec^{-1}, M sec^{-1} (b) sec^{-1}, M

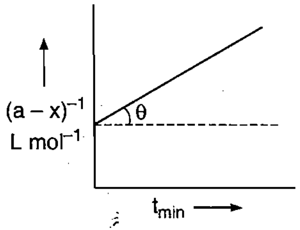
(c) M sec^{-1}, sec^{-1} (d) M, sec^{-1}

163. Following is the graph between log $t_{1/2}$ and log a (a = initial concentration) for a given reaction at 27°C. Hence, order is:



(a) 0 (b) 1 (c) 2 (d) 3

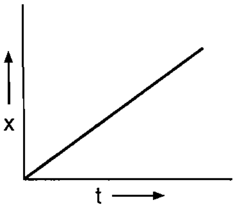
164. Following is the graph between $(a - x)^{-1}$ and time t for second order reaction. $\theta = \tan^{-1}(1/2)$; $OA = 2$ L mol^{-1}, hence rate at the start of reaction will be:



(a) 1.25 L mol^{-1} min^{-1} (b) 0.5 mol L^{-1} min^{-1}

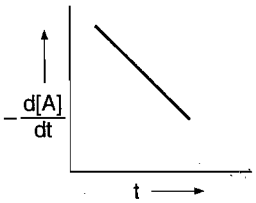
(c) 0.125 mol L^{-1} min^{-1} (d) 1.25 mol L^{-1} min^{-1}

165. Graph between concentration of the product 'x' and time 't' for $A \rightarrow B$ is given ahead:

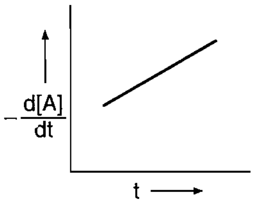


The graph between $-\frac{d[A]}{dt}$ and time will be of the type:

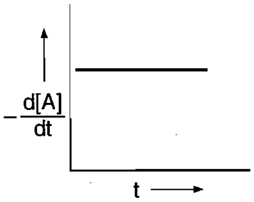
(a)



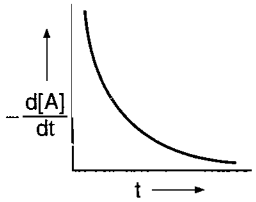
(b)



(c)



(d)



166. Consider the chemical reaction,

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

The rate of reaction can be expressed in terms of time derivative of concentration of $N_2(g)$, $H_2(g)$ or $NH_3(g)$. Identify the correct relationship amongst the rate expressions: **(IIT 2002)**

(a) $\text{rate} = -\frac{d[N_2]}{dt} = -\frac{1}{3}\frac{d[H_2]}{dt} = +\frac{1}{2}\frac{d[NH_3]}{dt}$

(b) $\text{rate} = -\frac{d[N_2]}{dt} = -3\frac{d[H_2]}{dt} = +2\frac{d[NH_3]}{dt}$

(c) $\text{rate} = \frac{d[N_2]}{dt} = \frac{1}{3}\frac{d[H_2]}{dt} = \frac{1}{2}\frac{d[NH_3]}{dt}$

(d) $\text{rate} = -\frac{d[N_2]}{dt} = -\frac{d[H_2]}{dt} = \frac{d[NH_3]}{dt}$

167. For the reaction,

$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$, if

$\frac{d[NH_3]}{dt} = 2 \times 10^{-4}$ mol L^{-1}s^{-1}, the value of $\frac{-d[H_2]}{dt}$ would be: **[CBSE (PMT) 2009]**

(a) 1×10^{-4} mol L^{-1}s^{-1} (b) 3×10^{-4} mol L^{-1}s^{-1}

(c) 4×10^{-4} mol L^{-1}s^{-1} (d) 6×10^{-4} mol L^{-1}s^{-1}

168. Temperature dependent equation can be written as: **[JEE (Orissa) 2005]**

(a) $\ln k = \ln A - e^{E_a/RT}$ (b) $\ln k = \ln A + e^{E_a/RT}$

(c) $\ln k = \ln A - e^{RT/E_a}$ (d) all of these

169. If the rate of reaction $A \longrightarrow B$ doubles on increasing the concentration of A by 4 times, the order of reaction is: **[CET (J&K) 2005]**

(a) 2 (b) 1 (c) 1/2 (d) 4

170. For the reaction: $2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$ if the concentration of NO_2 increases by 5.2×10^{-3} M in 100 sec, then the rate of reaction is: **[PET (Kerala) 2005]**

(a) 1.3×10^{-5} M s^{-1} (b) 5×10^{-4} M s^{-1}

(c) 7.6×10^{-4} M s^{-1} (d) 2×10^{-3} M s^{-1}

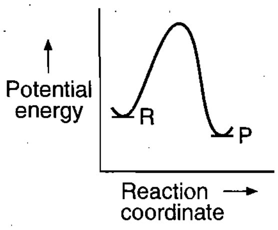
(e) 2.5×10^{-5} M s^{-1}

171. A first order reaction is 10% complete in 20 min. The time taken for 19% completion is: **[PET (Kerala) 2005]**

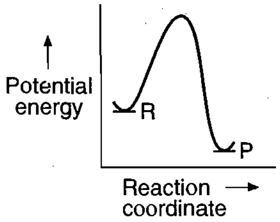
(a) 30 min (b) 40 min (c) 50 min (d) 38 min

(e) 45 min

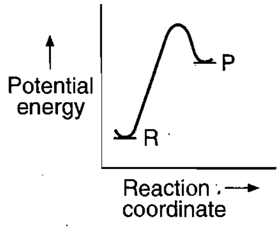
172. An endothermic reaction with high activation energy for the forward reaction is given by the diagram: **(AIIMS 2005)**



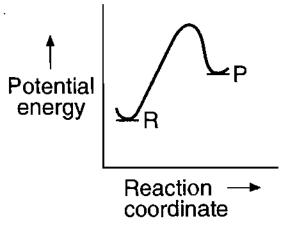
(a)



(b)



(c)



(d)

173. For reaction $aA \longrightarrow xP$, when $[A] = 2.2$ m-M, the rate was found to be 2.4 m M s^{-1}. On reducing concentration of A to half, the rate changes to 0.6 m M s^{-1}. The order of reaction with respect to A is: **(AIIMS 2005)**

(a) 1.5 (b) 2.0 (c) 2.5 (d) 3.0

[Hint: Rate = $k[A]^a$

$2.4 = k[2.2]^a$ ... (i)

$0.6 = k[1.1]^a$ ... (ii)

Dividing eq. (i) by eq. (ii), $a = 2$ ∴ order = 2]

174. According to the law of mass action, rate of a chemical reaction is proportional to: **(AFMC 2005)**

(a) concentration of reactants
(b) molar concentration of reactants
(c) concentration of products
(d) molar concentration of products

175. Consider the endothermic reaction $X \rightarrow Y$ with the activation energies E_b and E_f for backward and forward reactions, respectively. In general: **(AIEEE 2005)**
(a) $E_b < E_f$
(b) $E_b > E_f$
(c) $E_b = E_f$
(d) there is no definite relation between E_f and E_b

176. Which one of the following statements for order of reaction is not correct? **[IIT (S) 2005]**
(a) Order can be determined experimentally
(b) Order of reaction is equal to sum of powers of concentration terms in differential rate law
(c) It is not affected by the stoichiometric coefficient of the reactants
(d) Order cannot be fractional

177. The rate constant of a reaction is found to be 3×10^{-3} mol L^{-1} min^{-1}. The order of the reaction is: **[CET (J&K) 2006]**
(a) zero (b) 1 (c) 2 (d) 1.5
[**Hint:** Unit of rate and rate constants are same for zero order reaction.]

178. In the first order reaction, the concentration of the reactants is reduced to 25% in one hour. The half life period of the reaction is: **[UGET (Manipal) 2005]**
(a) 2 hrs (b) 4 hrs (c) 1/2 hr (d) 1/4 hr
[**Hint:** $k = \frac{2.303}{t} \log\left(\frac{a}{a-x}\right)$

$$k = \frac{2.303}{1} \log\left(\frac{100}{25}\right) = 2 \times 0.693$$

$$t_{1/2} = \frac{0.693}{k} = \frac{0.693}{2 \times 0.693} = \frac{1}{2} \text{ hr}]$$

179. A substance reacts with initial concentration of a mol dm^{-3} according to zero order kinetics. The time it takes for the completion of the reaction is: (k = rate constant) **[[illegible] 2006; CET (Karnataka) 2009]**
(a) $\frac{k}{a}$ (b) $\frac{a}{2k}$ (c) $\frac{a}{k}$ (d) $\frac{2k}{a}$
(e) ka
[**Hint:** $x = k \times t$

$$t = \frac{x}{k}$$

Time for completion of reaction (when $x = a$), i.e., $t = \frac{a}{k}$]

180. Rate of a reaction can be expressed by Arrhenius equation as, $k = Ae^{-E/RT}$. In this equation, E represents: **(AIEEE 2006)**
(a) the energy above which all the colliding molecules will react
(b) the energy below which colliding molecules will not react
(c) the total energy of the reacting molecules at a temperature T
(d) the fraction of molecules with energy greater than the activation energy of the reaction

181. The rate constant of a first order reaction at 27°C is 10^{-3} min^{-1}. The temperature coefficient of this reaction is 2. What is the rate constant (in min^{-1}) at 17°C for this reaction? **(ET 2006)**
(a) 10^{-3} (b) 5×10^{-4} (c) 2×10^{-3} (d) 10^{-2}
[**Hint:** $\frac{k_{T_2}}{k_{T_1}} = (\mu)^{\Delta T/10}$

$$\frac{10^{-3}}{k_{T_1}} = (\mu)^{10/10} = 2$$

$$k_{T_1} = \frac{10^{-3}}{2} = 0.5 \times 10^{-3}$$

$$= 5 \times 10^{-4} \text{ min}^{-1}]$$

182. In a chemical reaction, two reactants take part. The rate of reaction is directly proportional to the concentration of one of them and inversely proportional to the concentration of the other. The order of the reaction is: **[PMT (Raj.) 2006]**
(a) zero (b) 1 (c) 2 (d) 4

183. According to Arrhenius equation, the rate constant (k) is related to temperature (T) as: **(VITEEE 2007)**
(a) $\ln\left(\frac{k_2}{k_1}\right) = \frac{E_a}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$
(b) $\ln\left(\frac{k_2}{k_1}\right) = -\frac{E_a}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$
(c) $\ln\left(\frac{k_2}{k_1}\right) = \frac{E_a}{R}\left(\frac{1}{T_1} + \frac{1}{T_2}\right)$
(d) $\ln\left(\frac{k_2}{k_1}\right) = -\frac{E_a}{R}\left(\frac{1}{T_1} + \frac{1}{T_2}\right)$

184. Consider a reaction $aG + bH \longrightarrow$ Products. When concentration of both the reactants G and H are doubled, the rate increases by eight times. However, when the concentration of G is doubled keeping the concentration of H fixed, the rate is doubled. The overall order of reaction is: **(IIT 2007)**
(a) 0 (b) 1 (c) 2 (d) 3
[**Hint:** Order with respect to 'G' will two and with respect to 'H' the order will be one.

$$\text{Rate} = k[G]^2[H]^1$$

When concentration of both G and H are doubled, the rate will increase eight times.]

185. The temperature dependence of rate constant (k) of a chemical reaction is written in terms of Arrhenius equation $k = Ae^{-E_a/RT}$. Activation energy (E_a) of the reaction can be calculated by plotting: **(MS 2007)**
(a) $\log k$ *vs* T (b) $\log k$ *vs* $\frac{1}{T}$ (c) k *vs* T (d) k *vs* $\frac{1}{\log T}$

186. Consider the reaction, $2A + B \longrightarrow$ Products. When concentration of B alone was doubled, the half life did not change. When the concentration of A alone was doubled, the rate increased by two times. The unit of rate constant for this reaction is: **(AIEEE 2007)**
(a) s^{-1} (b) L $mol^{-1}s^{-1}$ (c) unitless (d) mol $L^{-1}s^{-1}$

[**Hint:** Concentration change in 'B' does not change half life, it means the reaction is first order with respect to B. When concentration of only 'A' is doubled, the rate of reaction becomes double, thus order with respect to A will also be one.

Overall order of reaction = 2

unit of rate constant = L $\text{mol}^{-1}\text{s}^{-1}$]

187. In a first order reaction $A \longrightarrow B$, if k is rate constant and initial concentration of the reactant A is 0.5 M then half life is: **[CBSE (Med) 2007]**

(a) $\frac{\log 2}{k}$ (b) $\frac{\log 2}{k\sqrt{0.5}}$ (c) $\frac{\ln 2}{k}$ (d) $\frac{0.693}{0.5k}$

188. For the first order reaction, half life is 14 sec, the time required for the initial concentration to reduce to 1/8 of its value is: **[CET (J&K) 2007]**

(a) $(14)^3$ sec (b) 28 sec (c) 42 sec (d) $(14)^2$ sec

189. 75% of a first order reaction was completed in 32 min, when was 50% of the reaction completed? **[BHU (Mains) 2007]**

(a) 24 min (b) 16 min (c) 8 min (d) 48 min

190. For a zero order reaction,

$$A \longrightarrow P$$

$t_{1/2}$ is: (k is rate constant) **[BHU (Mains) 2007]**

(a) $\frac{[A]_0}{2k}$ (b) $\frac{\ln 2}{k}$ (c) $\frac{1}{k[A]_0}$ (d) $\frac{\ln 2}{[A]_0 k}$

191. The rate constants k_1 and k_2 for two different reactions are $10^{16}\, e^{-2000/T}$ and $10^{15} e^{-1000/T}$, respectively. The temperature at which $k_1 = k_2$ is : **[CBSE (PMT) 2008]**

(a) 2000 K (b) $\frac{1000}{2.303}$ K (c) 1000 K (d) $\frac{2000}{2.303}$ K

[**Hint :** $10^{15}\, e^{-1000/T} = 10^{16} e^{-2000/T}$

$$\frac{e^{-2000/T}}{e^{-1000/T}} = \frac{10^{15}}{10^{16}}$$

$$e^{-1000/T} = 10^{-1}$$

$$\log_e e^{-1000/T} = \log_e 10^{-1}$$

$$\frac{-1000}{T} = 2.303 \log_{10} 10^{-1}$$

$$= -2.303$$

$$T = \frac{1000}{2.303}\text{K}]$$

192. Under the same reaction conditions, initial concentration of 1.386 mol dm^{-3} of a substance becomes half in 40 seconds and 20 seconds through first order and zero order kinetics respectively. Ratio $\left(\frac{k_1}{k_0}\right)$ of the rate constant for first order (k_1) and zero order (k_0) of the reaction is : **(IIT 2008)**

(a) 0.5 mol^{-1} dm^3 (b) 1 mol dm^{-3}

(c) 1.5 mol dm^{-3} (d) 2 mol^{-1} dm^3

[**Hint :** $t_{1/2} = \frac{0.693}{k_1}$, $t_{1/2} = \frac{a_0}{2k_0}$

$40 = \frac{0.693}{k_1}$, $20 = \frac{1.386}{2k_0} = \frac{0.693}{k_0}$

$$\frac{20}{40} = \frac{0.693/k_0}{0.693/k_1} = \frac{k_1}{k_0}$$

$$\frac{k_1}{k_0} = 0.5\, \frac{\text{sec}^{-1}}{\text{mol dm}^{-3}\ \text{sec}^{-1}} = 0.5\ \text{mol}^{-1}\ \text{dm}^3\ ]$$

193. The decomposition of HI on the surface of gold is : **[Comed (Karnataka) 2008]**

(a) Pseudofirst order (b) zero order

(c) first order (d) second order

194. Consider following two reactions

$$A \longrightarrow \text{Product},\qquad -\frac{d[A]}{dt} = k_1[A]_0$$

$$B \longrightarrow \text{Product},\qquad -\frac{d[B]}{dt} = k_2[B]_0$$

k_1 and k_2 are expressed in terms of molarity (mol L^{-1}) and time (s^{-1}) as: **[BHU (Mains) 2008]**

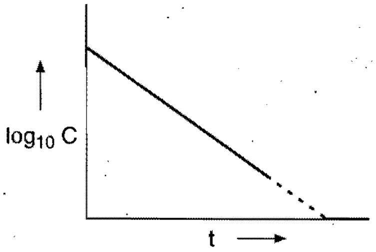
(a) $\text{s}^{-1}, M\ \text{s}^{-1}\ \text{L}^{-1}$ (b) $M\ \text{s}^{-1}, M\ \text{s}^{-1}$

(c) $\text{s}^{-1}, M^{-1}\text{s}^{-1}$ (d) $M\ \text{s}^{-1}, \text{s}^{-1}$

195. If a plot of $\log_{10} C$ versus t gives a straight line for a given reaction, then the reaction is : **(VITEEE 2008)**

(a) zero order (b) first order (c) second oder (d) third order

[**Hint:**



In first order reaction, $\log_{10} C$ when plotted against time 't' then we get straight line. Slope of the line $\left(\frac{2.303}{k}\right)$ gives the value of rate constant.]

196. For a zero order reaction the plot of concentration of reactant versus time is: (intercept refers to concentration axis) **[PET (Kerala) 2008]**

(a) linear with +ve slope and zero intercept

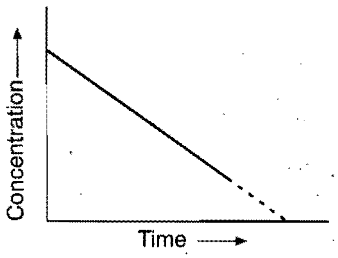
(b) linear with –ve slope and zero intercept

(c) linear with –ve slope and non zero intercept

(d) linear with +ve slope and non zero intercept

(e) a curve asymptotic to concentration axis

[**Hint :**



Linear with negative slope and non zero intercept.]

197. T_{50} of first order reaction is 10 min. Starting with 10 mol L^{-1}, rate after 20 min is : **(AIIMS 2008)**

(a) 0.0693 mol L^{-1} min^{-1}

(b) 0.0693 × 2.5 mol L^{-1} min^{-1}

(c) $0.0693 \times 5 \text{ mol L}^{-1} \text{ min}^{-1}$
(d) $0.0693 \times 10 \text{ mol L}^{-1} \text{ min}^{-1}$

[**Hint :** Remaining concentration of reactant after 20 min

$$= \frac{1}{4} \times 10 = 2.5 \text{ mol L}^{-1}$$

$$\begin{aligned} \text{Rate} &= k \times [\text{Reactant}] \\ &= \frac{0.693}{t_{1/2}} \times [\text{Reactant}] \\ &= \frac{0.693}{10} \times 2.5 = 0.0693 \times 2.5 \text{ mol L}^{-1} \text{ min}^{-1} \end{aligned}$$]

198. For the decomposition of AB at 600 K, the following data were obtained

[AB] mol dm^{-3}	**Rate of decomposition of AB in mol dm^{-3}s^{-1}**
0.20	2.75×10^{-8}
0.40	11×10^{-8}
0.60	24.75×10^{-8}

The order of the decomposition of AB is :
[CET (Karnataka) 2009]

(a) 0 (b) 1 (c) 2 (d) 1.5

199. For a reaction between A and B, the initial rate of reaction is measured for various initial concentrations of A and B. The data provided are: **(DCE 2009)**

Exp. No.	**[A]**	**[B]**	**Initial reaction rate (mol L^{-1}s^{-1})**
1.	0.2 M	0.3 M	5×10^{-5}
2.	0.2 M	0.1 M	5×10^{-5}
3.	0.4 M	0.05 M	7.5×10^{-5}

The overall order of the reaction is: **(DCE 2009)**

(a) one (1) (b) two (2)
(c) two and a half (2.5) (d) between 1 and 2

200. For a first order reaction $A \longrightarrow P$, the temperature (T) dependent rate constant (k) was found to follow the equation:

$$\log k = -(2000)\frac{1}{T} + 6.0$$

The pre exponential factor A and the activation energy E_a respectively, are : **(IIT 2009)**

(a) $1 \times 10^6 \text{ s}^{-1}$ and 9.2 kJ mol^{-1}
(b) 6 s^{-1} and 16.6 kJ mol^{-1}
(c) $1 \times 10^6 \text{ s}^{-1}$ and 16.6 kJ mol^{-1}
(d) $1 \times 10^6 \text{ s}^{-1}$ and 38.3 kJ mol^{-1}

[**Hint :** $\log k = \log_{10} A - \frac{E_a}{2.303} \times \frac{1}{T}$

Comparing this equation with the given equation we get,

$$A = 10^6 \text{ s}^{-1}, \; E_a = 38.3 \text{ kJ mol}^{-1}$$]

201. The time for half-life period of a certain reaction, $A \rightarrow$ Product is 1 hour. When the initial concentration of the reactant 'A' is 2 mol L^{-1}. How much time does it take for its concentration to come from 0.50 to 0.25 mol L^{-1} if it is a zero order reaction? **(AIEEE 2010)**

(a) 0.25 h (b) 1 h (c) 4 h (d) 0.5 h

[**Hint :** $\frac{t_1}{t_2} = \left(\frac{a_2}{a_1}\right)^{n-1}$

$$\frac{1}{t_2} = \left(\frac{0.5}{2}\right)^{0-1}$$

$$t_2 = 0.25 \text{ h}$$]

202. Consider the reaction :

$$Cl_2(aq) + H_2S(aq) \longrightarrow S(s) + 2H^+(aq) + 2Cl^-(aq)$$

The rate equation for this reaction is :

$$\text{Rate} = k\,[Cl_2][H_2S]$$

Which of these mechanisms is/are consistent with this rate equation?

A. $Cl_2 + H_2S \longrightarrow H^+ + Cl^- + Cl^+ + HS^-$ (slow)
$Cl^+ + HS^- \longrightarrow H^+ + Cl^- + S$ (fast)

B. $H_2S \rightleftharpoons H^+ + HS^-$ (fast equilibrium)
$Cl_2 + HS^- \longrightarrow 2Cl^- + H^+ + S$ (slow)

(AIEEE 2010)

(a) neither A nor B (b) A only
(c) B only (d) both A and B

Assertion-Reason TYPE QUESTIONS

he questions given below consist of two statements each printed as **'Assertion' (A)** and **'Reason' (R).** While answering these questions ou are required to choose any one of the following four options:

(a) If both (A) and (R) are correct and (R) is the correct explanation for (A).
(b) If both (A) and (R) are correct but (R) is not the correct explanation for (A).
(c) If (A) is correct but (R) is incorrect.
(d) If (A) is incorrect but (R) is correct.

1. (A) The rate of reaction sometimes does not depend on concentration.
   (R) The order of reaction can be negative.
2. (A) The rate of reaction increases generally by 2 to 3 times for every 10°C rise in temperature.
   (R) Increase in temperature increases the collision frequency.
3. (A) Hydrolysis of ethyl acetate in presence of acid is a reaction of first order whereas in presence of alkali, it is a reaction of second order.
   (R) Acid acts as catalyst only whereas alkali acts as one of the reactant.
4. (A) The molecularity of the reaction,
   $H_2 + Br_2 \longrightarrow 2HBr$ is 2.
   (R) The order of this reaction is 3/2.
5. (A) Positive catalysts lower the activation energy of the reaction whereas heat of reaction remains same.
   (R) Heat of reaction is equal to the difference between activation energies for forward and the backward reactions.
6. (A) Positive catalysts increase the rate of reaction.
   (R) Catalysts decrease the value of ΔG°.
7. (A) $k = Ae^{-E_a/RT}$, the Arrhenius equation represents the dependance of rate constant with temperature.
   (R) Plot of log k against $1/T$ is linear and the activation energy can be calculated with this plot.
8. (A) If the activation energy of a reaction is zero, temperature will have no effect on the rate constant.
   (R) Lower the activation energy, faster is the reaction.
9. (A) Order with respect to any reactant or product can be zero, positive, negative and fractional.
   (R) Rate cannot decrease with increase in concentration of a reactant or product.
10. (A) Formation of HI is a bimolecular reaction.
    (R) Two molecules of reactants are involved in this reaction.
11. (A) The order of the reaction,
    $CH_3COOC_2H_5 + H_2O \rightleftharpoons CH_3COOH + C_2H_5OH$
    is 2.
    (R) The molecularity of this reaction is 2.
12. (A) For: $aA + bB \longrightarrow$ Product. The order of the reaction is equal to $(a + b)$.
    (R) Rate of reaction $= k\,[A]^a[B]^b$.
13. (A) The hydrolysis of methyl acetate by dil HCl is a pseudo first order reaction.
    (R) HCl acts as a catalyst for the hydrolysis. **(AIIMS 2007)**
14. (A) The order of a reaction can have fractional value.
    (R) The order of a reaction cannot be written from balanced equation of a reaction. **(AIIMS 2008)**

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS for IIT ASPIRANTS

1. Which of the following is correct?
   (a) Molecularity of a reaction can be fractional
   (b) Zero order reaction never stops
   (c) A first order reaction must be homogeneous
   (d) The frequency factor 'A' in Arrhenius equation ($k = Ae^{-E_a/RT}$) increases with increase in temperature

2. The rate constant of the reaction,
$$2H_2O_2(aq.) \rightarrow 2H_2O(l) + O_2(g),$$
is $3 \times 10^{-3}\ \text{min}^{-1}$.
At what concentration of H_2O_2, the rate of the reaction will be $2 \times 10^{-4}\ M\,s^{-1}$?
   (a) $6.67 \times 10^{-3}\ M$ (b) $2\ M$
   (c) $4\ M$ (d) $0.08\ M$

[**Hint:** Rate $= k[H_2O_2]^1$
$$2 \times 10^{-4} = \frac{3 \times 10^{-3}}{60} \times [H_2O_2]$$
$$[H_2O_2] = 4\ M]$$

3. The mechanism of the reaction,
$$2NO(g) + 2H_2(g) \longrightarrow N_2(g) + 2H_2O(g),$$
is:

Step 1: $2NO(g) + H_2(g) \xrightarrow{\text{slow}} N_2 + H_2O_2$

Step 2: $H_2O_2 + H_2 \xrightarrow{\text{fast}} 2H_2O$

   (a) rate $= k[NO]^2[H_2]^2$
   (b) rate $= k[H_2O_2][H_2]$
   (c) on doubling the concentration of H_2, keeping the concentration of NO constant, the rate will become double
   (d) if the initial concentration of H_2 and NO is C_0 and after time 't' the concentration of N_2 is x, then
   Rate $= k(C_0 - 2x)^x$

[**Hint:** Slowest step is rate determining
$\therefore$ Rate $= k[NO]^2[H_2]$
$\therefore$ On doubling the concentration of H_2 without changing the concentration of NO, the rate will become double.]

4. The rate law for a reaction between A and B is given by:
$$\text{Rate} = k[A]^n[B]^m$$
On doubling the concentration of A and halving the concentration of B, the ratio of new rate to the earlier rate of the reaction will be as:
   (a) $n - m$ (b) 2^{n-m} (c) $2^{1/(n+m)}$ (d) 2^{m-n}

5. The reaction $A \xrightarrow{k}$ Product, is zero order while the reaction $B \xrightarrow{k}$ Product, is first order reaction. For what initial concentration of A are the half lives of the two reactions equal?
   (a) $(\log_e 4)M$ (b) $2\ M$ (c) $2 \log 2\ M$ (d) $\ln 2\ M$

[**Hint:** For zero order reaction,
$$x = kt$$
$$\therefore \quad \frac{a}{2} = k \times t_{1/2},\ i.e.,\ t_{1/2} = \frac{a}{2k} \qquad \text{... (i)}$$
For first order reaction,
$$t_{1/2} = \frac{\log_e 2}{k} \qquad \text{... (ii)}$$
From eqs. (i) and (ii), $\dfrac{a}{2k} = \dfrac{\log_e 2}{k}$
$$a = \log_e 4\ M]$$

6. Which of the following is pseudo-unimolecular reaction?
   (a) $2H_2O_2 \longrightarrow 2H_2O + O_2$
   (b) $C_6H_5N_2Cl + HOH \longrightarrow C_6H_5OH + N_2 + HCl$
   (c) $CH_3COOC_2H_5 + NaOH \longrightarrow CH_3COONa + C_2H_5OH$
   (d) $2O_3 \longrightarrow 3O_2$

7. The order and molecularity of the chain reaction,
$$H_2(g) + Cl_2(g) \xrightarrow{h\nu} 2HCl\ (g),$$
are:
   (a) 2, 0 (b) 0, 2 (c) 1, 1 (d) 3, 0

8. A reactant (A) forms two products:
$$A \xrightarrow{k_1} B \quad \text{Activation energy } E_{a_1}$$
$$A \xrightarrow{k_2} C \quad \text{Activation energy } E_{a_2}$$
If $E_{a_2} = 2E_{a_1}$, then k_1 and k_2 will be related as:
   (a) $k_2 = k_1 e^{E_{a_1}/RT}$ (b) $k_2 = k_1 e^{E_{a_2}/RT}$
   (c) $k_1 = Ak_2 e^{E_{a_1}/RT}$ (d) $k_1 = 2k_2 e^{E_{a_2}/RT}$

[**Hint:** $k_2 = Ae^{-E_{a_2}/RT}$
$$k_1 = Ae^{-E_{a_1}/RT}$$
$$\therefore \quad \frac{k_2}{k_1} = e^{(-E_{a_2} + E_{a_1})/RT}$$
$$\frac{k_2}{k_1} = e^{E_{a_1}/RT} \qquad \text{Since, } E_{a_2} = 2E_{a_1}$$
$$k_2 = k_1 e^{E_{a_1}/RT}]$$

9. Collision theory is satisfactory for:
   (a) first order reactions (b) second order reactions
   (c) bimolecular reactions (d) zeroth order reactions

10. Initial concentration of reactant for nth order reaction is 'a'. Which of the following relations is correct about $t_{1/2}$ of the reaction?
   (a) $\ln t_{1/2} = \ln(\text{constant}) - (n-1)\log_e a$
   (b) $\ln t_{1/2} = \ln n + \ln(\text{constant}) - \ln a$
   (c) $t_{1/2} \ln n = \ln(\text{constant}) + \ln a_0$
   (d) $\ln t_{1/2} = n \ln a_0$

[Hint: $t_{1/2} \propto \frac{1}{a^{n-1}}$

$$t_{1/2} = k\,\frac{1}{a^{n-1}}$$

$\ln t_{1/2} = \ln k - (n-1)\log_e a$]

11. Half life of a reaction becomes half when initial concentrations of reactants are made double. The order of the reaction will be:
(a) 1 (b) 2 (c) 0 (d) 3

[Hint: $t_{1/2} \propto \frac{1}{a^{n-1}}$

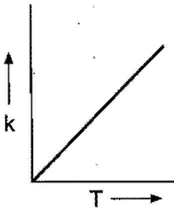
$$t_{1/2} \propto \frac{1}{a}$$

where, n = order of reaction for second order reaction.]

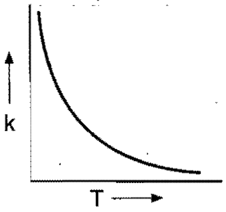
12. Arrhenius equation is:

$$k = Ae^{-E/RT}$$

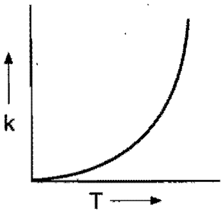
Which of the following graphs represents the variation of rate constant k against temperature T ? **(IIT 2010)**



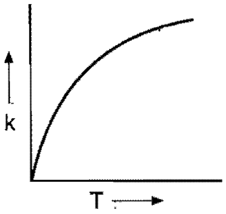
(a)



(b)

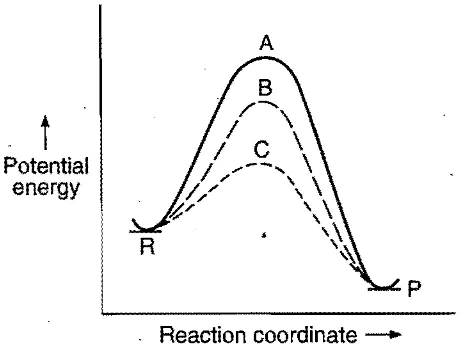


(c)



(d)

13. If a homogeneous catalytic reaction follows three alternative paths A, B and C, then which of the following indicates the relative ease with which the reaction moves?



(a) $A > B > C$ (b) $C > B > A$ (c) $A > C > B$ (d) $A = B = C$

14. The rate constant for the reaction,

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

is 3×10^{-5} sec^{-1}. If the rate is 2.4×10^{-5} mol litre^{-1} sec^{-1}, then the concentration of N_2O_5 in mol litre^{-1} will be:
(a) 1.4 (b) 2.1 (c) 1.27 (d) 0.8

[Hint: $\because$ Rate $= k\,[N_2O_5]$

$$2.4 \times 10^{-5} = 3 \times 10^{-5}\,[N_2O_5]$$

$[N_2O_5] = 0.8\,M$]

15. Consider the following statements:
1. The rate of reaction is always proportional to the concentrations of reactants.
2. The order of an elementary chemical reaction step can be determined by examining its stoichiometry.
3. The first order reactions follow an exponential time course.

Of these statements:
(a) 1, 2 and 3 are correct (b) 1 and 2 are correct
(c) 2 and 3 are correct (d) 1 and 3 are correct

[Hint: Statement (1) cannot be correct because the rate of zero order reactions does not depend on concentration of reactant.]

16. Two different first order reactions have rate constants k_1 and k_2 at T_1 $(k_1 > k_2)$. If temperature is increased from T_1 to T_2, then new constants become k_3 and k_4 respectively. Which among the following relations is correct?
(a) $k_1 > k_2 = k_3 = k_4$ (b) $k_1 < k_3$ and $k_2 < k_4$
(c) $k_1 = k_3 = k_4$ (d) $k_1 > k_2 > k_3 > k_4$

17. In the reaction, $A + B \longrightarrow C + D$, the rate $\left(\frac{dx}{dt}\right)$ when plotted against time 't' gives a straight line parallel to time axis. The order and rate of reaction will be:
(a) $1, k+1$ (b) $0, k$ (c) $1, k+1$ (d) $k, k+1$

18. In the Haber's process of ammonia manufacture,

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

the rate of appearance of NH_3 is:

$$\frac{d[NH_3]}{dt} = 2 \times 10^{-4} \text{ mol L}^{-1} \text{ sec}^{-1}$$

The rates of the reaction expressed in terms of N_2 and H_2 will be:

	Rates in terms of H_2 (mol L^{-1} sec^{-1})	**Rates in terms of N_2 (mol L^{-1} sec^{-1})**
(a)	3×10^{-4}	2×10^{-4}
(b)	3×10^{-4}	1×10^{-4}
(c)	1×10^{-4}	3×10^{-4}
(d)	2×10^{-4}	2×10^{-4}

[Hint: Rate $= +\frac{1}{2}\frac{d[NH_3]}{dt} = \frac{-d[N_2]}{dt} = -\frac{1}{3}\frac{d[N_2]}{dt}$

$$\frac{-d[H_2]}{dt} = \frac{3}{2} \times \frac{d[NH_3]}{dt}$$

$$= \frac{3}{2} \times 2 \times 10^{-4} = 3 \times 10^{-4} \text{ mol L}^{-1} \text{ sec}^{-1}$$

$$\frac{-d[N_2]}{dt} = \frac{1}{2}\frac{d[NH_3]}{dt} = \frac{1}{2} \times 2 \times 10^{-4}$$

$= 1 \times 10^{-4}$ mol L^{-1} sec^{-1}]

19. A reaction $A \longrightarrow B$, involves following mechanism:

Step 1: $A \xrightarrow{k_1} B$ (fast)

Step 2: $B \xrightarrow{k_2} C$ (slow)

Step 3: $C \xrightarrow{k_3} D$ (fast)

The rate law of the reaction may be given as:

(a) rate $= k_1[A]$ (b) rate $= k_2[B]$
(c) rate $= k_3[C]$ (d) rate $= k_1k_2k_3[B][C]$

20. For a gaseous reaction, the following data were recorded:

Concentration in mol L^{-1}	0.1	0.05	0.025	0.0125
Half life in sec	30	29.9	30.1	30

The order of reaction is:

(a) second (b) first (c) zero (d) fractional

21. The half life of second order reaction is:

(a) inversely proportional to the square of the initial concentration of the reactants
(b) inversely proportional to the initial concentration of reactants
(c) proportional to the initial concentration of reactants
(d) independent of the initial concentration of reactants

[**Hint:** $t_{1/2} \propto \frac{1}{a^{n-1}}$; where, a = initial conc., n = order

$t_{1/2}$ (second order) $\propto \frac{1}{a}$]

22. What names apply to chemical species corresponding to locations 1 and 2 on this reaction coordinate diagram?

	Location 1	**Location 2**
(a)	Activated complex	Activated complex
(b)	Reaction intermediate	Activated complex
(c)	Activated complex	Intermediate
(d)	Reaction intermediate	Intermediate

23. Consider this reaction:

$$2NO_2(g) + O_3(g) \longrightarrow N_2O_5(g) + O_2(g)$$

The reaction of nitrogen dioxide and ozone represented is first order in $NO_2(g)$ and in $O_3(g)$. Which of these possible reaction mechanisms is consistent with the rate law?

Mechanism I: $NO_2(g) + O_3(g) \longrightarrow NO_3(g) + O_2(g)$ (slow)
$NO_3(g) + NO_2(g) \longrightarrow N_2O_5(g)$ (fast)

Mechanism II: $O_3(g) \rightleftharpoons O_2(g) + [O]$ (fast)
$NO_2(g) + [O] \longrightarrow NO_3$ (slow)
$NO_3(g) + NO_2(g) \longrightarrow N_2O_5$ (fast)

(a) I only (b) II only
(c) Both I and II (d) Neither I nor II

[**Hint:** Mechanism I, Rate $= k[NO_2][O_2]$. Slow step is rate determining

Mechanism II, Rate $= k\,[NO_2][O]$ ... (i)

$$K = \frac{[O_2][O]}{[O_3]}, [O] = K\frac{[O_3]}{[O_2]}$$

From eq. (i), Rate $= kK[NO_2][O_3][O_2]^{-1}$

$\therefore$ Both mechanisms show that reaction is first order with respect to NO_2 and O_3.]

24. Use the experimental data in the table to determine the rate law for this reaction:

$$A + B \longrightarrow AB$$

These data were obtained when the reaction was studied:

$[A]$	$[B]$	$\frac{\Delta[AB]}{\Delta t}$ mol L^{-1} sec^{-1}
0.1 M	0.1 M	2×10^{-4}
0.2 M	0.1 M	2×10^{-4}
0.3 M	0.3 M	1.8×10^{-3}

What is the rate equation for the reaction?

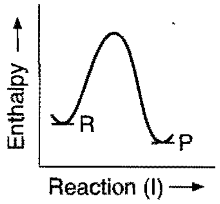
(a) Rate $= k[A][B]$ (b) Rate $= k[A]^2$
(c) Rate $= k[B]$ (d) Rate $= k[B]^2$

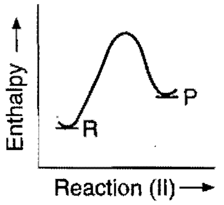
25. In which of the following reactions, the increase in the rate of reaction will be maximum?

	E_a	**Temperature rise**
(a)	40 kJ/mol	200 – 210 K
(b)	90 kJ/mol	300–320 K
(c)	80 kJ/mol	300–310 K

(d) All will have same rate

26. Which of the reactions represented in these diagrams will show the greatest increase in rate for a given increase in temperature?





(a) Reaction I forward (b) Reaction I reversed
(c) Reaction II forward (d) Reaction II reversed

27. Which function of $[X]$, plotted against time, will give a straight line for a second order reaction?

$$X \longrightarrow \text{Product}$$

(a) $[X]$ (b) $[X]^2$ (c) $\ln[X]$ (d) $\frac{1}{[X]}$

28. Decomposition of H_2O_2 is a first order reaction. A 16 volume solution of H_2O_2 of half life 30 min is present at start. When will the solution become one volume?

(a) After 120 min (b) After 90 min
(c) After 60 min (d) After 150 min

29. What is the activation energy for the reverse of this reaction?

$$N_2O_4(g) \longrightarrow 2NO_2(g)$$

Data for the given reaction is: $\Delta H = +54$ kJ and $E_a = +57.2$ kJ:

(a) –54 kJ (b) +3.2 kJ (c) +60.2 kJ (d) +111.2 kJ

30. The reaction between chloroform, $CHCl_3(g)$ and chlorine $Cl_2(g)$ to form $CCl_4(g)$ and $HCl(g)$ is believed to occur by this series of steps:

Step 1: $Cl_2(g) \longrightarrow Cl(g) + Cl(g)$

Step 2: $CHCl_3(g) + Cl(g) \longrightarrow CCl_3(g) + HCl(g)$

Step 3: $CCl_3(g) + Cl(g) \longrightarrow CCl_4(g)$

If this reaction is first order in $CHCl_3$ and half order in Cl_2, which statement about the relative rates of steps 1, 2 and 3 is correct?

(a) Step 1 is the slowest
(b) Steps 1 and 2 must both be slow
(c) Step 2 must be slower than step 1
(d) Step 3 must be the slowest

31. In the reaction,

$3BrO^- \longrightarrow BrO_3^- + 2Br^-$ (aqueous alkaline medium at 80°C)

the value of the rate constant in the rate law in terms of $-\frac{d}{dt}[BrO^-]$ is 0.056 L mol^{-1} s^{-1}. What will be the rate constant when the rate law is stated in terms of $\frac{d}{dt}[BrO_3^-]$?

(a) 18.7×10^{-3} L mol^{-1} s^{-1} (b) 37.4×10^{-3} L mol^{-1} s^{-1}
(c) 0.0187 L mol^{-1} s^{-1} (d) 18.7×10^{-2} L mol^{-1} s^{-1}

[Hint $-\frac{1}{3}\frac{d[BrO^-]}{dt} = \frac{d[BrO_3^-]}{dt} = +\frac{1}{2}\frac{d[Br^-]}{dt}$

Required rate constant $= \frac{1}{3} \times 0.056$ L mol^{-1} s^{-1}

$= 0.0187$ L mol^{-1} s^{-1}]

32. The dependence of the rate constant for a reaction on temperature is given by the equation $k = Ae^{-E_a/RT}$.

Under what conditions is the rate constant k the smallest?

(a) High T and large E_a (b) High T and small E_a
(c) Low T and large E_a (d) Low T and small E_a

33. The activation energy of a certain reaction is 87 kJ mol^{-1}. What is the ratio of the rate constants for this reaction when the temperature is decreased from 37°C to 15°C?

(a) 5/1 (b) 8.3/1 (c) 13/1 (d) 24/1

34. Consider this reaction,

$$2H_2(g) + 2NO(g) \longrightarrow N_2(g) + 2H_2O(g)$$

The rate law for this reaction is:

$$\text{Rate} = k[H_2][NO]^2$$

Under what conditions could these steps represent the mechanism?

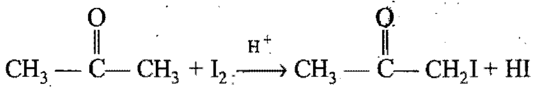
Step 1: $2NO \rightleftharpoons N_2O_2$

Step 2: $N_2O_2 + H_2 \longrightarrow N_2O + H_2O$

Step 3: $N_2O + H_2 \longrightarrow N_2 + H_2O$

(a) These steps cannot be the mechanism under any circumstances
(b) These steps could be the mechanism if step 1 is the slow step
(c) These steps could be the mechanism if step 2 is the slow step
(d) These steps could be the mechanism if step 3 is the slow step

35. Propanone reacts with iodine in acid medium according to the following equation:



$$CH_3-\overset{\overset{O}{\|}}{C}-CH_3 + I_2 \xrightarrow{H^+} CH_3-\overset{\overset{O}{\|}}{C}-CH_2I + HI$$

These data were obtained when the reaction was studied:

$[CH_3-\overset{\overset{O}{\|}}{C}-CH_3]$, M	$[I_2]$, M	$[H^+]$, M	Relative rate
0.010	0.010	0.010	1
0.020	0.010	0.010	2
0.020	0.020	0.010	2
0.020	0.010	0.020	4

What is the rate equation for the reaction?

(a) Rate $= k[CH_3-\overset{\overset{O}{\|}}{C}-CH_3][I_2]$

(b) Rate $= k[CH_3-\overset{\overset{O}{\|}}{C}-CH_3]^2$

(c) Rate $= k[CH_3-\overset{\overset{O}{\|}}{C}-CH_3][I_2][H^+]$

(d) Rate $= k[CH_3-\overset{\overset{O}{\|}}{C}-CH_3][H^+]$

36. Arrhenius equation $k = Ae^{-E_a/RT}$

If the activation energy of the reaction is found to be equal to RT, then:

(a) the rate of reaction does not depend upon initial concentration
(b) the rate constant becomes about 37% of the Arrhenius constant A
(c) the rate constant becomes equal to 73% of the Arrhenius constant A
(d) the rate of the reaction becomes infinite or zero

37. At 25°C, the values of rate constant, activation energy and Arrhenius constant of a reaction are 3×10^{-4} sec^{-1}, 129 kJ/mol and 2×10^{15} sec^{-1} respectively.

The value of rate constant as $T \to \infty$ is:

(a) zero (b) 2×10^{15} (c) 3×10^{-4} (d) 6×10^{11}

38. The observed rate of a chemical reaction is substantially lower than the collision frequency. One or more of the following statements is/are true to account for this fact.

A. the reactants do not have the required energy.
B. the partners do not collide in the proper orientation
C. collision complex exists for a very short time.
D. collision frequency over estimates the number of effective collisions **(ISAT 2010)**

(a) A, B and C (b) A, B and D
(c) B, C and D (d) A, C and D

39. The reaction between NO and Cl_2 takes place in the following two steps:

I. $NO + Cl_2 \underset{k_2 \text{ fast}}{\overset{k_1}{\rightleftharpoons}} NOCl_2$

II. $NOCl_2 + NO \xrightarrow[\text{slow}]{k_2} 2NOCl$

The rate law of overall reaction,

$$2NO + Cl_2 \longrightarrow 2NOCl$$

can be given by:

(a) rate = $k[NO]^2[Cl_2]$ (b) rate = $k[NO][Cl_2]$

(c) rate = $k[NOCl][NO]$ (d) rate = $k[NO][Cl_2]^2$

40. Which of the following reactions will have fractional order for A_2 or B_2?

(a)
$A_2 \rightleftharpoons A + A$ (fast)
$A + B_2 \rightleftharpoons AB + B$ (slow)
$A + B \rightleftharpoons AB$ (fast)

(b)
$A_2 \rightleftharpoons C$ (slow)
$C + B_2 \rightleftharpoons D$ (fast)
$D + A_2 \rightleftharpoons$ Products

(c)
$B_2 \rightleftharpoons B + B$ (fast)
$A_2 + B \rightleftharpoons AB + A$ (slow)
$AB \longrightarrow$ Products (fast)

(d) All have fractional order

41. In which of the following, E_a for backward reaction is greater than E_a for forward reaction?

(a) $A \xrightarrow{E_a = 50 \text{ kcal}} B;$ $\Delta H = -10$ kcal

(b) $A \xrightarrow{E_a = 50 \text{ kcal}} B;$ $\Delta H = +10$ kcal

(c) $A \xrightarrow{E_a = 60 \text{ kcal}} B;$ $\Delta H = +20$ kcal

(d) All of the above

[Hint: $\Delta H = (E_a)_f - (E_a)_b$

$(E_a)_b = (E_a)_f - \Delta H = 50 + 10 = 60$ kcal]

42. For n th order reaction $\frac{t_{1/2}}{t_{3/4}}$ depends on $(n \neq 1)$:

(a) initial concentration only

(b) 'n' only

(c) initial concentration and 'n' both

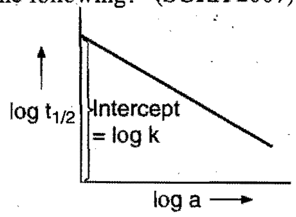
(d) sometimes 'n' and sometimes initial concentration

[Hint: Time for fractional change $\propto \frac{1}{a^{n-1}}$]

43. For a second order reaction, $2A \longrightarrow$ Products, a plot of log $t_{1/2}$ *vs* log a (where, a is initial concentration) will give an intercept equal to which one of the following? **(SCRA 2007)**

(a) $\frac{1}{k}$ (b) $\log\left(\frac{1}{2k}\right)$

(c) $\log\left(\frac{1}{k}\right)$ (d) $\log k$



[Hint: Kinetic equation for second order reaction is:

$$k = \frac{1}{t}\left[\frac{1}{(a-x)} - \frac{1}{a}\right]$$

when $x = \frac{a}{2}, t = t_{1/2}$

$$\therefore \quad t_{1/2} = \frac{1}{k} \times \frac{1}{a}$$

$\log t_{1/2} = -\log k - \log a$]

44. For a reaction taking place in three steps, the rate constants are k_1, k_2 and k_3. The overall rate constant $k = \frac{k_1 k_2}{k_3}$. If the energy of activation values for the first, second and third stages are respectively 40, 50 and 60 kJ mol^{-1}, then the overall energy of activation in kJ mol^{-1} is: **[PMT (Kerala) 2008]**

(a) 30 (b) 40 (c) 60 (d) 50

(e) 150

[Hint : $k = \frac{k_1 k_2}{k_3}$

$$Ae^{-E/RT} = \frac{Ae^{-E_1/RT} \times Ae^{-E_2/RT}}{Ae^{-E_3/RT}}$$

$$e^{-E/RT} = e^{(-E_1 - E_2 + E_3)/RT}$$

$$E = E_1 + E_2 - E_3$$

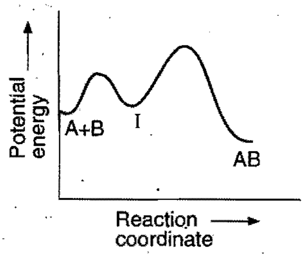
$$= 40 + 50 - 60 = 30 \text{ kJ mol}^{-1}]$$

45. For an exothermic reaction, following two steps are involved.

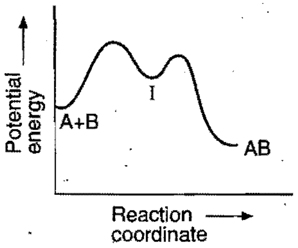
Step 1. $A + B \longrightarrow I$ (slow)

Step 2. $I \longrightarrow AB$ (fast)

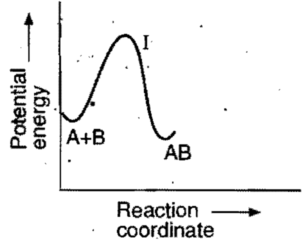
Which of the following graphs correctly represent this reaction ?



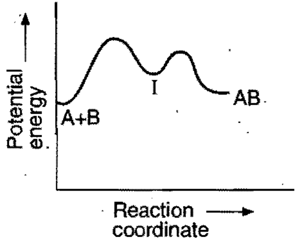
(a)



(b)



(c)



(d)

46. A reaction takes place in three steps with individual rate constant and activation energy,

	Rate constant	Activation energy
Step 1	k_1	$E_{a_1} = 180$ kJ/mol
Step 2	k_2	$E_{a_2} = 80$ kJ/mol
Step 3	k_3	$E_{a_3} = 50$ kJ/mol

overall rate constant, $k = \left(\frac{k_1 k_2}{k_3}\right)^{2/3}$

overall activation energy of the reaction will be :

(a) 140 kJ/mol (b) 150 kJ/mol

(c) 130 kJ/mol (d) 120 kJ/mol

[Hint : $Ae^{-E_a/RT} = \left[\frac{Ae^{-E_{a_1}/RT} Ae^{-E_{a_2}/RT}}{Ae^{-E_{a_3}/RT}}\right]^{2/3}$

$$= [Ae^{(-E_{a_1} - E_{a_2} + E_{a_3})/RT}]^{2/3}$$

$$E_a = \frac{2}{3}[E_{a_1} + E_{a_2} - E_{a_3}]$$

$$= \frac{2}{3}[180 + 80 - 50] = 140 \text{ kJ/mol}]$$

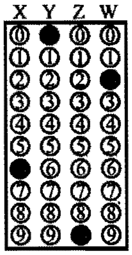
Integer Answer TYPE QUESTIONS

This section contains 10 questions. The answer to each of the questions is a single digit integer, ranging from 0 to 9. If the correct answers to question numbers X, Y, Z and W (say) are 6, 0, 9 and 2 respectively, then the correct darkening of bubbles will look like the given figure :



1. In the reaction, $A \longrightarrow B$ when the initial concentration of reactant is halved, the half-life increases by a factor of eight, what will be the order of the reaction?
2. Rate of a chemical reaction increases by 1024 times by 100°C rise in temperature; the temperature coefficient of the reaction will be:
3. The rate of a reaction at 10 sec intervals are as follows :

Time (sec)	Rate (mol L^{-1} sec^{-1})
0	4.8×10^{-2}
10	4.79×10^{-2}
20	4.78×10^{-2}
30	4.81×10^{-2}

What will be the order of the reaction?

4. How many times of the half-life will require to complete 75% of a reaction of first order?
5. Ozone depletion takes place as :

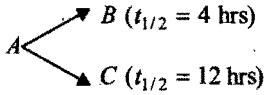
$$2O_3(g) \longrightarrow 3O_2(g)$$

Step 1 : $O_3(g) \overset{k}{\rightleftharpoons} O_2(g) + O(g)$ (fast)

Step 2 : $O_3(g) + [O] \xrightarrow{k} 2O_2(g)$ (slow)

order of the reaction will be :

6. If the $t_{1/2}$ for a first order reaction is 0.4 min, the time of or 99.9% completion of the reaction is .... min.
7. Consider following parallel first order reactions



The half-life for the decay of A is ....hrs.

8. The half-life period of a first order reaction is 1 hr. What is the time in hour taken for 87.5% completion of the reaction?
9. The half-life of a reaction is doubled when the initial concentration is doubled. The order of reaction is :
10. For the reaction $A_2 + 2B \longrightarrow 2AB$, the following data were observed :

Exp. No.	$[A_2]$	$[B]$	Rate (mol L^{-1} s^{-1})
1.	0.1	0.01	1.5×10^{-3}
2.	0.1	0.04	6.0×10^{-3}
3.	0.2	0.01	3.0×10^{-3}

The overall order of the reaction will be :

Answers

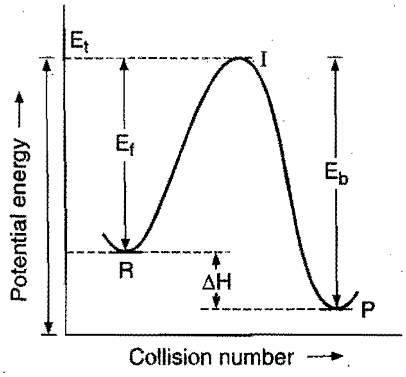
LINKED COMPREHENSION TYPE QUESTIONS

• Passage 1

A collision between reactant molecules must occur with a certain minimum energy before it is effective in yielding product molecules. This minimum energy is called activation energy E_a. Larger is the value of activation energy, smaller is the value of rate constant. Larger is the value of activation energy, greater is the effect of temperature rise on rate constant k.



E_f = *Activation energy of forward reaction*

E_b = *Activation energy of backward reaction*

$\Delta H = E_f - E_b$

E_t = *Threshold energy*

Answer the following questions:

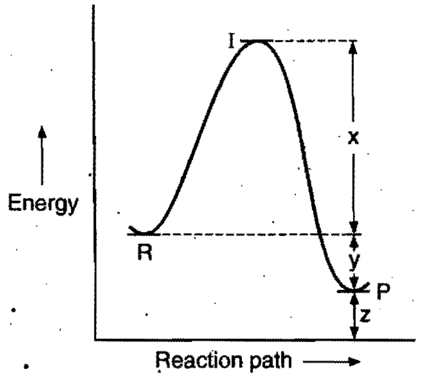
1. If a reaction, $A + B \longrightarrow C$, is exothermic to the extent of 30 kJ/mol and the forward reaction has an activation energy of 249 kJ/mol, the activation energy for reverse reaction in kJ/mol is:
   (a) 324 (b) 279 (c) 40 (d) 100
2. For the following reaction at a particular temperature, according to the equations,
   $$2N_2O_5 \longrightarrow 4NO_2 + O_2$$
   $$2NO_2 + \tfrac{1}{2}O_2 \longrightarrow N_2O_5$$
   the activation energies are E_1 and E_2 respectively. Then:
   (a) $E_1 > E_2$ (b) $E_1 < E_2$ (c) $E_1 = 2E_2$ (d) $\sqrt{E_1E_2^2} = 1$
3. In a hypothetical reaction, $A \rightarrow Y$, the activation energies for the forward and backward reactions are 15 and 9 kJ mol^{-1} respectively. The potential energy of A is 10 kJ mol^{-1}. Which of the following is wrong?
   (a) Threshold energy of the reaction is 25 kJ
   (b) The potential energy of B is 16 kJ
   (c) Heat of reaction is 6 kJ
   (d) The reaction is exothermic
4. For two reactions, activation energies are E_{a_1} and E_{a_2}; rate constants are k_1 and k_2 at the same temperature. If $k_1 > k_2$, then:
   (a) $E_{a_1} > E_{a_2}$ (b) $E_{a_1} = E_{a_2}$ (c) $E_{a_1} < E_{a_2}$ (d) $E_{a_1} \geq E_{a_2}$
5. The rate constant of a certain reaction is given by $k = Ae^{-E_a/RT}$ (where A = Arrhenius constant). Which factor should be lowered so that the rate of reaction may increase?
   (a) T (b) Z (c) A (d) E_a
6. The activation energies for forward and backward reactions in a chemical reaction are 30.5 and 45.4 kJ mol^{-1} respectively. The reaction is:
   (a) exothermic
   (b) endothermic
   (c) neither exothermic nor endothermic
   (d) independent of temperature

• Passage 2

The energy profile diagram for the reaction:

$$CO(g) + NO_2(g) \rightleftharpoons CO_2(g) + NO(g)$$

is given below:



Answer the following questions:

1. The activation energy of the forward reaction is:
   (a) x (b) y (c) $x + y$ (d) $x - y$
2. The activation energy of the backward reaction is:
   (a) x (b) y (c) $x + y$ (d) $x - y$
3. The heat of the reaction is:
   (a) x (b) y (c) $x + y$ (d) $x - y$
4. The threshold energy of the reaction is:
   (a) $x + y - z$ (b) $x - y + z$ (c) $x + y + z$ (d) $x - y - z$

• Passage 3

Population growth of humans and bacteria follows first order growth kinetics. Suppose 50 bacteria are placed in a flask containing nutrients for the bacteria so that they can multiply. A study at 35°C gave the following results:

Time (minutes)	0	15	30	45	60
Number of bacteria	100	200	400	800	1600

Answer the following questions:

1. The rate constant for the first order growth of bacteria can be calculated using:
   (a) $k = \dfrac{2.303}{t}\log_{10}\left(\dfrac{a}{a-x}\right)$ (b) $k = -\dfrac{2.303}{t}\log\left(\dfrac{a}{a+x}\right)$

(c) $k = \frac{0.693}{t}$ (d) $k = \frac{x}{t}$

2. Unit of rate constant for first order growth is:
(a) min^{-1} (b) min^{2} (c) min^{-3} (d) unitless
3. The rate constant for the reaction is:
(a) $0.0462\ \text{min}^{-1}$ (b) $0.462\ \text{min}^{-1}$
(c) $4.62\ \text{min}^{-1}$ (d) $46.2\ \text{min}^{-1}$
4. The rate of growth initially is:
(a) 4.62 bacteria per min (b) 23.1 bacteria per min
(c) 23.1 bacteria per sec (d) 0.231 bacteria per sec
5. At what time, there will be 6400 bacteria in the flask?
(a) 150 min (b) 90 min (c) 160 min (d) 120 min

• Passage 4

Order of reaction is an experimentally determined quantity. It may be zero, positive, negative and fractional. The kinetic equation of nth order reaction is:

$$k \times t = \frac{1}{(n-1)}\left[\frac{1}{(a-x)^{n-1}} - \frac{1}{a^{n-1}}\right]$$

Half life of nth order reaction depends on initial concentration according to the following relation:

$$t_{1/2} \propto \frac{1}{a^{n-1}}$$

Unit of the rate constant varies with the order but general relation for unit of nth order reaction is:

$$\textit{Unit of } k = \left[\frac{1}{\textit{conc.}}\right]^{n-1} \times \textit{time}^{-1}$$

The differential rate law for nth order reaction may be given as:

$$\frac{dx}{dt} = k[A]^n$$

where, A denotes the reactant.

Answer the following questions:

1. The unit of rate and rate constant are same for a:
(a) zero order reaction (b) first order reaction
(c) second order reaction (d) half order reaction
2. The rate constant for zero order reaction is:
(a) $k = \frac{C_0}{2t}$ (b) $k = \frac{C_0 - C_t}{t}$
(c) $k = \ln\frac{C_0 - C_t}{2t}$ (d) $k = \frac{C_0}{C_t}$
where C_0 and C_t are concentrations of reactants at respective times.
3. The half life for a zero order reaction equals to:
(a) $\frac{1}{2}\frac{k}{a^2}$ (b) $\frac{a^2}{2k}$ (c) $\frac{2k}{a}$ (d) $\frac{a}{2k}$
4. For a reaction:
$$I^- + OCl^- \longrightarrow IO^- + Cl^-$$
in an aqueous medium, the rate of the reaction is given by
$$\frac{d[IO^-]}{dt} = k\frac{[I^-][OCl^-]}{[OH^-]}$$
The overall order of the reaction is:
(a) -1 (b) 1 (c) zero (d) 2
5. In a chemical reaction $A \longrightarrow B$, it is found that the rate of the reaction doubles when the concentration of A is increased four times. The order of the reaction with respect to A is:
(a) 0 (b) 1/2 (c) 1 (d) 2

• Passage 5

Consider the reaction represented by the equation:

$$CH_3Cl(g) + H_2O(g) \longrightarrow CH_3OH(g) + HCl(g)$$

These kinetic data were obtained for the given reaction concentrations:

Initial conc. (*M*)		**Initial rate of disappearance of CH_3Cl $M\,s^{-1}$**
$[CH_3Cl]$	**$[H_2O]$**	
0.2	0.2	1
0.4	0.2	2
0.4	0.4	8

Answer the following questions based on these data:

1. The rate law for the reaction will be:
(a) $r = k[CH_3Cl][H_2O]$ (b) $r = k[CH_3Cl]^2[H_2O]$
(c) $r = k[CH_3Cl][H_2O]^2$ (d) $r = k[CH_3Cl]^2[H_2O]^4$
2. Order with respect to $[CH_3Cl]$ will be:
(a) 0 (b) 1 (c) 2 (d) 3
3. Overall order of the reaction will be:
(a) 0 (b) 1 (c) 2 (d) 3
4. Unit of rate constant will be:
(a) sec^{-1} (b) $\text{litre}^2\ \text{mol}^{-2}\ \text{sec}^{-1}$
(c) $\text{litre mol}^{-1}\ \text{sec}^{-1}$ (d) $\text{mol litre}^{-1}\ \text{sec}^{-1}$
5. If H_2O is taken in large excess, the order of the reaction will be:
(a) 1 (b) 0 (c) 3 (d) 2

SELF ASSESSMENT

ASSIGNMENT NO. 8

SECTION-I

Straight Objective Type Questions

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. What is the order of reaction,

$$A_2 + B_2 \longrightarrow 2AB\ ?$$

Mechanism:

$$A_2 \rightleftharpoons A + A \quad \text{(fast)}$$
$$A + B_2 \longrightarrow AB + B \quad \text{(slow)}$$
$$A + B \longrightarrow AB \quad \text{(fast)}$$

(a) 2 (b) 1 (c) $3/2$ (d) $1/2$

2. For a gaseous reaction, $A(g) \longrightarrow$ Product, which one of the following is correct relation among $\frac{dP}{dt}$, $\frac{dn}{dt}$ and $\frac{dc}{dt}$?

($\frac{dP}{dt}$ = Rate of reaction in atm sec^{-1}; $\frac{dc}{dt}$ = Rate of reaction in molarity sec^{-1}; $\frac{dn}{dt}$ = Rate of reaction in mol sec^{-1})

(a) $\frac{dc}{dt} = \frac{dn}{dt} = -\frac{dP}{dt}$ (b) $-\frac{dc}{dt} = -\frac{1}{V}\frac{dn}{dt} = -\frac{dP}{dt}$

(c) $\frac{dc}{dt} = \frac{V}{RT}\frac{dn}{dt} = \frac{dP}{dt}$ (d) None of these

3. The rate law for a reaction between the substances A and B is given by the, rate $= k[A]^n[B]^m$. On doubling the concentration of A and halving the concentration of B, the ratio of the new rate to the earlier rate of the reaction will be as:

(a) $\frac{1}{2^{m+n}}$ (b) $m + n$ (c) $n - m$ (d) $2^{(n-m)}$

4. A substance having initial concentration 'a' reacts according to zero order kinetics. What will be the time for the reaction to go to completion?

(a) $\frac{a}{k}$ (b) $\frac{k}{a}$ (c) $\frac{a}{2k}$ (d) $\frac{2k}{a}$

5. The rate constant for the reaction,

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$$

is $3 \times 10^{-5}\ \text{sec}^{-1}$. If the rate of reaction is 2.4×10^{-5} mol $\text{litre}^{-1}\ \text{sec}^{-1}$, then the concentration of N_2O_5 in mol litre^{-1} is:

(a) 1.4 (b) 1.2 (c) 0.04 (d) 0.8

6. Half life of a reaction is inversely proportional to cube of initial concentration. The order of reaction is:

(a) 4 (b) 3 (c) 5 (d) 2

7. The oxidation of ammonia takes place as,

$$NH_3(g) + 3O_2(g) \longrightarrow 2N_2(g) + 6H_2O(g)$$

if the rate of formation of N_2 is 0.7 M/s, determine the rate at which NH_3 is consumed:

(a) 1.4 mol $L^{-1}s^{-1}$ (b) 0.7 mol $L^{-1}s^{-1}$

(c) 1.5 mol $L^{-1}s^{-1}$ (d) none of these

8. Consider the reaction:

$$2H_2(g) + 2NO(g) \longrightarrow N_2(g) + 2H_2O(g)$$

The rate law for this reaction is:

$$\text{Rate} = k[H_2][NO]^2$$

Under what conditions could these steps represent the mechanism?

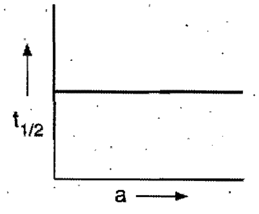
Step 1: $2NO(g) \rightleftharpoons N_2O_2(g)$

Step 2: $N_2O_2 + H_2 \longrightarrow N_2O + H_2O$

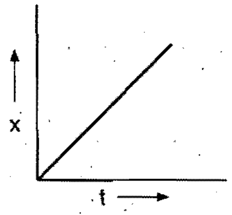
Step 3: $N_2O + H_2 \longrightarrow H_2O + N_2$

(a) These steps can never satisfy the rate law
(b) Step 1 should be the slowest step
(c) Step 2 should be the slowest step
(d) Step 3 should be the slowest step

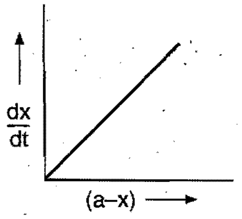
9. Which of the following is not for zero order reaction?



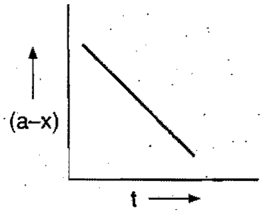
(a)



(b)



(c)



(d)

10. I. $E_a = 15\ \text{kJ mol}^{-1}$; $\Delta H = -70\ \text{kJ mol}^{-1}$

II. $E_a = 30\ \text{kJ mol}^{-1}$; $\Delta H = -15\ \text{kJ mol}^{-1}$

III. $E_a = 60\ \text{kJ mol}^{-1}$; $\Delta H = +20\ \text{kJ mol}^{-1}$

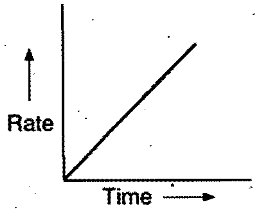
If above reactions are at same frequency factor then fastest and slowest reactions are:

(a) III is fastest, II is slowest
(b) I is fastest, III is slowest
(c) II is fastest, III is slowest
(d) III is fastest, I is slowest

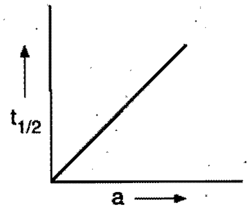
SECTION-II

Multiple Answers Type Objective Questions

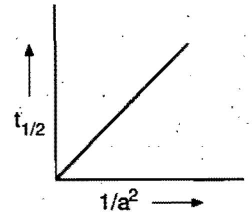
11. Which of the following graphs are correct?



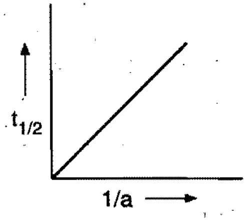
(a)



(b)



(c)



(d)

Here 'a' denotes initial concentration of reactants.

12. Arrhenius equation may be given as:

(a) $\ln \frac{A}{k} = \frac{E_a}{RT}$
(b) $\log A = \log k + \frac{E_a}{2.303\,RT}$
(c) $\log\left[\frac{-E_a}{RT}\right] = \frac{k}{a}$
(d) $\frac{d \ln k}{dt} = \frac{E_a}{RT}$

13. Which of the following is/are correct for second order reaction?

(a) $t_{1/2}$ is inversely proportional to initial concentration
(b) $k = \frac{1}{t}\left[\frac{1}{(a-x)} - \frac{1}{a}\right]$
(c) $k = \frac{2.303}{t} \log\left(\frac{a}{a-x}\right)$
(d) $k = \frac{1}{2t}\left[\frac{1}{(a-x)^2} - \frac{1}{a^2}\right]$

14. For a 1st order reaction:

$A \longrightarrow B$, with initial concentration = a

(a) $t_{1/2} = \frac{k}{a}$
(b) $t_{3/4} = 2t_{1/2}$
(c) $t_{1/2} = \frac{0.693}{k}$
(d) $t_{1/2} = k \times 0.693$

15. Select the correct statement for Arrhenius equation

$$k = Ae^{-Ea/RT}$$

(a) 'A' may be termed as the rate constant at very high temperature
(b) 'A' may be termed as the rate constant at zero activation energy
(c) E_a is the activation energy of reaction
(d) k is rate of reaction at zero concentration

SECTION-III

Assertion-Reason Type Questions

This section contains 3 questions. Each question of this section contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; Statement-2 is true; Statement-2 is a correct explanation for statement-1.
(b) Statement-1 is true; Statement-2 is true; Statement-2 is not a correct explanation for Statement-1.
(c) Statement-1 is true; Statement-2 is false.
(d) Statement-1 is false; Statement-2 is true.

16. **Statement-1:** If temperature does not affect the rate of reaction, $E_a = 0$.

Because

Statement-2: Lesser is the activation energy, slower is the rate.

17. **Statement-1:** In the reaction:

$$NO_2(g) + CO(g) \longrightarrow CO_2(g) + NO(g)$$
$$\text{Rate} = k[NO_2]^2$$

The rate of reaction does not depend on the concentration of CO.

Because

Statement-2: Carbon monoxide is involved in fast step.

18. **Statement-1:** The reciprocal of time in which 66% of the reactant is converted to product is equal to the rate constant of first order reaction.

Because

Statement-2: The rate constant for first order reaction depends on initial concentration of reactants.

SECTION-IV

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

If the correct matches are (a-p,s); (b-q,r); (c-p,q); and (d-s), then correct bubbled 4 × 4 matrix should be as follows:

	p	q	r	s
a	●	○	○	●
b	○	●	●	○
c	●	●	○	○
d	○	○	○	●

19. Match the Column-I with Column-II:

Column-I	Column-II
(a) Rate of reaction	(p) May be fractional
(b) Rate constant	(q) Whole number
(c) Order of reaction	(r) Independent of temperature
(d) Molecularity of reaction	(s) Increase with temperature

20. Match the Column-I with Column-II:

Column-I (Order of reaction)	**Column-II (Graph)**
(a) First order	(p) (b) Second order	(q) (c) Third order	(r) (d) Zero order	(s) 
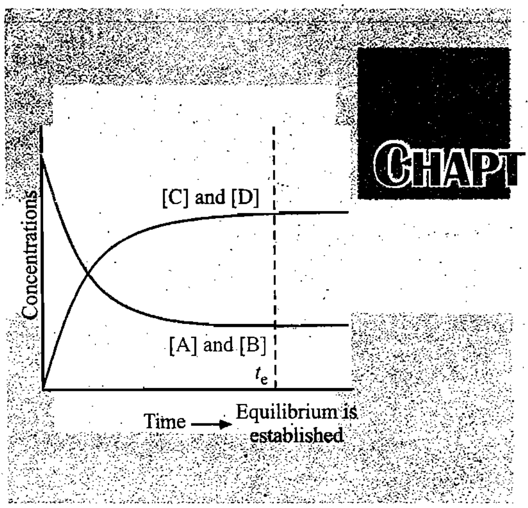
21. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) First order	(p) Unit of $k = \text{sec}^{-1}$
(b) Pseudo first order	(q) Unit of $k = \text{dm}^6\text{mol}^{-2}\text{s}^{-1}$
(c) Third order	(r) $t_{1/2} \propto 1/a^2$
(d) Second order	(s) $t_{1/2} \propto \frac{1}{a}$

Answers

1. (c) 2. (b) 3. (d) 4. (a) 5. (d) 6. (a) 7. (a) 8. (c)
9. (c) 10. (b) 11. (b,c) 12. (a,b) 13. (a,b) 14. (b,c) 15. (a,b,c) 16. (c)
17. (a) 18. (c) 19. (a-s) (b-s) (c-p,r) (d-q,r) 20. (a-r) (b-p) (c-q) (d-s) 21. (a-p) (b-p) (c-q,r) (d-s)



CHAPTER 9

CHEMICAL EQUILIBRIUM

9.1 INTRODUCTION

It is a well established fact that many reactions do not go to completion. They proceed to some extent leaving considerable amounts of unreacted reactants, *i.e.*, the resulting mixture contains both reactants and products. When such a stage is reached in a course of reaction that no further reaction is apparent, it is said in chemical language that the reaction has attained the state of equilibrium where the composition of the system becomes fixed. At equilibrium state both the forward and backward reactions move with equal speeds, *i.e.*, the rate of disappearance of reactants is exactly equal to rate of the appearance of reactants from the products. The study of chemical equilibrium helps in the elucidation of the optimum conditions for the greater yields of the products in the case of those reactions which attain equilibrium in the course of reaction.

Chemical reactions can be classified as **irreversible** and **reversible** reactions.

Irreversible reactions: The chemical reactions which proceed in such a way that reactants are completely converted into products, *i. e.*, the reactions which move in one direction, *i.e.*, forward direction only are called **irreversible reactions.** In such reactions, products do not react together to produce reactants again, *i. e.*, the reaction does not move in backward direction. For example, when solutions containing equimolar concentrations of barium chloride and sodium sulphate are mixed, reaction occurs and practically whole of barium is precipitated as barium sulphate.

$$BaCl_2 + Na_2SO_4 \longrightarrow \underset{\text{ppt.}}{BaSO_4} + 2NaCl$$

The reaction between $BaSO_4$ and NaCl, *i. e.*, backward reaction, is not possible under the experimental conditions. In such reactions the arrow (→) is placed between reactants and products which indicates the direction of the chemical change. Some more examples of irreversible reactions are given below:

1. (a) Thermal decomposition of potassium chlorate,

$$2KClO_3 \xrightarrow[\text{Heat}]{MnO_2} 2KCl + 3O_2$$

   (b) Decomposition of ammonium nitrite,

$$NH_4NO_2 \longrightarrow N_2 + 2H_2O$$

2. Precipitation reactions,

   (a) $AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$

   (b) $Pb(NO_3)_2 + 2KI \longrightarrow PbI_2 + 2KNO_3$

3. Neutralisation reactions,

$$\underset{\text{Strong acid}}{H_2SO_4} + \underset{\text{Strong base}}{2NaOH} \longrightarrow Na_2SO_4 + 2H_2O$$

4. Redox and combustion reactions,

   (a) $SnCl_2 + 2FeCl_3 \longrightarrow SnCl_4 + 2FeCl_2$

   (b) $2Mg + O_2 \longrightarrow 2MgO$

   (c) $C_2H_5OH + 3O_2 \longrightarrow 2CO_2 + 3H_2O$

Reversible reactions: The chemical reactions which take place in both directions under similar conditions are called **reversible reactions.** In such reactions, the products also react with each other and produce reactants again. For example, when hydrogen is passed over heated magnetic oxide, metallic iron and water are produced.

$$Fe_3O_4 + 4H_2 \longrightarrow 3Fe + 4H_2O$$

On the other hand, if steam is passed over powdered iron at the same temperature, magnetic oxide of iron and hydrogen are formed.

$$3Fe + 4H_2O \longrightarrow Fe_3O_4 + 4H_2$$

If the reaction is carried out in a closed vessel, it is found that in no case the reaction proceeds to completion. It is, thus, clear that either of the two reactions can take place independently if steam or hydrogen is allowed to escape from system by carrying out the reaction in open vessel but if a closed vessel is used and nothing is allowed to escape both forward and backward reactions can take place in the vessel.

Reactions which thus proceed in both the directions and do not reach to completion are known as reversible reactions. The reaction proceeding from left to right is conventionally called the **forward reaction** and the opposite one proceeding from right to left is called the **reverse** or **backward reaction.** In such reactions the arrow (→) or sign of equality (=) is replaced by two half arrows ($\rightleftharpoons$) pointing the reaction in both the directions. This sign ($\rightleftharpoons$) represents the reversibility of the reaction.

$$3Fe + 4H_2O \rightleftharpoons Fe_3O_4 + 4H_2$$

Some examples of reversible reactions are given below:

$$CaCO_3 \rightleftharpoons CaO + CO_2$$

$$CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$$

$$2HI \rightleftharpoons H_2 + I_2$$

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

$$2SO_2 + O_2 \rightleftharpoons 2SO_3$$

$$N_2 + O_2 \rightleftharpoons 2NO$$

$$NH_4HS \rightleftharpoons NH_3 + H_2S$$

$$CO_2 + H_2 \rightleftharpoons CO + H_2O$$

9.2 STATE OF CHEMICAL EQUILIBRIUM

The most important characteristic property of a reversible reaction is that it always attains a state of chemical equilibrium. Consider a general reversible reaction in a closed vessel.

$$A + B \rightleftharpoons C + D$$

In the initial state only A and B are present both react with each other, *i.e.*, rate of forward reaction is maximum as only the concentrations of A and B are involved (at the beginning, the concentrations of products C and D are nil). As soon as the products C and D are produced, the backward reaction starts functioning. By the expiry of time, the rate of forward reaction decreases as the concentrations of A and B decrease while the rate of backward reaction increases as the concentrations of products C and D increase. Ultimately, a stage comes when the rate of forward reaction becomes equal to rate of backward reaction. This state is called the **equilibrium state.**

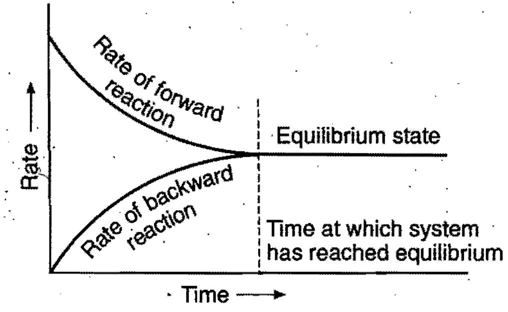


Fig. 9.1

At equilibrium state,

Rate of forward reaction = Rate of backward reaction.

It can be shown graphically as in Fig. 9.1.

Thus, chemical equilibrium in a reversible reaction is the state at which both forward and backward reactions or two opposing reactions occur at the same speed.

This state will continue indefinitely if the conditions such as temperature and concentration are not changed. At the state of equilibrium, the concentrations of reactants and products in the reaction mixture attain a constant value and the concentrations do not change with time.

When hydrogen gas and iodine vapours are heated in a closed vessel at a constant temperature 717 K, the two react to form hydrogen iodide. In the initial stage, the colour of the reaction mixture is deep violet due to the presence of large amounts of iodine. But as the reaction progresses, the intensity of the colour decreases as more and more iodine is converted into hydrogen iodide. After sometime, the intensity of the colour of the reaction mixture becomes constant. The constancy of intensity of colour indicates that concentration of both reactants and products have become constant and state of equilibrium has been attained.

The stage of the reversible reaction at which the concentrations of the reactants and products do not change with time is called the equilibrium state.

Or

The state in which the measurable properties of the system (such as pressure, density, colour or concentration) do not undergo any further noticeable change with time under given set of conditions is said to be a state of equilibrium.

The equilibrium state is **dynamic** and not static in nature. The reaction does not stop but both the opposing reactions are going on continuously with same speeds. At this stage, the number of moles of substances produced per second in the forward reaction is equal to the number of moles of substances which disappear per second in the backward reaction.

Characteristics of Equilibrium State

(i) Equilibrium state can only be achieved if a reversible reaction is carried out in closed space.

No product can leave nor any reactant from outside can enter the space. If the system is not closed, some of the products may escape and thus, the backward reaction will not occur.

(ii) Chemical equilibrium, at a given temperature, is characterised by constancy of certain properties such as pressure, concentration, density or colour.

(iii) Chemical equilibrium can be attained from either side, *i.e.*, from the side of reactants or products.

$$2HI \rightleftharpoons H_2 + I_2$$

or

$$H_2 + I_2 \rightleftharpoons 2HI$$

At equilibrium, each reactant and each product has a fixed concentration and this is independent of the fact whether we start the reaction with the reactants or with the products.

This reaction can be graphically represented as,

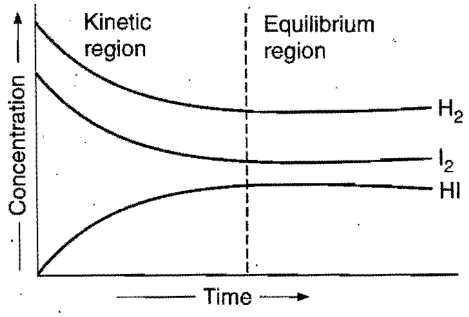

Fig. 9.2

(iv) Equilibrium state can be attained in a lesser time by the use of a positive catalyst, *i.e.*, the relative concentrations of reactants and products remain the same irrespective of the presence or absence of a catalyst. Thus, a catalyst does not change the equilibrium state but it helps in attaining it rapidly.

(v) It is dynamic in nature, *i.e.*, both the reactions move with same speed. However, the reaction seems to have come to stand still because the concentrations of reactants and products do not change.

Reversible chemical reactions are classified into two types heterogeneous and homogeneous reactions.

Heterogeneous reactions: The reversible reaction in which more than one-phase is present.

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$
$$MgCO_3(s) \rightleftharpoons MgO(s) + CO_2(g)$$
$$2Na_2O_2(s) + 2H_2O(l) \rightleftharpoons 4NaOH(l) + O_2(g)$$
$$3Fe(s) + 4H_2O(l) \rightleftharpoons Fe_3O_4(s) + 4H_2(g)$$

Homogeneous reactions: The reversible reaction in which only one-phase is present, *i.e.*, all the reactants and products are in the same physical state.

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$
$$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$$

Homogeneous reversible reactions are further classified into three types:

First type: When there is no change in number of molecules. Examples are:

(i) $H_2 + I_2 \rightleftharpoons 2HI$

(ii) $2NO \rightleftharpoons N_2 + O_2$

(iii) $CH_3COOH + C_2H_5OH \rightleftharpoons CH_3COOC_2H_5 + H_2O$

Second type: When there is an increase in number of molecules.

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$
$$2NH_3 \rightleftharpoons N_2 + 3H_2$$

Third type: When there is a decrease in number of molecules.

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$
$$2SO_2 + O_2 \rightleftharpoons 2SO_3$$

9.3 THE LAW OF CHEMICAL EQUILIBRIUM (Application of Law of Mass Action)

Consider a reversible homogeneous reaction which has attained equilibrium state at a particular temperature.

$$A + B \rightleftharpoons C + D$$

Let the active masses of A, B, C and D be $[A], [B], [C]$ and $[D]$ respectively at equilibrium.

According to law of mass action,

$$\text{Rate of forward reaction} \propto [A][B]$$

or $$\text{Rate of forward reaction} = k_f\,[A][B]$$

(where, k_f is the velocity constant for forward reaction).

Similarly,

$$\text{Rate of backward reaction} \propto [C][D]$$

or $$\text{Rate of backward reaction} = k_b[C][D]$$

(where, k_b is the velocity constant for backward reaction).

At equilibrium,

Rate of forward reaction = Rate of backward reaction,

i.e., $$k_f\,[A][B] = k_b[C][D]$$

or $$\frac{k_f}{k_b} = \frac{[C][D]}{[A][B]}$$

Since, k_f and k_b are both constants, the ratio k_f/k_b is also a new constant say K_c, *i.e.*,

$$K_c = \frac{[C][D]}{[A][B]} \qquad \text{... (i)}$$

K_c is known as equilibrium constant. K_c has a definite value for every chemical reaction at a given temperature regardless of the concentration of the reactants.

Considering a more general homogeneous reversible reaction at a particular temperature which is under chemical equilibrium,

$$m_1A_1 + m_2A_2 + m_3A_3 + \ldots \rightleftharpoons n_1B_1 + n_2B_2 + n_3B_3 + \ldots$$

$$\text{Rate of forward reaction} = k_f\,[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots$$

$$\text{Rate of backward reaction} = k_b[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots$$

At equilibrium,

$$k_f\,[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots = k_b[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots$$

or $$\frac{k_f}{k_b} = \frac{[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots}{[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots} = K_c \qquad \text{... (ii)}$$

The equilibrium constant, at a given temperature, is the ratio of the rate constants of forward and backward reactions.

Or

The equilibrium constant may be defined as the ratio between the product of the molar concentrations of the products to that of the product of the molar concentrations of the reactants with each concentration term raised to a power equal to stoichiometric coefficient in the balanced chemical equation.

The value of equilibrium constant is independent of the following factors:

1. Initial concentrations of the reactants involved.
2. The presence of a catalyst.
3. The direction from which the equilibrium has been attained.
4. The presence of inert materials.

The value of equilibrium constant depends on the following factors:

1. The mode of representation of the reaction: Conventionally, the concentrations of the products are put in the numerator and the concentrations of the reactants in denominator in the equilibrium law equation. Consider the reversible reaction,

$$A + B \rightleftharpoons C + D$$

The equilibrium constant for the reaction,

$$K_c = \frac{[C][D]}{[A][B]} \qquad \text{... (i)}$$

Now, if the products are made reactants, *i.e.*, the reaction is reversed,

$$C + D \rightleftharpoons A + B$$

The equilibrium constant for the reaction is

$$K_c' = \frac{[A][B]}{[C][D]} \qquad \text{... (ii)}$$

The equilibrium constant, K_c', is actually the reciprocal of K_c, *i.e.*,

$$K_c' = \frac{1}{K_c}$$

2. Stoichiometric representation of the chemical equation: (a) When a reversible reaction can be written with the help of two or more stoichiometric equations, the value of equilibrium constant will be numerically different in these cases. For example, the dissociation of NO_2 can be represented as:

$$2NO_2 \rightleftharpoons N_2 + 2O_2 \qquad \text{... (i)}$$

or

$$NO_2 \rightleftharpoons \frac{1}{2}N_2 + O_2 \qquad \text{... (ii)}$$

For equation (i), the value of $K_c = \dfrac{[N_2][O_2]^2}{[NO_2]^2}$ ... (iii)

For equation (ii), the value of $K_c' = \dfrac{[N_2]^{1/2}[O_2]}{[NO_2]}$ ... (iv)

Thus, the two constants are related to each other as:

$$K_c' = \sqrt{K_c} \qquad \text{... (v)}$$

In general, when a balanced equation having equilibrium constant K_c, is multiplied by a certain value n, the equilibrium constant for the new equation will be equal to $(K_c)^n$.

$$A + B \rightleftharpoons C + D, \qquad K_c = \frac{[C][D]}{[A][B]}$$

$$nA + nB \rightleftharpoons nC + nD, \qquad K_c' = \frac{[C]^n[D]^n}{[A]^n[B]^n} = (K_c)^n$$

(b) Consider the following chemical equation,

$$N_2(g) + O_2(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$$

$$K_c = \frac{[NOCl]^2}{[N_2][O_2][Cl_2]} \qquad \text{... (i)}$$

Suppose the above equation is split into two as:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g); \qquad K_1 = \frac{[NO]^2}{[N_2][O_2]} \qquad \text{... (ii)}$$

$$2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g); \qquad K_2 = \frac{[NOCl]^2}{[NO]^2[Cl_2]} \qquad \text{... (iii)}$$

Combining above two equations,

$$K_1 \times K_2 = \frac{[NO]^2}{[N_2][O_2]} \times \frac{[NOCl]^2}{[NO]^2[Cl_2]} = \frac{[NOCl]^2}{[N_2][O_2][Cl_2]} = K_c$$

Thus, when an equation (having equilibrium constant, K_c) is written in two steps (having equilibrium constant K_1 and K_2), then $K_c = K_1 \times K_2$.

3. Use of partial pressures instead of concentrations: When the reactants and products are in gaseous state, the partial pressures can be used instead of concentrations at a definite temperature, as the partial pressure of a substance is proportional to its concentration in the gas phase.

Consider a general reversible homogeneous gaseous reaction

$$m_1A_1 + m_2A_2 + m_3A_3 + \ldots \rightleftharpoons n_1B_1 + n_2B_2 + n_3B_3 + \ldots$$

Let the partial pressures of various reactants and products be $pA_1, pA_2, pA_3, \ldots,$ and $pB_1, pB_2, pB_3, \ldots$ respectively at equilibrium. The equilibrium constant for the reaction,

$$K_p = \frac{(pB_1)^{n_1}(pB_2)^{n_2}(pB_3)^{n_3}\ldots}{(pA_1)^{m_1}(pA_2)^{m_2}(pA_3)^{m_3}\ldots} \qquad \text{... (i)}$$

The value of K_c for the above reaction can be given as:

$$K_c = \frac{[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots}{[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots} \qquad \text{... (ii)}$$

For an ideal gas, $pV = nRT$

or

$$p = \frac{n}{V}RT$$

$$= \text{Active mass} \times RT$$

(where, n = number of moles and V = volume in litres. Thus, $\frac{n}{V}$ = molar concentration or active mass).

Substituting the values of partial pressures in eq. (i),

$$K_p = \frac{[B_1]^{n_1}(RT)^{n_1} \cdot [B_2]^{n_2}(RT)^{n_2} \cdot [B_3]^{n_3}(RT)^{n_3}\ldots}{[A_1]^{m_1}(RT)^{m_1} \cdot [A_2]^{m_2}(RT)^{m_2} \cdot [A_3]^{m_3}(RT)^{m_3}\ldots}$$

or

$$K_p = \frac{\{[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots\}(RT)^{n_1+n_2+n_3+\ldots}}{\{[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots\}(RT)^{m_1+m_2+m_3+\ldots}}$$

or

$$K_p = K_c \cdot \frac{(RT)^{\Sigma n}}{(RT)^{\Sigma m}}$$

$$= K_c (RT)^{\Sigma n - \Sigma m}$$

$$= K_c (RT)^{\Delta n} \qquad \text{... (iii)}$$

Δn = total number of molecules of gaseous products
– total number of molecules of gaseous reactants.

Three cases may arise:

First case: When, $\Delta n = 0$,

$$K_p = K_c\,(RT)^0 = K_c$$

Second case: When, $\Delta n = +\text{ve}$ or $\Delta n > 0$,

$$K_p > K_c$$

Third case: When, $\Delta n = -\text{ve}$ or $\Delta n < 0$,

$$K_p < K_c$$

4. **Temperature:** According to Arrhenius equation,

$$k = Ae^{-E/RT} \qquad \text{... (i)}$$

where, k = rate constant, E = activation energy, R = gas constant, T = absolute temperature and e = exponential constant.

$$\log \frac{k_2}{k_1} = -\frac{E}{2.303R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad \text{... (ii)}$$

when, $T_2 > T_1$

for forward reaction,

$$\log\left(\frac{k_{f_2}}{k_{f_1}}\right) = -\frac{E_f}{2.303R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad \text{... (iii)}$$

for backward reaction,

$$\log\left(\frac{k_{b_2}}{k_{b_1}}\right) = -\frac{E_b}{2.303R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad \text{... (iv)}$$

Subtracting eq. (iv) from eq. (iii), we get

$$\log\left(\frac{k_{f_2}/k_{b_2}}{k_{f_1}/k_{b_1}}\right) = -\frac{(E_f - E_b)}{2.303R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right]$$

or

$$\log\left(\frac{K_2}{K_1}\right) = -\frac{\Delta H}{2.303R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad \text{... (v)}$$

where, ΔH is the heat of reaction at constant volume and K_1 and K_2 are the equilibrium constants of a reaction at temperatures T_1 and T_2 $(T_2 > T_1)$.

The effect of temperature can be studied in the following three cases:

First case: $\Delta H = 0$, *i.e.*, neither heat is evolved, nor absorbed.

So, $\log K_2 - \log K_1 = 0$

or $\log K_2 = \log K_1$

or $K_2 = K_1$

Thus, equilibrium constant remains the same at all temperatures.

Second case: When, $\Delta H = +\text{ve}$, *i.e.*, heat is absorbed, the reaction is endothermic. The temperature T_2 is higher than T_1.

Thus, $\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$ is negative.

So, $\log K_2 - \log K_1 = +\text{ve}$

or $\log K_2 > \log K_1$

or $K_2 > K_1$

The value of equilibrium constant is higher at higher temperature in the case of endothermic reactions.

Third case: When $\Delta H = -\text{ve}$, *i.e.*, heat is evolved, the reaction is exothermic. The temperature T_2 is higher than T_1.

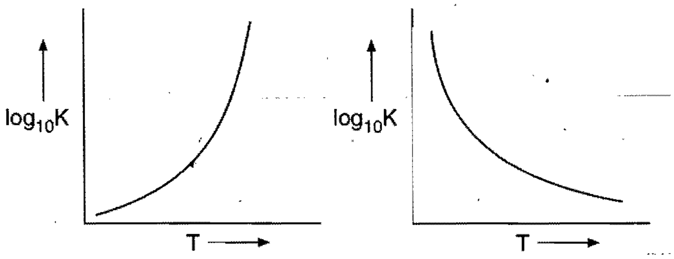
Thus, $\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$ is negative.

So, $\log K_2 - \log K_1 = -\text{ve}$

or $\log K_1 > \log K_2$

or $K_1 > K_2$

The value of equilibrium constant is lower at higher temperature in the case of exothermic reactions.



(a) Endothermic reaction
(Plots of log K versus T)

(b) Exothermic reaction

Fig. 9.3

Units of Equilibrium Constant

The units of equilibrium constant vary in case of different reactions. 'K' has no units for a reaction in which total number of moles of reactants and products are the same. For example, for dissociation of nitric oxide, K_c has no units.

$$2NO \rightleftharpoons N_2 + O_2$$

$$K_c = \frac{[N_2][O_2]}{[NO]^2}$$

K_c will have units for a reaction in which the total number of moles of reactants and products are different. For example, for decomposition of PCl_5, the K_c has mol/litre units.

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]}$$

In the formation of ammonia,

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

K_c has litre^2 mol^{-2} units.

In general; unit of $K_c = [M]^{\Delta n}$

where, M = mol litre^{-1} and Δn = number of gaseous moles of product or products – number of gaseous moles of reactant or reactants.

Note: (i) The above relation can be used in homogeneous liquid system also

Δn = number of moles of product or products – number of moles of reactant or reactants

(ii) Similarly, the unit of $K_p = [\text{atm}]^{\Delta n}$

where, Δn = number of gaseous moles of product or products – number of gaseous moles of reactant or reactants.

9.4 REACTION QUOTIENT OR MASS ACTION RATIO

Let us consider a reaction:

$$A + B \rightleftharpoons C + D$$

$$Q = \frac{[C][D]}{[A][B]}$$

Q is denoted as Q_c or Q_p depending upon whether the concentration is taken in terms of moles per litre or partial pressures respectively. With the help of mass action ratio we can determine whether the reaction is at equilibrium or not.

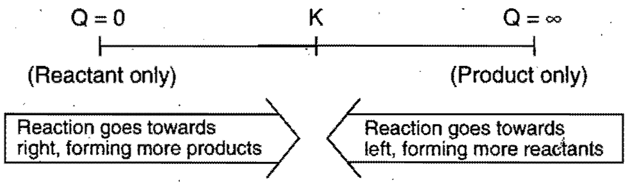
(I) When, $Q_c = K_c$ or $Q_p = K_p$ then the reversible reaction is at equilibrium, *i.e.*, the rate of forward and backward reaction becomes equal.

(II) When, $Q_c < K_c$ or $Q_p < K_p$ then the reaction is not at equilibrium. The reaction will be fast in forward direction, *i.e.*, reaction has a tendency to form product/products.

Rate of forward reaction > Rate of backward reaction.

(III) When, $Q_c > K_c$ or $Q_p > K_p$ then again the reaction is not at equilibrium. The reaction will be fast in backward direction, *i.e.*, have a tendency to form reactant/reactants.

Rate of forward reaction < Rate of backward reaction.



SOME SOLVED EXAMPLES

Example 1. *For the reactions,*

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

and $$\tfrac{1}{2}N_2 + \tfrac{3}{2}H_2 \rightleftharpoons NH_3$$

write down the expression for equilibrium constant K_c and K'_c. *How is* K_c *related to* K'_c *?*

Solution: For equation $N_2 + 3H_2 \rightleftharpoons 2NH_3$,

$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3} \quad \text{... (i)}$$

and for equation, $\tfrac{1}{2}N_2 + \tfrac{3}{2}H_2 \rightleftharpoons NH_3$,

$$K'_c = \frac{[NH_3]}{[N_2]^{1/2}[H_2]^{3/2}} \quad \text{... (ii)}$$

Squaring equation (ii),

$$(K'_c)^2 = \frac{[NH_3]^2}{[N_2][H_2]^3} \quad \text{... (iii)}$$

Equations (i) and (iii) are same

Thus, $$K_c = (K'_c)^2$$

or $$\sqrt{K_c} = K'_c$$

Example 2. *The equilibrium constant for the reaction,*

$$N_2 + 2O_2 \rightleftharpoons 2NO_2$$

at a particular temperature is 100. *Write down the equilibrium law equations for the following reactions and determine the values of equilibrium constants:*

$$2NO_2 \rightleftharpoons N_2 + 2O_2 \quad \text{... (i)}$$

$$NO_2 \rightleftharpoons \tfrac{1}{2}N_2 + O_2 \quad \text{... (ii)}$$

Solution: The equilibrium constant for the reaction,

$$N_2 + 2O_2 \rightleftharpoons 2NO_2$$

$$K_c = \frac{[NO_2]^2}{[N_2][O_2]^2} = 100 \quad \text{... (a)}$$

The equilibrium constant equation for reaction (i),

$$K_1 = \frac{[N_2][O_2]^2}{[NO_2]^2} \quad \text{... (b)}$$

This equation is reciprocal of eq. (a)

So, $$K_1 = \frac{1}{K_c} = \frac{1}{100} = 1 \times 10^{-2}$$

The equilibrium constant equation for reaction (ii),

$$K_2 = \frac{[N_2]^{1/2}[O_2]}{[NO_2]} \quad \text{... (c)}$$

Comparing eqs. (b) and (c),

$$K_2 = \sqrt{K_1} = \sqrt{10^{-2}} = 10^{-1} = 0.1$$

Example 3. *The value of* K_c *for the reaction,*

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

is 0.50 *at* 400°C. *Find the value of* K_p *at* 400°C *when concentrations are expressed in mol litre*$^{-1}$ *and pressure in atmosphere.*

Solution: Applying the relationship,

$$K_p = K_c(RT)^{\Delta n}$$

$$K_c = 0.50, \quad R = 0.082 \text{ litre-atm deg}^{-1} \text{ mol}^{-1}$$

$$T(400 + 273) = 673\text{ K}, \quad \Delta n = (2 - 4) = -2$$

$$K_p = 0.5(0.082 \times 673)^{-2}$$

$$= 0.5(55.185)^{-2} = 1.64 \times 10^{-4}$$

Example 4. *Determine K_c for the reaction,*

$$\frac{1}{2}N_2(g)+\frac{1}{2}O_2(g)+\frac{1}{2}Br_2(g)\rightleftharpoons NOBr(g)$$

from the following data at 298 K;

The equilibrium constants for the following reactions,

$$2NO(g)\rightleftharpoons N_2(g)+O_2(g)$$

and $$NO(g)+\frac{1}{2}Br_2(g)\rightleftharpoons NOBr(g)$$

are 2.4×10^{30} and 1.4 respectively.

Solution: The net reaction is,

$$\frac{1}{2}\mathrm{N_2}(g)+\frac{1}{2}\mathrm{O_2}(g)+\frac{1}{2}\mathrm{Br_2}(g)\rightleftharpoons \mathrm{NOBr}(g)$$

$$K_{c(\mathrm{net})}=\frac{[\mathrm{NOBr}]}{[\mathrm{N_2}]^{1/2}[\mathrm{O_2}]^{1/2}[\mathrm{Br_2}]^{1/2}}$$

Considering the given equations:

$2\mathrm{NO}(g)\rightleftharpoons \mathrm{N_2}(g)+\mathrm{O_2}(g)$; equilibrium constant $=2.4\times 10^{30}$

$\mathrm{N_2}(g)+\mathrm{O_2}(g)\rightleftharpoons 2\mathrm{NO}(g)$; equilibrium constant $=\dfrac{1}{2.4\times 10^{30}}$

$$\frac{1}{2}\mathrm{N_2}(g)+\frac{1}{2}\mathrm{O_2}(g)\rightleftharpoons \mathrm{NO}(g);$$

$$\text{Equilibrium constant}=\left(\frac{1}{2.4\times 10^{30}}\right)^{1/2}$$

$$=0.6455\times 10^{-15}$$

$$\frac{[\mathrm{NO}]}{[\mathrm{N_2}]^{1/2}[\mathrm{O_2}]^{1/2}}=K_c'=0.6455\times 10^{-15} \qquad \text{... (i)}$$

$$\mathrm{NO}(g)+\frac{1}{2}\mathrm{Br_2}(g)\rightleftharpoons \mathrm{NOBr}(g)$$

$$\frac{[\mathrm{NOBr}]}{[\mathrm{NO}][\mathrm{Br_2}]^{1/2}}=K_c''=1.4 \qquad \text{... (ii)}$$

Multiplying both equations

$$\frac{[\mathrm{NO}]}{[\mathrm{N_2}]^{1/2}[\mathrm{O_2}]^{1/2}}\times\frac{[\mathrm{NOBr}]}{[\mathrm{NO}][\mathrm{Br_2}]^{1/2}}=K_c'\times K_c''=0.6455\times 10^{-15}\times 1.4$$

or $$\frac{[\mathrm{NOBr}]}{[\mathrm{N_2}]^{1/2}[\mathrm{O_2}]^{1/2}[\mathrm{Br_2}]^{1/2}}=K_{c(\mathrm{net})}=0.9037\times 10^{-15}$$

$$=9.037\times 10^{-16}$$

Example 5. *The equilibrium constant, K_p, for the reaction*

$N_2(g)+3H_2(g)\rightleftharpoons 2NH_3(g)$ is 1.6×10^{-4} atm^{-2} at 400°C.

What will be the equilibrium constant at 500°C if heat of reaction in this temperature range is -25.14 kcal?

Solution: Using the relation,

$$\log\frac{K_{p_2}}{K_{p_1}}=\frac{\Delta H}{2.303R}\left[\frac{T_2-T_1}{T_2T_1}\right]$$

Given,

$K_{p_1}=1.6\times 10^{-4}$; $\quad \Delta H=-25.14$ kcal;

$R=2\times 10^{-3}$ kcal deg^{-1} mol^{-1}

$T_1=400+273=673\ \mathrm{K}$, $\quad T_2=500+273=773\ \mathrm{K}$

$$\log\frac{K_{p_2}}{(1.6\times 10^{-4})}=\frac{-25.14}{2.303\times 2\times 10^{-3}}\left[\frac{773-673}{773\times 673}\right]$$

$$\log K_{p_2}=\log(1.6\times 10^{-4})-\frac{25.14\times 10^3\times 100}{2.303\times 2\times 773\times 673}$$

$$=-3.7960-1.049=-4.8450$$

$$K_{p_2}=1.429\times 10^{-5}\ \mathrm{atm}^{-2}$$

Example 6. *The equilibrium constant for the reaction,*

$$H_2(g)+S(s)\rightleftharpoons H_2S(g)$$

is 18.5 at 925 K and 9.25 at 1000 K respectively. Calculate the enthalpy of the reaction.

Solution: Using the relation,

$$\log\frac{K_2}{K_1}=\frac{\Delta H}{2.303R}\left[\frac{T_2-T_1}{T_1T_2}\right]$$

$$\log\frac{9.25}{18.5}=\frac{\Delta H}{2.303\times 8.314}\times\frac{75}{925\times 1000}$$

$$-0.301=\frac{\Delta H\times 75}{2.303\times 8.314\times 925\times 1000}$$

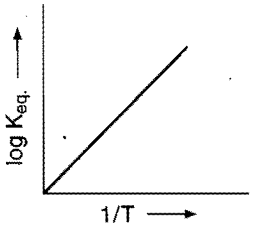
or $$\Delta H=-71080.57\ \mathrm{J\ mol^{-1}}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. For the hypothetical reactions, the equilibrium constant (K) values are given:
$A\rightleftharpoons B$; $K_1=2$; $B\rightleftharpoons C$; $K_2=4$; $C\rightleftharpoons D$; $K_3=3$
The equilibrium constant (K) for the reaction $A\rightleftharpoons D$ is: **[PMT (Kerala) 2005]**
(a) 48 (b) 6 (c) 2.7 (d) 12
(e) 24
[**Ans.** (e)]
[**Hint:** The reaction $A\rightleftharpoons D$ is obtained by adding the three given reactions.
$\therefore \quad K=K_1\times K_2\times K_3=2\times 4\times 3=24$]

2. If, in the reaction $\mathrm{N_2O_4}(g)\rightleftharpoons 2\mathrm{NO_2}(g)$, x is that part of $\mathrm{N_2O_4}$ which dissociates, then the number of molecules at equilibrium will be: **(KCET 2005)**
(a) 1 (b) 3
(c) $(1+x)$ (d) $(1+x)^2$
[**Ans.** (c)]
[**Hint:**
$$\begin{array}{lccc} & \mathrm{N_2O_4} & \rightleftharpoons & 2\mathrm{NO_2} \\ t=0 & 1 & & 0 \\ t_{\mathrm{eq.}} & 1-x & & 2x \end{array}$$
Total number of molecules at equilibrium $=1-x+2x=(1+x)$]

3. A schematic plot of ln $K_{eq.}$ *vs* inverse of temperature for a reaction is shown in the figure. The reaction must be: (AIEEE 2005)



(a) exothermic
(b) endothermic
(c) one with negligible enthalpy change
(d) highly spontaneous at ordinary temperature

[**Ans.** (a)]

[**Hint:** $K_e = Ae^{-\Delta H°/RT}$

$$\log K_{eq.} = \log A - \frac{\Delta H°}{2.303\,RT}$$

$$Y = C + MX$$

Slope of the line will be positive, when, $\Delta H° = -$ve, *i.e.*, the reaction is exothermic.]

4. Given:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g);\ K_1$$
$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g);\ K_2$$
$$H_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons H_2O(g);\ K_3$$

The equilibrium constant for

$$2NH_3(g) + \frac{5}{2}O_2(g) \rightleftharpoons 2NO(g) + 3H_2O(g)$$

will be: [CBSE (Med.) 2007]

(a) $K_1K_2K_3$ (b) $\frac{K_1K_2}{K_3}$ (c) $\frac{K_1K_3^{\,2}}{K_2}$ (d) $\frac{K_2K_3^{\,3}}{K_1}$

[**Ans.** (d)]

[**Hint:** $K_1 = \frac{[NH_3]^2}{[N_2][H_2]^3}$; $K_2 = \frac{[NO]^2}{[N_2][O_2]}$; $K_3 = \frac{[H_2O]}{[H_2][O_2]^{1/2}}$

The equilibrium constant for

$$2NH_3(g) + \frac{5}{2}O_2(g) \rightleftharpoons 2NO(g) + 3H_2O(g)$$

will be:

$$\frac{[NO]^2[H_2O]^3}{[NH_3]^2[O_2]^{5/2}} = \frac{K_2 \times K_3^{\,3}}{K_1}]$$

5. What is the equation for the equilibrium constant (K_c) for the following reaction? (EAMCET 2006)

$$\frac{1}{2}A(g) + \frac{1}{3}B(g) \overset{T\,K}{\rightleftharpoons} \frac{2}{3}C(g)$$

(a) $K_c = \frac{[A]^{1/2}[B]^{1/3}}{[C]^{3/2}}$ (b) $K_c = \frac{[C]^{3/2}}{[A]^2[B]^3}$

(c) $K_c = \frac{[C]^{2/3}}{[A]^{1/2}[B]^{1/3}}$ (d) $K_c = \frac{[C]^{2/3}}{[A]^{1/2} + [B]^{1/3}}$

[**Ans.** (c)]

[**Hint:** Coefficient goes to the power of respective active mass.

$$\therefore \quad K_c = \frac{[C]^{2/3}}{[A]^{1/2}[B]^{1/3}}]$$

6. For the following three reactions (i), (ii) and (iii), equilibrium constants are given:

(i) $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g);\ K_1$
(ii) $CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g);\ K_2$
(iii) $CH_4(g) + 2H_2O(g) \rightleftharpoons CO_2(g) + 4H_2(g);\ K_3$

Which of the following relations is correct? (AIEEE 2008)

(a) $K_3K_2^3 = K_1^2$ (b) $K_1\sqrt{K_2} = K_3$
(c) $K_2K_3 = K_1$ (d) $K_3 = K_1K_2$

[**Ans.** (d)]

[**Hint :** Reaction (iii) is obtained by adding (i) and (ii) hence $K_3 = K_1 \times K_2$]

9.5 ACTIVATION ENERGIES FOR FORWARD AND BACKWARD REACTIONS

In a reversible reaction, the molecules of the reactants in the forward reaction and the molecules of the products in the backward reaction follow the same path and form the same activated complex. However, the activation energies of both forward and backward reactions are different. Fig. 9.4 (a) and (b) show the activation energies, $E_a(f)$ and $E_a(b)$ respectively, for the forward and backward reactions for exothermic and endothermic reactions. Mathematically, $E_a(f)$ and $E_a(b)$ are related to overall energy change, ΔE, in the process as:

$$\Delta E = E_a(f) - E_a(b) = \Delta H \qquad \text{(At constant volume)}$$

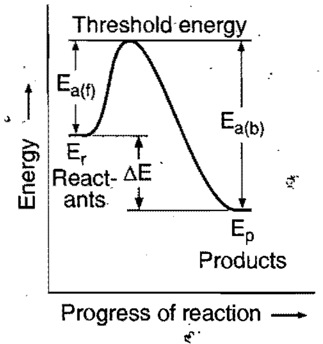


Fig. 9.4 (a) Activation energies for the forward and backward reactions where forward reaction is exothermic

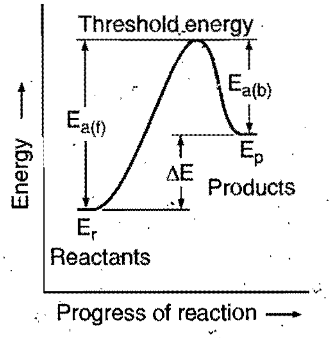

Fig. 9.4 (b) Activation energies for the forward and backward reactions where forward reaction is endothermic

For exothermic reaction,

$$E_a(f) < E_a(b)$$

Thus, ΔE is negative.

On the other hand, for the endothermic reaction,

$$E_a(f) > E_a(b).$$

Thus, ΔE is positive

Heat of reaction ΔH = Activation energy of forward reaction −Activation energy of backward reaction.

Example 7. *For the dissociation of gaseous HI, the energy of activation is 44.3 kcal. Calculate the energy of activation for the reverse reaction. Given, ΔH for the formation of 1 mole of HI from H_2 and I_2 is -1.35 kcal.*

Solution:

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g); \quad E_a = 44.3\ \text{kcal}$$

$$\frac{1}{2}H_2(g)+\frac{1}{2}I_2(g) \rightleftharpoons HI(g); \qquad \Delta H=-1.35\,\text{kcal}$$

$$2HI(g) \rightleftharpoons H_2(g)+I_2(g);\ \Delta H=2\times1.35=2.70\,\text{kcal}$$

$$\Delta H=E_a(f)-E_a(b)$$

$$2.70=44.3-E_a(b)$$

$$E_a(b)=(44.3-2.70)$$

or $$=41.60\,\text{kcal}$$

Example 8. *For a reaction $X \rightarrow Y$, heat of reaction is $+83.68$ kJ, energy of reactant X is 167.36 kJ and energy of activation is 209.20 kJ. Calculate (i) threshold energy (ii) energy of product Y and (iii) energy of activation for the reverse reaction ($Y \rightarrow X$).*

Solution: (i) Given, $E_a(f)=209.20$ kJ

$$\Delta E=+83.68\,\text{kJ}$$

Energy of reactant, $X=167.36$ kJ

Threshold energy = Energy of reactant X + Activation energy for forward reaction

$$=167.36+209.20=376.56\,\text{kJ}$$

(ii) Energy of reaction, ΔE = Energy of product − Energy of reactant

Energy of product $=83.68+167.36=251.04$ kJ

(iii) Activation energy for backward reaction

= Threshold energy − Energy of product

$=376.56-251.04=125.52$ kJ

9.6 STANDARD FREE ENERGY CHANGE OF A REACTION AND ITS EQUILIBRIUM CONSTANT

Let $\Delta G°$ be the difference in free energy of the reaction when all the reactants and products are in the standard state (1 atmospheric pressure and 298 K) and K_c or K_p be the thermodynamic equilibrium constant of the reaction. Both are related to each other at temperature T by the following relation:

$$\Delta G°=-2.303\,RT\log K_c$$

and $$\Delta G°=-2.303\,RT\log K_p \quad \text{(in case of ideal gases)}$$

This equation represents one of the most important results of thermodynamics and relates to the equilibrium constant of a reaction to a thermochemical property. It is sometimes easier to calculate the free energy in a reaction rather than to measure the equilibrium constant.

Standard free energy change can be thermodynamically calculated as:

$$\Delta G°=\Delta H°-T\Delta S°$$

Here, $\Delta H°$ = standard enthalpy change,

$\Delta S°$ = standard entropy change.

$$-RT\log_e K_p=\Delta H°-T\Delta S°$$

$$\log_e K_p=\frac{\Delta S°}{R}-\frac{\Delta H°}{RT}$$

$$\log_{10} K_p=\frac{\Delta S°}{2.303R}-\frac{\Delta H°}{2.303RT}$$

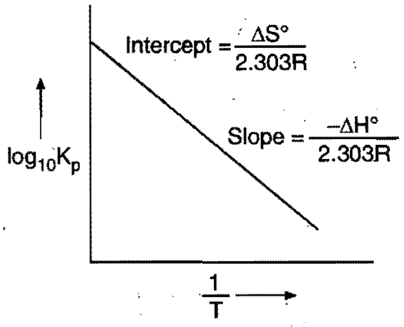

Fig. 9.5

(i) When, $\Delta G°=0$, then $K_c=1$.

(ii) When, $\Delta G°>0$, *i.e.*,+ve, then $K_c<1$. In this case reverse reaction is feasible, *i.e.*, less concentration of products at equilibrium state.

(iii) When, $\Delta G°<0$, *i.e.*, −ve, then $K_c>1$. In this case forward reaction is feasible showing thereby a large concentrations of products till the equilibrium is reached.

Example 9. *For the reaction,*

$$2NOCl(g) \rightleftharpoons 2NO(g)+Cl_2(g),$$

calculate the standard equilibrium constant at 298 K. Given that the values of $\Delta H°$ and $\Delta S°$ of the reaction at 298 K are 77.2 kJ mol^{-1} and 122 JK^{-1} mol^{-1}.

Solution: Using the relation,

$$\Delta G°=\Delta H°-T\Delta S°$$

$$=77200-298\times122$$

$$=40844\ \text{J mol}^{-1}$$

Let the equilibrium constant be $K_c°$. We know that,

$$\Delta G°=-2.303RT\log K_c°$$

or $$\log K_c°=-\frac{\Delta G°}{2.303\times8.314\times298}=-\frac{40844}{2.303\times8.314\times298}$$

$$=-7.158$$

$$K_c°=6.95\times10^{-8}$$

Example 10. *$\Delta G°$ for $\frac{1}{2}N_2(g)+\frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$ is -16.5 kJ mol^{-1}. Find out K_p for the reaction at 25°C. Also report K_p and $\Delta G°$ for $N_2(g)+3H_2(g) \rightleftharpoons 2NH_3(g)$ at 25°C.*

Solution:

$$\log K_p=-\frac{\Delta G°}{2.303RT}=-\frac{(-16.5\times10^3)}{2.303\times8.314\times298}=2.8917$$

$$K_p=779.41$$

K_p for reaction $N_2(g)+3H_2(g) \rightleftharpoons 2NH_3(g)$ is equal to $(779.41)^2=6.07\times10^5$

$$\Delta G°=-2.303\times8.314\times298\log 6.07\times10^5\ \text{joule}$$

$$=-32.998\ \text{kJ mol}^{-1}$$

9.7 EQUILIBRIUM CONSTANT EXPRESSIONS FOR SOME REACTIONS

Case I: Homogeneous gaseous equilibria when, $\Delta n = 0$.

Synthesis of hydrogen iodide: The formation of hydrogen iodide from hydrogen and iodine is represented by the equation:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

Let a start be made with 'a' moles of hydrogen and 'b' moles of I_2. These are heated in a sealed bulb having a volume V litre by keeping the bulb in a thermostat till equilibrium is established. If at equilibrium, x moles of each of H_2 and I_2 have reacted, $2x$ moles of HI will be formed.

Thus, the active masses of various reactants and products present at equilibrium are:

$$[H_2] = \frac{(a-x)}{V} \text{ mol L}^{-1}$$

$$[I_2] = \frac{(b-x)}{V} \text{ mol L}^{-1}$$

$$[HI] = \frac{2x}{V} \text{ mol L}^{-1}$$

Applying law of mass action,

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{\left(\frac{2x}{V}\right)^2}{\left(\frac{a-x}{V}\right)\left(\frac{b-x}{V}\right)} = \frac{4x^2}{(a-x)(b-x)}$$

When, $a = b = 1$, x becomes degree of formation of HI and

$$K_c = \frac{4x^2}{(1-x)^2}$$

The equilibrium constant, K_p, can also be calculated considering partial pressures of reactants and products at equilibrium.

	$H_2(g)$ +	$I_2(g)$ $\rightleftharpoons$	$2HI(g)$
Initial no. of moles	a	b	0
No. of moles at equilibrium	$(a-x)$	$(b-x)$	$2x$

Total number of moles at equilibrium

$$= (a-x) + (b-x) + 2x = (a+b)$$

Let the total pressure of the system at equilibrium be P atmosphere.

Partial pressure of H_2, $p_{H_2} = \frac{(a-x)}{(a+b)} \cdot P$

Partial pressure of I_2, $p_{I_2} = \frac{(b-x)}{(a+b)} \cdot P$

Partial pressure of HI, $p_{HI} = \frac{2x}{(a+b)} \cdot P$

$$K_p = \frac{(p_{HI})^2}{(p_{H_2})(p_{I_2})} = \frac{\left(\frac{2x}{a+b}\right)^2 P^2}{\left(\frac{a-x}{a+b}\right)P \times \left(\frac{b-x}{a+b}\right)P} = \frac{4x^2}{(a-x)(b-x)}$$

Thus, $K_p = K_c$

This also follows from the relationship, $K_p = K_c(RT)^{\Delta n}$.

$$\Delta n = 0, \text{ So } K_p = K_c,$$

i.e., for all gaseous reactions of first type, K_p and K_c are identical. Both K_p and K_c have no units.

(a) Effect of pressure: The equation, $K_c = \frac{4x^2}{(a-x)(b-x)}$, does not include the volume term; hence K_c is independent of pressure. **Thus, change of pressure will not alter the final state of equilibrium.**

(b) Effect of adding substances (Reactants or products): On adding H_2 to the equilibrium mixture, the value of denominator of equation $K_c = 4x^2/[(a-x)(b-x)]$ will increase. To maintain the constant value of K_c, the value of numerator must also increase. This can happen if more of HI is formed, *i.e.*, hydrogen combines with iodine to form more of HI. Thus, the reaction moves in a direction in which the added hydrogen is used up. A similar effect is observed when iodine is added to the equilibrium mixture.

The reverse effect is observed when HI is added to the equilibrium mixture, *i.e.*, HI decomposes into H_2 and I_2.

(c) Effect of temperature: The formation of HI from H_2 and I_2 is an exothermic reaction, *i.e.*, by increasing temperature, the value of equilibrium constant, K_c, decreases. Thus, the yield of HI decreases, *i.e.*, high temperature is not favourable for greater yield of HI.

(d) Effect of adding an inert gas: Addition of an inert gas to equilibrium mixture will make no effect on equilibrium state as in the first type of reactions, volume and pressure changes have no effect on equilibrium state.

Case II: Homogeneous gaseous reaction when, $\Delta n > 0$.

Dissociation of PCl_5: The dissociation of PCl_5 takes place according to the equation:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

Let a moles of PCl_5 be taken in a closed vessel of volume V litre. It is heated and by the time equilibrium is established, x moles are dissociated into PCl_3 and Cl_2. One molecule of PCl_5 on dissociation gives one molecule of PCl_3 and one molecule of Cl_2. Thus, x moles of PCl_5 will give x moles of PCl_3 and x moles of Cl_2.

At equilibrium,

$$[PCl_5] = \frac{(a-x)}{V}, [PCl_3] = \frac{x}{V}, [Cl_2] = \frac{x}{V}$$

Applying law of mass action,

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\frac{x}{V} \times \frac{x}{V}}{\frac{(a-x)}{V}} = \frac{x^2}{(a-x)V}$$

When, $a = 1$, x becomes degree of dissociation and

$$K_c = \frac{x^2}{(1-x)V} \qquad (\text{units} = \text{mol L}^{-1})$$

Calculation of K_p: Let the total pressure at equilibrium be P. Total number of moles at equilibrium

$$= (a-x)+x+x=(a+x)$$

$$p_{PCl_5} = \left(\frac{a-x}{a+x}\right)\cdot P;\quad p_{PCl_3} = \frac{x}{(a+x)}\cdot P;\quad p_{Cl_2} = \frac{x}{(a+x)}\cdot P$$

$$K_p = \frac{p_{PCl_3}\times p_{Cl_2}}{p_{PCl_5}} = \frac{\dfrac{x}{(a+x)}\cdot P\times\dfrac{x}{(a+x)}\cdot P}{\left(\dfrac{a-x}{a+x}\right)\cdot P} = \frac{x^2P}{(a-x)(a+x)};$$

(units = atm)

(a) Effect of pressure: In this case, $K_c = x^2/(a-x)V$. If pressure is increased, the value of 'V' decreases, *i.e.*, the value of denominator decreases. To maintain constant value of K_c, x must also decrease. In other words, the dissociation of PCl_5 decreases. Thus, the increase of pressure would suppress the dissociation of PCl_5.

(b) Effect of concentration: If PCl_5 is added to the equilibrium mixture, the rate of forward reaction increases, *i.e.*, dissociation of PCl_5 increases. In case PCl_3 or Cl_2 is added, the rate of backward reaction increases. This shall decrease the dissociation of PCl_5.

(c) Effect of temperature: The dissociation of PCl_5 is an endothermic reaction. Thus, the value of equilibrium constant increases with increase of temperature. It is thus concluded that dissociation increases with the increase of temperature.

(d) Effect of adding an inert gas: When an inert gas is added at constant volume the equilibrium state is not disturbed. In case an inert gas is added at constant pressure, the volume increases. To maintain the constant value of K_c, x must also increase. Thus, the addition of an inert gas at constant pressure increases the degree of dissociation of PCl_5.

Case III: Homogeneous gaseous reaction when, $\Delta n < 0$.

Synthesis of ammonia: The formation of ammonia from nitrogen and hydrogen is represented by the equation:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

Let a start be made by mixing 'a' moles of N_2 and 'b' moles of hydrogen in a closed vessel of V litre capacity. By the time equilibrium is established 'x' moles of nitrogen have combined with $3x$ moles of hydrogen and produced $2x$ moles of ammonia.

At equilibrium, $$[N_2] = \frac{(a-x)}{V}$$

$$[H_2] = \frac{(b-3x)}{V}$$

$$[NH_3] = \frac{2x}{V}$$

Applying law of mass action,

$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

$$= \frac{\left(\dfrac{2x}{V}\right)^2}{\left(\dfrac{a-x}{V}\right)\left(\dfrac{b-3x}{V}\right)^3} = \frac{4x^2V^2}{(a-x)(b-3x)^3}$$

If $a = 1$ and $b = 3$, then,

$$K_c = \frac{4x^2V^2}{27(1-x)^4};\qquad (\text{units} = \text{mol}^{-2}\ \text{L}^2)$$

The effect of various factors at equilibrium is discussed here.

(a) Effect of pressure: By increasing pressure, the volume term decreases. The value of x must increase to maintain the constant value of K_c. In other words, the formation of ammonia increases with increase of pressure.

(b) Effect of concentration: By increasing the concentration of either nitrogen or hydrogen in the reaction mixture, the rate of forward reaction increases, *i.e.*, the formation of ammonia increases.

(c) Effect of temperature: The synthesis of ammonia is an exothermic reaction. The value of equilibrium constant decreases with increase of temperature. Thus, high temperature is not favourable for the synthesis of ammonia.

Calculation of K_p: Let the total pressure at equilibrium be P.

Total number of moles at equilibrium

$$= (a-x)+(b-3x)+2x = (a+b-2x)$$

$$p_{NH_3} = \frac{2x}{(a+b-2x)}\times P;\qquad p_{N_2} = \frac{(a-x)}{(a+b-2x)}\times P;$$

$$p_{H_2} = \frac{(b-3x)}{(a+b-2x)}\times P$$

$$K_p = \frac{[p_{NH_3}]^2}{[p_{N_2}][p_{H_2}]^3} = \frac{\left[\dfrac{2x}{(a+b-2x)}P\right]^2}{\left[\dfrac{(a-x)}{(a+b-2x)}P\right]\left[\dfrac{(b-3x)}{(a+b-2x)}P\right]^3}$$

$$= \frac{4x^2(a+b-2x)^2}{(a-x)(b-3x)^3P^2}\qquad (\text{units} = \text{atm}^{-2})$$

Case IV: Homogeneous liquid system: Formation of ethyl acetate:

The reaction between alcohol and acid to form ester is an example of homogeneous equilibrium in liquid system.

$$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$$

Let a start be made by mixing 'a' moles of an acid and 'b' moles of an alcohol. By the time equilibrium is established, x moles of ester and 'x' moles of water are formed, *i.e.*, x moles of acid and x moles of alcohol have been consumed. Let V be the total volume. At equilibrium, the active masses of reactants and products are:

$$[CH_3COOH] = \frac{(a-x)}{V},\ [C_2H_5OH] = \frac{(b-x)}{V},$$

$$[CH_3COOC_2H_5] = \frac{x}{V} \text{ and } [H_2O] = \frac{x}{V}$$

Applying law of mass action,

$$K_c = \frac{[\text{ester}][\text{water}]}{[\text{acid}][\text{alcohol}]} = \frac{\dfrac{x}{V}\times\dfrac{x}{V}}{\left(\dfrac{a-x}{V}\right)\times\left(\dfrac{b-x}{V}\right)}$$

$$= \frac{x^2}{(a-x)(b-x)}$$

If $a = b = 1$, then $K_c = \dfrac{x^2}{(1-x)^2}$, ($K_c$ has no units)

This does not involve the volume term. Thus, K_c is not affected by the change of volume.

Case V: Heterogeneous equilibria:

Law of mass action can also be applied to the study of equilibria in which the substances are not in the same phase. Considering the decomposition of solid $NaHCO_3$ to produce solid Na_2CO_3, gaseous CO_2 and H_2O.

$$2NaHCO_3(s) \rightleftharpoons Na_2CO_3(s) + CO_2(g) + H_2O(g)$$

Applying the law of mass action,

$$K'_c = \frac{[Na_2CO_3][CO_2][H_2O]}{[NaHCO_3]^2}$$

It involves two pure solids, Na_2CO_3 and $NaHCO_3$. It is customary not to include the concentrations of pure solids in equilibrium expressions.

$$\therefore \quad \frac{K'_c[NaHCO_3]^2}{[Na_2CO_3]} = [CO_2][H_2O]$$

or $$K_c = [CO_2][H_2O]$$

In terms of partial pressures we have $K_p = p_{CO_2} \times p_{H_2O}$. Similarly, in reactions in which a reactant or product occurs as a pure liquid phase, the concentration of that substance in the pure liquid is also constant. **As a result, the concentrations of pure solid and pure liquid phases do not appear in the equilibrium constant expression.**

Many other examples of heterogeneous equilibria are available. Such as:

1. Decomposition of $CaCO_3$,

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

$$K_c = [CO_2] \quad \text{or} \quad K_p = p_{CO_2}$$

When $CaCO_3$ is heated in a closed vessel at a definite temperature, the pressure or concentration of CO_2 produced becomes constant irrespective of the amount of $CaCO_3$ taken.

2. Reaction of steam on heated iron,

$$3Fe(s) + 4H_2O(g) \rightleftharpoons Fe_3O_4(s) + 4H_2(g)$$

$$K_c = \frac{[H_2]^4}{[H_2O]^4} \text{ or } K'_p = \frac{p_{H_2}}{p_{H_2O}} = \sqrt[4]{K_p}$$

3. Reaction of steam on heated carbon,

$$C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$$

$$K_c = \frac{[CO][H_2]}{[H_2O]} \quad \text{or} \quad K_p = \frac{p_{CO} \times p_{H_2}}{p_{H_2O}}$$

4. Dissociation of ammonium carbamate,

$$NH_2COONH_4(s) \rightleftharpoons 2NH_3(g) + CO_2(g)$$

$$K_c = [NH_3]^2[CO_2]; \quad K_p = [p_{NH_3}]^2 \times [p_{CO_2}]$$

SOME SOLVED EXAMPLES

Example 11. *For the following reaction,*

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g),$$

If initially 25 mL of H_2 and 20 mL of I_2 are present in a container and at equilibrium 30 mL of HI is formed then calculate equilibrium constant. **[AIPMT (Mains) 2009]**

Solution: The given reaction is :

$$\begin{array}{lccc} & H_2(g) & +\ I_2(g) \rightleftharpoons & 2HI(g), \\ t_0 & 25\text{ mL} & 20\text{ mL} & 0 \\ t_{eq.} & 25-x & 20-x & 2x \end{array}$$

Give, $2x = 30\text{ mL} \quad \therefore \quad x = 15\text{ mL}$

Equilibrium constant may be calculated as,

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{[30]^2}{[10][5]} = \frac{900}{15} = 60$$

Example 12. *In the reaction,*

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

the amounts of H_2, I_2 and HI are 0.2 g, 9.2525 g and 44.8 g respectively at equilibrium at a certain temperature. Calculate the equilibrium constant of the reaction.

Solution: $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$,

Applying law of mass action,

$$K_c = \frac{[HI]^2}{[H_2][I_2]}$$

Let the total volume be V litre, then

$$[H_2] = \frac{0.2}{2V} = \frac{0.1}{V}; [I_2] = \frac{9.2525}{254V} = \frac{0.0364}{V}$$

$$[HI] = \frac{44.8}{128V} = \frac{0.35}{V} \text{ mol L}^{-1} \text{ respectively}$$

So, $$K_c = \frac{\left(\frac{0.35}{V}\right)^2}{\frac{0.1}{V} \times \frac{0.0364}{V}} = \frac{0.35 \times 0.35}{0.1 \times 0.0364} = 33.65$$

Example 13. 0.5 *mole of hydrogen and* 0.5 *mole of iodine react in a* 10 *litre evacuated vessel at* 448°C; *hydrogen iodide is formed. The equilibrium constant, K_c for the reaction is* 50.

(*a*) *Calculate the number of moles of iodine which remain unreacted at equilibrium.*

(*b*) *What is the value of K_p?*

Solution: (a)

$$\begin{array}{lccc} & H_2(g) & +\ I_2(g) \rightleftharpoons & 2HI(g) \\ \text{Initial moles} & 0.5 & 0.5 & 0 \\ \text{No. of moles at equilibrium} & (0.5-x) & (0.5-x) & 2x \end{array}$$

$$K_c = \frac{4x^2}{(0.5-x)(0.5-x)} = 50$$

$$\frac{2x}{(0.5-x)} = \sqrt{50} = 7.07$$

$$2x = 0.5 \times 7.07 - 7.07x$$

or $$2x + 7.07x = 0.5 \times 7.07$$

$$x = \frac{0.5 \times 7.07}{9.07} = 0.39 \text{ mole}$$

(b) No. of moles of I_2 at equilibrium $= (0.5 - 0.39) = 0.11$ mole

$$K_p = K_c(RT)^{\Delta n}$$

As $\Delta n = 0$, $\quad K_p = K_c = 50$

Example 14. *25 mL of H_2 and 18 mL of I_2 vapours were heated in a sealed glass tube at 465°C and at equilibrium 30.8 mL of HI was formed. Calculate the percentage degree of dissociation of HI at 465°C.*

Solution: Since, the number of moles in a gas under the same conditions of temperature and pressure are proportional to volumes (Avogadro's Law), the volumes in mL of gases may be used instead of concentrations in the case of reversible reactions in which there is no change in the number of molecules of reactants and products.

Given, $\quad 2x = 30.8$ mL

So, $\quad x = 15.4$ mL

Vol. of H_2 at equilibrium $= (25 - 15.4) = 9.6$ mL

Vol. of I_2 at equilibrium $= (18 - 15.4) = 2.6$ mL

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(30.8)^2}{9.6 \times 2.6} = 38.0$$

Consider the equation,

$$2\text{HI}(g) \rightleftharpoons \text{H}_2(g) + \text{I}_2(g)$$

Let the degree of dissociation be x

$$K_c' = \frac{x^2}{4(1-x)^2} \qquad \left(K_c' = \frac{1}{K_c} = \frac{1}{38}\right)$$

$$\frac{1}{38} = \frac{x^2}{4(1-x)^2} \quad \text{or} \quad \frac{1}{6.1644} = \frac{x}{2(1-x)}$$

or $\quad x = 0.245$, *i.e.*, 24.5% dissociated

Example 15. *3.2 mole of HI were heated in a sealed bulb at 444°C till the equilibrium state was reached. Its degree of dissociation was found to be 20%. Calculate the number of moles of hydrogen iodide, hydrogen and iodine present at the equilibrium point and determine the equilibrium constant.*

Solution: The dissociation of HI is represented by the equation,

$$\begin{array}{ccc} 2\text{HI}(g) \rightleftharpoons & \text{H}_2(g) & +\text{I}_2(g) \\ (1-x) & x/2 & x/2 \end{array}$$

Degree of dissociation, $x = 0.20$ and initial concentration of HI, $a = 3.2$ mole.

At equilibrium,

No. of moles of HI $= a(1-x) = 3.2 \times 0.8 = 2.56$

No. of moles of $H_2 = \dfrac{a \cdot x}{2} = 3.2 \times 0.1 = 0.32$

No. of moles of $I_2 = \dfrac{a \cdot x}{2} = 3.2 \times 0.1 = 0.32$

$$K_c = \frac{x^2}{4(1-x)^2} = \frac{0.2 \times 0.2}{4 \times 0.8 \times 0.8} = 0.0156$$

Also, $$K_c = \frac{[\text{H}_2][\text{I}_2]}{[\text{HI}]^2} = \frac{0.32 \times 0.32}{2.56 \times 2.56} = 0.0156$$

Example 16. *The equilibrium constant of the reaction,*

$$A_2(g) + B_2(g) \rightleftharpoons 2AB(g)$$

at 100°C is 50. If a one litre flask containing one mole of A_2 is connected to a two litre flask containing two moles of B_2, how many moles of AB will be formed at 373 K?

Solution: $\quad A_2(g) + B_2(g) \rightleftharpoons 2AB(g)$

	$A_2(g)$	$B_2(g)$	$2AB(g)$
Initial no. of moles	1	2	0
No. of moles at equilibrium	$(1-x)$	$(2-x)$	$2x$
(Total volume = 3 litre)			
Active masses	$\frac{(1-x)}{3}$	$\frac{(2-x)}{3}$	$\frac{2x}{3}$

Applying law of mass action,

$$K_c = \frac{[AB]^2}{[A_2][B_2]} = \frac{\left(\frac{2x}{3}\right)^2}{\left(\frac{1-x}{3}\right)\left(\frac{2-x}{3}\right)} = \frac{4x^2}{(1-x)(2-x)}$$

But, $$\frac{4x^2}{(1-x)(2-x)} = 50$$

or $\quad 4x^2 = (2 - 3x + x^2)50$

or $\quad 2x^2 = (2 - 3x + x^2)25$

or $\quad 23x^2 - 75x + 50 = 0$

$$x = \frac{75 \pm \sqrt{(75)^2 - 4 \times 23 \times 50}}{2 \times 23}$$

$x = 2.317$ or 0.934

The value of x cannot be more than 1, *i.e.*, greater than the number of moles of A_2 and hence $x = 0.943$.

No. of moles of $AB = 2x = (2 \times 0.934)$

$= 1.868$

Example 17. *The vapour density of N_2O_4 at a certain temperature is 30. Calculate the percentage dissociation of N_2O_4 at this temperature.*

Solution: $\quad \text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g)$

Mol. mass of $\text{N}_2\text{O}_4 = (28 + 64) = 92$

Vapour density, $D = \dfrac{92}{2} = 46$

Let the degree of dissociation be x

Given, $d = 30$

Applying the relationship,

$$x = \frac{D - d}{d} = \frac{(46 - 30)}{30} = \frac{16}{30} = 0.533$$

Degree of dissociation = 53.3%

Example 18. *3 g mole of phosphorus pentachloride is heated in a flask of 4 litre volume. At equilibrium it dissociates to give 40% of phosphorus trichloride and chlorine. Calculate the equilibrium constant.*

Solution: Degree of dissociation = 0.4

$$\begin{array}{llll} PCl_5(g) \rightleftharpoons & PCl_3(g) + & Cl_2(g) & \\ a(1-x) & ax & ax & \text{(at equilibrium)} \end{array}$$

Given, $a = 3, x = 0.4$ and $V = 4$.

So, at equilibrium,

$$[PCl_5] = \frac{3(1-0.4)}{4} = \frac{3\times 0.6}{4}\ \text{mol L}^{-1}$$

$$[PCl_3] = \frac{3\times 0.4}{4}\ \text{mol L}^{-1}$$

$$[Cl_2] = \frac{3\times 0.4}{4}\ \text{mol L}^{-1}$$

Applying law of mass action,

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{3\times 0.4\times 3\times 0.4}{4\times 3\times 0.6} = 0.2\ \text{mol L}^{-1}$$

Example 19. *N_2O_4 is 25% dissociated at 37°C and one atmospheric pressure. Calculate (i) K_p and (ii) the percentage dissociation at 0.1 atmosphere and 37°C.*

Solution: (i)

$$\begin{array}{lcc} & N_2O_4(g) \rightleftharpoons & 2NO_2(g) \\ \text{Initial} & 1 & 0 \\ \text{At equilibrium} & (1-x) & 2x \end{array}$$

$$\text{Total moles} = (1-x) + 2x = (1+x)$$

$$p_{N_2O_4} = \left(\frac{1-x}{1+x}\right)P, \quad p_{NO_2} = \frac{2x}{(1+x)}\cdot P$$

Given, $x = 0.25$ and $P = 1$ atm

$$p_{N_2O_4} = \left(\frac{1-0.25}{1+0.25}\right)\times 1 = 0.6\ \text{atm}$$

$$p_{NO_2} = \left(\frac{2\times 0.25}{1+0.25}\right)\times 1 = 0.4\ \text{atm}$$

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{0.4\times 0.4}{0.6} = 0.267\ \text{atm}$$

(ii) Let the degree of dissociation of N_2O_4 at 0.1 atm be 'α', then,

$$p_{N_2O_4} = \left(\frac{1-\alpha}{1+\alpha}\right)\times 0.1 \text{ and } p_{NO_2} = \frac{2\alpha}{(1+\alpha)}\times 0.1$$

$$K_p = \frac{\left(\frac{2\alpha}{1+\alpha}\right)^2\times (0.1)^2}{\left(\frac{1-\alpha}{1+\alpha}\right)\times 0.1} = \frac{4\alpha^2\times 0.1}{(1-\alpha)(1+\alpha)} = \frac{0.4\alpha^2}{(1-\alpha^2)}$$

or $$0.267 = \frac{0.4\alpha^2}{(1-\alpha^2)} \text{ or } 0.267 = 0.667\alpha^2$$

$$\alpha = 0.632$$

Hence, dissociation of $N_2O_4 = 63.2\%$

Example 20. *1.0 mole of nitrogen and 3.0 moles of PCl_5 are placed in 100 litre vessel heated to 227°C. The equilibrium pressure is 2.05 atm. Assuming ideal behaviour, calculate the degree of dissociation for PCl_5 and K_p for the reaction,*

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

Solution:

$$\begin{array}{lccc} & PCl_5(g) \rightleftharpoons & PCl_3(g) + & Cl_2(g) \\ \text{Initial} & 3 & 0 & 0 \\ \text{At equilibrium} & 3(1-x) & 3x & 3x \end{array}$$

(x = degree of dissociation)

$$\text{Total moles} = 3(1-x) + 3x + 3x = 3(1+x)$$

1 mole of nitrogen is present, hence actual total number of moles at equilibrium $= 3(1+x) + 1$

According to gas equation,

$$PV = nRT$$

Given, $P = 2.05$ atm, $V = 100$ litres, $R = 0.082$

and $T = (273 + 227) = 500\ \text{K}$

So, $$n = \frac{2.05\times 100}{0.082\times 500} = 5$$

or $$3(1+x) + 1 = 5$$

$$3x = 1 \text{ or } x = 0.333$$

Thus, $3(1+x) + 1 = 3 + 3\times 0.333 + 1 = 4 + 0.999$

At equilibrium, $$p_{PCl_5} = \frac{3(1-x)}{(3x+4)}\times 2.05$$

$$p_{PCl_3} = p_{Cl_2} = \frac{3x}{(3x+4)}\times 2.05$$

$$K_p = \frac{\frac{3x}{(3x+4)}\times 2.05\times \frac{3x}{(3x+4)}\times 2.05}{\frac{3(1-x)}{(3x+4)}\times 2.05}$$

$$= \frac{9x^2\times 2.05}{3(3x+4)(1-x)} = \frac{3\times (0.333)^2\times 2.05}{(4+0.999)(0.667)}$$

$$= 0.204\ \text{atm}$$

Example 21. *For a gas reaction, $3H_2(g) + N_2(g) \rightleftharpoons 2NH_3(g)$, the partial pressures of H_2 and N_2 are 0.4 and 0.8 atmosphere, respectively. The total pressure of the entire system is 2.8 atmosphere. What will be the value of K_p if all the concentrations are given in atmospheres?*

Solution:

$$\begin{array}{lccc} & N_2(g) + & 3H_2(g) \rightleftharpoons & 2NH_3(g) \\ \text{Partial pressures at equilibrium} & 0.8 & 0.4 & [2.8 - (0.8 + 0.4) = 1.6] \end{array}$$

Applying law of mass action,

$$K_p = \frac{(p_{NH_3})^2}{(p_{N_2})(p_{H_2})^3} = \frac{1.6\times 1.6}{0.8\times 0.4\times 0.4\times 0.4}$$

$$= 50\ \text{atm}^{-2}$$

Example 22. *One mole of nitrogen and three moles of hydrogen are mixed in a 4 litre container. If 0.25 per cent of nitrogen is converted to ammonia by the following reaction:*

$$N_2(g)+3H_2(g) \rightleftharpoons 2NH_3(g)$$

calculate the equilibrium constant (K_c) in concentration units. What will be the value of K for the following equilibrium?

$$\frac{1}{2}N_2(g)+\frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$$

Solution:

	$N_2(g)$	+ $3H_2(g)$	$\rightleftharpoons$ $2NH_3(g)$
At equilibrium	$(1-x)$	$(3-3x)$	$2x (x=0.0025)$
Active masses	$\frac{(1-0.0025)}{4}$	$\frac{(3-0.0075)}{4}$	$\frac{(0.0050)}{4}$

Applying law of mass action,

$$K_c=\frac{[NH_3]^2}{[N_2][H_2]^3}=\frac{\left(\frac{0.0050}{4}\right)^2}{\left(\frac{0.9975}{4}\right)\left(\frac{2.9925}{4}\right)^3}$$

$$=1.49\times10^{-5}\ \text{litre}^2\ \text{mol}^{-2}$$

K for the reaction,

$$\frac{1}{2}N_2(g)+\frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$$

is equal to $\sqrt{K_c}$.

$$K=\sqrt{K_c}=\sqrt{1.49\times10^{-5}}$$

$$=3.86\times10^{-3}\ \text{litre mol}^{-1}$$

Example 23. *In an experiment one mole of acetic acid and one mole of alcohol were allowed to react until equilibrium was established. The equilibrium mixture was found to contain 2/3 mole of ester. Calculate the equilibrium constant of the reaction.*

Solution:

$$CH_3COOH(l)+C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l)+H_2O(l)$$

	$CH_3COOH(l)$	$C_2H_5OH(l)$	$CH_3COOC_2H_5(l)$	$H_2O(l)$
Initial no. of moles	1	1	0	0
No. of moles at equilibrium	$\left(1-\frac{2}{3}\right)$	$\left(1-\frac{2}{3}\right)$	$\frac{2}{3}$	$\frac{2}{3}$
Active masses	$\frac{1}{3V}$	$\frac{1}{3V}$	$\frac{2}{3V}$	$\frac{2}{3V}$

V is the total volume in litres.

Applying law of mass action,

$$K_c=\frac{[\text{ester}][\text{water}]}{[\text{acid}][\text{alcohol}]}$$

$$=\frac{\frac{2}{3V}\times\frac{2}{3V}}{\frac{1}{3V}\times\frac{1}{3V}}=4$$

Example 24. *Ammonium hydrogen sulphide dissociates according to the equation:*

$$NH_4HS(s) \rightleftharpoons NH_3(g)+H_2S(g)$$

If the observed pressure at equilibrium is 1.12 atm at 380 K, what is the equilibrium constant K_p of the reaction?

Solution: $NH_4HS(s) \rightleftharpoons NH_3(g)+H_2S(g)$

$$p_{NH_3}=p_{H_2S}=\frac{1}{2}\times1.12=0.56\ \text{atm}$$

$$K_p=p_{NH_3}\times p_{H_2S}=0.56\times0.56=0.3136$$

Example 25. *A vessel at 1000 K contains carbon dioxide with a pressure of 0.5 atm. Some of the carbon dioxide is converted to carbon monoxide on addition of graphite. Calculate the value of K_p if total pressure at equilibrium is 0.8 atm.*

(IIT 1993)

Solution:

	$CO_2(g)$ + $C(s)$	$\rightleftharpoons$ $2CO(g)$
Initial	0.5 atm	0 atm
At equilibrium	$(0.5-x)$ atm	$2x$ atm

At equilibrium, the total pressure is 0.8 atm.

$$p_{\text{total}}=p_{CO_2}+p_{CO}$$

$$0.8=(0.5-x)+2x=0.5+x$$

or $x=0.3$ atm

Applying law of mass action,

$$K_p=\frac{(p_{CO})^2}{p_{CO_2}}=\frac{(2\times0.3)^2}{0.2}=\frac{0.36}{0.2}=1.8\ \text{atm}$$

Example 26. *A sample of $CaCO_3(s)$ is introduced into a sealed container of volume 0.654 litre and heated to 1000 K until equilibrium is reached. The equilibrium constant for the reaction,*

$$CaCO_3(s) \rightleftharpoons CaO(s)+CO_2(g),$$

is 3.9×10^{-2} atm at this temperature. Calculate the mass of CaO present at equilibrium.

Solution: $CaCO_3(s) \rightleftharpoons CaO(s)+CO_2(g)$

$$K_p=p_{CO_2}$$

Let the number of moles of CO_2 be formed $= n$

$$n=\frac{p_{CO_2}\times V}{RT}=\frac{3.9\times10^{-2}\times0.654}{0.082\times1000}$$

$$=3.11\times10^{-4}\ \text{mol}$$

The amount of CaO(s) formed will also be $=3.11\times10^{-4}$ mol

Hence, mass of CaO formed $=3.11\times10^{-4}\times56=0.0174$ g

Example 27. *The decomposition of ammonium carbamate at 30°C is represented as:*

$$NH_2COONH_4(s) \rightleftharpoons 2NH_3(g)+CO_2(g)$$

The equilibrium constant K_p is 2.9×10^{-5} atm^3.

What is the total pressure of gases in equilibrium with $NH_2COONH_4(s)$ at 30°C?

Solution: $NH_2COONH_4(s) \rightleftharpoons 2NH_3(g)+CO_2(g)$

	$NH_2COONH_4(s)$	$2NH_3(g)$	$CO_2(g)$
At equilibrium	$(1-x)$	$2x$	x

$$K_p=(p_{NH_3})^2\times p_{CO_2}$$

$$2.9\times10^{-5}=(2x)^2\times x=4x^3$$

$$x = \left(\frac{2.9 \times 10^{-5}}{4}\right)^{1/3} = 0.0194 \text{ atm}$$

Total pressure $= 2x + x = 3x = 3 \times 0.0194 = 0.0582$ atm

Example 28. *In an experiment starting with 1 mole of ethyl alcohol, 1 mole of acetic acid and 1 mole of water at 100°C, the equilibrium mixture on analysis shows that 54.3% of the acid is esterified. Calculate the equilibrium constant of this reaction.*

Solution:

$$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$$

Initial	1	1	0	1
At equilibrium	$1-x$	$1-x$	x	$1+x$
	$1-0.543$	$1-0.543$	0.543	$1+0.543$

Given, $x = 0.543$.

Applying law of mass action,

$$K_c = \frac{[\text{ester}][\text{water}]}{[\text{acid}][\text{alcohol}]} = \frac{0.543 \times 1.543}{0.457 \times 0.457} = 4.0$$

Example 29. *The equilibrium constant for the reaction, $CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$ is 4. What will be the composition of the equilibrium mixture when one mole of acetic acid is taken along with 4 moles of ethyl alcohol?*

Solution:

$$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$$

Initial	1	4	0	0
At equilibrium	$1-x$	$4-x$	x	x

$$K_c = \frac{[\text{ester}][\text{water}]}{[\text{acid}][\text{alcohol}]} = \frac{x^2}{(1-x)(4-x)} = 4$$

$$x^2 = 4(1-x)(4-x)$$

$$= 4[4 - 5x + x^2]$$

$$= 16 - 20x + 4x^2$$

or $$3x^2 - 20x + 16 = 0$$

$$x = \frac{20 \pm \sqrt{400 - 192}}{6} = \frac{20 \pm 14.42}{6}$$

$$x = 0.93 \quad \text{or} \quad 5.7366$$

The value 5.7366 is not possible, hence $x = 0.93$

Thus, the composition of mixture at equilibrium is

$$[CH_3COOH] = (1 - 0.93) = 0.07 \text{ mole}$$

$$[C_2H_5OH] = (4 - 0.93) = 3.07 \text{ mole}$$

$$[CH_3COOC_2H_5] = 0.93 \text{ mole}$$

$$[H_2O] = 0.93 \text{ mole}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

7. For the reaction, $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$, the value of K_c at 300°C is 0.1. When the equilibrium concentrations of both the reactants is 0.5 mol, what is the value of K_p at the same temperature? (KCET 2005)

(a) 0.5 (b) 0.1 (c) 0.01 (d) 0.025

[**Ans.** (b)]

[**Hint:** $K_p = K_c(RT)^{\Delta n}$

Since, $\Delta n = 0$, hence, $K_p = K_c$]

8. $A(g) + 3B(g) \rightleftharpoons 4C(g)$, initial concentration of A is equal to that of B. The equilibrium concentrations of A and C are equal. K_c of the reaction will be:

(a) 0.08 (b) 0.8 (c) 8 (d) 80 (e) 1/8

[**Ans.** (c)]

[**Hint:** $A(g) + 3B(g) \rightleftharpoons 4C(g)$

$t = 0$	a	a	0
$t_{eq.}$	$a - x$	$a - 3x$	$4x$

$a - x = 4x$ given

$a = 5x$

$$K_c = \frac{[C]^4}{[A][B]^3} = \frac{[4x]^4}{[4x][2x]^3} = \frac{256}{32} = 8]$$

9. For a hypothetical reaction:

$$4A(g) + 5B(g) \rightleftharpoons 4P(g) + 6Q(g)$$

The equilibrium constant K_c has units:

(a) mol L^{-1} (b) mol^{-1} L
(c) $(mol\ L^{-1})^{-2}$ (d) unitless

[**Ans.** (a)]

[**Hint:** Unit of $K_c = (mol\ L^{-1})^{\Delta n}$

$= (mol\ L^{-1})^1 = mol\ L^{-1}$]

10. Starting with 1 mol of O_2; 2 mol of SO_2, the equilibrium for the formation of $SO_3(g)$ was established at a certain temperature. If V is the volume of the vessel and $2x$ is the number of moles of SO_3 present, the equilibrium constant will be:

(a) $\frac{x^2V}{(1-x)^3}$ (b) $\frac{4x^2}{(2-x)(1-x)}$

(c) $\frac{(1-x)^3}{2V}$ (d) $\frac{x^2}{(2-x)(1-x)}$

[**Ans.** (a)]

[**Hint:** $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$

$t = 0$	2	1	0
$t_{eq.}$	$\left[\frac{2-2x}{V}\right]$	$\left[\frac{1-x}{V}\right]$	$\left[\frac{2x}{V}\right]$

$$\therefore K_c = \frac{[SO_3]^2}{[SO_2]^2[O_2]} = \frac{[2x/V]^2}{\left[\frac{2-2x}{V}\right]^2\left[\frac{1-x}{V}\right]} = \frac{x^2V}{(1-x)^3}]$$

11. For the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, $K = 47.6$, if the initial number of moles of each reactant and product is 1 mole, then at equilibrium: [JEE (Orissa) 2006]

(a) $[I_2] = [H_2]; [I_2] > [HI]$ (b) $[I_2] < [H_2]; [I_2] = [HI]$
(c) $[I_2] = [H_2]; [I_2] < [HI]$ (d) $[I_2] > [H_2]; [I_2] = [HI]$

[**Ans.** (c)]

[**Hint:** $K_c = \frac{[HI]^2}{[H_2][I_2]}$

$[H_2] = [I_2]$ will be same at equilibrium, since it is same at initial state.

$$K_c = \frac{[HI]^2}{[I_2]^2}$$

$$K_c [I_2]^2 = [HI]^2$$
$$47.6 [I_2]^2 = [HI]^2$$
$$\therefore \quad [I_2] < [HI]]$$

12. In a closed vessel of volume V, a mol of nitrogen and b mol of oxygen are made to react to give nitric oxide, according to the reaction:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$

If at equilibrium, $2x$ mol of NO are obtained, then: **[BV (Pune) 2006]**

(a) $K_c = \dfrac{4x^2}{(a-x)(b-x)} \times \dfrac{1}{V}$

(b) $K_c = \dfrac{4x^2}{(a-x)(b-x)} \times V$

(c) $K_c = \dfrac{x^2}{(a-x)(b-x)} \times V$

(d) $K_c = \dfrac{4x^2}{(a-x)(b-x)}$

[Ans. (d)]

[Hint:

$$\begin{array}{llll} & N_2(g) & + \; O_2(g) \rightleftharpoons & 2NO(g) \\ t = 0 & a & b & 0 \\ t_{eq.} & \dfrac{(a-x)}{V} & \left(\dfrac{b-x}{V}\right) & \dfrac{2x}{V} \end{array}$$

$$K_c = \frac{\left(\dfrac{2x}{V}\right)^2}{\left(\dfrac{a-x}{V}\right)\left(\dfrac{b-x}{V}\right)} = \frac{4x^2}{(a-x)(b-x)}]$$

13. Equivalent amounts of H_2 and I_2 are heated in a closed till equilibrium is obtained. If 80% of the hydrogen can be converted to HI, the K_c at this temperature is: **(VITEEE 2007)**

(a) 64 (b) 16 (c) 0.25 (d) 4

[Ans. (a)]

[Hint:

$$\begin{array}{llll} & H_2(g) & + \; I_2(g) \rightleftharpoons & 2HI(g) \\ t = 0 & 1 & 1 & 0 \\ t_{eq.} & \dfrac{1-0.8}{V} & \dfrac{1-0.8}{V} & \dfrac{2 \times 0.8}{V} \end{array}$$

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{\left[\dfrac{1.6}{V}\right]^2}{\dfrac{0.2}{V} \times \dfrac{0.2}{V}} = 64]$$

14. Equimolar concentration of H_2 and I_2 are heated to equilibrium in a 2 litre flask. At equilibrium, the forward and backward rate constants are found to be equal. What percentage of initial concentration of H_2 has reacted at equilibrium? **[PMT (Kerala) 2008]**

(a) 33% (b) 66%
(c) 50% (d) 40%
(e) 20%

[Ans. (a)]

[Hint :

$$\begin{array}{llll} & H_2(g) & + \; I_2(g) \rightleftharpoons & 2HI(g) \\ t_0 & 1 & 1 & 0 \\ t_{eq.} & \dfrac{1-x}{2} & \dfrac{1-x}{2} & \dfrac{2x}{2} \end{array}$$

$$K = \frac{k_f}{k_b} = 1 = \frac{[HI]^2}{[H_2][I_2]} = \frac{(x)^2}{\left(\dfrac{1-x}{2}\right)\left(\dfrac{1-x}{2}\right)}$$

$$1 = \frac{4x^2}{(1-x)^2}$$

$$1 = \frac{2x}{1-x}$$

$$x = 0.33$$

% of H_2 reacted = 33]

9.8 LE CHATELIER'S PRINCIPLE

There are three main factors which can change the state of equilibrium in a reversible system. These are concentration, pressure and temperature. Le Chatelier, a French chemist, presented a qualitative principle known as Le Chatelier's principle which can describe the effect of change in concentration, pressure and temperature on any reversible system whether physical or chemical.

According to this principle, **if a system at equilibrium is subjected to a change of concentration, pressure or temperature, the equilibrium shifts in the direction that tends to undo the effect of the change.**

Or

If a system at equilibrium is subjected to a change of any one of the factors such as concentration, pressure or temperature, the system adjusts itself in such a way as to annul the effect of that change.

(a) Change in concentration: If an additional amount of any reactant or product is added to the system, the stress is relieved as the reaction that consumes the added substance occurs more rapidly than its reverse reaction, *i.e.*, if any of the reactants is added, the rate of forward reaction increases and if any of the products is added, the rate of backward reaction increases.

In general, in a chemical equilibrium, increasing the concentrations of the reactants results in shifting the equilibrium in favour of products while increasing concentrations of the products results in shifting the equilibrium in favour of reactants.

(b) Change in pressure: If a system in equilibrium consists of gases, then the concentrations of all the components can be altered by changing the pressure. When the pressure on the system is increased, the volume decreases proportionately. The total number of moles per unit volume will now be more than before. According to Le Chatelier's principle, the equilibrium will shift in the direction in which there is decrease in number of moles, *i.e.*, towards the direction in which there is decrease in volume.

In general, **an increase in pressure applied to a system at equilibrium, favours the reaction in the direction that produces smaller number of moles of gases and a decrease in pressure favours the opposite reaction.** If there is no change in number of moles of gases in a reaction, a pressure change does not affect the equilibrium.

(c) Change in temperature: A chemical reaction (reversible) involves two opposing reactions, forward and backward. If one reaction is endothermic, the other will be exothermic in nature. When heat energy is added by raising temperature, the system can relieve itself from the stress if the reaction which absorbs heat moves faster, *i.e.*, **endothermic reaction is always favoured with increase of temperature.**

Conclusions:

(i) Increase in concentration of any substance favours the reaction in which it is used up.
(ii) High pressure is favourable for the reaction in which there is decrease in volume.
(iii) A rise in temperature favours the endothermic reaction.

(d) Role of catalyst: Positive catalyst increases the rate of both forward and backward reactions equally; the equilibrium will be attained in less time, *i.e.*, same amount of product will be formed in less time.

On the other hand, negative catalyst lowers the rate of both forward and backward reactions equally. Same amount of product will be formed in more time.

Catalyst does not affect equilibrium constant and heat of reaction.

Summary of Le Chatelier's Principle

Effect of inert gas addition

Condition		Effect
$\Delta V = 0, V = \text{Constant}$	$\Delta n = 0, +\text{ve or } -\text{ve}$	No effect
$\Delta V \neq 0, V \neq \text{Constant}$	$\Delta n = 0$	No effect
$\Delta V \neq 0, V \neq \text{Constant}$	$\Delta n > 0$	Forward shift
$\Delta V \neq 0, V \neq \text{Constant}$	$\Delta n < 0$	Backward shift

where, Δn = number of gaseous moles of product − number of gaseous moles of reactant

Effect of temperature and pressure

	Nature of reaction	Effect of increased temperature	Δn; Side with fewer mole of gas	Effect of increase in P
1.	Exothermic	backward shift	0; neither	no shift
2.	Exothermic	backward shift	−ve; right	forward shift
3.	Endothermic	forward shift	−ve; right	forward shift
4.	Endothermic	forward shift	+ve; left	backward shift
5.	Exothermic	backward shift	+ve; left	backward shift
6.	Exothermic	backward shift	−ve; right	forward shift
7.	Endothermic	forward shift	+ve; left	backward shift
8.	Endothermic	forward shift	+ve; left	backward shift

Application of Le Chatelier's Principle

(a) Formation of HI:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g) + 3000 \text{ cal}$$

Effect of concentration: When concentration of H_2 or I_2 is increased at equilibrium, the system moves in a direction which decreases the concentration, *i.e.*, the rate of forward reaction increases thereby increasing the concentration of HI.

Effect of pressure: As there is no change in the number of moles in the reaction, the equilibrium state remains unaffected by change of pressure.

Effect of temperature: By increasing temperature, the equilibrium state shifts towards the reaction which moves with absorption of heat. The formation of HI is an exothermic reaction. Thus, the backward reaction moves faster when temperature is increased.

In short, we can say that the favourable conditions for greater yield of HI are:

(i) High concentrations of H_2 and I_2 and
(ii) Low temperature.

(b) Formation of nitric oxide:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) - 43200 \text{ cal}$$

Effect of concentration: When concentration of N_2 or O_2 is increased, the system moves in a direction in which N_2 or O_2 is used up, *i.e.*, rate of forward reaction increases thereby increasing the concentration of NO.

Effect of pressure: In the formation of nitric oxide, the number of moles remains the same, *i.e.*, no change in volume occurs. Consequently, the equilibrium state is not affected by any change in pressure.

Effect of temperature: The formation of NO is endothermic in nature. If the temperature is raised, the equilibrium shifts in the direction in which heat is absorbed. The concentration of NO will, therefore, be higher at higher temperature.

Thus, favourable conditions for greater yield of nitric oxide are:

(i) High concentrations of N_2 and O_2 and
(ii) High temperature

(c) Dissociation of PCl_5:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g) - 15000 \text{ cal}$$

Effect of concentration: When concentration of PCl_5 is increased at equilibrium, the rate of forward reaction increases as to decrease the added concentration. Thus, more of PCl_3 and Cl_2 are formed.

Effect of pressure: The volume increases in the dissociation of PCl_5. When pressure is increased, the system moves in the direction in which there is decrease in volume. Thus, high pressure does not favour dissociation of PCl_5.

Effect of temperature: The dissociation of PCl_5 is an endothermic reaction. Thus, increase of temperature favours the dissociation.

Thus, favourable conditions for dissociation of PCl_5 are:

(i) High concentration of PCl_5,
(ii) Low pressure and
(iii) High temperature.

(d) Formation of ammonia:

$$N_2(g) + 3H_2(g) \overset{Fe}{\rightleftharpoons} 2NH_3(g); \Delta H = -22.4 \text{ kcal/mol}$$

(i) At high pressure reaction will shift in forward direction to form more product.
(ii) When concentration of N_2 and H_2 is raised or concentration of NH_3 is lowered, then again the equilibrium shifts in forward direction to form more ammonia.

If concentration of only one reactant is raised, then again the equilibrium shifts in forward direction till the other reactant is available for reaction.

(iii) The reaction shifts in forward direction at low temperature. But at very low temperature the rate of reaction becomes very low; thus moderate temperature is favourable for this reaction.

9.9 APPLICATION OF LE CHATELIER'S PRINCIPLE TO PHYSICAL EQUILIBRIA

(i) Solid $\rightleftharpoons$ Liquid $\rightleftharpoons$ Gas

When temperature is raised, the above equilibrium shifts in forward direction.

(ii) Effect of pressure on boiling point: When pressure is raised, condensation of vapour takes place. Thus, vapour pressure is lowered. Now more heat is required to equate vapour pressure with atmospheric pressure as a result of which boiling point increases.

(iii) Effect of pressure on melting point: There are two types of solids:

(a) Solids whose volume decreases on melting, *e.g.*, ice, diamond, carborundum, magnesium nitride and quartz.

$$\text{Solid (higher volume)} \rightleftharpoons \text{Liquid (lower volume)}$$

The process of melting is facilitated at high pressure, thus melting point is lowered.

(b) Solids whose volume increases on melting, *e.g.*, Fe, Cu, Ag, Au, etc.

$$\text{Solid (lower volume)} \rightleftharpoons \text{Liquid (higher volume)}$$

In this case the process of melting become difficult at high pressure; thus melting point becomes high.

(c) Solubility of substances: When solid substances are dissolved in water, either heat is evolved (exothermic) or heat is absorbed (endothermic).

$$\text{KCl} + aq. \rightleftharpoons \text{KCl}(aq.) - \text{heat}$$

In such cases, solubility increases with increase in temperature. Consider the case of KOH; when this is dissolved, heat is evolved.

$$\text{KOH} + aq. \rightleftharpoons \text{KOH}(aq.) + \text{heat}$$

In such cases, solubility decreases with increase in temperature.

(d) Solubility of gases in liquids: When a gas dissolves in liquid, there is decrease in volume. Thus, increase of pressure will favour the dissolution of gas in liquid.

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

15. Consider the following reversible reaction at equilibrium:

$$2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g);\ \Delta H = +24.7\ \text{kJ}$$

which one of the following changes in conditions will lead to maximum decomposition of $H_2O(g)$?

(a) Increasing both temperature and pressure
(b) Decreasing temperature and increasing pressure
(c) Increasing temperature and decreasing pressure
(d) Increasing temperature at constant pressure
(e) Increasing pressure at constant temperature

[**Ans.** (c)]

[**Hint:** Reaction is endothermic and $\Delta n > 0$, hence, the formation of product will be favoured by increasing the temperature and decreasing the pressure.]

16. The exothermic formation of ClF_3 is represented by the equation:

$$Cl_2(g) + 3F_2(g) \rightleftharpoons 2ClF_3(g);\ \Delta H = -329\ \text{kJ}$$

Which of the following will increase the quantity of ClF_3 in an equilibrium mixture of Cl_2, F_2 and ClF_3? (AIEEE 2005)

(a) Increasing the temperature
(b) Removing Cl_2
(c) Increasing the volume of the container
(d) Adding F_2

[**Ans.** (d)]

[**Hint:** Equilibrium will shift in forward direction by increasing the concentration of reactant.]

17. Which among the following reactions will be favoured at low pressure?

(a) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$
(b) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$
(c) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$
(d) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

[**Ans.** (c)]

[**Hint:** On lowering the pressure, equilibrium favours the direction of higher volume.]

18. At constant pressure, the addition of argon to:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

will:

(a) shift the equilibrium in forward direction
(b) shift the equilibrium in backward direction
(c) not affect the equilibrium
(d) stop the reaction

[**Ans.** (b)]

[**Hint:** If volume is not constant, the addition of inert gas favours the direction where volume is increasing.]

19. The equilibrium reaction that is not influenced by volume change at constant temperature is: [CET (J&K) 2006]

(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$
(b) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$
(c) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$
(d) $2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$

[**Ans.** (a)]

[**Hint:** When, $\Delta n = 0$, there is no effect of pressure and volume change on the equilibrium.]

20. $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) + \text{Heat}$

What is the effect of the increase of temperature on the equilibrium of the reaction? (KCET 2008)

(a) Equilibrium is unaltered
(b) Reaction rate does not change
(c) Equilibrium is shifted to the left
(d) Equilibrium is shifted to the right

[**Ans.** (c)]

[**Hint:** The given reaction is exothermic, therefore, the equilibrium will shift in backward direction by the increase of temperature.]

9.10 CALCULATION OF DEGREE OF DISSOCIATION FROM DENSITY MEASUREMENTS

Degree of dissociation is defined as the fraction of one molecule dissociated. It is denoted by x or α. Its value is always less than 1. When the value becomes equal to 1, it is said that the substance is completely dissociated.

The degree of dissociation in the case of second type of reactions (reversible) is determined by measuring density of reaction mixture at equilibrium.

Consider the general reversible reaction,

	A	$\rightleftharpoons$	nB
Initial no. of moles	1		0
No. of moles at equilibrium	$(1-x)$		nx

Total number of moles at equilibrium $= (1-x) + nx$
$= 1 + (n-1)x$

Let the initial volume be V litre. Thus, the volume at equilibrium $= [1+(n-1)x]V$.

Let 'd' be the observed vapour density at a particular temperature when degree of dissociation is 'x' and D be the vapour density when there is no dissociation. Again,

$$D \propto \frac{1}{V} \quad \text{... (i)}$$

and
$$d \propto \frac{1}{[1+(n-1)x]V} \quad \text{... (ii)}$$

Dividing eq. (i) by eq. (ii),

$$\frac{D}{d} = 1 + (n-1)x$$

or
$$\frac{D}{d} - 1 = (n-1)x$$

or
$$\frac{D-d}{d} = (n-1)x$$

or
$$x = \frac{D-d}{(n-1)d} \quad \text{... (iii)}$$

$$x = \frac{M-m}{(n-1)m}$$

where, M = initial molecular mass

m = molecular mass at equilibrium.

In the dissociation of PCl_5, NH_4Cl and N_2O_4, the value of $n = 2$.

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$
$$NH_4Cl \rightleftharpoons NH_3 + HCl$$
$$N_2O_4 \rightleftharpoons 2NO_2$$

So,
$$x = \frac{D-d}{(2-1)d} = \frac{D-d}{d}$$

Calculation of Degree of Reaction using Pressure-Temperature Determination

Let us consider the following gaseous reaction:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

Initial pressure and temperature are P_1 and T_1. At equilibrium, pressure and temperature are P_2 and T_2 respectively. The volume of vessel is constant, equal to 'V'.

	$PCl_5(g) \rightleftharpoons$	$PCl_3(g) +$	$Cl_2(g)$	n	V	T	P
$t = 0$	a	0	0	a	V	T_1	P_1
$t_{eq.}$	$a - ax$	ax	ax	$a + ax$	V	T_2	P_2

Initial state $\quad P_1V = aRT_1 \quad$ ... (i)

Equilibrium state $\quad P_2V = (a + ax)RT_2 \quad$ ... (ii)

Dividing equation (i) by eq. (ii), we get

$$\frac{P_1}{P_2} = \frac{T_1}{(1+x)T_2}$$

$$(1+x) = \frac{T_1P_2}{T_2P_1}$$

$$x = \frac{T_1P_2 - T_2P_1}{T_2P_1}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

21. At equilibrium:

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

the observed molecular weight of N_2O_4 is 80 g mol^{-1} at 350 K. The percentage dissociation of $N_2O_4(g)$ at 350 K is:

[PMT (Kerala) [illegible]]

(a) 10% (b) 15% (c) 20% (d) 18%
(e) 13%

[Ans. (b)]

[Hint: Degree of dissociation may be calculated as,

$$x = \frac{M-m}{(n-1)m} \quad \because n = 2 \text{ (number of gas moles produced by 1 mol reactant)}$$

$$= \frac{92-80}{(2-1)80} \quad (M = 92, m = 80)$$

$$= \frac{12}{80} = 0.15$$

Percentage dissociation $= 0.15 \times 100 = 15$]

22. The vapour density of PCl_5 is 104.25 but when heated to 230°C, its vapour density is reduced to 62. The degree of dissociation of PCl_5 at this temperature will be:

(a) 6.8% (b) 68% (c) 46% (d) 64%

[Ans. (b)]

[Hint: The reaction is:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$
$$n = 2$$

$$\alpha = \frac{D-d}{(n-1)d} = \frac{104.25-62}{(2-1)\times 62}$$

$$= 0.68$$

Percentage dissociation $= 0.68 \times 100 = 68\%$]

MISCELLANEOUS NUMERICAL EXAMPLES

Example 1. *At a certain temperature, equilibrium constant (K_c) is 16 for the reaction:*

$$SO_2(g) + NO_2(g) \rightleftharpoons SO_3(g) + NO(g)$$

If we take one mole of each of the four gases in one litre container, what would be the equilibrium concentration of NO and NO_2?

Solution:	$SO_2(g)$ +	$NO_2(g) \rightleftharpoons$	$SO_3(g)$ +	$NO(g)$
Initial concentration	1	1	1	1
Equilibrium concentration	$1-x$	$1-x$	$1+x$	$1+x$

Applying law of mass action,

$$K_c = \frac{[SO_3][NO]}{[SO_2][NO_2]} = \frac{(1+x)(1+x)}{(1-x)(1-x)} = 16$$

$$\frac{1+x}{1-x} = 4 \text{ or } 1+x = 4-4x$$

or $$5x = 3, \textit{i.e.}, x = \frac{3}{5} = 0.6$$

Conc. of NO_2 at equilibrium $= (1-0.6) = 0.4$ mole

Conc. of NO at equilibrium $= (1+0.6) = 1.6$ mole

Example 2. *At 817°C, K_p for the reaction between $CO_2(g)$ and excess of hot graphite (s) is 10 atm.*

(*a*) *What are the equilibrium concentrations of the gases at 817°C and a total pressure of 5 atm?*

(*b*) *At what total pressure does the gas contain 5% CO_2 by volume?* (IIT 2000)

Solution: (a) $CO_2(g) + C(s) \rightleftharpoons 2CO(g); K_p = 10$ atm

Given: $p_{CO(g)} + p_{CO_2(g)} = 5$ atm

Let $p_{CO(g)} = x$ atm

So, $p_{CO_2(g)} = (5-x)$ atm

$$K_p = \frac{[p_{CO}]^2}{p_{CO_2}} = \frac{x^2}{(5-x)}$$

or $$10 = \frac{x^2}{(5-x)}$$

or $$x^2 + 10x - 50 = 0$$

On solving, we get

$$x = 3.66$$

$$p_{CO(g)} = 3.66 \text{ atm}$$

or Mole fraction CO at equilibrium = 73.2% (by volume)

$$p_{CO_2(g)} = 1.34 \text{ atm}$$

or Mole fraction CO_2 at equilibrium = 26.8% (by volume)

(b) Let the total pressure be P atm

Given, % CO_2 (by volume) = 5 and % CO (by volume) = 95

$$p_{CO_2} = \frac{5}{100} \times P = 0.05P \text{ and } p_{CO} = \frac{95}{100} \times P = 0.95P$$

$$K_p = 10 = \frac{[p_{CO}]^2}{p_{CO_2}} = \frac{0.95P \times 0.95P}{0.05P} = 18.05P$$

or $$P = 0.554 \text{ atm}$$

Example 3. *At 700 K, CO_2 and H_2 react to form CO and H_2O. For this process K_c is 0.11. If a mixture of 0.45 mole of CO_2 and 0.45 mole of H_2 is heated to 700 K.*

(*i*) *Find out the amount of each gas at equilibrium state.*

(*ii*) *After equilibrium is reached another 0.34 mole of CO_2 and 0.34 mole of H_2 are added to the reaction mixture. Find the composition of the mixture at the new equilibrium state.*

Solution: (i)	$CO_2(g)$ +	$H_2(g) \rightleftharpoons$	$CO(g)$ +	$H_2O(g)$
Initial no. of moles	0.45	0.45	0	0
of moles at equilibrium	$0.45-x$	$0.45-x$	x	x

Applying law of mass action,

$$K_c = \frac{[CO][H_2O]}{[CO_2][H_2]} = \frac{x \times x}{(0.45-x)(0.45-x)} = \frac{x^2}{(0.45-x)^2} = 0.11$$

So, $$\frac{x}{(0.45-x)} = 0.33$$

$$x = 0.11$$

At equilibrium, $[CO_2] = [H_2] = 0.34$ mole

$[CO] = [H_2O] = 0.11$ mole

(ii)	CO_2 +	$H_2 \rightleftharpoons$	CO +	H_2O
Initial moles	$0.34 + 0.34$ $= 0.68$	$0.34 + 0.34$ $= 0.68$	0.11	0.11
At equilibrium	$0.68-y$	$0.68-y$	$0.11+y$	$0.11+y$

$$K_c = \frac{[CO][H_2O]}{[CO_2][H_2]} = \frac{(0.11+y)(0.11+y)}{(0.68-y)(0.68-y)} = 0.11$$

or $$\frac{0.11+y}{0.68-y} = 0.33$$

or $$0.11 + y = 0.33 \times 0.68 - 0.33y$$

or $$y = 0.086$$

At equilibrium, $[CO] = [H_2O] = 0.11 + 0.086 = 0.196$ mole

$[CO_2] = [H_2] = 0.68 - 0.086 = 0.594$ mole

Example 4. *A mixture of SO_3, SO_2 and O_2 gases is maintained in a 10 litre flask at a temperature at which the equilibrium constant for the reaction is 100:*

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

(*i*) *If the number of moles of SO_2 and SO_3 in the flask are equal, how many moles of O_2 are present?*

(*ii*) *If the number of moles of SO_3 in the flask is twice the number of moles of SO_2, how many moles of oxygen are present?*

Solution: (i) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$

At equilibrium, let the number of moles of each of SO_2 and SO_3 be n_1 and of oxygen n_2, *i.e.*,

$$[SO_2] = \frac{n_1}{10}$$

$$[O_2] = \frac{n_2}{10}$$

$$[SO_3] = \frac{n_1}{10}$$

Applying law of mass action,

$$K_c = \frac{[SO_3]^2}{[SO_2]^2[O_2]} = \frac{\left(\frac{n_1}{10}\right)^2}{\left(\frac{n_1}{10}\right)^2\left(\frac{n_2}{10}\right)} = 100$$

or $$n_2 = 0.1 \text{ mole}$$

Oxygen = 0.1 mole

(ii) Let the number of moles of SO_2 be $= n_1$

So, number of moles of $SO_3 = 2n_1$

Let the number of moles of oxygen be $= n_2$

$$K_c = \frac{\left(\frac{2n_1}{10}\right)^2}{\left(\frac{n_1}{10}\right)^2\left(\frac{n_2}{10}\right)} \text{ or } 100 = \frac{40}{n_2}$$

$$n_2 = 0.4 \text{ mole}$$

Oxygen = 0.4 mole

Example 5. *At 250°C and 1 atmospheric pressure, the vapour density of PCl_5 is 57.9. Calculate (i) K_p for the reaction,*

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g),$$

at 250°C, (ii) the percentage dissociation when pressure is doubled.

Solution: (i) Mol. mass of $PCl_5 = 208.5$

$$\text{Vapour density, } D = \frac{208.5}{2} = 104.25$$

Observed vapour density, $d = 57.9$

$$\text{Degree of dissociation, } \alpha = \frac{D-d}{d} = \frac{104.25 - 57.9}{57.9}$$

$$= 0.80$$

	$PCl_5(g) \rightleftharpoons$	$PCl_3(g) +$	$Cl_2(g)$
At equilibrium	$1-\alpha$	α	α
	$(1-0.80)$	0.80	0.80

Total number of moles $= (1+\alpha) = (1+0.80) = 1.80$

$$\text{Partial pressure of } PCl_5 = \frac{0.2}{1.80} \times 1 = \frac{1}{9}$$

$$\text{Partial pressure of } PCl_3 = \frac{0.80}{1.80} \times 1 = \frac{4}{9}$$

$$\text{Partial pressure of } Cl_2 = \frac{0.80}{1.80} \times 1 = \frac{4}{9}$$

So, $$K_p = \frac{p_{PCl_3} \times p_{Cl_2}}{p_{PCl_5}} = \frac{4/9 \times 4/9}{1/9} = \frac{16}{9} = 1.78$$

(ii) Let the degree of dissociation be α when pressure is 2 atmospheres.

At equilibrium

$$p_{PCl_5} = \frac{(1-\alpha)}{(1+\alpha)} \cdot P = \frac{(1-\alpha)}{(1+\alpha)} \times 2$$

$$p_{PCl_3} = \frac{\alpha}{(1+\alpha)} \cdot P = \frac{\alpha}{(1+\alpha)} \times 2$$

$$p_{Cl_2} = \frac{\alpha}{(1+\alpha)} \cdot P = \frac{\alpha}{(1+\alpha)} \times 2$$

$$K_p = \frac{\frac{\alpha}{(1+\alpha)} \times 2 \times \frac{\alpha}{(1+\alpha)} \times 2}{\frac{(1-\alpha)}{(1+\alpha)} \times 2} = \frac{\alpha^2}{(1-\alpha^2)} \times 2 = 1.78$$

or $$\frac{\alpha^2}{(1-\alpha^2)} = 0.89$$

or $$\alpha^2 = 0.89 - 0.89\alpha^2$$

or $$1.89\alpha^2 = 0.89$$

$$\alpha^2 = \frac{0.89}{1.89}$$

$$\alpha = 0.686$$

Thus, PCl_5 is 68.6% dissociated.

Example 6. *For the reaction,*

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

hydrogen gas is introduced into a five litre flask at 327°C, containing 0.2 mole of $CO(g)$ and a catalyst, until the pressure is 4.92 atmosphere. At this point 0.1 mole of $CH_3OH(g)$ is formed. Calculate the equilibrium constants K_p and K_c. (IIT 1993)

Solution: Let the number of moles of hydrogen introduced be m moles.

Total moles of CO and hydrogen $= 0.2 + m$

Applying, $PV = nRT$

$$P = 4.92 \text{ atm}, \ V = 5 \text{ litre}, \ R = 0.082,$$

$$T = (273 + 327) = 600 \text{ K}$$

$$4.92 \times 5 = 0.082 \times 600 \times (0.2 + m)$$

or $$0.2 + m = \frac{4.92 \times 5}{0.082 \times 600}$$

or $$m = 0.3 \text{ mole}$$

	$CO(g) +$	$2H_2(g) \rightleftharpoons$	$CH_3OH(g)$	
	$0.2-x$	$0.3-2x$	x	(No. of moles
or	$0.2-0.1$	$0.3-0.2$	0.1	at equilibrium)
or	0.1	0.1	0.1	
	$\frac{0.1}{5}$	$\frac{0.1}{5}$	$\frac{0.1}{5}$	(Active masses)

Applying law of mass action,

$$K_c = \frac{[CH_3OH]}{[CO][H_2]^2} = \frac{\frac{0.1}{5}}{\frac{0.1}{5} \times \left(\frac{0.1}{5}\right)^2} = 2500 \text{ mol}^{-2} \text{ L}^2$$

We know that, $K_p = K_c(RT)^{\Delta n}, \Delta n = -2$

or $K_p = 2500(0.082 \times 600)^{-2}$

or $$K_p = \frac{2500}{49.2 \times 49.2} = 1.0327 \text{ atm}^{-2}$$

Example 7. *When sulphur in the form of S_8 is heated at 900 K the initial pressure of 1 atm falls by 29% at equilibrium. This is because of conversion of some S_8 to S_2. Find the value of equilibrium constant for this reaction.*

Solution: $S_8(g) \rightleftharpoons 4S_2(g)$

	$S_8(g)$	$4S_2(g)$
Initial mole	1	0
At equilibrium	$1-x$	$4x$
	$(1-0.29)$ $= 0.71$	(4×0.29) $= 1.16$

Applying law of mass action,

$$K_p = \frac{[p_{S_2}]^4}{[p_{S_8}]} = \frac{(1.16)^4}{0.71} = 2.5582 \text{ atm}^3$$

Example 8. *For the equilibrium,*

$$AB(g) \rightleftharpoons A(g) + B(g),$$

K_p is equal to four times the total pressure. Calculate the number of moles of A formed.

Solution: Let the total equilibrium pressure be = P atm

Given, $K_p = 4P$

Let the start be made with 1 mole of $AB(g)$ and the degree of dissociation be x.

	$AB(g) \rightleftharpoons$	$A(g) +$	$B(g)$
At equilibrium	$1-x$	x	x

Total moles at equilibrium $= 1 - x + x + x = 1 + x$

Thus, p_A = Partial pressure of $A = \frac{x}{1+x} \cdot P$

p_B = Partial pressure of $B = \frac{x}{1+x} \cdot P$

p_{AB} = Partial pressure of $AB = \frac{1-x}{1+x} \cdot P$

Applying the law of mass action,

$$K_p = \frac{p_A \times p_B}{p_{AB}} = \frac{\left(\frac{x}{1+x} \cdot P\right)\left(\frac{x}{1+x} \cdot P\right)}{\left(\frac{1-x}{1+x} \cdot P\right)}$$

So, $$4P = \frac{x^2}{1-x^2} \cdot P$$

or $4 - 4x^2 = x^2$

or $5x^2 = 4$

or $$x = \frac{2}{\sqrt{5}}$$

Hence, number of moles of A formed $= \frac{2}{\sqrt{5}}$ times initial moles of AB taken

Example 9. *0.15 mole of CO taken in a 2.5 litre flask is maintained at 705 K along with a catalyst so that the following reaction can take place:*

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$$

Hydrogen is introduced until the total pressure of the system is 8.5 atm at equilibrium and 0.08 mole of methanol is formed. Calculate (i) K_p and K_c and (ii) the final pressure if the same amount of CO and H_2 as before are used, but with no catalyst so that the reaction does not take place. (IIT 1993)

Solution: (i) Let the total number of moles of gases be n at equilibrium.

Applying equation, $PV = nRT$

Given, $P = 8.5$ atm; $V = 2.5$ L;

$R = 0.0821$ atm L mol^{-1} K^{-1} and $T = 705$ K

$$n = \frac{8.5 \times 2.5}{0.0821 \times 705} = 0.367 \text{ mol}$$

	$CO(g) +$	$2H_2(g) \rightleftharpoons$	$CH_3OH(g)$
Initial mole	0.15	$(nH_2)_0$	0
At equilibrium	$0.15 - x$	$[(nH_2)_0 - 2x]$	$x = 0.08$

Number of moles of CO at equilibrium

$= (0.15 - 0.08) = 0.07$ mole

Number of moles of H_2 at equilibrium

= total moles − moles of CO − moles of CH_3OH

$= (0.367 - 0.07 - 0.08)$

$= 0.217$ mole

Applying law of mass action,

$$K_c = \frac{[CH_3OH]}{[CO][H_2]^2} = \frac{\frac{0.08}{2.5}}{\frac{0.07}{2.5} \times \left(\frac{0.217}{2.5}\right)^2} = 151.6 \text{ mol}^{-2} \text{ L}^2$$

Now, $K_p = K_c(RT)^{\Delta n} = 151.6 \times (0.0821 \times 705)^{-2}$

$= 0.045 \text{ atm}^{-2}$

(ii) Since, $[(n_{H_2})_0 - 2x] = 0.217$

or $(n_{H_2})_0 = 0.217 + 2 \times 0.08$

$= 0.377$ mole

$(n_{CO})_0 = 0.15$

Total moles $(n_0) = 0.377 + 0.15 = 0.527$

Hence, $$p_0 = \frac{n_0RT}{V} = \frac{0.527 \times 0.0821 \times 705}{2.5}$$

$= 12.20$ atm

Example 10. *The equilibrium constant for the reaction,*

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g),$$

at 986°C is 0.63. A mixture of 1.0 mole of water vapour and 3.0 mole of CO is allowed to come to equilibrium. The equilibrium pressure is 2.0 atm.

(*i*) *How many moles of H_2 are present at equilibrium?*

(*ii*) *Calculate the partial pressures of gases in equilibrium mixture.* (IIT 1992)

Solution: (i) In the given reaction, $\Delta n = 0$, hence, $K_c = K_p$

$$\begin{array}{lcccc} & \text{CO}(g) + & \text{H}_2\text{O}(g) \rightleftharpoons & \text{CO}_2(g) + & \text{H}_2(g) \\ \text{At equilibrium} & (3-x) & (1-x) & x & x \end{array}$$

Applying law of mass action,

$$\frac{x \times x}{(3-x)(1-x)} = 0.63$$

$$x^2 = 0.63(3 - 4x + x^2)$$

$$0.37x^2 + 2.52x - 1.89 = 0$$

or $$x^2 + 6.81x - 5.1 = 0$$

$$x = \frac{-6.81 \pm [6.81 \times 6.81 - 4 \times (-5.1)]^{1/2}}{2} = 0.68 \text{ mole} = \text{H}_2$$

(ii) Partial pressure of CO_2 = partial pressure of H_2

$$= \text{mole fraction} \times \text{total pressure}$$

$$= \frac{0.68}{4} \times 2 = 0.34 \text{ atm}$$

$$\text{Partial pressure of CO}(g) = \frac{(3-0.68)}{4} \times 2 = 1.16 \text{ atm}$$

$$\text{Partial pressure of H}_2\text{O}(g) = \frac{(1-0.68)}{4} \times 2 = 0.16 \text{ atm}$$

Example 11. *The equilibrium constant K_p for the reaction,*

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

is 900 atm^{-1} at 800 K. A mixture containing SO_3 and O_2 having initial partial pressure of 1 and 2 atm respectively is heated at constant volume to equilibrate. Calculate the partial pressure of each gas at 800 K.

Solution: The system in the initial stage does not contain SO_2. SO_3 will, thus, decompose to form SO_2 and O_2 until equilibrium is reached. The partial pressure of SO_3 will decrease. Let the decrease in partial pressure be $2x$.

$$\begin{array}{lccc} & 2\text{SO}_2(g) + & \text{O}_2(g) \rightleftharpoons & 2\text{SO}_3(g) \\ \text{At equilibrium} & (2x) & (2+x) & (1-2x) \end{array}$$

Applying law of mass action,

$$K_p = \frac{(1-2x)^2}{(2x)^2(2+x)} \qquad (2+x) \to 2$$

$$900 = \frac{(1-2x)^2}{8x^2}$$

or $$\frac{1-2x}{x} = 84.85$$

or $$x = 0.0115 \text{ atm}$$

Thus, the partial pressures at equilibrium are:

$$p_{\text{SO}_2} = 2 \times 0.0115 = 0.023 \text{ atm}$$

$$p_{\text{O}_2} = 2 + 0.0115 = 2.0115 \text{ atm}$$

$$p_{\text{SO}_3} = 1 - 2 \times 0.0115 = 0.977 \text{ atm}$$

Example 12. *What is the concentration of CO in equilibrium at 25°C in a sample of a gas originally containing 1.00 mol L^{-1} of CO_2? For the dissociation of CO_2 at 25°C, $K_c = 2.96 \times 10^{-92}$.*

Solution:
$$\begin{array}{lccc} & 2\text{CO}_2(g) \rightleftharpoons & 2\text{CO}(g) + & \text{O}_2(g) \\ \text{At equilibrium} & (1-2x) & (2x) & (x) \end{array}$$

Applying law of mass action,

$$K_c = \frac{[\text{O}_2][\text{CO}]^2}{[\text{CO}_2]^2} = \frac{x \times (2x)^2}{(1-2x)^2} = 2.96 \times 10^{-92}$$

It can be assumed that $1 - 2x \approx 1.0$ as K_c is very small.

So, $$4x^3 = 2.96 \times 10^{-92}$$

or $$x = 1.95 \times 10^{-31} \text{ mol L}^{-1}$$

$$[\text{CO}] = 2x = 2 \times 1.95 \times 10^{-31}$$

$$= 3.90 \times 10^{-31} \text{ mol L}^{-1}$$

Example 13. *Ammonia is heated at 15 atm from 27°C to 347°C assuming volume constant. The new pressure becomes 50 atm at equilibrium. Calculate % of NH_3 actually decomposed.* (MLNR 1995)

Solution: Pressure of NH_3 at 27°C = 15 atm

Pressure of NH_3 at 347° C = P atm

$$\frac{P}{620} = \frac{15}{300}$$

$$P = 31 \text{ atm}$$

Let a moles of ammonia be present. Total pressure at equilibrium = 50 atm

$$\begin{array}{lccc} & 2\text{NH}_3(g) \rightleftharpoons & \text{N}_2(g) + & 3\text{H}_2(g) \\ \text{At equilibrium} & (a-2x) & x & 3x \\ \text{Total moles} & \multicolumn{3}{l}{a - 2x + x + 3x = a + 2x} \end{array}$$

$$\frac{\text{Initial number of moles}}{\text{Moles at equilibrium}} = \frac{\text{Initial pressure}}{\text{Equilibrium pressure}}$$

$$\frac{a}{(a+2x)} = \frac{31}{50}$$

$$x = \frac{19}{62}a$$

$$\text{Amount of ammonia decomposed} = 2x = 2 \times \frac{19}{62}a = \frac{19}{31}a$$

$$\%\text{ of ammonia decomposed} = \frac{19 \times a}{31 \times a} \times 100$$

$$= 61.3$$

Example 14. *Calculate the per cent dissociation of $H_2S(g)$ if 0.1 mole of H_2S is kept in 0.4 litre vessel at 1000 K for the reaction,*

$$2H_2S(g) \rightleftharpoons 2H_2(g) + S_2(g)$$

The value of K_c is 1.0×10^{-6}.

Solution: $2H_2S(g) \rightleftharpoons 2H_2(g) + S_2(g)$

$$\begin{array}{llll} \text{At equilibrium} & (0.1-x) & x & x/2 \\ \text{Molar conc.} & \dfrac{(0.1-x)}{0.4} & \dfrac{x}{0.4} & \dfrac{x}{0.8} \end{array}$$

$$K_c = \frac{[H_2]^2[S_2]}{[H_2S]^2} = \frac{\left(\frac{x}{0.4}\right)^2\left(\frac{x}{0.8}\right)}{\left(\frac{0.1-x}{0.4}\right)^2} = 1.0 \times 10^{-6}$$

or $$\frac{x^3}{0.8(0.1-x)^2} = 1.0 \times 10^{-6}$$

as x is very small; $0.1 - x \rightarrow 0.1$

$$\frac{x^3}{0.8 \times (0.1)^2} = 1.0 \times 10^{-6}$$

$$x^3 = 8 \times 10^{-9}$$

or $$x = 2 \times 10^{-3}$$

So, per cent dissociation $= \dfrac{2 \times 10^{-3}}{0.1} \times 100 = 2.0$

Example 15. *The vapour density (hydrogen = 1) of a mixture containing NO_2 and N_2O_4 is 38.3 at 26.7° C. Calculate the number of moles of NO_2 in 100 grams of the mixture.* (MLNR 1993)

Solution: $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

$$\begin{array}{lll} \text{At equilibrium} & (1-x) & 2x \end{array}$$

$$x \text{ (degree of dissociation)} = \frac{D-d}{(n-1)d}$$

Given, $d = 38.3$, $D = \dfrac{\text{Mol. mass of } N_2O_4}{2} = \dfrac{92}{2} = 46$, $n = 2$

So, $$x = \frac{46 - 38.3}{38.3} = 0.2$$

At equilibrium, amount of $N_2O_4 = 1 - 0.2 = 0.8$ mol

and amount of $NO_2 = 2 \times 0.2 = 0.4$ mol

Mass of the mixture $= 0.8 \times 92 + 0.4 \times 46$

$= 73.6 + 18.4 = 92.0$ g

Since, 92 gram of the mixture contains = 0.4 mol NO_2

So,

100 gram of the mixture contains $= \dfrac{0.4 \times 100}{92} = 0.43$ mol NO_2

Example 16. *At temperature T, the compound $AB_2(g)$ dissociates according to the reaction,*

$$2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$$

with a degree of dissociation, x, which is small compared with unity. Deduce the expression for x in terms of the equilibrium constant, K_p and the total pressure, P. (IIT 1994)

Solution: $2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$

$$\begin{array}{llll} \text{At equilibrium} & (1-x) & x & x/2 \end{array}$$

Total moles at equilibrium $= 1 - x + x + x/2$

$$= \frac{2+x}{2}$$

$$p_{AB_2} = \frac{2(1-x)}{(2+x)} \cdot P;\ p_{AB} = \frac{2x}{(2+x)} \cdot P;\ p_{B_2} = \frac{x}{(2+x)} \cdot P;$$

$$K_p = \frac{(p_{AB})^2(p_{B_2})}{(p_{AB_2})^2} = \frac{\left[\frac{2x}{(2+x)}P\right]^2\left(\frac{x}{2+x}\right)P}{\left(\frac{2(1-x)}{(2+x)}P\right)^2}$$

$$= \frac{x^3P}{(2+x)(1-x)^2}$$

As x is very small, $(2+x) \rightarrow 2$ and $(1-x) \rightarrow 1$.

So, $$K_p = \frac{x^3P}{2}$$

or $$x^3 = \frac{2K_p}{P}$$

or $$x = \left(\frac{2K_p}{P}\right)^{1/3}$$

Example 17. *At 25°C and one atmospheric pressure, the partial pressures in an equilibrium mixture of N_2O_4 and NO_2 are 0.7 and 0.3 atmosphere, respectively. Calculate the partial pressures of these gases when they are in equilibrium at 25°C and at a total pressure of 10 atmospheres.* (MLNR 1990)

Solution: $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

$$\begin{array}{lll} \text{At equilibrium} & 0.7 & 0.3 \text{ atm} \end{array}$$

$$K_p = \frac{(p_{NO_2})^2}{p_{N_2O_4}} = \frac{0.3 \times 0.3}{0.7} = 0.1285 \text{ atm}$$

Let the degree of dissociation of N_2O_4 be x when total pressure is 10 atmosphere.

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

$$\begin{array}{lll} \text{At equilibrium} & (1-x) & 2x \end{array}$$

Total number of moles $= 1 - x + 2x = 1 + x$

$$p_{N_2O_4} = \frac{(1-x)}{(1+x)} \times 10;\ p_{NO_2} = \frac{2x}{(1+x)} \times 10$$

$$K_p = 0.1285 = \frac{\left(\frac{2x}{1+x}\right)^2 \times 10^2}{\left(\frac{1-x}{1+x}\right) \times 10} = \frac{40x^2}{1-x^2}$$

Since, x is very small, $(1-x^2) \rightarrow 1$

So, $$x^2 = \frac{0.1285}{40}$$

or $$x = 0.0566$$

$$p_{N_2O_4} = \frac{(1-x)}{(1+x)} \times 10 = \frac{1-0.0566}{1+0.0566} \times 10 = \frac{0.9436\times 10}{1.0566} = 8.93 \text{ atm}$$

$$p_{NO_2} = \frac{2x}{(1+x)} \times 10 = \frac{2\times 0.0566}{1+0.0566} \times 10 = \frac{0.1132}{1.0566} \times 10 = 1.07 \text{ atm}$$

Example 18. *At 450°C, the equilibrium constant, K_p, for the reaction,*

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

was found to be 1.6×10^{-5} at a pressure of 200 atm. If N_2 and H_2 are taken in 1 : 3 ratio what is % of NH_3 formed at this temperature?

Solution: $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

At equilibrium $(1-x)$ $(3-3x)$ $2x$

Total number of moles $= 1 - x + 3 - 3x + 2x = 4 - 2x$

$$p_{N_2} = \frac{(1-x)}{(4-2x)}P;\ p_{H_2} = \frac{(3-3x)}{(4-2x)}P;\ p_{NH_3} = \frac{2x}{(4-2x)}P$$

$$K_p = \frac{(p_{NH_3})^2}{p_{N_2}\times(p_{H_2})^3} = \frac{\left(\frac{2x}{4-2x}P\right)^2}{\left(\frac{1-x}{4-2x}P\right)\left(\frac{3-3x}{4-2x}P\right)^3}$$

$$= \frac{4x^2(4-2x)^2}{(1-x)\times 27\times(1-x)^3P^2}$$

$$1.6\times 10^{-5} = \frac{16}{27}\times\frac{x^2(2-x)^2}{(1-x)^4\times(200)^2}$$

or $$\frac{x^2(2-x)^2}{(1-x)^4} = \frac{1.6\times 10^{-5}\times 27\times(200)^2}{16}$$

$$= \frac{16\times 10^{-6}\times 27\times(200)^2}{16}$$

or $$\frac{x(2-x)}{(1-x)^2} = 200\times 10^{-3}\times\sqrt{27} = 1.039$$

or $x = 0.30$

Moles of ammonia formed $= 2\times 0.30 = 0.60$

Total moles at equilibrium $= (4-2x) = (4 - 2\times 0.30) = 3.40$

$$\% \text{ of } NH_3 \text{ at equilibrium} = \frac{0.60}{3.40}\times 100 = 17.64$$

Example 19. *A mixture of SO_2 and O_2 at 1 atmosphere in the ratio of 2 : 1 is passed through a catalyst at 1170°C for attainment of equilibrium. The exit gas is found to contain 87% SO_3 by volume. Calculate K_p for the reaction,*

$$SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$$

Solution: The volume of SO_2 and O_2 at equilibrium

$= (100 - 87) = 13$ mL

$$\text{Volume of } SO_2 = \frac{2}{3}\times 13 = 8.67 \text{ mL}$$

$$\text{Volume of oxygen} = \frac{1}{3}\times 13 = 4.33 \text{ mL}$$

$$p_{SO_3} = \frac{87}{100}\times 1 = 0.87 \text{ atm}$$

$$p_{SO_2} = \frac{8.67}{100}\times 1 = 0.0867 \text{ atm}$$

$$p_{O_2} = \frac{4.33}{100}\times 1 = 0.0433 \text{ atm}$$

$$K_p = \frac{p_{SO_3}}{p_{SO_2}\times(p_{O_2})^{1/2}} = \frac{0.87}{(0.0867)\times(0.0433)^{1/2}}$$

$$= \frac{0.87}{(0.0867)\times 0.208}$$

$$= 48.24 \text{ atm}^{-1/2}$$

Example 20. *N_2O_4 dissociates as.*

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

at 55°C and one atmosphere % decomposition of N_2O_4 is 50.3%. At what pressure and same temperature, the equilibrium mixture has the ratio of $N_2O_4 : NO_2$ as 1 : 8?

Solution:

Case I: $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

At equilibrium $(1-x)$ $2x$

$$p_{N_2O_4} = \frac{(1-x)}{(1+x)}\times P;\ p_{NO_2} = \frac{2x}{(1+x)}\times P$$

$$K_p = \frac{\left(\frac{2x}{1+x}\cdot P\right)^2}{\left(\frac{1-x}{1+x}\cdot P\right)} = \frac{4x^2P}{(1-x^2)}$$

Given, $x = 0.503$ and $P = 1$

$K_p = 1.3548$ atm

Case II: $N_2O_4 \rightleftharpoons 2NO_2$

$(1-x)$ $2x$

Given, $$\frac{(1-x)}{2x} = \frac{1}{8}$$

$x = 0.8$

Let the new pressure be P atm.

$$K_p = \frac{4x^2P}{(1-x^2)} = \frac{4\times 0.8\times 0.8\times P}{(1+0.8)(1-0.8)} = 1.3548$$

$P = 0.19$ atm

Example 21. *At 627°C and one atmosphere SO_3 is partially dissociated into SO_2 and O_2 by the reaction,*

$$SO_3(g) \rightleftharpoons SO_2(g) + 1/2O_2(g).$$

The density of the equilibrium mixture is $0.925\ g\ L^{-1}$. What is the degree of dissociation?

Solution: Let the molecular mass of the mixture at equilibrium be M_{mix}.

Applying the relation,

$$M_{mix} = \frac{dRT}{P} = \frac{0.925\times 0.0821\times 900}{1}$$

$$= 68.348$$

$$\text{Molecular mass of } SO_3 = 80$$

$$\text{Vapour density of } SO_3, D = \frac{80}{2} = 40$$

$$\text{Vapour density of mixture, } d = \frac{68.348}{2} = 34.174$$

Let the degree of dissociation be x.

$$x = \frac{D-d}{(n-1)d} = \frac{40 - 34.174}{\left(\frac{3}{2} - 1\right) \times 34.174} = \frac{5.826 \times 2}{34.174} = 0.34$$

or $\quad x = 34\%$ dissociated

i.e., SO_3 is 34% dissociated.

Example 22. *Density of equilibrium mixture of N_2O_4 and NO_2 at 1 atm and 384 K is 1.84 g dm^{-3}. Calculate the equilibrium constant of the reaction.*

$$N_2O_4 \rightleftharpoons 2NO_2$$

Solution: We know that,

$$Pm = dRT$$

$$1 \times m = 1.84 \times 0.0821 \times 384$$

$$m = 29 \times 2$$

Vapour density (d) at equilibrium = 29

Initial vapour density $= M/2 = 92/2 = 46$

$$x = \frac{D-d}{(n-1)\,d} = \frac{46-29}{29} = 0.586$$

	$N_2O_4 \rightleftharpoons$	$2NO_2$	
$t = 0$	1	0	
$t_{eq.}$	$1-x$	$2x$	(Total moles = $1 + x$)

$$p_{N_2O_4} = \frac{1-x}{1+x} \times P; \; p_{NO_2} = \frac{2x}{1+x} \times P$$

$$K_p = \frac{4x^2P}{1-x^2} = \frac{4 \times (0.586)^2 \times 1}{1-(0.586)^2} = 2.09 \text{ atm}$$

Example 23. *For the reaction,*

$$NH_3(g) \rightleftharpoons \frac{1}{2}N_2(g) + \frac{3}{2}H_2(g)$$

show that degree of dissociation of NH_3 is given as:

$$\alpha = \left[1 + \frac{3\sqrt{3}}{4}\frac{p}{K_p}\right]^{-1/2}$$

where, 'p' is equilibrium pressure. If K_p of the above reaction is 78.1 atm at 400°C, calculate K_c.

Solution:

	$NH_3(g) \rightleftharpoons$	$\frac{1}{2}N_2$ +	$\frac{3}{2}H_2(g)$	Total moles
$t = 0$	1	0	0	1
$t_{eq.}$	$1-\alpha$	$\alpha/2$	$3\alpha/2$	$1+\alpha$
p_i	$\left(\frac{1-\alpha}{1+\alpha}\right)p$	$\left(\frac{\alpha}{2(1+\alpha)}\right)p$	$\left(\frac{3\alpha}{2(1+\alpha)}\right)p$	($P_i \rightarrow$ partial pressure)

$$K_p = \frac{[N_2]^{1/2}[H_2]^{3/2}}{[NH_3]}$$

$$= \frac{\left[\frac{\alpha}{2(1+\alpha)}p\right]^{1/2}\left[\frac{3\alpha}{2(1+\alpha)}p\right]^{3/2}}{\left[\frac{1-\alpha}{1+\alpha}p\right]} = \frac{p\alpha^2\sqrt{27}}{4(1-\alpha^2)}$$

$$\text{Solving for } \alpha \text{, we get } \quad \alpha = \left[1 + \frac{3\sqrt{3}}{4}\frac{p}{K_p}\right]^{-1/2}$$

K_c can be calculated by using $K_p = K_c(RT)^{\Delta n}$

$K_p = 78.1; T = 673\text{K}; \Delta n = 1$

Example 24. *The equilibrium constant K_p for the reaction,*

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

is 1.64×10^{-4} at 400°C and 0.144×10^{-4} at 500°C. Calculate the mean heat of formation of 1 mole of NH_3 from its elements in this temperature range.

Solution: We know that, $\log \dfrac{K_2}{K_1} = \dfrac{\Delta H}{2.303R}\left(\dfrac{1}{T_1} - \dfrac{1}{T_2}\right)$

$$\log \frac{0.144}{1.64} = \frac{\Delta H}{2.303 \times 1.987 \times 10^{-3}}\left(\frac{1}{673} - \frac{1}{773}\right)$$

$$\Delta H = -25.14 \text{ kcal for 2 mole}$$

$$= -12.57 \text{ kcal mol}^{-1}$$

Example 25. *When limestone is heated, quicklime is formed according to the equation,*

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

The experiment was carried out in the temperature range 800–900°C. Equilibrium constant K_p follows the relation,

$$\log K_p = 7.282 - 8500/T$$

where, T is temperature in Kelvin. At what temperature the decomposition will give $CO_2(g)$ at 1 atm?

Solution: $\quad K_p = p_{CO_2} = 1$

$$\log K_p = 7.282 - \frac{8500}{T}$$

$$\log 1 = 7.282 - \frac{8500}{T}$$

$$T = \frac{8500}{7.282} = 1167.26 \text{ K}$$

$$= 894.26°\text{C}$$

Example 26. *Equilibrium constant for the reaction of iodine with propane according to the following equation was determined.*

Some results obtained at 545 K were as given ahead:

Initial Pressures (mm Hg)			Equilibrium Pressures (mm)	
I_2	**C_3H_6**	**HI**	**HI**	**C_3H_5I**
23.9	505.8	0	1.80	1.80
16.1	355.3	1.62	2.27	0.645

Calculate equilibrium constant according to the following equation,

$$I_2(g)+C_3H_6(g)\rightleftharpoons C_3H_5I(g)+HI(g)$$

Solution: Ist experiment:

$$\begin{array}{lcccccc} & I_2(g) & + & C_3H_6(g) & \rightleftharpoons & C_3H_5I(g) & + \; HI(g) \\ t=0 & 23.9 & & 505.8 & & 0 & 0 \\ t_{eq.} & (23.9-1.8) & & (505.8-1.8) & & 1.80 & 1.80 \end{array}$$

$$K_p=\frac{p_{C_3H_5I}\times p_{HI}}{p_{I_2}\times p_{C_3H_6}}=\frac{1.8\times 1.8}{22.1\times 504}=2.9\times 10^{-4}$$

Similarly, solve for second experiment.

Example 27. *At 817°C K_p for the reaction between CO_2 and excess hot graphite to form $2CO(g)$ is 10.*

(*i*) *What is the analysis (mole fraction) of the gases at equilibrium at 817°C and a total pressure of 4 atm? What is the partial pressure of CO_2 at equilibrium?*

(*ii*) *At what total pressure will the gas mixture have 6% CO_2 by volume?*

Solution: (i) $CO_2(g)+C(s)\rightleftharpoons 2CO(g)$

$$\begin{array}{lcc} t=0 & 1 & 0 \\ t_{eq.} & 1-\alpha & 2\alpha \\ p_{eq.} & \left(\frac{1-\alpha}{1+\alpha}\right)p & \left(\frac{2\alpha}{1+\alpha}\right)p \end{array}$$

$$K_p=\frac{4\alpha^2 p}{1-\alpha^2};\ 10=\frac{4\alpha^2 4}{1-\alpha^2}$$

On solving, we get $\alpha = 0.62$

$$x_{CO_2}=\frac{1-\alpha}{1+\alpha}=\frac{1-0.62}{1+0.62}=0.2345=23.45\%\text{ (by volume)}$$

$$x_{CO}=0.7655=76.55\%\text{ (by volume)}$$

$$p_{CO_2}=(0.2345\times 4.0)\text{ atm}=0.938\text{ atm}$$

(ii) Let the total pressure be P atm.

$$K_p=10=\frac{[p_{CO}]^2}{p_{CO_2}}=\frac{0.94\times P\times 0.94\times P}{0.06\times P}$$

$$P=0.68\text{ atm}$$

Example 28. *Ammonia under a pressure of 20 atm at 127°C is heated to 327°C in a closed vessel. Under these conditions NH_3 is partially decomposed to N_2 and H_2 according to the equation:*

$$2NH_3(g)\rightleftharpoons N_2(g)+3H_2(g)$$

After decomposition at constant volume in a vessel the pressure increases to 45 atm. What is the percentage of ammonia dissociated?

Solution:

$$\begin{array}{lccccccc} 2NH_3(g)\rightleftharpoons & N_2(g) & +\,3H_2(g) & n & P & V & T \\ t=0\quad a & 0 & 0 & a & 20 & V & 400 \\ t_{eq.}\quad a-a\alpha & a\alpha/2 & 3a\alpha/2 & a+a\alpha & 40 & V & 600 \end{array}$$

$$V=\frac{nRT}{P}=\frac{a\times R\times 400}{20} \qquad \text{... (1)}$$

$$V=\frac{nRT}{P}=\frac{a(1+\alpha)\times R\times 600}{45} \qquad \text{... (2)}$$

On dividing, we get $1=\dfrac{400\times 45}{(1+\alpha)20\times 600}$

$$\alpha=0.5$$

Percentage dissociation of $NH_3 = 50$

Example 29. *When 3.06 g of solid NH_4HS is introduced into a two litre evacuated flask at 27°C, 30% of the solid decomposes into gaseous ammonia and hydrogen sulphide. (i) Calculate K_c and K_p for the reaction at 27°C. (ii) What would happen to the equilibrium when more solid NH_4HS is introduced into the flask?* (IIT 1999)

Solution: $NH_4HS(s)\rightleftharpoons NH_3(g)+H_2S(g)$

$$\text{Moles of }NH_4HS=\frac{3.06}{51}=0.06$$

Degree of dissociation = 0.3

At equilibrium,

$$[NH_3(g)]=\frac{0.3\times 0.06}{2};\quad [H_2S(g)]=\frac{0.3}{2}\times 0.06$$

$$K_c=[NH_3(g)][H_2S(g)]=\frac{0.3\times 0.06\times 0.3\times 0.06}{2\times 2}$$

$$=8.1\times 10^{-5}$$

Now applying,

$$K_p=K_c(RT)^{\Delta n}=8.1\times 10^{-5}\times(0.082\times 300)^2$$

$$=0.049$$

Since, NH_4HS is solid, so it causes no change in equilibrium.

Example 30. *At 540 K, 0.10 mole of PCl_5 are heated in a 8 litre flask. The pressure of equilibrium mixture is found to be 1.0 atm. Calculate K_p and K_c for the reaction.* (IIT 1998)

Solution: $PCl_5\rightleftharpoons PCl_3+Cl_2$

$$\begin{array}{lccc} \text{At equilibrium (mole)} & (0.1-x) & x & x \end{array}$$

Total number of moles, $n=(0.1-x)+x+x=(0.1+x)$

$$PV=nRT$$

$$1\times 8=(0.1+x)\times 0.082\times 540$$

or $$x=0.08$$

$$K_c=\frac{[PCl_3][Cl_2]}{[PCl_5]}=\frac{x^2}{(0.1-x)\times 8}$$

$$=\frac{0.08\times 0.08}{(0.1-0.08)8}=4\times 10^{-2}\text{ mol L}^{-1}$$

$$K_p=K_c(RT)^{\Delta n}=K_c\,RT\ (\Delta n=+1)$$

$$=4\times 10^{-2}\times 0.082\times 540=1.77\text{ atm}$$

Example 31. *At 817°C, K_p for the reaction between $CO_2(g)$ and excess hot graphite(s) is 10 atm.*

(a) What are the equilibrium concentrations of gases at 817°C and a total pressure of 5 atm?

(b) At what total pressure, the gas contains 5% CO_2 by volume? (IIT 2000)

Solution: (a) $CO_2(g) + C(s) \rightleftharpoons 2CO(g)$

$$\begin{array}{lcc} \text{At equilibrium} & (5-x)\,\text{atm} & x\,\text{atm} \end{array}$$

$$K_p = \frac{[CO]^2}{[CO_2]} = \frac{x^2}{(5-x)}$$

$$10 = \frac{x^2}{5-x}$$

$$x^2 = 50 - 10x$$

$$x^2 + 10x - 50 = 0$$

$$x = \frac{-10 \pm \sqrt{100+200}}{2} = 3.66$$

i.e., $p_{CO} = 3.66$ atm; $p_{CO_2} = 1.34$ atm

$$\text{Concentration of CO} = \frac{p}{RT} = \frac{3.66}{0.0821 \times 1090} = 0.041\ \text{mol litre}^{-1}$$

$$\text{Concentration of CO}_2 = \frac{p}{RT} = \frac{1.34}{0.0821 \times 1090} = 0.015\ \text{mol litre}^{-1}$$

(b) $CO_2(g) + C(s) \rightleftharpoons 2CO(g)$

$$\begin{array}{lccc} t=0 & 1 & 0 & 0 \\ t_{eq.} & 1-\alpha & & 2\alpha \\ p_i & \frac{1-\alpha}{1+\alpha}p & & \frac{2\alpha}{1+\alpha}p \end{array}$$

$$K_p = \frac{\left[\frac{2\alpha}{1+\alpha}p\right]^2}{\left[\frac{1-\alpha}{1+\alpha}p\right]} = \frac{4\alpha^2 p}{1-\alpha^2} \quad \text{... (i)}$$

$$\frac{5}{100} = \frac{1-\alpha}{1+\alpha}$$

$$\alpha = 0.95$$

$$\therefore \text{ From eq. (i), } 10 = \frac{4 \times (0.95)^2}{1-(0.95)^2} \times p$$

$$p = 0.27\ \text{atm}$$

Example 32. *The value of K_p is 1×10^{-3} atm^{-1} at 25°C for the reaction $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$. A flask contains NO at 0.02 atm and at 25°C. Calculate the mole of Cl_2 that must be added if 1% of the NO is to be converted to NOCl at equilibrium. The volume of the flask is such that 0.2 mole of gas produces 1 atm pressure at 25°C. (Ignore probable association of NO to N_2O_2).* (IIT 2001)

Solution: $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$

$$\begin{array}{lccc} t=0 & 0.02 & 0 & 0 \\ t_{eq.} & \frac{0.02 \times 99}{100} & p & \frac{0.02 \times 1}{100} \end{array}$$

$$K_p = \frac{[p_{NOCl}]^2}{[p_{NO}]^2[p_{Cl_2}]} = \frac{(0.02 \times 0.01)^2}{(0.99 \times 0.02)^2 \times p} = 10^{-3}$$

$$\therefore \quad p = 0.102\ \text{atm}$$

$$PV = nRT$$

$$0.102 \times V = n \times R \times T \quad \text{... (i)}$$

$$1 \times V = 0.2 \times R \times T \quad \text{... (ii)}$$

From eqs. (i) and (ii), $n = 0.0204$ (no. of moles of Cl_2 at equilibrium)

Pressure of Cl_2 involved in reaction

$$= \frac{1}{2} \times \text{pressure of NOCl}$$

$$= \frac{1}{2} \times \frac{0.02}{100} = 0.0001\ \text{atm}$$

$$PV = nRT$$

$$0.0001 \times V = n \times RT \quad \text{... (iii)}$$

From eqs. (ii) and (iii), $n = 2 \times 10^{-5}$ (moles of Cl_2 involved in reaction)

Initial moles of Cl_2 taken $= 0.0204 + 2 \times 10^{-5}$

$= 0.02042$

Example 33. *In the following equilibrium,*

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

when 5 moles of each is taken and the temperature is kept at 298 K, the total pressure was found to be 20 bar.

Given : $\Delta G^\circ_{f\,N_2O_4} = 100\,kJ, \Delta G^\circ_{f\,NO_2} = 50\,kJ$

(a) Find ΔG of the reaction at 298 K.

(b) Find the direction of the reaction. (IIT 2004)

Solution: $\text{Reaction Quotient} = \frac{[p_{NO_2}]^2}{p_{N_2O_4}} = \frac{100}{10} = 10$

$$\Delta G^\circ_{\text{reaction}} = 2\Delta G^\circ_{f\,NO_2} - \Delta G^\circ_{f\,N_2O_4}$$

$$= 2 \times 50 - 100 = 0$$

We know that, $\Delta G = \Delta G^\circ - 2.303\,RT \log Q_p$

$$= 0 - 2.303 \times 8.314 \times 298 \log 10$$

$$= -5705.8\ \text{J} = -5.705\ \text{kJ}$$

Negative value shows that reaction will be in forward direction..

SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. Irreversible and reversible reactions: Chemical reactions can be classified as irreversible and reversible reactions. The reactions which move in one direction only are called **irreversible reactions.** In these reactions products do not react to produce original reactants. In such reactions an arrow (→) is placed between reactants and products. The chemical reactions which take place in both directions under similar conditions are called **reversible reactions.** In such reactions products also react with each other to produce reactants again. The sign ($\rightleftharpoons$) is placed between reactants and products.

2. Chemical equilibrium: Chemical equilibrium is the most important characteristic property of reversible reactions. It is the state at which both forward and backward reactions occur at the same speed.

At equilibrium state,

Rate of forward reaction = Rate of backward reaction

At equilibrium state, the concentrations of the reactants and products do not change with time. The following are the characteristics of the equilibrium state:

(i) It can be achieved only if the reversible reaction is carried out in a closed space.

(ii) It is characterised by constancy of certain properties such as concentration, pressure, density, colour, etc.

(iii) It can be attained from either side of the reaction.

(iv) It can be attained in lesser time by use of a catalyst.

(v) It is dynamic in nature, *i.e.,* reaction does not stop, but both the forward and backward reactions move with the same speed.

(vi) Change of pressure, concentration or temperature favours one of the reaction and thus shifts the equilibrium point in one direction.

Reversible chemical reactions are classified into two types:

(i) **Heterogeneous reactions:** The reversible reactions in which more than one-phase is present.

(ii) **Homogeneous reactions:** The reversible reactions in which only one-phase is present. These are further classified into three types:

(a) When there is no change in the number of molecules, *i.e.*, $\Delta n = 0$.

(b) When there is an increase in the number of molecules, *i.e.*, $\Delta n = +\text{ve}$.

(c) When there is a decrease in the number of molecules, *i.e.*, $\Delta n = -\text{ve}$.

3. Law of chemical equilibrium (Application of law of mass action): Consider the general homogeneous reversible reaction in which equilibrium has been attained at a certain temperature.

$$m_1A_1 + m_2A_2 + m_3A_3 + \ldots \rightleftharpoons n_1B_1 + n_2B_2 + n_3B_3 + \ldots$$

Rate of forward reaction = Rate of backward reaction

$$k_f[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots = k_b[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots$$

or
$$\frac{\{[B_1]^{n_1}[B_2]^{n_2}[B_3]^{n_3}\ldots\}}{\{[A_1]^{m_1}[A_2]^{m_2}[A_3]^{m_3}\ldots\}} = \frac{k_f}{k_b} = K_c$$

The equilibrium constant, K_c, at a given temperature, is the ratio of rate constants of forward and backward reactions. It is also defined as the ratio between the molar concentrations of the products to the molar concentrations of the reactants with each concentration term raised to the power equal to stoichiometric coefficient in the balanced chemical equation.

The value of equilibrium constant is independent of the following factors;

(i) Initial concentration of reactants.

(ii) The direction from which equilibrium has been attained.

(iii) The presence of a catalyst.

(iv) The presence of inert materials.

The value of equilibrium constant depends upon the following factors:

(i) The mode of representation of the reaction: Consider the reversible reaction,

$$A + B \rightleftharpoons C + D$$

$$K_c = \frac{[C][D]}{[A][B]}$$

The products are made the reactants, *i.e.*, the reaction is reversed:

$$C + D \rightleftharpoons A + B$$

$$K'_c = \frac{[A][B]}{[C][D]}$$

So, $$K'_c = \frac{1}{K_c}$$

(ii) Stoichiometric representation of a chemical equation: The value of equilibrium constant will be numerically different if the reaction can be written with the help of two or more stoichiometric equations.

i.e., $2NO_2(g) \rightleftharpoons N_2(g) + 2O_2(g)$; $\quad K_c = \dfrac{[N_2][O_2]^2}{[NO_2]^2}$

or $NO_2(g) \rightleftharpoons (1/2)N_2(g) + O_2(g)$; $\quad K'_c = \dfrac{[N_2]^{1/2}[O_2]}{[NO_2]}$

Thus, $$K'_c = \sqrt{K_c}$$

(iii) Use of partial pressures: When the reactants and products are in gaseous state, the partial pressures can be used instead of concentrations at a definite temperature.

$$m_1A_1 + m_2A_2 + m_3A_3 + \ldots \rightleftharpoons n_1B_1 + n_2B_2 + n_3B_3 + \ldots$$

$$K_p = \frac{(p_{B_1})^{n_1}(p_{B_2})^{n_2}(p_{B_3})^{n_3}\ldots}{(p_{A_1})^{m_1}(p_{A_2})^{m_2}(p_{A_3})^{m_3}\ldots}$$

$$K_p = K_c(RT)^{\Delta n}$$

where, Δn = total number of molecules of products − total number of molecules of reactants.

When, $\Delta n = 0$, $K_p = K_c$;
$\Delta n = +\text{ve}$, $K_p > K_c$;
and $\Delta n = -\text{ve}$, $K_p < K_c$;

(iv) Temperature: The value of equilibrium constant changes with temperature. The values of equilibrium constants at two different temperatures are related by the following equation:

$$\log K_2 - \log K_1 = -\frac{\Delta H}{2.303R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad T_2 > T_1$$

When, $\Delta H = 0$, *i.e.*, heat of reaction at constant volume is zero,
$K_2 = K_1$

When, $\Delta H = +\text{ve}$, *i.e.*, endothermic reaction,
$K_2 > K_1$

and when, $\Delta H = -\text{ve}$, *i.e.*, exothermic reaction
$K_2 < K_1$

Units of equilibrium constant: Partial pressures are measured in terms of atmospheres. Therefore, units of K_p will be $(\text{atm})^{\Delta n}$. Since, concentrations are measured in terms of moles per litre, the units of K_c are $(\text{mol L}^{-1})^{\Delta n}$.

K_p and K_c will be pure numbers when, $\Delta n = 0$.

4. Equilibrium expressions for some reactions:

(a) $$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

Initially	a	b	0
At equilibrium	$(a-x)$	$(b-x)$	$(2x)$

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{(2x)^2}{(a-x)(b-x)} = \frac{4x^2}{(a-x)(b-x)}$$

$$K_p = \frac{[p_{HI}]^2}{p_{H_2} \times p_{I_2}} = \frac{\dfrac{(2x)^2}{(a+b)^2}P^2}{\left(\dfrac{a-x}{a+b}\cdot P\right)\left(\dfrac{b-x}{a+b}\cdot P\right)} = \frac{4x^2}{(a-x)(b-x)}$$

So, $K_c = K_p$

(b) $$2NO(g) \rightleftharpoons N_2(g) + O_2(g)$$

Initially	a	0	0
At equilibrium	$(a-x)$	$x/2$	$x/2$

$$K_c = \frac{[N_2][O_2]}{[NO]^2} = \frac{x/2 \times x/2}{(a-x)^2} = \frac{x^2}{4(a-x)^2}$$

(c)
$$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$$

Initially	a	b	0	0
At equil.	$(a-x)$	$(b-x)$	x	x

$$K_c = \frac{[CH_3COOC_2H_5][H_2O]}{[CH_3COOH][C_2H_5OH]} = \frac{x^2}{(a-x)(b-x)}$$

(d) $$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

Initially	a	0	0
At equilibrium	$(a-x)$	x	x
Active masses	$\dfrac{(a-x)}{V}$	$\dfrac{x}{V}$	$\dfrac{x}{V}$

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\dfrac{x}{V} \times \dfrac{x}{V}}{\dfrac{(a-x)}{V}} = \frac{x^2}{(a-x)V}$$

$$K_p = \frac{p_{PCl_3} \times p_{Cl_2}}{p_{PCl_5}} = \frac{\left(\dfrac{x}{a+x}\cdot P\right) \times \left(\dfrac{x}{a+x}\cdot P\right)}{\left(\dfrac{a-x}{a+x}\cdot P\right)} = \frac{x^2 P}{(a+x)(a-x)}$$

(e) $$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

Initially	a	b	0
At equilibrium	$(a-x)$	$(b-3x)$	$2x$
Active masses	$\left(\dfrac{a-x}{V}\right)$	$\left(\dfrac{b-3x}{V}\right)$	$\left(\dfrac{2x}{V}\right)$

$$K_c = \frac{[NH_3]^2}{[N_2][H_2]^3} = \frac{\left(\dfrac{2x}{V}\right)^2}{\left(\dfrac{a-x}{V}\right)\left(\dfrac{b-3x}{V}\right)^3} = \frac{4x^2V^2}{(a-x)(b-3x)^3}$$

$$K_p = \frac{(p_{NH_3})^2}{p_{N_2} \times (p_{H_2})^3} = \frac{\left[\dfrac{2x}{(a+b-2x)}P\right]^2}{\left[\dfrac{(a-x)}{(a+b-2x)}P\right]\left[\dfrac{(b-3x)}{(a+b-2x)}P\right]^3}$$

$$= \frac{4x^2(a+b-2x)^2}{(a-x)(b-3x)^3P^2}$$

5. Activation energies for the forward and backward reactions: Both forward and backward reactions follow the same path and from the same activated complex. However, the activation energies of both reactions are different.

$$\Delta E = E_a\,(f) - E_a\,(b)$$

For exothermic reaction, $E_a\,(f) < E_a\,(b)$, *i.e.*, $\Delta E = -\text{ ve}$

For endothermic reaction, $E_a\,(f) > E_a\,(b)$, *i.e.*, $\Delta E = +\text{ ve}$

Threshold energy = Energy of reactants + Activation energy of forward reaction

Threshold energy = Energy of products + Activation energy of backward reaction

6. Standard free energy change of a reaction and its equilibrium constant are related to each other at temperature *T* by the following relation:

$$\Delta G^\circ = -2.303RT \log K_p$$
$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

When, $\Delta G^\circ = -\text{ve}$, the value of equilibrium constant will be large positive quantity and when ΔG° is positive, the value of K is less than 1, *i.e.*, low concentration of products at equilibrium state.

7. Degree of dissociation from density measurements: Degree of dissociation in the case of reversible reactions in which there is increase in the number of molecules can be determined by measuring density of the reaction mixture at equilibrium. Let d be the observed density at a particular temperature when degree of dissociation is x and D be the vapour density when there is no dissociation.

$x = \frac{D-d}{(n-1)d}$; where, n is the number of molecules of products.

8. Heterogeneous equilibria: Law of mass action can also be applied to the heterogeneous system. In such systems the concentrations of pure solids and liquids are not considered in equilibrium expressions.

$$C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$$

$$K_p = \frac{p_{CO} \times p_{H_2}}{p_{H_2O}} \quad \text{or} \quad K_c = \frac{[CO][H_2]}{[H_2O]}$$

i.e., concentration of C(s) is not taken into account.

9. Le Chatelier's principle: It is a qualitative principle which can describe the effect of change in concentration, pressure and temperature on the reversible system whether physical or chemical. It is stated as "If the system at equilibrium is subjected to a change of any one of the factors such as concentration, temperature or pressure, the system adjusts itself in such a way as to annul the effect of that change." The following conclusions have been derived from this principle:

(i) Increase in concentration of any substance favours the reaction in which it is used up.

(ii) High pressure is favourable for the reaction in which there is decrease in volume.

(iii) A rise in temperature favours the endothermic reaction.

Applications of Le Chatelier's Principle

(i) Ice water system (melting of ice):

$$\text{Ice} + \text{Heat} \rightleftharpoons \text{Water}$$

It is an endothermic process and there is decrease in volume. Thus, the favourable conditions for melting of ice are:
(a) High temperature and (b) High pressure.

(ii) Solubility of gases in liquids: When a gas dissolves in a liquid, there is decrease in volume. Thus, increase in pressure will favour the dissolution of a gas in liquid.

(iii) Formation of nitric oxide:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) - 43200 \text{ calorie}$$

In this chemical reaction, there is no change in the number of molecules and heat is absorbed (endothermic). Thus, favourable conditions for greater yields of NO are:

(a) High concentrations of N_2 and O_2,

(b) High temperature and

(c) No effect of pressure and catalyst.

(iv) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) + 22400$ calorie: The reaction involves decrease in number of molecules and evolution of heat (exothermic). The favourable conditions are:

(a) High concentrations of N_2 and H_2,

(b) High pressure and

(c) Low temperature.

To speed up the rate of reaction at low temperature, a suitable catalyst is always employed.

Questions

1. Match List I (Equations) with List II (Type of Processes) and select the correct option:

List-I (Equations)	**List-II (Type of Processes)**
(a) $K_p > Q$	(i) Non-spontaneous
(b) $\Delta G^\circ < RT \log_e Q$	(ii) Equilibrium
(c) $K_p = Q$	(iii) Spontaneous and endothermic
(d) $T > \dfrac{\Delta H}{\Delta S}$	(iv) Spontaneous

(A) a = (i); b = (ii); c = (iii); d = (iv)
(B) a = (iii); b = (iv); c = (ii); d = (i)
(C) a = (iv); b = (i); c = (ii); d = (iii)
(D) a = (ii); b = (i); c = (iv); d = (iii) **[CBSE (PMT) 2010]**

[**Hint:** When $K_p > Q$; rate of forward reaction > rate of backward reaction, *i.e.*, process is spontaneous.

When $\Delta G^\circ < RT \log_e Q$, ΔG° is positive, thus reaction is non spontaneous.

When $K_p = Q$, reaction is at equilibrium.

When $T\Delta S > \Delta H$, ΔG will be negative only when ΔH = +ve, thus is spontaneous and endothermic.]

2. **Matrix-Matching Problems (For IIT Aspirants):**

[A] Match the Column-I with Column-II:

Column-I	**Column-II**
(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$	(p) Unaffected by inert gas addition
(b) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$	(q) Forward shift by rise in pressure and backward shift by inert gas addition
(c) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$	(r) Unaffected by increase in pressure
(d) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$	(s) Backward shift by rise in pressure and forward shift by inert gas addition

[B] Match the reactions in the Column-I with the units of equilibrium constant in Column-II:

Column-I	**Column-II**
(a) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$	(p) mol L
(b) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$	(q) Unitless
(c) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$	(r) atm
(d) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$	(s) $(atm)^{-2}$

[C] Match the reactions of the Column-I with the factors in Column-II:

Column-I	**Column-II**
(a) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ (Exothermic)	(p) Forward shift by rise in pressure
(b) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ (Exothermic)	(q) Unaffected by change in pressure
(c) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$ (Endothermic)	(r) Forward shift by rise in temperature
(d) $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$ (Endothermic)	(s) Forward shift by lowering the temperature

[D] Match the reactions of the Column-I with the relations in Column-II:

Column-I	**Column-II**
(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$	(p) $K_p = K_c(RT)$
(b) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$	(q) $K_p = K_c(RT)^2$
(c) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$	(r) $K_p = K_c(RT)^{-2}$
(d) $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$	(s) $K_p = K_c$

[E] Match the List-I with List-II:

List-I	**List-II**
(a) $Q = K$	(p) Reaction is nearer to completion
(b) $Q < K$	(q) Reaction is not at equilibrium
(c) $Q > K$	(r) Reaction is fast in forward direction
(d) $K >>> 1$	(s) Reaction at equilibrium

[F] Match the List-I with List-II:

List-I (Reaction)	**List-II (K_p/K_c)**
(a) $A_2(g) + 3B_2(g) \rightleftharpoons 2AB_3(g)$	(p) $(RT)^{-2}$
(b) $A_2(g) + B_2(g) \rightleftharpoons 2AB(g)$	(q) $(RT)^0$
(c) $A(s) + \frac{3}{2}B_2(g) \rightleftharpoons AB_3(g)$	(r) $(RT)^{1/2}$
(d) $AB_2(g) \rightleftharpoons AB(g) + \frac{1}{2}B_2(g)$	(s) $(RT)^{-1/2}$

Answers

• PRACTICE PROBLEMS •

1. K_c for the reaction, $NH_3(g) \rightleftharpoons 1/2 N_2(g) + 3/2\, H_2(g)$, at 298 K is 5.2×10^{-5}. What is the value of K_c at 298 K for the reaction,

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)?$$

[**Hint:** K_c' for reaction $1/2\, N_2(g) + 3/2 H_2(g) \rightleftharpoons NH_3$ is $\frac{1}{K_c}$, *i.e.*, $\frac{1}{5.2 \times 10^{-5}}$

K_c for the reaction, $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$, will be $= (K_c')^2$

$$= \left[\frac{1}{5.2 \times 10^{-5}}\right]^2 = 3.7 \times 10^8\ ]$$

2. The value of K_p for the reaction,

$$2H_2O(g) + 2Cl_2(g) \rightleftharpoons 4HCl(g) + O_2(g),$$

is 0.035 atm at 400°C, when the partial pressures are expressed in atmosphere. Calculate the value of K_c for the same reaction.
[**Ans.** 6.342×10^{-4} mol L^{-1}]

3. For the reaction,

$$2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g),$$

the equilibrium constant $K_c = 2.52 \times 10^{-2}$ at 27°C; calculate K_p. (Given, $R = 0.082$ litre-atm deg^{-1} mol^{-1})
[**Ans.** 61.99×10^{-2}]

4. If K_p for the reaction, $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$, is 1.64×10^{-4} atm^{-2} at 400°C. What will be the equilibrium constant at 500°C, if heat of reaction in this temperature range is – 105185.8 joule?
[**Ans.** 1.44×10^{-5} atm]

5. For the reaction, $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, $K_p = 0.157$ atm at 300 K. Calculate the value of K_c for the same reaction at the same temperature.
[**Ans.** 6.38×10^{-3} mol L^{-1}]

6. For the reaction, $SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$, the value of K_c is 1.7×10^{12} at 300 K. Calculate the equilibrium constants for the following reactions at 300 K:

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

and $$SO_3(g) \rightleftharpoons SO_2(g) + 1/2O_2(g)$$

[**Ans.** 2.89×10^{24}, 5.88×10^{-13}]

7. Determine K_p for the following reactions:
(a) $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$;
$K_c = 23.2$ at 600 K
(b) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$; $K_c = 4.62 \times 10^{-3}$ *M* at 298 K
(c) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$;
$K_c = 2.8 \times 10^2$ M^{-1} at 1000 K
[**Ans.** (a) 23.2 (b) 11.45 kPa (c) 0.0337 kPa]

8. From the following data at 1000 K:

$$COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g); \quad K_1 = 0.329$$
$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g); \quad K_2 = 2.24 \times 10^{22}$$

Calculate the equilibrium constant for the following reaction:

$$2COCl_2(g) + O_2(g) \rightleftharpoons 2CO_2(g) + Cl_2(g)$$

[**Ans.** 2.43×10^{21}]

9. For the reaction, $SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$, K_p is $32\,(atm)^{-1/2}$ at 800 K and ΔH for the reaction is −187.9 kJ mol^{-1}. Calculate its value at 900 K, if it is assumed that ΔH remains constant over this range of temperature.
[**Ans.** 1.387 $atm^{-1/2}$]

10. The equilibrium constants for the reaction, $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$, at 1727°C and 2227°C are 4.08×10^{-4} and 3.6×10^{-3} respectively. Calculate the enthalpy change for the reaction. (Given, $R = 1.987$ cal.)
[**Ans.** 43273 cal]

11. Calculate the equilibrium constant (K_p) for the reaction, $C(s) + CO_2(g) \rightleftharpoons 2CO(g)$, at 1300 K from the following data: $C(s) + 2H_2O(g) \rightleftharpoons CO_2(g) + 2H_2(g)$;
K_p (1300 K) = 3.9 atm

$$H_2(g) + CO_2(g) \rightleftharpoons CO(g) + H_2O(g);$$

K_p (1300 K) = 0.7 atm
[**Ans.** 1.91 atm]

[**Hint:** $$\frac{[CO]^2}{[CO_2]} = K_{p\,(\text{net})} = \frac{[CO]^2[H_2O]^2}{[H_2]^2[CO_2]^2} \times \frac{[H_2]^2[CO_2]}{[H_2O]^2} = (0.7)^2 \times 3.9\ ]$$

12. The standard equilibrium constant for the reaction,

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g),$$

is 1.8×10^{-7} at 298 K. Calculate its $\Delta G°$ value.
[**Ans.** 38.49 kJ mol^{-1}]

13. For the equilibrium, $Ag_2CO_3(s) \rightleftharpoons Ag_2O(s) + CO_2(g)$, equilibrium constants are 3.98×10^{-4} and 1.41×10^{-2} respectively at 350 K and 400 K. Calculate the standard enthalpy of decomposition.
[**Ans.** 83.06 kJ/mol]

14. The equilibrium constant for the reaction,

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g),$$

at 715 K is 6.0×10^{-2}. If in a particular reaction, there are 0.25 mol L^{-1} of H_2 and 0.06 mol L^{-1} of NH_3 present, calculate the concentration of N_2 at equilibrium.

[**Ans.** $[N_2] = 3.84$ mol L^{-1}]

15. One mole of H_2O and one mole of CO were heated in a 10 litre closed vessel at 1260 K. At equilibrium, 40% of water was found to react in the equation,

$$H_2O(g) + CO(g) \rightleftharpoons H_2(g) + CO_2(g)$$

Calculate the equilibrium constant of the reaction.

[**Ans.** 0.44]

[**Hint:** $\underset{(1-0.4)}{H_2O(g)} + \underset{(1-0.4)}{CO(g)} \rightleftharpoons \underset{0.4}{CO_2(g)} + \underset{0.4}{H_2(g)}$

(at equilibrium)]

16. Two moles of PCl_5 were introduced in a 2 litre flask and heated at 600 K to attain equilibrium. PCl_5 was found to be 40% dissociated into PCl_3 and Cl_2. Calculate the value of K_c.

[**Ans.** $K_c = 0.267$ mole L^{-1}]

17. 0.1 mole of PCl_5 is heated in a litre vessel at 533 K. Determine the concentration of various species present at equilibrium, if the equilibrium constant for the dissociation of PCl_5 at 533 K is 0.414.

[**Ans.** $[PCl_5] = 0.0531$ mol L^{-1}; $[PCl_3] = 0.0469$ mol L^{-1}; $[Cl_2] = 0.0469$ mol L^{-1}]

18. At 1000 K, the equilibrium constant, K_c, for the reaction,

$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

is equal to 3.04. If 1 mole of CO and 1 mole of Cl_2 are introduced into a 1 litre box at 1000 K, what will be the final concentration of $COCl_2$ at equilibrium?

[**Ans.** $[COCl_2] = 0.568$ mol L^{-1}]

19. Given, that $K_c = 13.7$ at 546 K for

$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$, calculate what pressure will develop in a 10 litre box at equilibrium at 546 K when 1.00 mole of PCl_5 is injected into the empty box?

[**Ans.** $P = 8.93$ atm]

[**Hint:** First determine degree of dissociation, then evaluate the total pressure by applying, $P = \frac{n}{V} RT$ where, $n = 1 + \alpha$.]

20. In the following reaction,

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

the amounts of H_2, I_2 and HI are 7.8 g, 203.2 g and 1638.4 g respectively at equilibrium at a certain temperature. Calculate the equilibrium constant of the reaction.

[**Ans.** 0.019]

21. Concentrations of two reactants *A* and *B* are 0.8 mol L^{-1} each. On mixing the two, the reaction sets in at a slow rate to form *C* and *D*.

$$A + B \rightleftharpoons C + D$$

At equilibrium, concentration of *C* was found to be 0.60 mol L^{-1}. Calculate the equilibrium constant.

[**Ans.** $K_c = 9$]

22. 15 moles of hydrogen reacting with 5.2 moles of iodine form 10 g mole of hydrogen iodide. Calculate the equilibrium constant of the reaction.

[**Ans.** $K_c = 50$]

23. In the dissociation of HI, it is found that 20% of the acid is dissociated when equilibrium is reached. Calculate the value of K_p for the equilibrium,

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

[**Ans.** $K_p = 1.56 \times 10^{-2}$]

24. The equilibrium constant of the reaction,

$$A + B \rightleftharpoons C + D$$

is unity. What per cent of *A* will be transformed if three moles of *A* are mixed with 5 moles of *B*?

[**Ans.** 62.5%]

[**Hint:** At equilibrium,

$$\underset{(3-x)}{A} + \underset{(5-x)}{B} \rightleftharpoons \underset{x}{C} + \underset{x}{D}$$

Find the value of x. % of *A* transformed $= \frac{x}{3} \times 100$]

25. 2 moles of *A* and 3 moles of *B* are mixed and the reaction is carried at 400°C according to the equation,

$$A + B \rightleftharpoons 2C$$

the equilibrium constant of the reaction is 4. Find the concentration of *C* at equilibrium.

[**Ans.** 2.4 mole]

26. A combination of hydrogen and iodine is carried out by heating 60 mL of hydrogen and 42 mL of iodine in a closed vessel. At equilibrium 28 mL of hydroiodic acid is present in the vessel. Calculate the degree of dissociation of HI.

[**Hint:** $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$

At equilibrium $(60-14)$ $(42-14)$ 28 mL

$$K_c = \frac{28 \times 28}{46 \times 28} = \frac{14}{23}$$

$$\underset{1-x}{2HI(g)} \rightleftharpoons \underset{x/2}{H_2(g)} + \underset{x/2}{I_2(g)}$$

(x is the degree of [illegible]iation)

$$K'_c = \frac{x/2 \times x/2}{(1-x)^2} =$$ [illegible]

or $$\frac{x}{2(1-x} \quad \overline{\frac{23}{14}} = 1.2817$$

$x = 0.72$]

27. One mole of H_2, 2 moles of I_2 and 3 moles of HI are injected in a one litre flask. What will be the concentration of H_2, I_2 and HI at equilibrium when K_c is 45.9?

[**Ans.** $[H_2] = 0.316$ mol L^{-1}, $[I_2] = 1.316$ mol L^{-1}, $[HI] = 4.368$ mol L^{-1}]

[**Hint:** $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$

At equilibrium $(1-x)$ $(2-x)$ $(3+2x)$

$$K_c = \frac{(3+2x)^2}{(1-x)(2-x)} = 45.9,$$

On solving, $x = 0.684$ mole]

28. Four moles of hydrogen iodide were taken in a 10 litre flask kept at 800 K. When equilibrium was attained, the mixture was found to contain 0.42 mole of iodine. Calculate the equilibrium constant for dissociation of HI.

[**Ans.** $K_c = 1.76 \times 10^{-2}$]

29. The equilibrium constant, K_c, for the reaction,

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

is 56.8 at 800 K. When the mixture was analysed, it was found to contain 0.316 mol/L HI at 800 K. What are the concentrations of H_2 and I_2 at equilibrium? (Assume that initial concentrations of H_2 and I_2 were the same.)

[**Ans.** $[H_2] = [I_2] = 0.0419$ mol L^{-1}]

30. At same temperature and under a pressure of 4 atm, PCl_5 is 10% dissociation. Calculate the pressure at which PCl_5 will be 20% dissociated, temperature remaining same. **(IIT 1996)**

[**Ans.** 0.96 atm]

31. The reaction of the formation of phosgene gas from CO and Cl_2 is as follows:

$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

In an experiment, starting with equimolecular CO and Cl_2 in a 250 mL flask, the equilibrium mixture on analysis is found to contain 0.05 mole CO, 0.05 mole Cl_2 and 0.15 mole $COCl_2$. Calculate the equilibrium constant of the reaction.

[**Ans.** $K_c = 15\ \text{mol}^{-1}\text{L}$]

32. At 35°C and 1 atmospheric pressure, N_2O_4 is 27.2% dissociated into NO_2. What is the value of K_p under these conditions?

[**Ans.** $K_p = 0.3195$ atm]

33. Nitrogen and hydrogen are added to a 5 litre flask under pressure. The flask was sealed and heated. The equilibrium mixture contained 19.0 g of ammonia, 0.16 g of hydrogen and 3.4 g of nitrogen. Calculate the equilibrium constant, K_c, of the reaction:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

[**Ans.** $K_c = 5.02 \times 10^5\ \text{mol}^{-2}\text{L}^2$]

34. An equilibrium mixture at 300 K contains N_2O_4 and NO_2 at 0.28 and 1.1 atm pressures respectively. If the volume of the container is doubled, calculate the new equilibrium pressure of the two gases. **(IIT 1991)**

[**Hint:** $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

$$K_p = \frac{(p_{NO_2})^2}{(p_{N_2O_4})} = \frac{(1.1)^2}{0.28} = 4.32 \text{ atm}$$

When the volume is doubled, the pressure becomes half and the system again adjusts to achieve equilibrium.

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

$$\left(\frac{0.28}{2} - x\right)\left(\frac{1.1}{2} + 2x\right)$$

$$(0.14 - x)\ (0.55 + 2x)$$

$$K_p = \frac{(0.55 + 2x)^2}{(0.14 - x)} = 4.32$$

$$x = 0.045$$

$$p_{N_2O_4} = (0.14 - 0.045) = 0.095 \text{ atm}$$

$$p_{NO_2} = (0.55 + 2 \times 0.045) = 0.64 \text{ atm}]$$

35. At 21.5°C and a total pressure of 0.0787 atm, N_2O_4 is 48.3% dissociated into NO_2. At what total pressure will the per cent dissociation be 10.0%?

[**Ans.** 2.37 atm]

[**Hint:** First calculate the value of K_p and then evaluate the pressure by applying,

$$K_p = \frac{\left(\frac{0.2}{1.1}\right)^2 P^2}{\left(\frac{0.9}{1.1}\right) P} = 0.0959]$$

36. At 3000 K, chlorine gas dissociates into chlorine atoms in an equilibrium reaction for which $K = 0.37$. What is the concentration of chlorine atoms in a vessel that originally contained 1.0 mol L^{-1} of molecular chlorine?

[**Ans.** [Cl] = 0.54 mol L^{-1}]

37. The equilibrium constant K_p for the reaction,

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$

at 1500°C is 120. If N_2 and O_2 at an initial pressure of 0.25 atm each are maintained at 1500°C till equilibrium is established, calculate the partial pressure of N_2, O_2 and NO in the equilibrium mixture.

[**Ans.** $p_{N_2} = p_{O_2} = 0.04$; $p_{NO} = 0.42$ atm]

38. Find K_p for the following reaction,

$$SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$$

If sulphuryl chloride decomposes to the extent of 91.2% at 102°C and total pressure 1 atmosphere.

[**Ans.** $K_p = 4.94$ atm]

39. If carbon dioxide is 2% dissociated at 1800°C and 1 atmospheric pressure,

$$2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g)$$

Calculate K_p for the reaction.

[**Ans.** $K_p = 4.12 \times 10^{-6}$ atm]

40. At a certain temperature, K_c for the reaction,

$$POCl_3(g) \rightleftharpoons POCl(g) + Cl_2(g)$$

is 0.30. If 0.6 mole of $POCl_3$ is placed in a closed vessel of 3.0 litre capacity at this temperature, what percentage of it will be dissociated when equilibrium is established?

[**Ans.** 68.5%]

41. A reaction carried out by 1 mole of N_2 and 3 moles of H_2 shows at equilibrium the mole fraction of NH_3 as 0.012 at 500°C and total pressure 10 atmosphere; calculate K_p. Also report the pressure at which mole percentage of NH_3 in equilibrium mixture increased to 10.4.

[**Ans.** $K_p = 1.431 \times 10^{-5}\ \text{atm}^{-2}$; $P = 105.41$ atm]

42. The degree of dissociation of N_2O_4 into NO_2 at one atmosphere and 40°C is 0.310. Calculate its K_p at 40°C. Also report degree of dissociation at 10 atmospheric pressure at the same temperature.

[**Ans.** $K_p = 0.425$ atm; degree of dissociation = 0.1025]

43. The vapour density of PCl_5 at 200°C and 252°C are 70.2 and 57.2 respectively at one atmosphere. Calculate its value of dissociation constant at these temperatures.

[**Ans.** $K_p = 0.307, 1.19$]

44. Some solid NH_4HS is placed in a flask containing 0.5 atm of NH_3. What would be the pressures of NH_3 and H_2S when equilibrium is reached?

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g); \quad K_p = 0.11$$

[**Ans.** $NH_3 = 0.83$ atm; $H_2S = 0.33$ atm] **(MLNR 1994)**

[**Hint:** $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$

At equilibrium $\qquad x + 0.5 \qquad x$

$$K_p = (x + 0.5)x = 0.11]$$

45. $SnO_2(s) + 2H_2(g) \rightleftharpoons 2H_2O_{(steam)} + Sn(s)$

For the above reaction find K_p, if at 900 K, the equilibrium mixture contains 45% H_2 by volume.

[**Ans.** $K_p = 1.5$]

46. The equilibrium constant for the reaction is 9.40 at 900°C.

$$S_2(g) + C(s) \rightleftharpoons CS_2(g)$$

Calculate the pressure of two gases at equilibrium, when 1.42 atm of S_2 and excess of $C(s)$ come to equilibrium.

[**Ans.** $p_{CS_2} = 1.28$ atm; $p_{S_2} = 0.14$ atm]

47. For the reaction,

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

$K_p = 1.16$ atm at 800°C. If 20.0 g of $CaCO_3$ were kept in a 10 litre container and heated up to 800°C, what percentage of $CaCO_3$ would remain unreacted at equilibrium?

[**Ans.** 34%]

[**Hint:** $K_p = p_{CO_2} = 1.16$ atm

$$n = \frac{p_{CO_2} \times V}{RT} = \frac{1.16 \times 10}{0.0821 \times 1073} = 0.132 \text{ mol}$$

$$\text{Initial amount of } CaCO_3 = \frac{20.0}{100} = 0.2 \text{ mol}$$

$$\text{Unreacted } CaCO_3 = 0.2 - 0.132 = 0.068 \text{ mol}$$

$$\% \text{ unreacted } CaCO_3 = \frac{0.068}{0.2} \times 100 = 34$$]

48. In the reaction, $C(s) + CO_2(g) \rightleftharpoons 2CO(g)$, the equilibrium pressure is 12 atm. If 50% of CO_2 reacts, calculate K_p.

[**Ans.** $K_p = 16$ atm]

49. A mixture of 0.373 atm of $NO(g)$ and 0.310 atm of $Cl_2(g)$ is prepared at 500°C. The reaction, $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl$, occurs. The total pressure at equilibrium is 0.544 atm. Determine K_p of the reaction.

[**Ans.** $K_p = 50.08 \text{ atm}^{-1}$]

50. For the reaction,

$$3A(g) + B(g) \rightleftharpoons 2C(g)$$

at a given temperature, K_c is 9.0. What must be the volume of a flask if the mixture of 2.0 moles each of A, B and C is obtained at equilibrium?

[**Ans.** $V = 6$ litre]

51. At 700 K hydrogen and bromine react to form hydrogen bromide. The value of equilibrium constant for this reaction is 5×10^8. Calculate the amount of H_2, Br_2 and HBr at equilibrium if a mixture of 0.6 mole of H_2 and 0.2 mole of bromine is heated to 700 K. **(IIT 1995)**

[**Hint:** $H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$

Initial 0.6 0.2

Since, equilibrium constant is very high the reaction will be complete and bromine is consumed.

Thus, 0.2 mole of Br_2 and 0.2 mole of H_2 will be consumed to produce 0.4 mole of HBr. This can be calculated by applying law of mass action.

$$\frac{[HBr]^2}{[H_2][Br_2]} = K \text{ or } \frac{4x^2}{(0.6-x)(0.2-x)} = 5 \times 10^8$$

$$x = 0.6 \text{ or } 0.2$$

The value of x cannot be more than 0.2 as Br_2 is a limiting reactant. Thus, when reaction is complete,

$H_2 = (0.6 - 0.2) = 0.4$ mol; $Br_2 = 0$; HBr = 0.4 mol

At this point some HBr will dissociate.

$$\begin{array}{lccc} & 2HBr(g) & \rightleftharpoons H_2(g) & + \; Br_2(g) \\ \text{At equilibrium} & (0.4 - 2x) & (0.4 + x) & (x) \end{array}$$

$$\frac{(0.4 + x) \times x}{(0.4 - 2x)} = \frac{1}{5 \times 10^8}$$

or $$\frac{0.4x}{0.4} = 2 \times 10^{-10} (\text{since, } x \text{ is very small})$$

or $$x = 2 \times 10^{-10}$$

$[Br_2] = 2 \times 10^{-10}$ mol; $[H_2] = 0.4$ mol; $[HBr] = 0.4$ mol]

52. One mole of H_2, two moles of I_2 and three moles of HI are injected in a 1 litre flask. What will be the concentration of H_2, I_2 and HI at equilibrium at 490°C? The equilibrium constant for the reaction at 490°C is 45.9.

[**Ans.** $[H_2] = 0.316$; $[I_2] = 1.316$; $[HI] = 4.36$ mol]

53. Solid ammonium carbamate dissociates to give ammonia and carbon dioxide as follows:

$$NH_2COONH_4(s) \rightleftharpoons 2NH_3(g) + CO_2(g)$$

At equilibrium, ammonia is added such that partial pressure of NH_3 now equals to the original total pressure. Calculate the ratio of total pressure now to the original total pressure.

[**Ans.** $^{31}/_{27}$]

54. Two solid compounds A and C dissociate into gaseous product at temperature T as follows:

(i) $A(s) \rightleftharpoons B(g) + D(g)$

(ii) $C(s) \rightleftharpoons E(g) + D(g)$

At 20°C, pressure over excess solid A is 50 atm [illegible] that over excess solid C is 68 atm. Find the total pressure [illegible] gases over the solid mixture.

[**Ans.** 84.38 atm]

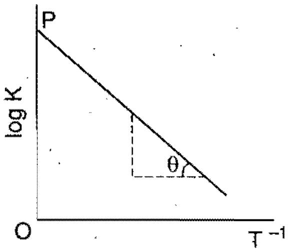
55. Variation of equilibrium constant K with temperature T is given by van't Hoff equation,

$$\log K = \log A - \frac{\Delta H°}{2.303\, RT}$$

A graph between $\log K$ and T^{-1} was a straight line as shown in the figure and having $\theta = \tan^{-1}$ (0.5) and $OP = 10$. Calculate:

(a) $\Delta H°$ (standard heat of reaction) when $T = 298$ K,

(b) A (pre-exponential factor),



(c) Equilibrium constant K at 298 K,

(d) K at 798 K, if $\Delta H°$ is independent of temperature.

[**Ans.** (a) 9.574 J mol^{-1}; (b) $A = 10^{10}$; (c) 9.96×10^9; (d) 9.98×10^9]

[**Hint:** (a) $\log K = \log A - \frac{\Delta H^\circ}{2.303RT}$

It is equation of straight line of the type $y = c + mx$

$$\text{Slope 'm'} = \tan\theta = \frac{\Delta H^\circ}{2.303R}$$

$$0.5 = \frac{\Delta H^\circ}{2.303 \times 8.314}$$

$$\Delta H^\circ = 9.574 \text{ J mol}^{-1}$$

(b) Intercept 'c' = $\log A = 10$

$\therefore$ $A = 10^{10}$

(c) $$\log K = 10 - \frac{9.574}{2.303 \times 8.314 \times 298}$$

$$K = 9.96 \times 10^9$$

(d) $$\log\left(\frac{K_2}{K_1}\right) = \frac{\Delta H}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

$$\log\frac{K_2}{9.96 \times 10^9} = \frac{9.574}{2.303 \times 8.314}\left(\frac{1}{298} - \frac{1}{798}\right)$$

On solving, $K_2 = 9.98 \times 10^9$]

56. When 0.112 mole of NO and 18.22 g of bromine are placed in a 1.00 L reaction vessel and sealed, the mixture is heated to 350 K and the following equilibrium is established:

$$2NO(g) + Br_2(g) \rightleftharpoons 2NOBr(g)$$

If the equilibrium concentration of nitrosyl bromide is 0.0824 M, what is K_c?

[**Ans.** 106.74]

[**Hint:**

$$\begin{array}{llll} & 2NO(g) + & Br_2(g) \rightleftharpoons & 2NOBr(g); \; n_{Br_2} = \frac{18.22}{160} = 0.1138 \\ t=0 & 0.112 & 0.1138 & 0 \\ t_{eq.} & \left[\frac{0.112 - 2x}{1}\right] & \left[\frac{0.1138 - x}{1}\right] & \frac{2x}{1} \end{array}$$

$$2x = 0.0824$$

$\therefore$ $[NO] = 0.112 - 2x$

$$= 0.112 - 0.0824 = 0.0296\,M$$

$$[Br_2] = 0.1138 - \frac{0.0824}{2} = 0.0726\,M$$

$$K_c = \frac{[NOBr]^2}{[NO]^2[Br_2]} = \frac{[0.0824]^2}{[0.0296]^2[0.0726]} = 106.74\,]$$

57. Solid ammonium carbamate is put into a closed container and allowed to come to equilibrium with the gaseous products at 35°C, the total pressure is found to be 0.30 atmospheres. What is the value of K_p for this reaction at 35°C?

[**Ans.** 4×10^{-3}]

58. K_p for the equilibrium of,

$$FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g)$$

at 1000°C is 0.403, if CO(g), at a pressure of 1.0 atm and excess of FeO(s) are placed in a container at 1000°C. What are the pressures of CO(g) and $CO_2(g)$ when the equilibrium is attained?

[**Ans.** $p_{CO} = 0.713$ atm; $p_{CO_2} = 0.287$ atm]

59. A mixture of 1.0 mole of sulphur and 0.2 mole of hydrogen is heated at 90°C in a one litre flask. The equilibrium constant for the formation of hydrogen sulphide, $H_2(g) + S(s) \rightleftharpoons H_2S(g)$ is 6.8×10^{-2}. Calculate the partial pressure of H_2S at equilibrium.

[**Ans.** $p_{H_2S} = 0.397$ atm]

[**Hint:** First determine the initial pressure of H_2 by applying

$$p_0 = \frac{n}{V} \cdot RT = 5.953 \text{ atm}]$$

OBJECTIVE QUESTIONS

Set-1: Questions with single correct answer

1. A reversible reaction is one which:
(a) proceeds in one direction
(b) proceeds in both directions
(c) proceeds spontaneously
(d) all the statements are wrong

2. An example of reversible reaction is:
(a) $Pb(NO_3)_2 + 2NaI = PbI_2 + 2NaNO_3$
(b) $AgNO_3 + HCl = AgCl + HNO_3$
(c) $2Na + 2H_2O = 2NaOH + H_2$
(d) $KNO_3 + NaCl = KCl + NaNO_3$

3. Which one of the following is not a reversible reaction?
(a) $2HI(g) = H_2(g) + I_2(g)$
(b) $PCl_5(g) = PCl_3(g) + Cl_2(g)$
(c) $2KClO_3(s) = 2KCl(s) + 3O_2(g)$
(d) $CaCO_3(s) = CaO(s) + CO_2(g)$

4. Which one is not correct for a reversible reaction?
(a) The reaction is never completed
(b) The reactants are present in the initial stage but after that the reactants and products are always present in the reaction mixture
(c) At equilibrium only products are present
(d) When the reaction is carried out in closed space, it attains equilibrium state after suitable time

5. The law of mass action was proposed by:
(a) Guldberg and Waage (b) Le Chatelier and Braun
(c) Kossel and Lewis (d) van't Hoff

6. The rate at which a substance reacts, depends on its:
(a) active mass (b) molecular mass
(c) equivalent mass (d) total volume

7. Active mass is defined as:
(a) number of g equivalent per unit volume
(b) number of g mol per litre
(c) amount of substance in gram per unit volume
(d) number of g mole in 100 litre

8. 8.50 g of NH_3 is present in 250 mL volume. Its active mass is:
(a) $1.0\,M\,L^{-1}$ (b) $0.5\,M\,L^{-1}$ (c) $1.5\,M\,L^{-1}$ (d) $2.0\,M\,L^{-1}$

9. Theory of 'active mass' indicates that the rate of a chemical reaction is directly proportional to the: **[PET (MP) 1990]**
(a) equilibrium constant (b) properties of reactants
(c) volume of apparatus (d) concentration of reactants

10. The state of equilibrium refers to: **[PMT (Pb.) 1993]**
(a) state of rest (b) dynamic state
(c) stationary state (d) state of inertness

11. In a reversible chemical reaction equilibrium is said to have been established when the:
(a) concentrations of reactants and products are equal
(b) opposing reactions cease
(c) speeds of opposing reactions become equal
(d) temperatures of opposing reactions are equal

12. A chemical reaction, $A \rightleftharpoons B$, is said to be in equilibrium when:
(a) rate of forward reaction is equal to rate of backward reaction
(b) conversion of A to B is only 50% complete
(c) complete conversion of A to B has taken place
(d) only 25% conversion of A to B has taken place

13. The reaction between barium chloride and sodium sulphate goes to completion because:
(a) barium sulphate is almost insoluble
(b) the solubility of barium chloride decreases
(c) lattice energy of barium sulphate is very high
(d) the reaction is irreversible in nature

14. What is the equilibrium constant expression for the reaction,

$$P_4(s) + 5O_2(g) \rightleftharpoons P_4O_{10}(s)?$$

(Jamia Millia Islamia Engg. Ent. 2007; UPSEE 2007)

(a) $K_c = \dfrac{[P_4O_{10}]}{[P_4]\,[O_2]^5}$ (b) $K_c = \dfrac{[P_4O_{10}]}{5\,[P_4]\,[O_2]}$

(c) $K_c = [O_2]^5$ (d) $K_c = \dfrac{1}{[O_2]^5}$

15. Equilibrium constant for the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, is correctly given by the expression:

(a) $K_c = \dfrac{[H_2][I_2]}{[HI]}$ (b) $K_c = \dfrac{[HI]^2}{[H_2][I_2]}$

(c) $K_c = \dfrac{[HI]}{[H_2][I_2]}$ (d) $K_c = \dfrac{[2HI]}{[H_2][I_2]}$

16. Equilibrium constant for the reaction, $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$, is correctly given by the expression:

(a) $K = \dfrac{[NOCl]^2}{[NO]^2[Cl_2]}$ (b) $K = \dfrac{[2NOCl]}{[2NO][Cl_2]}$

(c) $K = \dfrac{[NO]^2 + [Cl_2]}{[NOCl]}$ (d) $K = \dfrac{[NO]^2[Cl_2]}{[NOCl]^2}$

17. For the system, $3A + 2B \rightleftharpoons C$, the expression for equilibrium constant is: **[JEE (WB) 2007]**

(a) $\dfrac{[A]^3[B]^2}{[C]}$ (b) $\dfrac{[C]}{[A]^3[B]^2}$ (c) $\dfrac{[A]^2[B]^3}{[C]}$ (d) $\dfrac{[C]}{[A][B]}$

18. The equilibrium constants of the reactions,

$$SO_2(g) + \frac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$$

and $$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

are K_1 and K_2 respectively. The relationship between K_1 and K_2 is:

(a) $K_1 = K_2$ (b) $K_2^2 = K_1$
(c) $K_1^2 = K_2$ (d) $K_2 = \sqrt{K_1}$

19. The equilibrium constant for the given reaction is 100.

$$N_2(g) + 2O_2(g) \rightleftharpoons 2NO_2(g)$$

What is the equilibrium constant for the reaction given below:

$$NO_2(g) \rightleftharpoons \frac{1}{2}N_2(g) + O_2(g)$$

(EAMCET 2009)

(a) 10 (b) 1
(c) 0.1 (d) 0.01

20. For the reaction, $2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$, $K_c = 1.8 \times 10^{-6}$ at 185°C. The value of K_c at 185°C for the reaction;

$$NO(g) + \frac{1}{2}O_2(g) \rightleftharpoons NO_2(g) \text{ is:}$$ **(MLNR 1993)**

(a) 0.9×10^6 (b) 1.95×10^{-3}
(c) 1.95×10^3 (d) 7.5×10^2

21. The equilibrium constant for the synthesis of HI at 490°C is 50.0. The value of K for the dissociation of HI will be: **(IIT 1990)**
(a) 0.02 (b) 50.0 (c) 0.50 (d) 0.20

22. Consider the following equilibrium,

$$SO_2(g) + \frac{1}{2}O_2(g) \overset{K_1}{\rightleftharpoons} SO_3(g);$$

$$2SO_3(g) \overset{K_2}{\rightleftharpoons} 2SO_2(g) + O_2(g)$$

What is the relation between K_1 and K_2? **[PET (MP) 1993]**

(a) $K_1 = \dfrac{1}{K_2}$ (b) $K_1 = \dfrac{1}{\sqrt{K_2}}$ (c) $K_1 = K_2$ (d) $K_1 = \dfrac{1}{K_2^2}$

23. For the reaction $AB(g) \rightleftharpoons A(g) + B(g)$, AB is 33%, dissociated at a total pressure of P. Therefore, P is related to K_p by one of the following option : **[AMU (Med.) 2010]**
(a) $P = K_p$ (b) $P = 3K_p$
(c) $P = 4K_p$ (d) $P = 8K_p$

[Hint:

$$\begin{array}{lccc} & AB(g) & \rightleftharpoons A(g) & + B(g) \\ t_0 & 1 & 0 & 0 \\ t_{eq} & 1-\frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{array}$$

$$p_{AB} = \frac{2/3}{4/3} \times p = \frac{p}{2};$$

$$p_A = p_B = \frac{1/3}{4/3} \times p = \frac{p}{4}$$

$$K_p = \frac{\frac{p}{4} \times \frac{p}{4}}{\frac{p}{2}} = \frac{p}{8}$$

$$p = 8K_p\ ]$$

24. For a system, $A + 2B \rightleftharpoons C$, the equilibrium concentrations are $[A] = 0.06$, $[B] = 0.12$ and $[C] = 0.216$. The K_c for the reaction is:
(a) 125 (b) 415
(c) 4×10^{-3} (d) 250

25. The equilibrium concentrations of x, y and yx_2 are 4, 2 and 2 respectively for the equilibrium $2x + y \rightleftharpoons yx_2$. The value of equilibrium constant, K_c is: **(EAMCET 1990)**
(a) 0.625 (b) 6.25 (c) 0.0625 (d) 62.5

26. 4 mole of A are mixed with 4 mole of B when 2 mole of C are formed at equilibrium, according to the reaction,

$$A + B \rightleftharpoons C + D$$

the equilibrium constant is: **(CPMT 1992)**
(a) $\sqrt{2}$ (b) 2 (c) 1 (d) 4

27. If the equilibrium constant of the reaction $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$ is 0.25, the equilibrium constant of $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, under similar conditions, will be:
(a) 4.0 (b) 3.0 (c) 2.0 (d) 1.0

28. HI was heated in a sealed tube at 400°C till the equilibrium was reached. HI was found to be 22% decomposed. The equilibrium constant for dissociation is:
(a) 1.99 (b) 0.0199 (c) 0.0796 (d) 0.282

29. For a reversible reaction if the concentrations of the reactants are doubled at a definite temperature, then equilibrium constant will: **(CPMT 1990; MLNR 1992)**
(a) also be doubled (b) be halved
(c) become one-fourth (d) remain the same

30. In a reversible gaseous system, molar concentrations (active masses) of reactants and products are proportional to:
(a) partial pressure
(b) total pressure
(c) amounts of reactants and products
(d) none of the above

31. At 3000 K, the equilibrium partial pressure of CO_2, CO and O_2 are 0.6, 0.4 and 0.2 atmospheres respectively. K_p for the reaction,

$$2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g) \text{ is :}$$

[BHU (Mains) 2010]
(a) 0.088 (b) 0.0533 (c) 0.133 (d) 0.177

32. Equilibrium constant depends on:
(a) the actual quantities of reactants and products
(b) the presence of a catalyst
(c) temperature
(d) the presence of inert material

33. For the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, the equilibrium constant, K_p, changes with:
(a) total pressure
(b) catalyst
(c) the amounts of H_2 and I_2 taken
(d) temperature

34. $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$
The equilibrium constant of the above reaction is 6.4 at 300 K. If 0.25 mole each of H_2 and I_2 are added to the system, the equilibrium constant will be: **(CET Karnataka 2009)**
(a) 0.8 (b) 3.2 (c) 1.6 (d) 6.4

35. 3.1 mol of $FeCl_3$ and 3.2 mol of NH_4SCN are added to one litre of water. At equilibrium, 3.0 mol of $FeSCN^{2+}$ are formed. The equilibrium constant K_c of the reaction :

$$Fe^{3+} + SCN^- \rightleftharpoons FeSCN^{2+}$$

will be : **[BHU (Screening) 2010]**
(a) 6.66×10^{-3} (b) 0.30
(c) 3.30 (d) 150

[Hint:

	Fe^{3+} +	SCN^- $\rightleftharpoons$	$FeSCN^{2+}$
t_0	3.1	3.2	0
$t_{eq.}$	$\frac{0.1}{1}$	$\frac{0.2}{1}$	$\frac{3}{1}$

$$K_c = \frac{[FeSCN^{2+}]}{[Fe^{3+}][SCN^-]}$$

$$= \frac{3}{0.1 \times 0.2} = 150]$$

36. K_p and K'_p are the equilibrium constants of the two reactions, given below:

$$\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$$

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

Therefore, K_p and K'_p are related by **[AMU (PMT) 2009]**
(a) $K_p = K'^2_p$ (b) $K_p = \sqrt{K'_p}$
(c) $K_p = 2K'_p$ (d) $K_p = K'_p$

37. In which of the following equilibrium K_c and K_p are not equal? **[CBSE (PMT) 2010]**
(a) $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$
(b) $SO_2(g) + NO_2(g) \rightleftharpoons SO_3(g) + NO(g)$
(c) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$
(d) $2C(s) + O_2(g) \rightleftharpoons 2CO_2(g)$

38. Select the correct statement from the following:
(a) equilibrium constant changes with addition of a catalyst
(b) catalyst increases the rate of forward reaction
(c) the ratio of mixture at equilibrium does not change by catalyst
(d) catalysts are active only in solution

39. In which of the following, the reaction proceeds towards completion? **(MLNR 1990)**
(a) $K = 1$ (b) $K = 10^{-2}$
(c) $K = 10$ (d) $K = 10^3$

40. For the following reaction at 250°C, the value of K_c is 26, then the value of K_p at the same temperature will be:
$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$ **(MLNR 1990; CBSE 1993)**
(a) 0.57 (b) 0.61 (c) 0.83 (d) 0.91

41. In the reaction, $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$, the amounts of PCl_5, PCl_3 and Cl_2 are 2 mole each at equilibrium and the total pressure is 3 atmospheres. The equilibrium constant, K_p, is: **(IIT 1991)**
(a) 1 atm (b) 2 atm (c) 3 atm (d) 1.5 atm

42. In which of the following K_p is less than K_c?
(a) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$
(b) $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$
(c) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$
(d) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

43. For a reversible reaction, the rate constants for the forward and backward reactions are 2.38×10^{-4} and 8.15×10^{-5} respectively. The equilibrium constant for the reaction is:
(a) 0.342 (b) 2.92
(c) 0.292 (d) 3.42

44. The equilibrium constant in a reversible reaction at a given temperature:

(a) depends on the initial concentration of the reactants
(b) depends on the concentration of products at equilibrium
(c) it is not characteristic of the reaction
(d) does not depend on initial concentrations

45. 1.0 g mole of ethyl alcohol and 1.0 g mole of acetic acid are mixed. At equilibrium 0.666 g mole of the ester is present. The value of equilibrium constant is: **[PET (MP) 1993]**

(a) $\frac{1}{4}$ (b) $\frac{1}{2}$ (c) 2 (d) 4

46. The equilibrium constant of the reaction,

$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$

is 4. If one mole of each of acetic acid and ethyl alcohol are heated in presence of a little concentrated H_2SO_4, at equilibrium the amount of ester present is: **[PET (MP) 1992]**

(a) 1 mole (b) 2 mole
(c) $\frac{2}{3}$ mole (d) $\frac{1}{2}$ mole

47. If different quantities of ethanol and acetic acid are used in the following reversible reaction,

$CH_3COOH(l) + C_2H_5OH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$

the equilibrium constant will have values which will be?

(a) Different in all cases
(b) Same in all cases
(c) Higher in cases where higher concentration of ethanol is used
(d) Higher in cases where higher concentration of acetic acid is used

48. The reaction,

$$2A(g) + B(g) \rightleftharpoons 3C(g) + D(g)$$

is begun with concentration of A and B both at initial value of 1M. When equilibrium is reached, the concentration of D is measured and found to be 0.25 M. The value for the equilibrium constant for this reaction is given by the expression : **[CBSE (PMT) 2010]**

(a) $[(0.75)^3(0.25)] \div [(1.00)^2(1.00)]$
(b) $[(0.75)^3(0.25)] \div [(0.50)^2(0.75)]$
(c) $[(0.75)^3(0.25)] \div [(0.50)^2(0.25)]$
(d) $[(0.75)^3(0.25)] \div [(0.75)^2(0.25)]$

[**Hint:**

	$2A(g)$	+ $B(g)$	$\rightleftharpoons$	$3C(g)$	+ $D(g)$
t_0	1	1		0	0
$t_{eq.}$	0.50	0.75		0.75	0.25

$$K = \frac{[C]^3[D]}{[A]^2[B]} = \frac{(0.75)^3(0.25)}{(0.50)^2(0.75)}]$$

49. The decomposition of N_2O_4 to NO_2 is carried at 280 K in chloroform. When equilibrium has been established, 0.2 mole of N_2O_4 and 2×10^{-3} mole of NO_2 are present in 2 litre solution. The equilibrium constant for the reaction, $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, is:

(a) 1×10^{-2} (b) 2×10^{-3}
(c) 1×10^{-5} (d) 2×10^{-5}

50. The unit of equilibrium constant, K_c, for the reaction $A + B \rightleftharpoons C$ would be:

(a) mol^{-1} L (b) mol L^{-1} (c) mol L (d) no unit

51. For which of the following reactions does the equilibrium constant depend on the units of concentration?

(a) $NO(g) \rightleftharpoons \frac{1}{2}N_2(g) + \frac{1}{2}O_2(g)$
(b) $C_2H_5OH(l) + CH_3COOH(l) \rightleftharpoons CH_3COOC_2H_5(l) + H_2O(l)$
(c) $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$
(d) $COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g)$

52. The units of K_p in the following reaction are:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

(a) atm (b) atm^{-2} (c) atm^2 (d) atm^{-1}

53. The equilibrium of formation of phosgene is represented as:

$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

The reaction is carried out in a 500 mL flask. At equilibrium 0.3 mole of phosgene, 0.1 mole of CO and 0.1 mole of Cl_2 are present. The equilibrium constant of the reaction is:

(a) 30 (b) 15 (c) 5 (d) 3

54. In an equilibrium reaction, for which $\Delta G° = 0$, the equilibrium constant K should be equal to:

(a) zero (b) 10 (c) 1 (d) 2

55. The equilibrium constant K_p for the homogeneous gaseous reaction is 10^{-3}. The standard Gibbs free energy change $\Delta G°$ for the reaction at 27°C (using $R = 2$ cal K^{-1} mol^{-1}) is:

(a) zero (b) − 1.8 kcal
(c) − 4.154 kcal (d) + 4.154 kcal

56. At 500 K, the equilibrium constant for reaction $cis\text{-}C_2H_2Cl_2 \rightleftharpoons trans\text{-}C_2H_2Cl_2$ is 0.6. At the same temperature, the equilibrium constant for the reaction $trans\text{-}C_2H_2Cl_2 \rightleftharpoons cis\text{-}C_2H_2Cl_2$, will be:

(a) 1.67 (b) 0.6 (c) 1.76 (d) 1.64

57. Which one of the following oxides is most stable? The equilibrium constants are given at the same temperature:

(a) $2N_2O_5(g) \rightleftharpoons 2N_2(g) + 5O_2(g)$; $K = 1.2 \times 10^{34}$
(b) $2N_2O(g) \rightleftharpoons 2N_2(g) + O_2(g)$; $K = 3.5 \times 10^{35}$
(c) $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$; $K = 2.2 \times 10^{30}$
(d) $2NO_2(g) \rightleftharpoons N_2(g) + 2O_2(g)$; $K = 6.71 \times 10^{16}$

58. In a chemical equilibrium, $K_c = K_p$ when: **[CEE (Bihar) 1992]**

(a) the number of molecules entering into a reaction is more than the number of molecules produced
(b) the number of molecules entering into the reaction is equal to the number of molecules produced
(c) the number of molecules entering into the reaction is less to the number of molecules produced
(d) none of the above

59. In a general reaction, $A + B \rightleftharpoons AB$, which value of equilibrium constant most favours the production of AB?

(a) 9.0×10^{-3} (b) 3.5×10^{-3}
(c) 4.0×10^{-7} (d) 4.0×10^{-12}

60. During thermal dissociation of a gas, the vapour density:

(a) remains the same
(b) increases
(c) decreases
(d) increases in some cases and decreases in others

61. The vapour density of fully dissociated NH_4Cl would be:
(a) less than half of the vapour density of pure NH_4Cl
(b) double of the vapour density of pure NH_4Cl
(c) half of the vapour density of pure NH_4Cl
(d) one-third of the vapour density of pure NH_4Cl

62. In the dissociation of $2HI \rightleftharpoons H_2 + I_2$, the degree of dissociation will be affected by:
(a) increase of temperature (b) addition of an inert gas
(c) addition of H_2 and I_2 (d) increase of pressure

63. In lime kilns, the following reversible reaction,

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

proceeds to completion because of: **(CPMT 1990)**
(a) high temperature
(b) CO_2 escapes
(c) low temperature
(d) molecular mass of CaO is less than that of $CaCO_3$

64. The equilibrium constant for the reaction,

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g), \text{ is:}$$

(a) $K_c = \dfrac{1}{[CO_2]}$ (b) $K_c = [CO_2]$
(c) $K_c = \dfrac{[CaO][CO_2]}{[CaCO_3]}$ (d) $K_c = \dfrac{[CaCO_3]}{[CaO][CO_2]}$

65. For the reaction, $C(s) + CO_2(g) \rightleftharpoons 2CO(g)$, the partial pressure of CO_2 and CO are 2.0 and 4.0 atm, respectively, at equilibrium. The K_p of the reaction is: **(IIT 1992)**
(a) 0.5 (b) 4.0
(c) 32.0 (d) 8.0

66. Iron fillings and water were placed in a 5 litre vessel and sealed. The tank was heated to 1000°C. Upon analysis the tank was found to contain 1.1 g of hydrogen and 42.5 g of water vapour. If the reaction in the tank is represented by,

$$3Fe(s) + 4H_2O(g) \rightleftharpoons Fe_3O_4(s) + 4H_2(g)$$

the value of equilibrium constant, K_c, is:
(a) 30 (b) 0.03
(c) 3 (d) 0.003

67. Ammonium hydrogen sulphide is contained in a closed vessel at 313 K when total pressure at equilibrium is found to be 0.8 atm. The value of K_p for the reaction, $NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$ is:
(a) 0.16 (b) 1.6 (c) 0.016 (d) 16

68. Variation of K with temperature as given by van't Hoff equation can be written as:
(a) $\log \dfrac{K_2}{K_1} = -\dfrac{\Delta H}{2.303R}\left[\dfrac{1}{T_1} - \dfrac{1}{T_2}\right]$
(b) $\log \dfrac{K_2}{K_1} = \dfrac{\Delta H}{2.303R}\left[\dfrac{1}{T_2} - \dfrac{1}{T_1}\right]$
(c) $\log \dfrac{K_2}{K_1} = -\dfrac{\Delta H}{2.303R}\left[\dfrac{1}{T_2} - \dfrac{1}{T_1}\right]$
(d) none of the above

69. When any system in equilibrium is subjected to a change in pressure, concentration or temperature, the equilibrium is shifted in the direction which tends to undo the effect of the change. This statement is known as:
(a) First law of thermodynamics
(b) Le Chatelier's principle
(c) Hess's law
(d) Ostwald's law

70. Le Chatelier's principle is applicable to:
(a) only homogeneous chemical reversible reactions
(b) only heterogeneous chemical reversible reactions
(c) only physical equilibria
(d) all systems, chemical or physical, in equilibrium

71. In the melting of ice, which one of the conditions will be more favourable?
(a) High temperature and high pressure
(b) Low temperature and low pressure
(c) Low temperature and high pressure
(d) High temperature and low pressure

72. Solubility of a gas in liquid increases on:
(a) addition of a catalyst (b) decreasing of pressure
(c) increasing of pressure (d) increasing of temperature

73. When KOH is dissolved in water, heat is evolved. If the temperature is raised, the solubility of KOH:
(a) increases (b) decreases
(c) remains the same (d) cannot be predicted

74. The yield of product in the reaction,

$$A_2(g) + 2B(g) \rightleftharpoons C(g) + Q \text{ kJ}$$

would be higher at:
(a) low temperature and high pressure
(b) high temperature and high pressure
(c) low temperature and low pressure
(d) high temperature and low pressure

75. Manufacture of ammonia from the elements is represented by,

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) + 22.4 \text{ kcal}$$

The maximum yield of ammonia will be obtained when the process is made to take place:
(a) at low pressure and high temperature
(b) at low pressure and low temperature
(c) at high pressure and high temperature
(d) at high pressure and low temperature

76. In the reaction, $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g) + X$ cal, most favourable conditions of temperature and pressure for greater yield of SO_3 are:
(a) low temperature and low pressure
(b) high temperature and low pressure
(c) high temperature and high pressure
(d) low temperature and high pressure

77. What is the direction of a reversible reaction when one of the products of the reaction is removed?
(a) The reaction moves towards right hand side
(b) The reaction moves towards left hand side
(c) The reaction moves equally on both the sides
(d) The reaction stops

78. In the reaction, $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$, $\Delta H = -93.6$ kJ, the yield of ammonia does not increase when:
(a) pressure is increased
(b) pressure is decreased
(c) temperature is lowered
(d) volume of the reaction vessel is decreased

79. A cylinder provided with a piston has some PCl_5 which is in equilibrium with PCl_3 and Cl_2. The system is compressed with the help of piston. Indicate the correct statement:
(a) some more PCl_5 will decompose
(b) the system remains unaffected
(c) PCl_3 and Cl_2 will combine to form PCl_5
(d) explosion occurs

80. In the manufacture of nitric oxide, the forward reaction is favoured by:
(a) high pressure (b) low pressure
(c) high temperature (d) low temperature

81. The reaction,

$$C_2H_4(g) + H_2(g) \rightleftharpoons C_2H_6(g); \Delta H = -32.7 \text{ kcal}$$

is carried out in a vessel. The equilibrium concentration of C_2H_4 can be increased by:
(a) increasing the temperature
(b) decreasing the pressure
(c) removing some hydrogen
(d) all of these

82. In an exothermic reaction, a 10°C rise in temperature will: **[PMT (Bangalore) 1993]**
(a) decrease the value of equilibrium constant
(b) double the value of equilibrium constant
(c) not produce any change in equilibrium constant
(d) produce some increase in equilibrium constant

83. If K_p for a reaction,

$$A(g) + 2B(g) \rightleftharpoons 3C(g) + D(g)$$

is 0.05 atm at 1000 K, its K_c in terms of R will be:
(a) $20000\,R$ (b) $0.02\,R$ (c) $5\times10^{-5}\,R$ (d) $\dfrac{5\times10^{-5}}{R}$

84. Consider the reaction, $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$ in closed container at equilibrium. What would be the effect of addition of $CaCO_3$ on the equilibrium concentration of CO_2? **(AIIMS 1991)**
(a) Increases
(b) Decreases
(c) Remains unaffected
(d) Data is not sufficient to predict it

85. XY_2 dissociates as:

$$XY_2(g) \rightleftharpoons XY(g) + Y(g)$$

Initial pressure of XY_2 is 600 mm Hg. The total pressure at equilibrium is 800 mm Hg. Assuming volume of system to remain constant, the value of K_p is: **(BHU 1992)**
(a) 50 (b) 100 (c) 200 (d) 400

[Hint: $XY_2(g) \rightleftharpoons XY(g) + Y(g)$
$600 - x \quad x \quad x$
$600 + x = 800$ or $x = 200$]

86. Which of the following reactions will be favoured at low pressure?
(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$
(b) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$
(c) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$
(d) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

87. According to Le Chatelier's principle, adding heat to a solid and liquid in equilibrium will cause the: **(MLNR 1990)**
(a) amount of solid to decrease
(b) amount of liquid to decrease
(c) temperature to rise
(d) temperature to fall

88. For the reaction:

$$2A(g) + B(g) \rightleftharpoons 3C(g) + D(g)$$

two moles each of A and B were taken into a flask. The following must always be true when the system attained equilibrium:
(a) $[A] = [B]$ (b) $[A] < [B]$
(c) $[B] = [C]$ (d) $[A] > [B]$

89. In a vessel containing SO_3, SO_2 and O_2 at equilibrium, some helium gas is introduced so that total pressure increases while temperature and volume remain the same. According to Le Chatelier's principle, the dissociation of SO_3: **(MLNR 1991)**
(a) increases (b) decreases
(c) remains unaltered (d) changes unpredictably

90. The equilibrium, $SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$ is attained at 25°C in a closed container and an inert gas, helium, is introduced. Which of the following statements is correct?
(a) Concentrations of SO_2Cl_2, SO_2 and Cl_2 do not change
(b) More Cl_2 is formed
(c) Concentration of SO_2 is reduced
(d) More SO_2Cl_2 is formed

91. The vapour density of undecomposed N_2O_4 is 46. When heated, vapour density decreases to 24.5 due to its dissociation to NO_2. The % dissociation of N_2O_4 is:
(a) 40 (b) 57
(c) 67 (d) 87

92. K_p/K_c for the reaction, $CO(g) + \frac{1}{2}O_2(g) \rightleftharpoons CO_2(g)$ is:
(a) RT (b) $\dfrac{1}{\sqrt{RT}}$ (c) $\sqrt{RT}$ (d) 1

93. For the reactions,
$A \rightleftharpoons B, K_c = 1$; $B \rightleftharpoons C, K_c = 3$; $C \rightleftharpoons D, K_c = 5$
K_c for the reaction $A \rightleftharpoons D$ is:
(a) 15 (b) 5 (c) 3 (d) 1

[Hint: $\dfrac{[B]}{[A]} = 1$; $\dfrac{[C]}{[B]} = 3$; $\dfrac{[D]}{[C]} = 5$,

Multiplying all the three, $\dfrac{[D]}{[A]} = 1\times3\times5$]

94. The equilibrium constant of the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ is 50. If the volume of the container is reduced to one half of its original value, the equilibrium constant will be:
(a) 25 (b) 50
(c) 75 (d) 100

95. $C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$
The above equilibrium when subjected to pressure: **[PMT (Raj.) 1992]**
(a) remains unaffected
(b) proceeds in the backward direction
(c) proceeds in the forward direction
(d) none of the above

96. Reaction, $A + B \longrightarrow C + D + 38$ kcal has activation energy 20 kcal. Activation energy for the reaction, $C + D \longrightarrow A + B$ is: **[PMT (Pb.) 1993]**

(a) 20 kcal (b) –20 kcal
(c) 18 kcal (d) 58 kcal

97. The equilibrium constant for the reaction,

$$CaSO_4 \cdot 5H_2O(s) \rightleftharpoons CaSO_4 \cdot 3H_2O(s) + 2H_2O(g),$$

is equal to:

(a) $\dfrac{[CaSO_4 \cdot 3H_2O][H_2O]^2}{[CaSO_4 \cdot 5H_2O]}$ (b) $\dfrac{[CaSO_4 \cdot 3H_2O]}{[CaSO_4 \cdot 5H_2O]}$
(c) $[H_2O]^2$ (d) $[H_2O]$

98. One mole of $N_2O_4(g)$ at 300 K is kept in a closed container under one atmosphere. It is heated to 600 K when 20% by mass of $N_2O_4(g)$ decomposes to $NO_2(g)$. The resultant pressure is:

(a) 1.2 atm (b) 2.4 atm (c) 2.0 atm (d) 1.0 atm

99. The equilibrium constant for the reaction, $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$ is 4.0×10^{-4} at 2000 K. In the presence of a catalyst the equilibrium is attained ten times faster. Therefore, the equilibrium constant in presence of the catalyst at 2000 K is: **(MLNR 1994)**

(a) 4×10^{-4}
(b) 40×10^{-4}
(c) 4×10^{-2}
(d) difficult to compute without more data

100. The equilibrium constant for a reaction, $A + B \rightleftharpoons C + D$ is 1×10^{-2} at 298 K and is 2 at 273 K. The chemical process resulting in the formation of C and D is:

(a) exothermic
(b) endothermic
(c) unpredictable
(d) there is no relationship between ΔH and K

101. The equilibrium constant for the reaction, $A + B \rightleftharpoons C + D$ is 2.85 at room temperature and 1.4×10^{-2} at 698 K. This shows that forward reaction is:

(a) exothermic
(b) endothermic
(c) unpredictable
(d) there is no relationship between ΔH and K

102. If E_f and E_r are the activation energies of forward and backward reactions and the reaction is known to be exothermic, then:

(a) $E_f > E_r$
(b) $E_f < E_r$
(c) $E_f = E_r$
(d) no relation can be given between E_f and E_r

103. K_p for a reaction at 25°C is 10 atm. The activation energy for forward and reverse reactions are 12 and 20 kJ/mol respectively. The K_c for the reaction at 40°C will be:

(a) $4.33 \times 10^{-1}\ M$ (b) $3.33 \times 10^{-2}\ M$
(c) $3.33 \times 10^{-1}\ M$ (d) $4.33 \times 10^{-2}\ M$

104. Concentration of pure solid and liquid is not included in the expression of equilibrium constant because:

(a) solid and liquid concentrations are independent of their quantities
(b) solid and liquids react slowly
(c) solid and liquids at equilibrium do not interact with gaseous phase
(d) the molecules of solids and liquids cannot migrate to the gaseous phase

105. For an equilibrium reaction involving gases, the forward reaction is first order while the reverse reaction is second order. The units of K_p for forward equilibrium is:

(a) atm (b) atm^2 (c) atm^{-1} (d) atm^{-2}

106. At temperature T, a compound $AB_2(g)$ dissociates according to the reaction:

$$2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$$

with a degree of dissociation 'x' which is small as compared to unity. The expression for K_p, in terms of 'x' and total pressure 'P' is

(a) $\dfrac{Px^3}{2}$ (b) $\dfrac{Px^2}{3}$
(c) $\dfrac{Px^3}{3}$ (d) $\dfrac{Px^2}{2}$

107. 40% mixture of 0.2 mole of N_2 and 0.6 mole of H_2 react to give NH_3 according to the equation:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

at constant temperature and pressure. Then the ratio of the final volume to the initial volume of gases is:

(a) 4 : 5 (b) 5 : 4
(c) 7 : 10 (d) 8 : 5

108. Two systems,

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

and $$COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g)$$

are simultaneously in equilibrium in a vessel at constant volume. If some $CO(g)$ is introduced in the vessel at constant volume, then at new equilibrium, the concentration of:

(a) PCl_5 is greater (b) PCl_3 remains unchanged
(c) PCl_5 is less (d) Cl_2 is greater

109. For the reaction, $[Ag(CN)_2]^- \rightleftharpoons Ag^+ + 2CN^-$, the equilibrium constant K_c at 25°C is 4×10^{-19}; then Ag^+ concentration in a solution which has 0.1 M KCN and 0.03 M $AgNO_3$ is:

(a) 7.5×10^{18} (b) 7.5×10^{-18}
(c) 7.5×10^{19} (d) 7.5×10^{-19}

110. When $NaNO_3$ is heated in a closed vessel, oxygen is liberated and $NaNO_2$ is left behind. At equilibrium:

(a) addition of $NaNO_2$ favours reverse reaction
(b) addition of $NaNO_2$ favours forward reaction
(c) increasing temperature favours forward reaction
(d) decreasing pressure favours reverse reaction

111. For the reaction,

$$CuSO_4 \cdot 5H_2O(s) \rightleftharpoons CuSO_4 \cdot 3H_2O(s) + 2H_2O(g)$$

which one is the correct representation?

(a) $K_p = [p_{H_2O}]^2$ (b) $K_c = [H_2O]^2$
(c) $K_p = K_c(RT)^2$ (d) All of these

112. Which one is the correct representation for,

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)?$$

(a) $K_p = \dfrac{[p_{SO_3}]^2}{[p_{SO_2}]^2[p_{O_2}]}$

(b) $K_c = \dfrac{[SO_3]^2}{[SO_2]^2[O_2]}$

(c) $K_p = \dfrac{[n_{SO_3}]^2}{[n_{SO_2}]^2[n_{O_2}]} \times \left[\dfrac{P}{\text{Total mole}}\right]^{-1}$

(d) All of the above

113. For the reaction,

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$ **(IIT 1991)**

The forward reaction at constant temperature is favoured by:

(a) introducing inert gas at constant volume

(b) introducing chlorine gas at constant volume

(c) introducing an inert gas at constant pressure

(d) none of the above

114. In a flask colourless N_2O_4 is in equilibrium with brown coloured NO_2. At equilibrium, when the flask is heated to 100°C the brown colour deepens and on cooling, the brown colour became less coloured. The change in enthalpy ΔH for the system is: **(KCET 1993)**

(a) negative (b) positive (c) zero (d) not defined

115. Le Chatelier's principle is not applicable to:

(a) $Fe(s) + S(s) \rightleftharpoons FeS(s)$

(b) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$

(c) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

(d) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

116. Densities of diamond and graphite are 3.5 and 2.3 g/mL respectively. Increase in pressure on the equilibrium $C_{\text{diamond}} \rightleftharpoons C_{\text{graphite}}$:

(a) favours backward reaction

(b) favours forward reaction

(c) has no effect

(d) increases the reaction rate

117. For the reaction, $N_2 + 3H_2 \rightleftharpoons 2NH_3$ in a vessel, after the addition of equal number of moles of N_2 and H_2 equilibrium state is achieved. Which of the following is correct?

(a) $[H_2] = [N_2]$ (b) $[H_2] < [N_2]$

(c) $[H_2] > [N_2]$ (d) $[H_2] > [NH_3]$

118. If pressure is applied to the equilibrium of solid $\rightleftharpoons$ liquid, the melting point of the solid:

(a) will not change

(b) may increase or decrease depending upon its nature

(c) will always increase

(d) will always decrease

119. If concentrations of N_2, H_2 and NH_3 are 1, 2 and 3 respectively, their concentration at equilibrium will be:

	N_2 +	$3H_2 \rightleftharpoons$	$2NH_3$
(a)	$(1-x)$	$(2-3x)$	$2x$
(b)	$(1-x/3)$	$(2-x)$	$2x/3$
(c)	$(1-x)$	$(2-x)$	$(3+x)$
(d)	$(1-x)$	$(2-3x)$	$(3+2x)$

120. A reaction attains equilibrium, when the free energy change is:

(a) zero (b) positive and large

(c) negative and small (d) negative and large

121. If 340 g of a mixture of N_2 and H_2 in the correct ratio gave a 20% yield of NH_3, the mass produced would be:

(a) 16 g (b) 17 g (c) 20 g (d) 68 g

122. If the pressure of N_2 / H_2 mixture in a closed apparatus is 100 atm and 20% of the mixture then reacts, the pressure at the same temperature would be:

(a) 100 (b) 90 (c) 85 (d) 80

123. The equilibrium constants for the reaction, $Br_2 \rightleftharpoons 2Br$, at 500 K and 700 K are 1×10^{-10} and 1×10^{-5} respectively. The reaction is:

(a) endothermic (b) exothermic

(c) fast (d) slow

124. If the concentration of OH^- ions in the reaction:

$$Fe(OH)_3(s) \rightleftharpoons Fe^{3+}(aq.) + 3OH^-(aq.)$$

is decreased by $\frac{1}{4}$ times, then equilibrium concentration of Fe^{3+} will increase by: **[CBSE (PMT) 2008]**

(a) 64 times (b) 4 times (c) 8 times (d) 16 times

125. K_c for $A + B \rightleftharpoons C + D$ is 10 at 25°C. If a container contains 1, 2, 3 and 4 mol per litre of A, B, C and D respectively at 25°C, the reaction shall:

(a) proceed from left to right (b) proceed from right to left

(c) be at equilibrium (d) none of these

126. In the preparation of CaO from $CaCO_3$ using the equilibrium,

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

K_p is expressed as:

$$\log K_p = 7.282 - \frac{8500}{T}$$

For complete decomposition of $CaCO_3$ the temperature in celsius to be used is:

(a) 1167 (b) 894

(c) 8500 (d) 850

127. To the system,

$$LaCl_3(s) + H_2O(g) \rightleftharpoons LaClO(s) + 2HCl(g) - \text{heat}$$

already at equilibrium, more water vapour is added without altering T or V of the system. When equilibrium is re-established, the pressure of water vapour is doubled. The pressure of HCl present in the system increases by a factor of:

(a) 2 (b) $2^{1/2}$ (c) 3 (d) 4

128. For the chemical reaction,

$$3X(g) + Y(g) \rightleftharpoons X_3Y(g)$$

the amount of X_3Y at equilibrium is affected by: **(IIT 1999)**

(a) temperature and pressure

(b) temperature only

(c) pressure only

(d) temperature, pressure and catalyst

129. In a 500 mL capacity vessel CO and Cl_2 are mixed to form $COCl_2$. At equilibrium, it contains 0.2 mole of $COCl_2$ and 0.1 mole of each of CO and Cl_2. The equilibrium constant K_c for reaction, $CO + Cl_2 \rightleftharpoons COCl_2$ is: **(CBSE 1998)**

(a) 5 (b) 10 (c) 15 (d) 20

130. The partial pressures of CH_3OH, CO and H_2 in the equilibrium mixture for the reaction,

$$CO + 2H_2 \rightleftharpoons CH_3OH$$

at 427°C are 2.0, 1.0 and 0.1 atm respectively. The value of K_p for the decomposition of CH_3OH into CO and H_2 is:

(IIT 1999)

(a) 1×10^2 atm (b) 2×10^2 atm^{-1}
(c) 50 atm^2 (d) 5×10^{-3} atm^2

131. 8 mole of a gas AB_3 are introduced into a 1.0 dm^3 vessel. It dissociates as:

$$2AB_3(g) \rightleftharpoons A_2(g) + 3B_2(g)$$

At equilibrium, 2 mole of A_2 are found to be present. The equilibrium constant of the reaction is: **(IIT 1997)**

(a) 2 mol^2 L^{-2} (b) 3 mol^2 L^{-2}
(c) 27 mol^2 L^{-2} (d) 36 mol^2 L^{-2}

132. At constant temperature, the equilibrium constant (K_p) for the decomposition reaction,

$$N_2O_4 \rightleftharpoons 2NO_2$$

is expressed by:

$$K_p = \frac{4x^2P}{(1-x^2)}$$

Where, P = pressure, x = extent of decomposition. Which one of the following statements is true? **[IIT (Screening) 2000]**

(a) K_p increases with increase of P
(b) K_p increases with increase of x
(c) K_p increases with decrease of x
(d) K_p remains constant with change in P and x

133. Consider the reactions,

$$NO_2(g) \rightleftharpoons \frac{1}{2}N_2(g) + O_2(g) \qquad K_1$$

$$N_2O_4(g) \rightleftharpoons 2NO_2(g) \qquad K_2$$

Give the equilibrium constant for the formation of N_2O_4 from N_2 and O_2: **(DCE 2006)**

(a) $\frac{1}{K_1^2} \times \frac{1}{K_2}$ (b) $\frac{1}{2K_1} + \frac{1}{K_2}$ (c) $\sqrt{\frac{1}{K_1K_2}}$ (d) $\frac{K_2}{K_1}$

[Hint: $NO_2(g) \rightleftharpoons \frac{1}{2}N_2(g) + O_2(g) \; K_1$

$\therefore \quad N_2(g) + 2O_2(g) \rightleftharpoons 2NO_2(g) \qquad K = \frac{1}{K_1^2} \qquad$ ... (i)

$N_2O_4(g) \rightleftharpoons 2NO_2(g) \qquad K_2$

$\therefore \quad 2NO_2(g) \rightleftharpoons N_2O_4(g) \qquad K = \frac{1}{K_2} \qquad$ ... (ii)

Adding eqs. (i) and (ii),

$N_2(g) + 2O_2(g) \rightleftharpoons N_2O_4(g) \qquad K = \frac{1}{K_1^2} \times \frac{1}{K_2}$]

134. Phosphorous pentachloride dissociates as follows:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g).$$

If total pressure at equilibrium is P and the degree of dissociation of PCl_5 is x, the partial pressure of PCl_3 will be: **(AIEEE 2006)**

(a) $\left(\frac{x}{x+1}\right)P$ (b) $\left(\frac{2x}{1-x}\right)P$ (c) $\left(\frac{x}{x-1}\right)P$ (d) $\left(\frac{x}{1-x}\right)P$

135. At $t = 0$ a vessel (volume 1 litre) contains 1 mole N_2, 3 mole H_2 and 2 mole NH_3. The value of K_c for $N_2 + 3H_2 \rightleftharpoons 2NH_3$ is 17.5 L^2 mol^{-2}. Then:

(a) total gaseous weight at equilibrium is more than 68 g
(b) total number of moles (gaseous) at equilibrium are more than 6 moles
(c) $\frac{dM}{dt}$ is +ve for $t \in (0, T_{eq.})$ where, M is average molar mass of the reaction mixture
(d) total gaseous weight at equilibrium is less than 68 g

136. A vessel (volume = 2 L) contains 60 g of water gas. When steam is passed through the vessel, the reaction, $CO + H_2O \rightleftharpoons CO_2 + H_2$ occurs and equilibrium is attained:

(a) $\frac{n(H_2)}{n(CO)} < 1$ (at equilibrium)
(b) $n(H_2) + n(CO) = 4$ (at any instant)
(c) $\frac{dM}{dt} > 0$ (where, M is average molar mass of gas mixture before the attainment of equilibrium)
(d) $\frac{dM}{dt} < 0$

137. A vessel contains CO_2 and CO with pressures 2 atm and 3 atm respectively at 27°C. At a temperature of 2727°C, the reaction $2CO(g) \rightleftharpoons CO_2(g) + C(s)$ occurs and equilibrium is attained. If the equilibrium pressure is 45 atm, then:

(a) $K_p = 2/9$ atm^{-1}
(b) $p_{CO} : p_{CO_2} = 4:5$ at equilibrium
(c) $K_p = 16$ atm^{-1}
(d) % dissociation of CO = 0.333

138. A vessel (volume 8.2 L) contains $H_2(g)$ at 2 atm pressure. When $H_2S(g)$ at a pressure of 4 atm is introduced into the vessel, the reaction, $8H_2S(g) \rightleftharpoons 8H_2(g) + S_8(s)$ occurs at a temperature of 2000 K. It is found that:

$$\left[\frac{n(H_2)}{n(H_2S)}\right]_{\text{at equilibrium}} = \left[\frac{n(H_2S)}{n(H_2)}\right]_{\text{at } t=0}$$

(a) maximum weight of solid formed is 32 g
(b) maximum weight of solid formed is 0.32 g
(c) $K_p = K_c\,RT$
(d) $K_c = 256$

139. $N_2(g)$ and $H_2(g)$ are taken in a vessel in mass ratio of 7 : 1. The only reaction $N_2 + 2H_2 \rightleftharpoons N_2H_4(g)$ occurs. Pressure due to N_2H_4 at equilibrium is 0.2 times of total pressure 'P'. Then at equilibrium:

(a) partial pressure of $N_2 = 2P/15$
(b) partial pressure of $H_2 = 8P/25$
(c) $2p_{N_2} = p_{H_2}$
(d) $p_{N_2} = 2p_{H_2}$

140. In the equilibrium, $SO_2Cl_2 \rightleftharpoons SO_2 + Cl_2$ at 2000 K and 10 atm pressure, % Cl_2 = % SO_2 = 40 by volume. Then:

(a) $K_p = 2$ atm
(b) $\frac{n(SO_2Cl_2)}{n(SO_2)} = \frac{1}{4}$ at equilibrium
(c) $K_p = 8$ atm
(d) $n(SOCl_2) = n(SO_2) = n(Cl_2)$

141. A 20 litre box contains O_3 and O_2 at equilibrium at 202 K. $K_p = 2 \times 10^{14}$ for $2O_3 \rightleftharpoons 3O_2$. Assume that $p_{O_2} >> p_{O_3}$ and total pressure is 8 atm; the partial pressure of O_3 is:

(a) exactly 1.6×10^{-6} atm
(b) sufficiently less than 1.6×10^{-6} atm

(c) slightly more than 1.6×10^{-6} atm

(d) very slightly less than 1.6×10^{-6} atm

142. For the reactions, $A \rightleftharpoons B, B \rightleftharpoons C$ and $C \rightleftharpoons D$, equilibrium constants are K_1, K_2 and K_3 respectively. What is the value of equilibrium constant for $A \rightleftharpoons D$?

(a) $K_1 + K_2 + K_3$ (b) $K_1 \times K_2 \times K_3$

(c) $K_1K_2/3$ (d) None of these

143. $AO \rightleftharpoons \left(\frac{1}{2}\right) A_2 + \left(\frac{1}{2}\right) O_2; K = 5 \times 10^5$

$BO \rightleftharpoons \left(\frac{1}{2}\right) B_2 + \left(\frac{1}{2}\right) O_2; K = 1.10 \times 10^{12}$

$CO \rightleftharpoons \left(\frac{1}{2}\right) C_2 + \left(\frac{1}{2}\right) O_2; K = 2.3 \times 10^{18}$

$DO \rightleftharpoons \left(\frac{1}{2}\right) D_2 + \left(\frac{1}{2}\right) O_2; K = 1.4 \times 10^{21}$

Which oxide is most stable?

(a) AO (b) BO (c) CO (d) DO

144. Which graph will show equilibrium condition?

(a) 
(b) 
(c) 
(d) None of these

145. For the reaction, $N_2 + O_2 \rightleftharpoons 2NO$ equilibrium constant $K_c = 2$. Degrees of dissociation of N_2 and O_2 are:

(a) $\frac{1}{1+\sqrt{2}}, \frac{1}{1-\sqrt{2}}$ (b) $\frac{1}{1-\sqrt{2}}, \frac{1}{1+\sqrt{2}}$

(c) both are $\frac{1}{1+\sqrt{2}}$ (d) $\frac{2}{1+\sqrt{2}}, \frac{2}{1-\sqrt{2}}$

146. $A \rightleftharpoons 2B, K_p$; $C \rightleftharpoons D + E, K_{p'}$. If degrees of dissociation of A and C are same and $K_p = 2K_{p'}$, then the ratio of total pressure p/p' = ?

(a) 1/2 (b) 1/3 (c) 1/4 (d) 2

147. Equilibrium constants for four different reactions are given as: $K_1 = 10^6$, $K_2 = 10^{-4}$, $K_3 = 10$, $K_4 = 1$. Which reaction will take maximum time to attain equilibrium?

(a) $K_1 = 10^6$ (b) $K_2 = 10^{-4}$

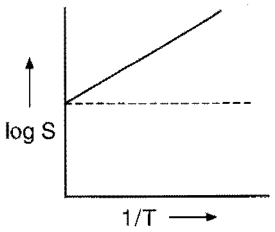
(c) $K_3 = 10$ (d) $K_4 = 1$

148. Solubility of a solute in water is dependent on temperature as given by,

$S = Ae^{-\Delta H/RT}$ where, ΔH = heat of solution

Solute + $H_2O(l) \rightleftharpoons$ Solution; $\Delta H = \pm x$

For a given solution, variation of log S with temperature is shown graphically. Hence, solute is:



(a) $CuSO_4 \cdot 5H_2O$

(b) NaCl

(c) sucrose

(d) CaO

149. $CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-CH_3(g) \rightleftharpoons CH_3-CH_3(g) + CO(g)$

Initial pressure of CH_3COCH_3 is 100 mm. When equilibrium is achieved, the mole fraction of $CO(g)$ is 1/3 hence, K_p is:

(a) 100 mm (b) 50 mm (c) 25 mm (d) 150 mm

150. In which of the following equilibrium, change in the volume of the system does not alter the number of moles? **(AIEEE 2002)**

(a) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

(b) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

(c) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

(d) $SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$

151. What are the most favourable conditions for the reaction;

$$SO_2(g) + \frac{1}{2} O_2(g) \rightleftharpoons SO_3(g); \Delta H^\circ = -\text{ve}$$

to occur? **[DPMT 2002; JEE (Orissa) 2[illegible]]**

(a) low temp. and high press. (b) low temp. and low press.

(c) high temp. and low press. (d) high temp. and high press.

152. Consider the following reactions in which all the reactants and products are in gaseous state

$$2PQ \rightleftharpoons P_2 + Q_2; \ K_1 = 2.5 \times 10^5$$

$$PQ + \frac{1}{2}R_2 \rightleftharpoons PQR \ ; \ K_2 = 5 \times 10^{-3}$$

The value of K_3 for the equilibrium :

$\frac{1}{2}P_2 + \frac{1}{2}Q_2 + \frac{1}{2}R_2 \rightleftharpoons PQR$ is : **[PET (Kerala) 2010]**

(a) 2.5×10^{-3} (b) 2.5×10^3

(c) 1.0×10^{-5} (d) 5×10^3

(e) 5×10^{-3}

[Hint:

$$\begin{array}{ll} \frac{1}{2}P_2 + \frac{1}{2}Q_2 \rightleftharpoons PQ & K = \frac{1}{K_1^{1/2}} \\ PQ + \frac{1}{2}R_2 \rightleftharpoons PQR & K_2 \\ \hline \frac{1}{2}P_2 + \frac{1}{2}Q + \frac{1}{2}R_2 \rightleftharpoons PQR & K_3 = \frac{1}{K_1^{1/2}} \times K_2 \\ \hline & = \frac{5 \times 10^{-3}}{(2.5 \times 10^5)^{1/2}} \\ & = 1 \times 10^{-5} \end{array}$$

]

153. Consider the following equilibrium in a closed container,

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

At a fixed temperature, the volume of the reaction container is halved. For this change, which of the following statements holds true regarding the equilibrium constant (K_p) and degree of dissociation (α)? **(IIT 2002)**

(a) neither K_p nor 'α' changes

(b) both K_p and 'α' change

(c) K_p changes but 'α' does not

(d) K_p does not change but 'α' changes

154. For the reaction, $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$, the position of equilibrium can be shifted to the right by: **[PET (MP) 2004]**

(a) doubling the volume

(b) increasing the temperature

(c) addition of equimolar quantities of PCl_3 and PCl_5

(d) addition of Cl_2 at constant volume

155. The most favourable condition for the manufacture of NH_3 is: **[CECE (Bihar) 2004]**

(a) high temperature and high pressure

(b) low temperature and low pressure

(c) high temperature and low pressure

(d) low temperature and high pressure

156. The chemical equilibrium of a reversible reaction is not influenced by: **(KCET 2004)**

(a) catalyst (b) pressure

(c) temperature (d) concentration

157. Which of the following change will shift the reaction in forward direction?

$I_2(g) \rightleftharpoons 2I(g); \Delta H° = +150$ kJ **(AIIMS 2004)**

(a) Increase in total pressure

(b) Increase in temperature

(c) Increase in concentration of I

(d) Decrease in concentration of I_2

158. For the reaction, $CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$, the $\frac{K_p}{K_c}$ is equal to: **(AIEEE 2004)**

(a) $1/RT$ (b) RT (c) $\sqrt{RT}$ (d) 1

159. The equilibrium constant for the reaction,

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$

at temperature T is 4×10^{-4}.

The value of K_c for the reaction,

$$NO(g) \rightleftharpoons \frac{1}{2} N_2(g) + \frac{1}{2} O_2(g)$$

at the same temperature is: **(AIEEE 2004)**

(a) 2.5×10^2 (b) 50 (c) 4×10^{-4} (d) 0.02

160. 2 moles of N_2 are mixed with 6 moles of H_2 in a closed vessel of one litre capacity. If 50% N_2 is converted into NH_3 at equilibrium, the value of K_c for the reaction,

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

[PMT (Kerala) 2004]

(a) 4/27 (b) 27/4

(c) 1/27 (d) 27

(e) 9

161. For the reaction, $H_2(g) + CO_2(g) \rightleftharpoons CO(g) + H_2O(g)$, if the initial concentration of $[H_2] = [CO_2]$ and x mol/litre of H_2 is consumed at equilibrium, the correct expression of K_p is: **[JEE (Orissa) 2005]**

(a) $\frac{x^2}{(1-x)^2}$ (b) $\frac{(1+x)^2}{(1-x)^2}$ (c) $\frac{x^2}{(2+x)^2}$ (d) $\frac{x^2}{1-x^2}$

162. Partial pressure of O_2 in the reaction,

$$2Ag_2O(s) \rightleftharpoons 4Ag(s) + O_2(g)$$

is: **(DCE 2005)**

(a) K_p (b) $\sqrt{K_p}$ (c) $\sqrt[3]{K_p}$ (d) $2K_p$

163. Two moles of PCl_5 are heated in a closed vessel of 2 litre capacity. When the equilibrium is attained 40% of it has been found to be dissociated. What is the value of K_c in mol/dm³? **[PET (Kerala) 2005]**

(a) 0.532 (b) 0.266 (c) 0.133 (d) 0.174

(e) 0.25

[Hint:

$$\begin{array}{llll} & PCl_5(g) & \rightleftharpoons PCl_3(g) & + \; Cl_2(g) \\ t = 0 & 2 & 0 & 0 \\ t_{eq.} & \frac{2-0.8}{2} & \frac{0.8}{2} & \frac{0.8}{2} \end{array}$$

$$K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{\frac{0.8}{2} \times \frac{0.8}{2}}{\frac{1.2}{2}} = \frac{0.64}{2.4} = 0.266]$$

164. For the reaction:

$$2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$$

$K_c = 1.8 \times 10^{-6}$ at 184°C

$R = 0.0831$ kJ K^{-1} mol^{-1}

when, K_p and K_c are compared at 184°C it is found that: **(AIEEE 2005)**

(a) K_p is greater than K_c

(b) K_p is less than K_c

(c) $K_p = K_c$

(d) whether K_p is greater than, less than or equal to K_c depends upon the total gas pressure

[Hint: $K_p = K_c\,(RT)^{\Delta n}$

$\Delta n = 3 - 2 = 1$

$K_p = K_c\,(RT)^1$

$\therefore \quad K_p > K_c$]

165. $NH_4COONH_2(s) \rightleftharpoons 2NH_3(g) + CO_2(g)$. If equilibrium pressure is 3 atm for the above reaction; K_p will be: **(DPMT 2005)**

(a) 4 (b) 27 (c) 4/27 (d) 1/27

[Hint: $p_{NH_3} : p_{CO_2} = 2 : 1$

$\therefore \quad p_{NH_3} = 2$ atm; $p_{CO_2} = 1$ atm

$K_p = [p_{NH_3}]^2[p_{CO_2}] = 2^2 \times 1 = 4$]

166. $A + B \rightleftharpoons C + D$. If initially the concentration of A and B are both equal but at equilibrium, concentration of D will be twice of that of A, then what will be the equilibrium constant of the reaction? **[BHU (Pre.) 2005; JIPMER 2006]**

(a) $\frac{4}{9}$ (b) $\frac{9}{4}$ (c) $\frac{1}{9}$ (d) 4

[Hint:

$$\begin{array}{lllll} & A & + \; B & \rightleftharpoons C & + \; D \\ t = 0 & a & a & 0 & 0 \\ t_{eq.} & a - x & a - x & x & x \end{array}$$

$x = 2(a - x)$

$3x = 2a$

$$K = \frac{x \times x}{(a-x)(a-x)} = \frac{x \times x}{\frac{x}{2} \times \frac{x}{2}} = 4]$$

167. 15 moles of H_2 and 5.2 moles of I_2 are mixed and allowed to attain equilibrium at 500°C. At equilibrium, the concentration of HI is found to be 10 moles. The equilibrium constant for the formation of HI is: **(KCET 2005)**

(a) 50 (b) 15 (c) 100 (d) 25

[Hint:

$$\begin{array}{lccc} & H_2 & + \; I_2 & \rightleftharpoons 2HI \\ t=0 & 15 & 5.2 & 0 \\ t_{eq.} & 15-5 & 5.2-5 & 10 \end{array}$$

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{100}{10 \times 0.2} = 50]$$

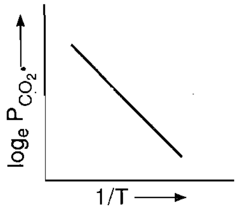
168. For the reaction: $2NOCl(g) \rightleftharpoons 2NO(g) + Cl_2(g)$, K_c at 427°C is 3×10^6 L mol^{-1}. The value of K_p is nearly: **(AIIMS 2005)**

(a) 7.5×10^{-5} (b) 2.5×10^{-5} (c) 2.5×10^{-4} (d) 1.75×10^{-4}

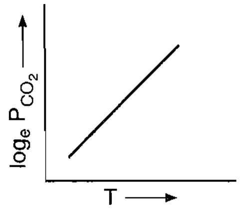
169. For the chemical equilibrium,

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

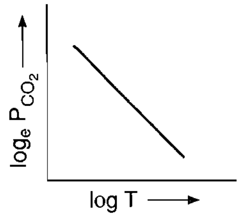
ΔH_r° can be determined from which one of the following plots? **(AIIMS 2005)**



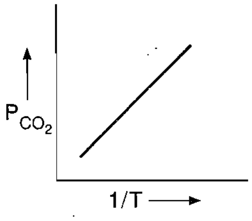
(a)



(b)



(c)



(d)

[Hint: $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

$$K_p = P_{CO_2}$$

According to Arrhenius equation:

$$K = Ae^{-\Delta H_r^\circ/RT}$$

$$\log K_p = \log A - \frac{\Delta H_r^\circ}{2.303RT}$$

$$\log P_{CO_2} = \log A - \frac{\Delta H_r^\circ}{2.303R}\frac{1}{T} \quad \text{... (i)}$$

$$Y = C + MX$$

Graph (a) represents (i) and its slope will be used to determine the heat of the reaction.]

170. In gaseous reversible reaction,

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) + \text{Heat}$$

If pressure is increased, then the equilibrium constant would be: **[UGET (Manipal, Medical) 2006]**

(a) unchanged
(b) increased
(c) decreased
(d) sometimes increased, sometimes decreased

171. If the equilibrium constant for the reaction,

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

at 750 K is 49, then the equilibrium constant for the reaction,

$$NH_3(g) \rightleftharpoons \frac{1}{2}N_2(g) + \frac{3}{2}H_2(g)$$

at the same temperature is: **[PMT (Kerala) 2006]**

(a) 1/49 (b) 49 (c) 7 (d) 49^2
(e) 1/7

172. The equilibrium constant for the reaction,

$$SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$$

is $K_c = 4.9 \times 10^{-2}$.

The value of K_c for the reaction,

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

will be: **(AIEEE 2006)**

(a) 416 (b) 2.40×10^{-3}
(c) 9.8×10^{-2} (d) 4.9×10^{-2}

[Hint: $SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$; $K_c = 4.9 \times 10^{-2}$

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g); \qquad K_c = \left(\frac{1}{4.9 \times 10^{-2}}\right)^2$$

$$= 416.5 \approx 416]$$

173. For a reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ at 721 K, the value of equilibrium constant is 50. If 0.5 mol each of H_2 and I_2 is added to the system, the value of equilibrium constant will be: **[VMMC (Safdarjung) 2006]**

(a) 40 (b) 60 (c) 50 (d) 30

[Hint: Equilibrium constant does not change on adding the reactant.]

174. In the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, in a 2 litre flask 0.4 mole of each H_2 and I_2 are taken. At equilibrium 0.5 mole of HI are formed. What will be the value of equilibrium constant K_c? **[PMT (Raj.) 2006]**

(a) 20.2 (b) 25.4 (c) 0.284 (d) 11.1

175. For the reaction, $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$, the equilibrium constant K_p changes with: **(VITEEE 2007)**

(a) total pressure (b) catalyst
(c) the amount of H_2 and I_2 (d) temperature

176. Given the equilibrium system,

$$NH_4Cl(s) \rightleftharpoons NH_4^+(aq.) + Cl^-(aq.)$$

$$(\Delta H^\circ = +3.5 \text{ kcal/mol})$$

what change will shift the equilibrium to the right? **(VITEEE 2007)**

(a) Decreasing the temperature
(b) Increasing the temperature
(c) Dissolving NaCl crystals in equilibrium mixture
(d) Dissolving NH_4NO_3 crystals in the equilibrium mixture

177. The equilibrium constant (K_p) for the decomposition of gaseous H_2O:

$H_2O(g) \rightleftharpoons H_2(g) + \frac{1}{2}O_2(g)$ is related to degree of dissociation (α) at a total pressure P is given by: **[PMT (Kerala) 2007]**

(a) $K_p = \dfrac{\alpha^3 P^{1/2}}{(1+\alpha)(2+\alpha)^{1/2}}$ (b) $K_p = \dfrac{\alpha^3 P^{3/2}}{(1-\alpha)(2+\alpha)^{1/2}}$

(c) $K_p = \dfrac{\alpha^{3/2} P^2}{(1-\alpha)(2+\alpha)^{1/2}}$ (d) $K_p = \dfrac{\alpha^{3/2} P^{1/2}}{(1-\alpha)(2+\alpha)^{1/2}}$

(e) $K_p = \dfrac{\alpha^2 P}{\sqrt{2}}$

[**Hint:** $H_2O(g) \rightleftharpoons H_2(g) + \frac{1}{2}O_2(g)$

$$\begin{array}{llll} t = 0 & 1 & 0 & 0 \\ t_{eq.} & 1-\alpha & \alpha & \alpha/2 \end{array}$$

$$\Sigma n = 1 - \alpha + \alpha + \frac{\alpha}{2} = 1 + \frac{\alpha}{2} = \left(\frac{2+\alpha}{2}\right)$$

$$K_p = \frac{n_{H_2} \times n_{O_2}^{1/2}}{n_{H_2O}} \times \left(\frac{P}{\Sigma n}\right)^{\Delta n}$$

$$= \frac{\alpha \times \left(\frac{\alpha}{2}\right)^{1/2}}{(1-\alpha)} \times \left[\frac{P}{\left(\frac{2+\alpha}{2}\right)}\right]^{1/2}$$

$$= \frac{\alpha^{3/2} P^{1/2}}{(1-\alpha)(2+\alpha)^{1/2}}]$$

178. The equilibrium constant for the reaction,

$2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$ is 2×10^{-6} at 185° C

Then, the equilibrium constant for the reaction, $4NO(g) + 2O_2(g) \rightleftharpoons 4NO_2(g)$ at the same temperature would be: **[PET (Kerala) 2007]**

(a) 2.5×10^{-5} (b) 4×10^{-12} (c) 2.5×10^{11} (d) 2×10^6

(e) 5×10^5

179. 1 mole of H_2 and 2 mole of I_2 are taken initially in a 2 L vessel. The number of moles H_2 at equilibrium is 0.2. Then, the number of moles of I_2 and HI at equilibrium are: **[PMT (Raj.) 2007]**

(a) 1.2, 1.6 (b) 1.8, 1.0 (c) 0.4, 2.4 (d) 0.8, 2.0

180. The dissociation equilibrium of a gas AB_2 can be represented as,

$$2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$$

The degree of dissociation is x and is small as compared to 1. The expression relating the degree of dissociation (x) with equilibrium constant K_p and total pressure P is:

(a) $(2K_p/P)^{1/2}$ (b) K_p/P (c) $2K_p/P$ (d) $(2K_p/P)^{1/3}$

[CBSE (PMT) 2008]

[**Hint :** $2AB_2(g) \rightleftharpoons 2AB(g) + B_2(g)$

$$\begin{array}{lllll} t_0 & 2 & 0 & 0 & \\ t_{eq.} & 2(1-x) & 2x & x & \text{Total moles} = 2 + x \\ \text{Partial pressure} & \frac{2(1-x)}{2+x} \times P & \frac{2x}{2+x} \times P & \frac{x}{2+x} \times P & \end{array}$$

$$K_p = \frac{p_{AB}^2 \times p_{B_2}}{(p_{AB_2})^2} = \frac{\left[\frac{2}{(2+x)} P\right]^2 \left[\frac{xP}{(2+x)}\right]}{\left[\frac{2(1-x)}{2+x} \times P\right]^2}$$

$$= \frac{4x^3 \times P}{4(2+x)(1-x)^2}$$

$(2+x) \approx 2, (1-x) \approx 1$

$K_p = \dfrac{Px^3}{2}$ $\quad \therefore x = (2K_p/P)^{1/3}$]

181. In which of the following reactions, the concentration of the product is higher than the concentration of reactant at equilibrium ? (K = equilibrium constant) **(AIIMS 2008)**

(a) $A \rightleftharpoons B$; $K = 0.001$ (b) $M \rightleftharpoons N$; $K = 10$

(c) $X \rightleftharpoons Y$; $K = 0.005$ (d) $R \rightleftharpoons P$; $K = 0.01$

182. 1.6 mole of $PCl_5(g)$ is placed in 4 dm^3 closed vessel. When the temperature is raised to 500 K, it decomposes and at equilibrium 1.2 mole of $PCl_5(g)$ remains. What is the K_c value for the decomposition of $PCl_5(g)$ to $PCl_3(g)$ and $Cl_2(g)$ at 500K? [PET (Kerala) 2008]

(a) 0.013 (b) 0.050 (c) 0.033 (d) 0.067

(e) 0.045

183. Consider the following statements regarding chemical equilibrium:

1. For the gaseous reaction, the equilibrium can be established in open vessel.
2. The state of equilibrium is dynamic in nature.
3. If temperature is kept constant, the colour of the reacting system changes with time.

Which of the statements given above is/are correct? (SCRA 2009)

(a) 1 (b) 2 only

(c) 3 only (d) 2 and 3 only

184. The dissociation constants for acetic acid and HCN at 25°C are 1.5×10^{-5} and 4.5×10^{-10} respectively. The equilibrium constant for the equilibrium:

$$CN^- + CH_3COOH \rightleftharpoons HCN + CH_3COO^-$$

would be : **[CBSE (PMT) 2009]**

(a) 3×10^4 (b) 3×10^5

(c) 3×10^{-5} (d) 3×10^{-4}

[**Hint :** Given

(i) $CH_3COOH \rightleftharpoons CH_3COO^- + H^+ \quad K_1 = 1.5 \times 10^{-5}$

(ii) $HCN \rightleftharpoons H^+ + CN^- \quad K_2 = 4.5 \times 10^{-10}$

(iii) $H^+ + CN^- \rightleftharpoons HCN \quad K_3 = \dfrac{1}{K_2} = \dfrac{1}{4.5 \times 10^{-10}}$

Adding (i) and (iii) we get

$$CH_3COOH + CN^- \rightleftharpoons CH_3COO^- + HCN$$

$$K = 1.5 \times 10^{-5} \times \frac{1}{4.5 \times 10^{-10}}$$

$$= 3 \times 10^4]$$

185. One mole of N_2O_4 is heated in a flask with a volume of 0.1 dm^3. At equilibrium, 1.708 mole of NO_2 and 0.146 mole of N_2O_4 were found 134°C. The equilibrium constant will be: (MPPET 2009)

(a) 250 mol dm^{-3} (b) 300 mol dm^{-3}

(c) 200 mol dm^{-3} (d) 230 mol dm^{-3}

186. What is the effect of a tenfold increase in pressure on K_p in the reaction?

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

At equilibrium : (EAMCET 2010)

(a) a tenfold increase
(b) a tenfold decrease
(c) no change
(d) equal to K_c

Set–2: The Questions given below may have more than one correct answers

1. Unit of equilibrium constant is:
(a) $(\text{mol/L})^{1-n}$
(b) $(\text{mol/L})^{\Delta n}$
(c) $(\text{atm})^{\Delta n}$
(d) all of these

2. Which is/are correct?
(a) $2.303 \log K = -\Delta H°/RT + \Delta S°/R$
(b) $\Delta G° = -2.303RT \log K$
(c) $-2.303 \log K = -\Delta H°/RT^2 + \Delta S°/R$
(d) $2.303 \log K = (1/RT)(\Delta H° + \Delta S°)$

3. For the reaction, $CaCO_3(s) \rightarrow CaO(s) + CO_2(g)$, which is correct representation?
(a) $K_p = (p_{CO_2})$
(b) $K_p = K_c(RT)$
(c) $K_c = (CO_2)/1$
(d) All of these

4. $N_2 + O_2 \rightleftharpoons 2NO, K_1; \left(\frac{1}{2}\right) N_2 + \left(\frac{1}{2}\right) O_2 \rightleftharpoons NO, K_2;$

$2NO \rightleftharpoons N_2 + O_2, K_3; NO \rightleftharpoons \left(\frac{1}{2}\right) N_2 + \left(\frac{1}{2}\right) O_2, K_4$

Correct relation(s) between K_1, K_2, K_3 and K_4 is/are:
(a) $K_1 \times K_3 = 1$
(b) $\sqrt{K_1} \times K_4 = 1$
(c) $\sqrt{K_3} \times K_2 = 1$
(d) none of these

5. For the reaction, $N_2O_4 \rightleftharpoons 2NO_2$, if degree of dissociation of N_2O_4 are 25%, 50%, 75% and 100%, the gradation of observed vapour densities is:
(a) $d_1 > d_2 > d_3 > d_4$
(b) $d_4 > d_3 > d_2 > d_1$
(c) $d_1 = d_2 = d_3 = d_4$
(d) none of these

6. The equation, $\alpha = \frac{D-d}{(n-1)d}$ is correctly matched for:
(a) $A \rightleftharpoons nB/2 + nC/3$
(b) $A \rightleftharpoons nB/3 + (2n/3)C$
(c) $A \rightarrow (n/2)B + (n/4)C$
(d) $A \rightleftharpoons (n/2)B + C$

7. For a reaction, $nA \rightleftharpoons A_n$, degree of dissociation when A trimerises is:
(a) $2\left(\frac{d-D}{d}\right)$
(b) $\frac{3}{2}\left(\frac{d-D}{d}\right)$
(c) $\frac{4}{3}\left(\frac{d-D}{d}\right)$
(d) $2\left(\frac{D-d}{d}\right)$

8. For the reaction,

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

the forward reaction at constant temperature is favoured by:
(a) introducing an inert gas at constant volume
(b) introducing chlorine gas at constant volume
(c) introducing an inert gas at constant pressure
(d) increasing the volume of the container
(e) introducing PCl_5 at constant volume

9. Which of the following will favour the formation of NH_3 by Haber's process?
(a) Increase of temperature
(b) Increase of pressure
(c) Addition of catalyst
(d) Addition of promoter

10. Which of the following will not affect the value of equilibrium constant of a reaction?
(a) Change in the concentration of the reactants
(b) Change in temperature
(c) Change in pressure
(d) Addition of catalyst

11. Which of the following statements is/are wrong?
(a) At equilibrium, concentrations of reactants and products become constant because the reaction stops
(b) Addition of catalyst speeds up the forward reaction more than the backward reaction
(c) Equilibrium constant of an exothermic reaction decreases with increase of temperature
(d) K_p is always greater than K_c

12. For the gas phase reaction,

$$C_2H_4 + H_2 \rightleftharpoons C_2H_6; \quad \Delta H° = -136.8 \text{ kJ mol}^{-1}$$

carried out in a vessel, the equilibrium concentration of C_2H_4 can be increased by: **[BHU (Mains) 2008]**
(a) increasing the temperature
(b) decreasing the pressure
(c) removing some H_2
(d) adding some C_2H_6

13. When $NaNO_3$ is heated in a closed vessel oxygen is liberated and $NaNO_2$ is left behind. At equilibrium, which are not correct?
(a) Addition of $NaNO_2$ favours reverse reaction
(b) Addition of $NaNO_3$ favours forward reaction
(c) Increasing temperature favours forward reaction
(d) Increasing pressure favours reverse reaction

14. An increase in temperature increases which of the following?
1. The rate constant of a reaction
2. The ionic product of water
3. The equilibrium constant of an exothermic reaction

Select the correct answer using the code given below: (SCRA 2007)
(a) 1 and 2 only
(b) 1 and 3 only
(c) 2 and 3 only
(d) 1, 2 and 3 only

15. In the following question, more than one answers are correct. Select the correct answer and mark it according to the codes :

Codes : **[BHU (Mains) 2010]**
(a) 1, 2 and 3 are correct
(b) 1 and 2 are correct
(c) 2 and 4 are correct
(d) 1 and 3 are correct

Water gas, an industrial fuel, consisting CO and H_2 in equimolar amounts is obtained by passing steam over red-hot carbon in accordance with the reaction :

$$C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g); \quad \Delta H = +130.5 \text{ kJ}$$

The yield of water gas can be increased by
(1) → Reducing the total presure of the system
(2) → Increasing pressure of steam
(3) → Raising the temperature
(4) → Introducing hot carbon

Assertion-Reason TYPE QUESTIONS

The questions given below consist of two statements each printed as **'Assertion' (A)** and **'Reason' (R).** While answering these questions you are required to choose any one of the following four:

(a) If both (A) and (R) are correct and (R) is the correct explanation for (A).

(b) If both (A) and (R) are correct and (R) is not the correct explanation for (A).

(c) If (A) is correct but (R) is incorrect.

(d) If (A) is incorrect but (R) is correct.

1. (A) K_p can be equal to or less than or even greater than the value of K_c.

   (R) $K_p = K_c\,(RT)^{\Delta n}$

   Relation between K_p and K_c depends on the change in the number of moles of gaseous reactants and products.

2. (A) For $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$, the equilibrium constant is 'K' then for $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$ the equilibrium constant will be $\sqrt{K}$.

   (R) If concentrations are changed to half the equilibrium constant will be halved.

3. (A) A catalyst does not influence the values of equilibrium constant.

   (R) Catalysts influence the rate of both forward and backward reactions equally.

4. (A) The active mass of pure solid and pure liquid is taken unity.

   (R) The active mass of pure solids and liquids depends on density and molecular mass. The density and molecular mass of pure liquids and solids are constant.

5. (A) For $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$. If more Cl_2 is added the equilibrium will shift in backward direction hence, equilibrium constant will decrease.

   (R) Addition of inert gas to the equilibrium mixture at constant volume, does not alter the equilibrium.

6. (A) At equilibrium $\Delta G = 0$

   (R) $\Delta G^\circ = -RT \log_e K_c$ at equilibrium.

7. (A) At equilibrium $\Delta G = 0$

   (R) The Gibbs free energy of reactants and products decreases and become equal at equilibrium.

8. (A) Equilibrium constant of a reaction changes on changing the stoichiometric coefficients of the reaction.

   (R) The reactions : $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ and $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \rightleftharpoons NH_3(g)$ have same equilibrium constant.

9. (A) The Q_c for the reaction :

   $$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g) \text{ is } Q_c = \frac{[SO_3]^2}{[SO_2]^2[O_2]}$$

   (R) When $Q_c < K_c$, the reaction is not at equilibrium and it will be fast in backward direction.

10. (A) The equilibrium of $[PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)]$ is not affected by changing the volume of container.

    (R) $K_c = \frac{[PCl_3][Cl_2]}{[PCl_5]}$

    Equilibrium constant K_c does not depend on the volume of vessel.

11. (A) The reaction : $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ will shift in forward direction by increase in pressure.

    (R) On increasing the pressure, the equilibrium will shift in forward direction.

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS *for* IIT ASPIRANTS

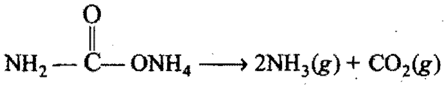
1. Ammonium carbamate when heated to 200°C gives a mixture of NH_3 and CO_2 vapour with a density of 13. What is the degree of dissociation of ammonium carbamate?

[CEE (Kerala) 2004]

(a) $\frac{3}{2}$ (b) $\frac{1}{2}$ (c) 2 (d) 1

(e) $\frac{5}{2}$

[**Hint:**



$$NH_2-\overset{\overset{\displaystyle O}{\|}}{C}-ONH_4 \longrightarrow 2NH_3(g) + CO_2(g)$$

Initial vapour density $D = \frac{\text{Molecular mass}}{2}$

$$= \frac{79}{2} \simeq 39$$

$$\alpha = \frac{D-d}{(n-1)d} = \frac{39-13}{(3-1)\times 13} = \frac{26}{26} = 1$$

here, n = number of moles of product formed by dissociation of 1 mole reactant.]

2. In the heterogeneous equilibrium:

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

what would be the effect of addition of $CaCO_3$ on the equilibrium concentration of CO_2?

(a) Increases (b) Unpredictable

(c) Decreases (d) Remains unaffected

[**Hint:** Gaseous components are not present on both sides, hence, equilibrium will not be affected on addition of $CaCO_3$

$K_p = p_{CO_2}$ = constant (at constant temperature)]

3. For the reaction, $N_2O_4(g) \rightleftharpoons 2NO_2(g)$; if percentage dissociation of N_2O_4 are 25%, 50%, 75% and 100%, then the sequence of observed vapour densities will be:

(a) $d_1 > d_2 > d_3 > d_4$ (b) $d_4 > d_3 > d_2 > d_1$

(c) $d_1 = d_2 = d_3 = d_4$ (d) $(d_1 = d_2) > (d_3 = d_4)$

[**Hint:** Lesser is the percentage dissociation; greater is the vapour density.]

4. In a system:

$$A(s) \rightleftharpoons 2B(g) + 3C(g)$$

if the concentration of C at equilibrium is increased by a factor of 2, it will cause the equilibrium concentration of B to change to:

(a) two times the original value

(b) one half of its original value

(c) $2\sqrt{2}$ times the original value

(d) $\frac{1}{2\sqrt{2}}$ times the original value

5. For the decomposition of $NH_3(g)$ in a sealed tube:

$$2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$$

(a) K_p does not change with pressure

(b) concentration of $H_2(g)$ is less than that of nitrogen

(c) concentration of ammonia does not change with pressure

(d) K_p changes significantly with pressure

6. The equilibrium constant for the decomposition of water,

$$[H_2O(g) \rightleftharpoons H_2(g) + \frac{1}{2}O_2(g)]$$

is given by:

(a) $K = \frac{\alpha^3 p^{1/2}}{(1-\alpha)(2-\alpha)^{1/2}}$ (b) $K = \frac{\alpha^{3/2} p^{1/2}}{(1-\alpha)(2+\alpha)^{1/2}}$

(c) $K = \frac{\alpha^3 p^{1/2}}{\sqrt{2}}$ (d) $K = \frac{\alpha^3 p^{3/2}}{(1-\alpha)(2+\alpha)^{1/2}}$

7. On heating a mixture of SO_2Cl_2 and CO, two equilibria are simultaneously established:

$$SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$$
$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

On adding more SO_2 at equilibrium what will happen?

(a) Amount of CO will decrease

(b) Amount of SO_2Cl_2 and $COCl_2$ will increase

(c) Amount of CO will remain unaffected

(d) Amount of SO_2Cl_2 and CO will increase

8. Consider the reactions,

(i) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

(ii) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

The addition of an inert gas at constant volume:

(a) will increase the dissociation of PCl_5 as well as N_2O_4

(b) will reduce the dissociation of PCl_5 as well as N_2O_4

(c) will increase the dissociation of PCl_5 and step up the formation of NO_2

(d) will not disturb the equilibrium of the reactions

[**Hint:** At constant volume, inert gas will not affect any of the equilibrium.]

9. Densities of diamond and graphite are 3.5 and 2.3 g/mL respectively. Increase of pressure on the equilibrium

$$C\text{ (diamond)} \rightleftharpoons C\text{ (graphite)}$$

(a) favours backward reaction (b) favours forward reaction

(c) has no effect (d) increases the reaction rate

10. A reaction at equilibrium involving 2 moles each of PCl_5, PCl_3 and Cl_2 is maintained at 250°C and a total pressure of 3 atm. The value of K_p is:

(a) 2 (b) 3 (c) 4 (d) 1

[**Hint:**

$$\begin{array}{lccccc} & PCl_5 & \rightleftharpoons & PCl_3 & + & Cl_2 \\ \text{At equilibrium} & 2 & & 2 & & 2 \end{array}$$

$$p_{PCl_5} = \frac{2}{6}\times 3,\ p_{PCl_3} = \frac{2}{6}\times 3,\ p_{Cl_2} = \frac{2}{6}\times 3$$

$$K_p = \frac{p_{PCl_3}\times p_{Cl_2}}{p_{PCl_5}} = \frac{1\times 1}{1} = 1]$$

11. In case of gaseous homogeneous reaction, the active mass of the reactant is given by the expression:

(a) $\frac{RT}{P}$ (b) $\frac{P}{RT}$ (c) $\frac{PV}{RT}$ (d) $\frac{n}{V}RT$

[Hint:

$$PV = nRT$$

$$\frac{n}{V} = \frac{P}{RT}$$

$\therefore$ Active mass (mol L^{-1}) $= \frac{P}{RT}$]

12. In the dissociation of $I_2(g)$ at 1000 K in a container of 1 litre:

$$I_2(g) \rightleftharpoons 2I^-(g);\ K_c = 10^{-6}$$

Select the correct relation:

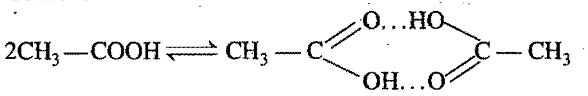
(a) $[I_2] > [I^-]$ (b) $[I_2] < [I^-]$ (c) $[I_2] = [I^-]$ (d) $[I_2] = \frac{1}{2}[I^-]$

[Hint: $K_c = \frac{[I^-]^2}{[I_2]}$

$$10^{-6} = \frac{[I^-]^2}{[I_2]}$$

$\therefore$ $[I_2] > [I^-]$]

13. Acetic acid undergoes dimerisation, when dissolved in benzene



Molecular mass of acetic acid is found 120. Which among the following relation is correct?

(a) $\alpha = 2\left(\frac{D-d}{d}\right)$ (b) $\alpha = 2\left(\frac{D-d}{D}\right)$

(c) $\alpha = 2\left(\frac{d-D}{d}\right)$ (d) $\alpha = \frac{2d}{D-d}$

where, d = Observed vapour density

D = Theoretical vapour density

[Hint: For association of molecule

$$\alpha = \frac{d-D}{d(1-1/n)} = \frac{d-D}{d(1-1/2)}$$

$$= \frac{2(d-D)}{d}]$$

14. The equilibrium:

$$P_4(g) + 6Cl_2(g) \rightleftharpoons 4PCl_3(g)$$

is attained by mixing equal moles of P_4 and Cl_2 in an evacuated vessel. Then at equilibrium:

(a) $[Cl_2] > [PCl_3]$ (b) $[Cl_2] > [P_4]$

(c) $[P_4] > [Cl_2]$ (d) $[PCl_3] > [P_4]$

15. In the reaction: $A + B \rightleftharpoons 2C + D$. The initial concentration of A and B are 1 M each. The value of K_c is 10^8. What is the equilibrium concentration of A?

(a) 2×10^{-4} M (b) 2×10^{4} M (c) 0.005 M (d) 0.0025 M

16. For the reaction:

$A(g) + 2B(g) \rightleftharpoons 3C(g) + D(g);\ K_p = 0.05$ atm at 1000 K

The value of K_c is represented by:

(a) $5\times10^{-4}R$ (b) $\frac{5\times10^{-4}}{R}$ (c) $5\times10^{-5}R$ (d) $\frac{5\times10^{-5}}{R}$

[Hint: $K_p = K_c(RT)^{\Delta n}$

$$K_c = \frac{K_p}{(RT)^{\Delta n}} = \frac{0.05}{(1000\times R)^1} = \frac{5\times10^{-5}}{R}]$$

17. Match the List-I (equilibria) with List-II (conditions) and select the correct answer using the options given below:

List-I	List-II
P. $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$	1. High temperature
Q. $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$	2. Low temperature
R. $2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$	3. High pressure
	4. Low pressure
	5. Independent of pressure

	P	*Q*	*R*
(a)	1, 3	2, 3	2, 4
(b)	2, 3	1, 4	1, 3
(c)	1, 5	2, 3	2, 4
(d)	2, 4	1, 5	1, 3

18. At constant pressure, the presence of inert gases:

(a) reduces the dissociation of PCl_5

(b) increases the dissociation of PCl_5

(c) does not affect the degree of dissociation of PCl_5

(d) steps up the formation of PCl_5

[Hint: $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

On adding inert gas, the equilibrium will shift towards higher volume direction.]

19. Which of the following expressions is correct?

(a) $K_p = K_c\left(\frac{RT}{\Sigma n}\right)^{\Delta n}$ (b) $K_p = K_x\left(\frac{P}{\Sigma n}\right)^{\Delta n}$

(c) $K_p = K_n\left(\frac{P}{\Sigma n}\right)^{\Delta n - 1}$ (d) $K_p = K_c\left(\frac{P}{\Sigma n}\right)^{-\Delta n + 1}$

20. The most stable oxide of nitrogen will be:

(a) $2NO(g) \rightleftharpoons N_2(g) + O_2(g);$ $K = 2.2\times10^{30}$

(b) $2N_2O(g) \rightleftharpoons 2N_2(g) + O_2(g);$ $K = 3.5\times10^{33}$

(c) $2N_2O_5(g) \rightleftharpoons 2N_2(g) + 5O_2(g);$ $K = 1.2\times10^{24}$

(d) $2NO_2(g) \rightleftharpoons N_2(g) + 2O_2(g);$ $K = 6.7\times10^{16}$

[Hint: Stability constant $= \frac{1}{K}$

$\therefore$ Smaller is the value of equilibrium constant greater is the stability of oxide.]

21. Equilibrium constant for two complexes are:

A: $K_4[Fe(CN)_6]$ 2.6×10^{37} (for dissociation)

B: $K_3[Fe(CN)_6]$ 1.9×10^{17} (for dissociation)

(a) *A* and *B* are equally stable (b) *A* is more stable than *B*

(c) *B* is more stable than *A* (d) the predictable stability

[Hint: Stability $\propto \frac{1}{\text{Equilibrium constant for dissociation}}$]

22. At the equilibrium of the reaction, $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, the observed molar mass of N_2O_4 is 77.70 g. The percentage dissociation of N_2O_4 is:

(a) 28.4 (b) 46.7 (c) 22.4 (d) 18.4

[Hint: $\alpha = \dfrac{M_0 - M}{(n-1)M}$

$$= \frac{92 - 77.7}{(2-1) \times 77.7} = 0.184$$

% Dissociation = 18.4]

23. Consider the following statements :
In the Haber method of synthesis of ammonia
1. Increase of pressure favours the formation of NH_3
2. Decrease of pressure produces more NH_3
3. Increase of temperature dissociates NH_3
4. Addition of inert gas favours the formation of NH_3
Which of the statements given above are correct?
(SCRA 2009)
(a) 1 and 3 (b) 2 and 4 (c) 1 and 4 (d) 2 and 3

24. For the decomposition of $PCl_5(g)$ in a closed vessel, the degree of dissociation is α at total pressure P.

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g); \quad K_p$$

Which among the following relations is correct?

(a) $\alpha = \sqrt{\dfrac{K_p}{K_p + P}}$ (b) $\alpha = \sqrt{\dfrac{K_p + P}{K_p}}$

(c) $\alpha = \sqrt{K_p + P}$ (d) $\alpha = \dfrac{1}{\sqrt{K_p + P}}$

25. In the decomposition reaction of ammonia:

$$2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$$

2 moles of NH_3 are introduced in the vessel of 1 litre. At equilibrium, 1 mole NH_3 was left, the value of K_c will be:
(a) 0.75 (b) 0.70 (c) 1.75 (d) 1.70

[Hint:

$$\begin{array}{lccc} & 2NH_3(g) & \rightleftharpoons N_2(g) & + 3H_2(g) \\ t=0 & 2 & 0 & 0 \\ t_{eq.} & 1 & 1/2 & 3/2 \end{array}$$

$$K_c = \frac{[N_2][H_2]^3}{[NH_3]^2}$$

$$= \frac{\frac{1}{2} \times \left(\frac{3}{2}\right)^3}{1^2} = 1.685 \approx 1.7]$$

26. By which of the following relations, the equilibrium constant varies with temperature?

(a) $\ln K_2 - \ln K_1 = \dfrac{\Delta H^\circ}{R} \displaystyle\int_{T_1}^{T_2} d\left(\frac{1}{T}\right)$

(b) $\ln K_2 - \ln K_1 = -\dfrac{\Delta H^\circ}{R} \displaystyle\int_{1/T_1}^{1/T_2} d\left(\frac{1}{T^2}\right)$

(c) $\ln K_2 - \ln K_1 = -\dfrac{\Delta H^\circ}{R} \displaystyle\int_{T_1}^{T_2} d\left(\frac{1}{T}\right)$

(d) $\ln K_2 - \ln K_1 = -\dfrac{\Delta H^\circ}{R} \displaystyle\int_{1/T_2}^{1/T_1} d\left(\frac{1}{T}\right)$

27. For dissociation of a gas N_2O_5 as:

$$N_2O_5(g) \rightleftharpoons 2NO_2(g) + \frac{1}{2} O_2(g);$$

If 'D' is the vapour density of equilibrium mixture and P_0 is the initial pressure of $N_2O_5(g)$, then its equilibrium pressure must not be (M is molecular mass of N_2O_5):

(a) $P_0 \dfrac{(M - 2D)}{3D}$ (b) $\dfrac{P_0 M}{3D - M}$

(c) $\dfrac{P_0 M}{2D}$ (d) $\dfrac{2P_0 D}{M}$

28. $SO_3(g)$ is heated in a closed vessel. An equilibrium:

$$2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g)$$

is established. The vapour density of the mixture, in which SO_3 is 50% dissociated, is:
(a) 26.5 (b) 35 (c) 42 (d) 55

[Hint: $\alpha = \dfrac{D - d}{(n-1)d}$

$$0.5 = \frac{40 - d}{(2-1)d}$$

$$d = 26.5]$$

29. When $\ln K$ is plotted against $\dfrac{1}{T}$ using the van't Hoff equation, a straight line is expected with a slope equal to:
(a) $\Delta H^\circ/RT$ (b) $-\Delta H^\circ/R$ (c) $\Delta H^\circ/R$ (d) $R/\Delta H^\circ$

30. $AB_2(g)$ dissociates as,

$$AB_2(g) \rightleftharpoons AB(g) + B(g)$$

The initial pressure of AB_2 is 600 mm Hg and total pressure is 800 mm Hg. The equilibrium constant for the reaction will be:
(a) 500 (b) 100 (c) 200 (d) 400

31. For the gaseous reaction,

$$C_2H_4 + H_2 \rightleftharpoons C_2H_6,$$

the equilibrium constant has the units:
(a) $mol^2\ dm^{-3}$ (b) $dm^3\ mol^{-1}$ (c) $dm^{-3}\ mol^{-1}$ (d) $mol\ dm^{-3}$

32. The equilibrium constant for the reaction:

$$H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$$

is 67.8 at 300 K. The equilibrium constant for the dissociation of HBr is:
(a) 0.0147 (b) 67.8 (c) 33.90 (d) 8.349

[Hint: $K_{\text{dissociation}} = \dfrac{1}{K_{\text{formation}}}$]

33. A large positive value of ΔG° corresponds to which of these?
(a) Small positive K (b) Small negative K
(c) Large positive K (d) Large negative K
[Hint: $\Delta G^\circ = -2.303RT \log K_e$]

34. What is ΔG° for the following reaction?

$$\frac{1}{2} N_2(g) + \frac{3}{2} H_2(g) \rightleftharpoons NH_3(g); \ K_p = 4.42 \times 10^4 \text{ at } 25^\circ C$$

(a) $-26.5\ kJ\ mol^{-1}$ (b) $-11.5\ kJ\ mol^{-1}$
(c) $-2.2\ kJ\ mol^{-1}$ (d) $-0.97\ kJ\ mol^{-1}$

35. For the following reaction: $K = 1.7 \times 10^7$ at 25°C

$$Ag^+(aq.) + 2NH_3(aq.) \rightleftharpoons [Ag(NH_3)_2]^+$$

what is the value of ΔG° in kJ?
(a) −41.2 (b) −17.9 (c) +17.9 (d) +41.2

36. If E°_{cell} for a given reaction is negative, which gives the correct relationships for the values of ΔG° and K_{eq}?
(a) $\Delta G^\circ > 0, K_{eq.} < 1$ (b) $\Delta G^\circ > 0, K_{eq.} > 1$
(c) $\Delta G^\circ < 0, K_{eq.} > 1$ (d) $\Delta G^\circ < 0, K_{eq.} < 1$

37. The free energy of formation of NO is 78 kJ mol^{-1} at the temperature of an automobile engine (1000 K). What is the equilibrium constant for this reaction at 1000 K?

$$\frac{1}{2}N_2(g)+\frac{1}{2}O_2(g) \rightleftharpoons NO(g).$$

(a) 8.4×10^{-5} (b) 7.1×10^{-9} (c) 4.2×10^{-10} (d) 1.7×10^{-19}

38. $$2SO_2(g)+O_2(g) \rightleftharpoons 2SO_3(g)$$

Given, that the equilibrium constant for the reaction above has a value of 278 at a particular temperature, what is the value of equilibrium constant for the following reaction at same temperature?

$$SO_3(g) \rightleftharpoons SO_2(g)+\frac{1}{2}O_2(g)$$

(a) 1.3×10^{-5} (b) 1.8×10^{-3} (c) 3.6×10^{-3} (d) 6×10^{-2}

39. In which of the following reactions, the increase in volume of the container will favour the formation of products?

(a) $C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$

(b) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$

(c) $4NH_3(g) + 5O_2(g) \rightleftharpoons 4NO(g) + 6H_2O(l)$

(d) $3O_2(g) \rightleftharpoons 2O_3(g)$

40. Consider the reaction, whose $K_c = 33$,

$$SO_2(g) + NO_2(g) \rightleftharpoons SO_3(g) + NO(g)$$

If 0.1 mol each of SO_2 and NO_2 are placed in 1 L container, what is the concentration of SO_2 at equilibrium?

(a) 0.003 *M* (b) 0.015 *M* (c) 0.085 *M* (d) 0.097 *M*

41.

Reaction	*K*
$\frac{1}{2}N_2(g)+O_2(g) \rightleftharpoons NO_2(g)$	K_1
$2NO_2(g) \rightleftharpoons N_2O_4(g)$	K_2

Using above equations, write down expression for *K* of the following reaction:

$$N_2O_4(g) \rightleftharpoons N_2(g)+\frac{1}{2}O_2(g)$$

(a) K_1K_2 (b) $\frac{K_2^2}{K_1}$ (c) $\frac{1}{K_2K_1^2}$ (d) $\frac{1}{K_1^2K_2}$

42. Cu^{2+} ions react with Fe^{2+} ions according to the following reaction:

$$Cu^{2+} + 2Fe^{2+} \rightleftharpoons Cu + 2Fe^{3+}$$

At equilibrium, the concentration of Cu^{2+} ions is not changed by the addition of:

(a) Cu^{2+} (b) Fe^{2+} (c) Cu (d) Fe^{3+}

43. Consider this equilibrium, for which $\Delta H < 0$,

$$HgO(s) + 4I^-(aq.) + H_2O(l) \rightleftharpoons HgI_4^{2-} + 2OH^-$$

Which changes will increase the equilibrium concentration of HgI_4^{2-}?

I. Increasing the mass of $HgO(s)$ present.

II. Increasing $[I^-]$.

III. Adding 1 *M* HCl.

(a) I only (b) II only

(c) II and III only (d) I, II and III

44. Which of the following do not change the value of *K* for a reaction?

(a) Addition of catalyst

(b) Increase in temperature

(c) Increase in pressure

(d) Removal of one of the products

45. For which of the following reactions at equilibrium at constant temperature doubling the volume will cause a shift to the right?

(a) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$

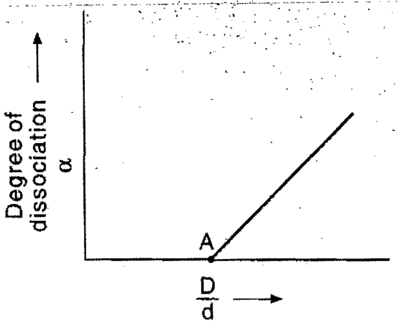
(b) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

(c) $2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g)$

(d) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

46. In the reaction,

$N_2O_4(g) \rightleftharpoons 2NO_2(g)$ if *D* and *d* are the vapour densities at initial stage and at equilibrium then what will be the value of $\frac{D}{d}$ at point *A* in the following graph?



(a) 0 (b) 1.5 (c) 1 (d) 0.5

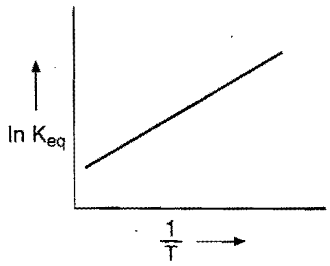
[Hint: $\alpha = \frac{D-d}{(n-1)d}$

For the given reaction, $n = 2$ and $\alpha = 0$ at *A*

$$\therefore \quad \frac{D-d}{(2-1)d} = 0$$

$$\frac{D}{d} = 1]$$

47. A schematic plot of $\ln K_{eq}$ *versus* inverse of temperature for a reaction is shown below:



The reaction must be:

(a) exothermic

(b) endothermic

(c) one with negligible enthalpy change

(d) highly spontaneous at ordinary temperature

[Hint: We know that, $\frac{d \ln K_{eq.}}{dT} = \frac{\Delta H^\circ}{RT^2}$

$$\therefore \qquad \ln K_{eq.} = -\frac{\Delta H^\circ}{RT} + C$$

The plot has positive slope, hence ΔH° will be negative.]

48. The equilibrium:

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g),$$

is followed to set-up at 127°C in a closed vessel. The total pressure at equilibrium was 20 atm. The K_c for the reaction is:

(a) $0.092\,M^2$ (b) $0.085\,M^2$

(c) $3.045\,M^2$ (d) none of these

[Hint: $pNH_3 = pH_2S = \frac{20}{2}$ atm

$$K_p = pNH_3 \times pH_2S = 100 \text{ atm}^2$$

$$K_p = K_c\,(RT)^{\Delta n}$$

$$100 = K_c \times (0.0821 \times 400)^2$$

$$K_c = 0.092\,M^2]$$

49. 20% of N_2O_4 molecules are dissociated in a sample of gas at 27°C and 760 torr. Mixture has the density at equilibrium equal to:

(a) 1.48 g/L (b) 1.84 g/L

(c) 2.25 g/L (d) 3.12 g/L

[Hint: The reaction is:

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

$$n = 2 \text{ and } \alpha = \frac{20}{100} = 0.2$$

$D = 46$, initial vapour density

d = vapour density at equilibrium

$$\alpha = \frac{D-d}{(n-1)d}$$

$$0.2 = \frac{46-d}{(2-1)d}$$

$$d = 38.3$$

Molar mass equilibrium = 2 × 38.3 = 76.6

$Pm = dRT$ Here, d = density of gas mixture

$$d(\text{mix}) = \frac{Pm}{RT} = \frac{1 \times 76.6}{0.0821 \times 300} = 3.12 \text{ g/L}]$$

50. The equilibrium constants K_{p_1} and K_{p_2} for the reactions $X \rightleftharpoons 2Y$ and $Z \rightleftharpoons P + Q$; respectively are in the ratio of 1 : 9. If the degree of dissociation of X and Z be equal then the ratio of total pressures at these equilibria is: **(AIEEE 2008)**

(a) 1 : 9 (b) 1 : 36

(c) 1 : 1 (d) 1 : 3

[Hint :

$$\begin{array}{lccccccc} & X & \rightleftharpoons & 2Y & & Z & \rightleftharpoons & P & + & Q \\ t_0 & 1 & & 0 & & 1 & & 0 & & 0 \\ t_{eq.} & 1-\alpha & & 2\alpha & & 1-\alpha & & \alpha & & \alpha \end{array}$$

$$K_{p_1} = \frac{\left[\frac{2\alpha}{1+\alpha}P_1\right]^2}{\left[\frac{1-\alpha}{1+\alpha}P_1\right]} \qquad K_{p_2} = \frac{\left[\frac{\alpha}{1+\alpha}P_2\right]\left[\frac{\alpha}{1+\alpha}P_2\right]}{\left[\frac{1-\alpha}{1+\alpha}P_2\right]}$$

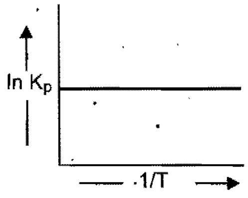
$$= \frac{4\alpha^2 P_1}{1-\alpha^2} \qquad = \frac{\alpha^2 P_2}{1-\alpha^2}$$

$$\frac{K_{p_1}}{K_{p_2}} = \frac{4\alpha^2 P_1}{1-\alpha^2} \Big/ \frac{\alpha^2 P_2}{1-\alpha^2}$$

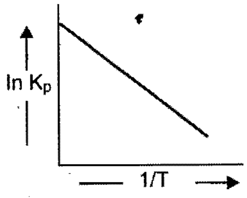
$$\frac{1}{9} = \frac{4P_1}{P_2}$$

$$\frac{P_1}{P_2} = \frac{1}{36}]$$

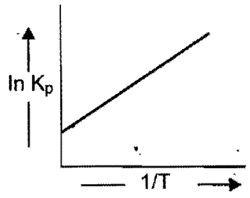
51. Which of the following plots is correct about endothermic reaction ?



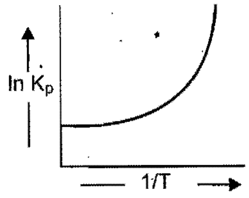
(a)



(b)



(c)



(d)

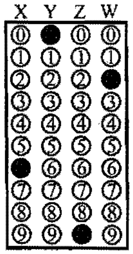
Integer Answer TYPE QUESTIONS

This section contains 10 questions. The answer to each of the questions is a single digit integer, ranging from 0 to 9. If the correct answers to question numbers X, Y, Z and W (say) are 6, 0, 9 and 2 respectively, then the correct darkening of bubbles will look like the given figure :



1. For the reaction:
$$AB(g) \rightleftharpoons A(g) + B(g)$$
AB is 33% dissociated at a total pressure of p. Then, $\frac{p}{K_p}$ will be equal to :
2. If the reaction $A \rightleftharpoons B$, has $\Delta G^\circ = 0$, then its equilibrium constant will be equal to :
3. Consider the following reaction
$$A + B \rightleftharpoons E \qquad K_c = 6$$
$$2B + C \rightleftharpoons 2D \qquad K_c = 4$$
What will be the equilibrium constant (K_c) for the following reaction?
$$A + D \rightleftharpoons E + C$$
4. For the equilibrium of the reaction :
$$NH_4Cl(s) \rightleftharpoons NH_3(g) + HCl(g) \quad K_p = 81 \text{ atm}^2$$
Total pressure at equilibrium will be x times the pressure of NH_3.
The value of x will be :
5. Mixing 4 moles of A with 4 moles of B forms 2 moles of C at equilibrium, according to the following reaction :
$$A(g) + B(g) \rightleftharpoons C(g) + D(g)$$
The value of equilibrium constant is :
6. A reaction at equilibrium involving 2 mol each of PCl_5, PCl_3, Cl_2 is maintained at 250°C and total pressure of 3 atm. The value of K_p is :
7. For the reaction:
$$A(g) + B(g) \rightleftharpoons C(g) + D(g)$$
The initial concentrations of A and B are equal. The equilibrium concentration of C is two times the equilibrium concentration of A. The value of equilibrium constant is :
8. $$N_2 + O_2 \rightleftharpoons 2NO; K_1$$
$$\frac{1}{2}N_2 + \frac{1}{2}O_2 \rightleftharpoons NO; K_2$$
$$2NO \rightleftharpoons N_2 + O_2; K_3$$
$$NO \rightleftharpoons \frac{1}{2}N_2 + \frac{1}{2}O_2; K_4$$
$K_1 \times K_3 = x;\quad \sqrt{K_1} \times K_4 = y;\quad \sqrt{K_3} \times K_2 = z$
What will be the value of xyz?
9. 4.5 moles each of H_2 and I_2 are heated in a sealed 10 L vessel. At equilibrium, 3 mole of HI were found. The equilibrium constant for :
$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g) \text{ is :}$$
10. SO_2Cl_2 and Cl_2 are introduced into a 3 L vessel. Partial pressure of SO_2Cl_2 and Cl_2 at equilibrium are 1 atm and 2 atm respectively. The value of K_p for the following reaction is 10.
$$SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$$
The total pressure in atm at equilibrium would be :

Answers

LINKED COMPREHENSION TYPE QUESTIONS

• Passage 1

Phosphorous pentachloride when heated in a sealed tube at 700 K, it undergoes decomposition as,

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g); \quad K_p = 38\,atm$$

vapour density of the mixture is 74.25.

Answer the following questions:

1. The reaction is:
   (a) endothermic
   (b) exothermic
   (c) may be endothermic or exothermic
   (d) unpredictable
2. Percentage dissociation of PCl_5 may be given as:
   (a) 4.04 (b) 40.4 (c) 44.0 (d) 0.404
3. Equilibrium constant K_c for the reaction will be:
   (a) 0.66 *M* (b) 0.56 *M* (c) 0.46 *M* (d) 0.36 *M*
4. If pressure is increased then the equilibrium will:
   (a) be unaffected
   (b) shift in backward direction
   (c) shift in forward direction
   (d) cannot be predicted
5. When inert gas is added to the given reversible process then the equilibrium will:
   (a) be unaffected
   (b) shift in backward direction
   (c) shift in forward direction
   (d) cannot be predicted

• Passage 2

In Haber's process, the ammonia is manufactured according to the following reaction:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g); \Delta H^\circ = -(22.4\,kJ)$$

The pressure inside the chamber is maintained at 200 *atm and temperature at* 500°C. *Generally, this reaction is carried out in presence of Fe catalyst.*

Answer the following questions:

1. If K_p for the given reaction is 1.44×10^{-5}, then the value of K_c will be:
   (a) $\dfrac{1.44 \times 10^{-5}}{(0.082 \times 500)^{-2}}$ mol L^{-1}
   (b) $\dfrac{1.44 \times 10^{-5}}{(8.314 \times 773)^{-2}}$ mol L^{-1}
   (c) $\dfrac{1.44 \times 10^{-5}}{(0.082 \times 773)^{2}}$ mol L^{-1}
   (d) $\dfrac{1.44 \times 10^{-5}}{(0.082 \times 773)^{-2}}$ mol L^{-1}
2. The preparation of ammonia by Haber's process is an exothermic reaction. If the preparation follows the following temperature pressure relationship for its % yield. Then for temperature T_1, T_2 and T_3 the correct option is:

   (a) $T_3 > T_2 > T_1$ (b) $T_1 > T_2 > T_3$
   (c) $T_1 = T_2 = T_3$ (d) nothing could be predicted
   [**Hint:** The % yield will decrease with rise in temperature, since it is exothermic.]
3. 500°C is considered optimum temperature for Haber's process because:
   (a) catalyst has maximum activity at this temperature
   (b) energy required is easily obtained at this temperature
   (c) yield is maximum at this temperature
   (d) rate is fast enough while the yield is also appreciable at this temperature
4. If K_p for the reaction is 1.44×10^{-5}, then the value of K_p for the decomposition of NH_3,
   $$2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$$
   will be:
   (a) $\sqrt{1.44 \times 10^{-5}}$ (b) $(1.44 \times 10^{-5})^2$
   (c) $\dfrac{1}{1.44 \times 10^{-5}}$ (d) 2.88×10^{-5}
5. 30 litre $H_2(g)$ and 30 litre were taken for the reaction in Haber's process which yields only 50% of the expected ammonia due to reversibility of the reaction. What will be the composition of reaction mixture under the given condition?

	NH_3	N_2	H_2
(a)	20 L	20 L	20 L
(b)	10 L	25 L	15 L
(c)	20 L	10 L	30 L
(d)	20 L	25 L	15 L

• Passage 3

When all the coefficients in a balanced chemical equation are multiplied by a constant factor J, the equilibrium constant (originally K) becomes K^J. Similarly, when balanced equations are added together, the equilibrium constant for the combined process is equal to the product of the equilibrium constants for each step.

Equilibrium constant of the reversed reaction is numerically equal to the reciprocal of the equilibrium constant of the original equation.

$$\text{Unit of } K_p = (atm)^{\Delta n}; \text{ Unit of } K_c = [mol\,L^{-1}]^{\Delta n}$$

Answer the following questions:

1. Consider the reactions:

(i) $CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g); K_1$
(ii) $CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g); K_2$
(iii) $CH_4(g) + 2H_2O(g) \rightleftharpoons CO_2(g) + 4H_2(g); K_3$

Which of the following is correct?

(a) $K_3 = K_1/K_2$ (b) $K_3 = K_1^2/K_2^3$
(c) $K_3 = K_1K_2$ (d) $K_3 = K_1\sqrt{K_2}$

2. The equilibrium constants for the following reactions at 1400 K are given:

$$2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g);\ K_1 = 2.1\times10^{-13}$$
$$2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g); K_2 = 1.4\times10^{-12}$$

Then, the equilibrium constant K for the reaction,

$$H_2(g) + CO_2(g) \rightleftharpoons CO(g) + H_2O(g)$$

is:

(a) 2.04 (b) 20.5 (c) 2.6 (d) 8.4

3. Given: $2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g); K_1$
$2NO_2(g) \rightleftharpoons N_2O_4(g); K_2$
$2NO(g) + O_2(g) \rightleftharpoons N_2O_4(g); K_3$

Which of the following relations is correct?

(a) $K_3 = K_1/K_2$ (b) $K_3 = K_1 \times K_2$
(c) $K_3 = K_1 + K_2$ (d) $K_3 = \frac{K_1}{\sqrt{K_2}}$

4. H_3PO_4 is a tribasic acid, it undergoes ionization as:

$$H_3PO_4 \rightleftharpoons H^+ + H_2PO_4^-; K_1$$
$$H_2PO_4^- \rightleftharpoons H^+ + HPO_4^{2-}; K_2$$
$$HPO_4^{2-} \rightleftharpoons H^+ + PO_4^{3-}; K_3$$

Then, equilibrium constant for the following reaction will be:

$$H_3PO_4 \rightleftharpoons 3H^+ + PO_4^{3-}$$

(a) $K_1K_2K_3$ (b) $\frac{K_1K_2}{K_3}$ (c) $\frac{K_1K_3}{K_2}$ (d) $\frac{K_1K_2}{K_3^2}$

5. Consider the two reactions:

$$XeF_6(g) + H_2O(g) \rightleftharpoons XeOF_4(g) + 2HF(g); K_1$$
$$XeO_4(g) + XeF_6(g) \rightleftharpoons XeOF_4(g) + XeO_3F_2(g); K_2$$

Then, the equilibrium constant for the following reaction will be:

$$XeO_4(g) + 2HF(g) \rightleftharpoons XeO_3F_2(g) + H_2O(g)$$

is given by:

(a) K_1/K_2^2 (b) K_1/K_2 (c) K_1^2/K_2 (d) K_2/K_1

• Passage 4

Mass action ratio or reaction quotient Q for a reaction can be calculated using the law of mass action,

$$A(g) + B(g) \rightleftharpoons C(g) + D(g)$$
$$Q = \frac{[C][D]}{[A][B]}$$

The value of Q decides whether the reaction is at equilibrium or not.

At equilibrium, $Q = K$
For non-equilibrium process, $Q \neq K$

when $Q > K$, reaction will favour backward direction and when $Q < K$, it will favour forward direction.

Answer the following questions:

1. The reaction quotient Q for:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

is given by $Q = \frac{[NH_3]^2}{[N_2][H_2]^3}$. The reaction will proceed in backward direction, when:

(a) $Q = K_c$ (b) $Q < K_c$ (c) $Q > K_c$ (d) $Q = 0$

2. For the reaction:

$$2A + B \rightleftharpoons 3C \quad \text{at 298 K, } K_c = 49$$

A 3L vessel contains 2, 1 and 3 moles of A, B and C respectively. The reaction at the same temperature:

(a) must proceed in forward direction
(b) must proceed in backward direction
(c) must be in equilibrium
(d) cannot be predicted

3. In a reaction mixture containing H_2, N_2 and NH_3 at partial pressure of 2 atm, 1 atm and 3 atm respectively, the value of K_p at 725 K is 4.28×10^{-5} atm^{-2}. In which direction the net reaction will go?

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

(a) Forward
(b) Backward
(c) No net reaction
(d) Direction cannot be predicted

4. In the following reaction:

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

the equilibrium is not attained. The rate of forward reaction is greater than that of backward reaction. Thus, which of the following is the correct relation between K_p and Q_p?

(a) $K_p = Q_p$ (b) $Q_p > K_p$ (c) $Q_p < K_p$ (d) $K_p = Q_p = 1$

5. In the reaction:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

a graph is plotted to show the variation of rate of forward and backward reactions against time:

Which of following is correct?

	$Q > K$	$Q = K$	$Q < K$
(a)	3	2	1
(b)	1	2	3
(c)	2	3	1
(d)	2	1	3

• Passage 5

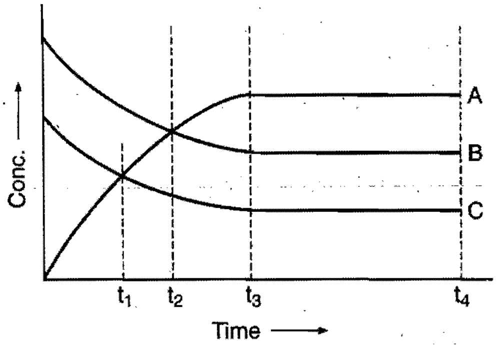
In a reversible chemical reaction, the rate of forward reaction decreases and that of backward reaction increases with the passage of time; at equilibrium the rate of forward and backward reactions become same.

Let us consider the formation of SO_3 in the following reversible reaction:

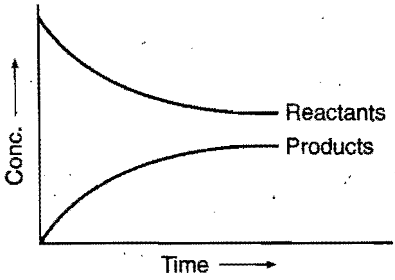
$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

Following graphs are plotted for this reaction:

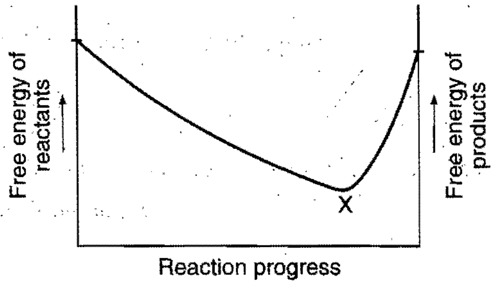
Graph 1



Graph 2



Graph 3



Answer the following questions:

1. In the graph (1), A, B and C respectively are:
   (a) SO_3, SO_2 and O_2 (b) SO_3, O_2 and SO_2
   (c) SO_2, O_2 and SO_3 (d) O_2, SO_2 and SO_3
2. In the graph (1), the equilibrium state is reached at:
   (a) t_1 (b) t_2 (c) t_3 (d) t_4
3. The graph (2) tells us that:
   (a) the reaction is irreversible
   (b) the reaction is reversible
   (c) the reaction is exothermic
   (d) the reaction is endothermic
4. The graph (2) tells us that:
   (a) equilibrium is never achievable
   (b) equilibrium is achieved after the concentrations of reactants and products become equal
   (c) equilibrium is achieved before the concentrations of reactants and products become equal
   (d) none of the above
5. From the graph (3), it can be interpreted that:
   (a) equilibrium is achieved at X
   (b) reaction is nearer to the completion
   (c) $\Delta G = 0$ at X
   (d) all of the above

SELF ASSESSMENT

ASSIGNMENT NO. 9

SECTION-I

Straight Objective Type Questions

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. By applying the law of mass action, the equilibrium constant K for the reaction:

$$HA + H_2O \rightleftharpoons H_3^+O + A^- \quad \text{[CET (J\&K) 2007]}$$

(a) $K = \dfrac{[HA][H_2O]}{[H_3O^+][A^-]}$ (b) $K = \dfrac{[H_3^+O][A^-]}{[HA][H_2O]}$

(c) $K = \dfrac{[H_3^+O][H_2O]}{[A^-][HA]}$ (d) $K = \dfrac{[HA][A^-]}{[H_2O][H_3O^+]}$

2. For the reaction,

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) + \text{Heat}$$

When temperature increases: **[PMT (Haryana) 2007]**

(a) formation of NH_3 increases

(b) formation of NH_3 decreases

(c) concentration of N_2 decreases

(d) concentration of H_2 decreases

3. For the reaction 1 g mole of $CaCO_3$ is enclosed in 5 L container

$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$ $K_p = 1.16$ atm at 1073 K then percentage dissociation of $CaCO_3$ is:

(a) 65% (b) 100% (c) 6.5% (d) zero

4. The activation energy for forward and backward reactions are 50 kJ / mol and 40 kJ / mol respectively. If K_1 and K_2 are the equilibrium constants of reaction at temperature T_1 and T_2 respectively and $T_2 > T_1$ then:

(a) $K_1 < K_2$ (b) $K_1 = K_2$ (c) $K_1 > K_2$ (d) $K_2 = K_1^2$

[**Hint:** $\Delta H = E_f - E_b = 50 - 40 = 10$ kJ / mol. In endothermic reactions, equilibrium constant increases with increase in temperature.]

5. Given, $X(g) \rightleftharpoons nY(g)$.

If degree of dissociation is α, then K_c of the reaction in a vessel of 1 litre is:

(a) $\dfrac{n\alpha^n}{1-\alpha}$ (b) $\dfrac{n\alpha}{1-\alpha}$ (c) $\dfrac{(n\alpha)^n}{1+\alpha}$ (d) $\dfrac{(n\alpha)^n}{1-\alpha}$

6. Consider the following equation in a closed container,

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

at a fixed temperature, the volume of the reaction container is halved, for this change, which of the following statement holds true regarding the K_p and degree of dissociation 'α':

(a) neither K_p nor α changes

(b) both K_p and α change

(c) K_p changes but α does not change

(d) K_p does not change but α changes

7. The reaction, $A(g) + B(g) \rightleftharpoons C(g) + D(g)$ is studied in a vessel of one litre at 250° C. The initial concentration of A was $3x$ and that of B was x. At equilibrium, concentration of C was found to be equal to the equilibrium concentration of B. What is the concentration of D at equilibrium:

(a) $\dfrac{x}{2}$ (b) $3x - \dfrac{1}{2}$ (c) $x - \dfrac{x}{2}$ (d) x

SECTION-II

Multiple Answers Type Objective Questions

8. Equilibrium constant does not depend on:

(a) catalyst (b) temperature

(c) pressure (d) inert gas

9. Which of the following reactions have $K_p < K_c$?

(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$

(b) $CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$

(c) $2BrCl(g) \rightleftharpoons Br_2(g) + Cl_2(g)$

(d) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

10. Which of the following reactions are not affected by inert gas addition?

(a) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$

(b) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$

(In a rigid container of constant volume)

(c) $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$

(d) $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$

11. Which of the following are not affected by pressure change?

(a) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

(b) $2NaNO_2(s) + O_2(g) \rightleftharpoons 2NaNO_3(s)$

(c) $NH_2COONH_4(s) \rightleftharpoons 2NH_3(g) + CO_2(g)$

(d) $C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$

12. The reaction,

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g) \text{ (Exothermic)}$$

will shift in forward direction by:

(a) adding SO_3 at constant volume

(b) increasing volume of container

(c) adding SO_2 at constant volume

(d) adding inert gas at constant volume

SECTION-III

Assertion-Reason Type Questions

This section contains 5 questions. Each question contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; statement-2 is true; statement-2 is a correct explanation for statement-1.

(b) Statement-1 is true; statement-2 is true; statement-2 is not a correct explanation for statement-1.

(c) Statement-1 is true; statement-2 is false.

(d) Statement-1 is false; statement-2 is true.

13. **Statement-1:** The value of equilibrium constant depends on the stoichiometry of the equation.

Because

Statement-2: The value of equilibrium constant does not change when the equation is multiplied or divided by a number.

14. **Statement-1:** $K_p = K_c$ for all reactions.

Because

Statement-2: K_p and K_c are interrelated by the equation $K_p = K_c(RT)^{\Delta n}$.

15. **Statement-1:** Catalyst does not change the position of equilibrium.

Because

Statement-2: Catalyst only changes the equilibrium time.

16. **Statement-1:** Free energy of both reactants and products are minimum at equilibrium.

Because

Statement-2: The free energy of reactants and products decreases with passage of time and become equal at equilibrium.

17. **Statement-1:** Addition of inert gases at equilibrium will support the dissociation of PCl_5 at constant temperature.

Because

Statement-2: The addition of inert gas at constant volume will not affect the equilibrium.

SECTION-IV

Matrix-Matching Type Questions

This section contains 4 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in List-I have to be matched with statements (p, q, r and s) in List-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

If the correct matches are (a-p,s); (b-q,r); (c-p,q) and (d-s), then correct bubbled 4 × 4 matrix should be as follows:

	p	q	r	s
a	●	○	○	●
b	○	●	●	○
c	●	●	○	○
d	○	○	○	●

18. Match the List-I with List-II:

List-I	List-II
(a) $A(g) \rightleftharpoons B(g) + C(g)$	(p) $\alpha = \sqrt{\frac{K_p}{K_p + 4P}}$
(b) $A_2(g) \rightleftharpoons 2A(g)$	(q) $\alpha = \sqrt{\frac{K_p}{P + K_p}}$
(c) $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$	(r) $M_{mix} = \frac{M_{reactant}}{1+\alpha}$
(d) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$	(s) Forward shift on decreasing the pressure

19. Match the List-I with List-II:

List-I (Mathematical process)	List-II (New equilibrium constant)
(a) Divided by n	(p) K^n
(b) Multiplied by n	(q) $\frac{1}{K}$
(c) Reaction is reversed	(r) $K_1 \times K_2 \times K_3 \times \ldots \times K_n$
(d) n-equations are added	(s) $(K)^{1/n}$

20. Match the List-I with List-II for the following reaction:

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$$

List-I	List-II
(a) Partial pressure of $NH_4HS(s)$	(p) $p_{NH_3} \times p_{H_2S}$
(b) K_p	(q) $p_{NH_3} + p_{H_2S}$
(c) Total pressure at equilibrium	(r) $(p_{NH_3} \times p_{H_2})(RT)^{-2}$
(d) K_c	(s) Zero

Answers

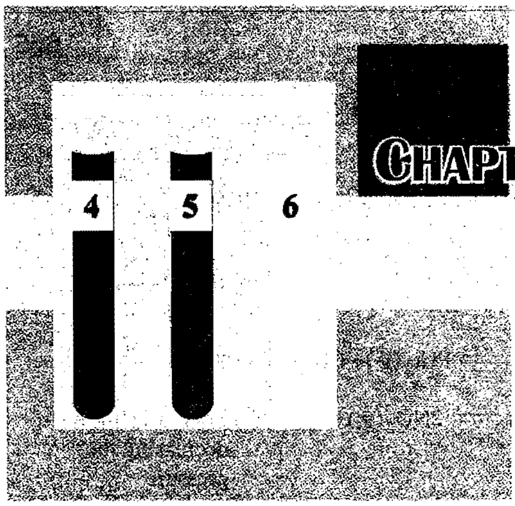
20. (a-s) (b-p) (c-q) (d-r)



CHAPTER 10

IONIC EQUILIBRIUM

10.1 INTRODUCTION

The compounds which give ions either in molten state or in solution are called electrolytes. In the solid state they are bad conductors, but become good conductors either in the molten state or in solution.

There are two types of electrolytes:

(1) Strong electrolytes: These electrolytes are almost completely ionised when dissolved in a polar medium like water. In solution they are excellent conductors, *e.g.*, HNO_3, HCl, KOH, NaOH, etc. Their degree of ionization is high and approaches unity.

(2) Weak electrolytes: These are not completely ionized when dissolved in a polar solvent and they behave as poor conductors of electricity, *e.g.*, CH_3COOH, H_3PO_4, H_3BO_3, NH_4OH, etc. Equilibrium between ions and unionised molecules is established in solution; *e.g.*,

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$

The above equilibrium is termed as ionic equilibrium. Degree of ionization of weak electrolytes is much less than unity.

Degree of ionization 'α' may be defined as a fraction of total number of molecules of an electrolyte which dissociate into ions.

$$\alpha = \frac{\%\text{ ionization}}{100}$$

$$= \frac{\text{Number of molecules dissociated as ions}}{\text{Total number of molecules of electrolyte dissolved}}$$

The following classification of electrolytes is based on their behaviour in a particular solvent, *i.e.*, water.

Solutions (aqueous)

- Conducting (solutions of electrolytes, *i.e.*, acids, bases and salts)
  - Strongly conducting (solns. of strong electrolytes which ionise almost completely in water such as HCl, H_2SO_4, HNO_3, NH_4Cl, NaCl, NaOH, KOH, etc.)
  - Weakly conducting (solutions of weak electrolytes which slightly ionise in water such as CH_3COOH, NH_4OH, H_3PO_4, HCN, etc.)
- Non-conducting (solutions of non-electrolytes such as urea, glucose, sugar, glycerine, etc.)

However, an electrolyte may behave as a strong one in aqueous solution, but it may behave as a weak one in another solvent. For example, sodium chloride behaves as a strong electrolyte and acetic acid as a weak electrolyte when dissolved in water but their conducting abilities are comparable in liquid ammonia solvent.

10.2 OSTWALD'S DILUTION LAW

According to Arrhenius theory of electrolytic dissociation, the molecules of an electrolyte in solution are constantly splitting up into ions and the ions are constantly reuniting to form unionized molecules. Therefore, a dynamic equilibrium exists between ions and unionized molecules of the electrolyte in solution. It was pointed out by Ostwald that like chemical equilibrium, **law of mass action** can be applied to such systems also.

Consider a binary electrolyte *AB* which dissociates into A^+ and B^- ions and the equilibrium state is represented by the equation:

	AB	$\rightleftharpoons$	A^+	$+$	B^-
Initially $t = 0$	C		0		0
At equilibrium	$C(1-\alpha)$		$C\alpha$		$C\alpha$

So, dissociation constant may be given as:

$$K = \frac{[A^+][B^-]}{[AB]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)}$$

$$= \frac{C\alpha^2}{(1-\alpha)} \qquad \text{... (i)}$$

For very weak electrolytes,

$$\alpha <<< 1, (1-\alpha) \approx 1$$

$$\therefore \quad K = C\alpha^2$$

$$\alpha = \sqrt{K/C} \qquad \text{... (ii)}$$

Concentration of any ion = $C\alpha = \sqrt{CK}$.

From equation (ii), it is clear that degree of ionization increases on dilution.

Thus, **degree of dissociation of a weak electrolyte is proportional to the square root of dilution.**

Limitations of Ostwald's dilution law: The law holds good only for weak electrolytes and fails completely in the case of strong electrolytes. The value of 'α' is determined by conductivity measurements by applying the formula Λ / Λ_∞. The value of 'α' determined at various dilutions of an electrolyte when substituted in eq. (i) gives a constant value of K only in the case of weak electrolytes like CH_3COOH, NH_4OH, etc. The cause of failure of Ostwald's dilution law in the case of strong electrolytes is due to the following factors:

(i) The law is based on the fact that only a portion of the electrolyte is dissociated into ions at ordinary dilution and completely at infinite dilution. Strong electrolytes are almost completely ionised at all dilutions and Λ / Λ_∞ does not give accurate value of 'α'.

(ii) When concentration of the ions is very high, the presence of charges on the ions appreciably affects the equilibrium. Hence, law of mass action in its simple form cannot be strictly applied in the case of strong electrolytes.

SOME SOLVED EXAMPLES

Example 1. *A 0.01 M solution of acetic acid is 5% ionised at 25° C. Calculate its dissociation constant.*

Solution: According to Ostwald's dilution law,

$$K_a = \frac{\alpha^2}{(1-\alpha)V}$$

$$\alpha = 0.05, \quad V = \frac{1}{0.01} = 100 \text{ litre}$$

Hence, $$K_a = \frac{0.05 \times 0.05}{(1-0.05)100} = 2.63 \times 10^{-5}$$

Example 2. *Calculate the H^+ ion concentration of a 0.01 N weak monobasic acid. The value of dissociation constant is 4.0×10^{-10}.*

Solution: $HA \rightleftharpoons H^+ + A^-$

Applying Ostwald's dilution law for a weak acid,

$$\alpha = \sqrt{K_a V}$$

$$K_a = 4.0 \times 10^{-10}, \quad V = \frac{1}{0.01} = 100 \text{ litre}$$

$$\alpha = \sqrt{4 \times 10^{-10} \times 10^2} = 2 \times 10^{-4}$$

Concentration of hydrogen ions

$$= \frac{\alpha}{V} = \frac{2 \times 10^{-4}}{100} = 2 \times 10^{-6} \text{ mol L}^{-1}$$

or concentration of hydrogen ions

$$= \sqrt{CK} = \sqrt{0.01 \times 4 \times 10^{-10}} = 2 \times 10^{-6} \text{ mol L}^{-1}$$

Example 3. *The concentration of H^+ ions in 0.10 M solution of a weak acid is 1.0×10^{-5} mol L^{-1}. Calculate the dissociation constant of the acid.*

Solution:	HA	$\rightleftharpoons$	H^+	$+$	A^-
Initial concentration	0.1		0		0
Equilibrium concentration (mol L^{-1})	$0.1 - 1.0 \times 10^{-5}$		1.0×10^{-5}		1.0×10^{-5}

[HA] can be taken as 0.1 M as 1.0×10^{-5} is very small.

Applying law of mass action,

$$K_a = \frac{[H^+][A^-]}{[HA]} = \frac{1.0 \times 10^{-5} \times 1.0 \times 10^{-5}}{0.10}$$

$$= 1 \times 10^{-9}$$

Example 4. *What will be the dissociation constant of 0.1N aqueous ammonia solution in terms of degree of dissociation 'α'? What will be the value if the concentration is 0.01N?*

Solution: $NH_4OH \rightleftharpoons NH_4^+ + OH^-$

At equilibrium $\quad (1-\alpha) \quad \alpha \quad \alpha$

Since, the solution is 0.1 N,

$$V = \frac{1}{0.1} = 10 \text{ litre}$$

$$[NH_4OH] = \frac{(1-\alpha)}{10}, \; [NH_4^+] = \frac{\alpha}{10} \text{ and } [OH^-] = \frac{\alpha}{10}$$

Applying law of mass action,

$$K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]} = \frac{\frac{\alpha}{10} \times \frac{\alpha}{10}}{\frac{1-\alpha}{10}} = \frac{\alpha^2}{10(1-\alpha)}$$

For 0.01 N solution, K_b remains the same at the same temperature but degree of dissociation value becomes different.

Example 5. *A 0.0128 N solution of acetic acid has $\Lambda = 14$ mho equiv^{-1} and $\Lambda_\infty = 391$ mho eq^{-1} at 25°C. Calculate the dissociation constant of the acid.*

Solution: Degree of dissociation,

$$\alpha = \frac{\Lambda}{\Lambda_\infty} = \frac{14}{391} = 3.58\times 10^{-2}$$

$$[1-\alpha \longrightarrow 1 \text{ as } \alpha \text{ is very small}]$$

Now applying Ostwald's dilution law,

$$K_a = \frac{\alpha^2}{(1-\alpha)V}$$

$$\alpha = 3.58\times 10^{-2} \quad \text{and} \quad V = \frac{1}{0.0128} \text{ litre}$$

So, $K_a = 3.58\times 10^{-2}\times 3.58\times 10^{-2}\times 0.0128 = 1.64\times 10^{-5}$

10.3 COMMON ION EFFECT

Let AB be the weak electrolyte. Considering its dissociation,

$$AB \rightleftharpoons A^+ + B^-$$

and applying law of mass action, we have

$$K = \frac{[A^+][B^-]}{[AB]}$$

The equilibrium constant, K, has a definite value at any given temperature. If now another electrolyte furnishing the A^+ and B^- ions be added to the above solution, it will increase the concentration of either A^+ ions or B^- ions (whichever has been added) and in order that K may remain constant, the concentration of AB must increase, *i.e.*, the equilibrium will shift to the left hand side.

In other words, **the degree of dissociation of an electrolyte (weak) is suppressed by the addition of another electrolyte (strong) containing a common ion.** This is termed as **common ion effect.** Acetic acid is a weak electrolyte and its ionisation is suppressed in presence of a strong acid (H^+ ion as common ion) or a strong salt like sodium acetate (acetate ion as common ion). Similarly, the addition of NH_4Cl or NaOH to NH_4OH solution will suppress the dissociation of NH_4OH due to common ion either NH_4^+ or OH^-.

As a result of common ion effect, the concentration of the ion not in common in two electrolytes, is decreased. The use of this phenomenon is made in qualitative analysis to adjust concentration of S^{2-} ions in second group and OH^- ion concentration in third group of analysis.

SOME SOLVED EXAMPLES

Example 6. *The ionisation constant of HCN is* 4×10^{-10}. *Calculate the concentration of hydrogen ions in* 0.2 *M solution of HCN containing* 1 *mol* L^{-1} *of KCN.*

Solution: The dissociation of HCN is represented as

$$HCN \rightleftharpoons H^+ + CN^-$$

Applying law of mass action,

$$K_a = \frac{[H^+][CN^-]}{[HCN]} \quad \text{or} \quad [H^+] = \frac{K_a\,[HCN]}{[CN^-]}$$

In presence of strong electrolyte, the total CN^- concentration comes from KCN which undergoes complete dissociation. It is further assumed that dissociation of HCN is very-very small and the concentration of HCN can be taken as the concentration of undissociated HCN.

Thus, $[HCN] = 0.2\,M$ and $[CN^-] = 1\,M$

Putting these values in the expression

$$[H^+] = \frac{K_b\,[HCN]}{[CN^-]} = \frac{4\times 10^{-10}\times 0.2}{1} = 8\times 10^{-11} \text{ mol L}^{-1}$$

Note: When KCN is not present, the $[H^+]$ concentration is equal to $\sqrt{CK}$, *i.e.*, $\sqrt{0.2\times 4\times 10^{-10}} = 8.94\times 10^{-6}$ mol L^{-1}. This shows that concentration of H^+ ions falls considerably when KCN is added to HCN solution.

Example 7. *Determine the concentration of hydroxyl ions in* 0.4 *M* NH_4OH *solution having* (*i*) *no ammonium chloride and* (*ii*) 5.35 *g of* NH_4Cl *in a litre of the solution. Ionisation constant of* NH_4OH *is* 1.8×10^{-5}.

Solution: (i) Let 'α' be the degree of dissociation of NH_4OH in absence of NH_4Cl.

$$\alpha = \sqrt{\frac{K_b}{C}}$$

So, $$[OH^-] = C\alpha = \sqrt{K_b C} = \sqrt{1.8\times 10^{-5}\times 0.4}$$

$$= 2.68\times 10^{-3} \text{ mol L}^{-1}$$

(ii) In presence of NH_4Cl,

$$[NH_4^+] = \frac{5.35}{53.5} = 0.1M \quad \text{and} \quad [NH_4OH] = 0.4\,M$$

So, $$[OH^-] = \frac{K_b[NH_4OH]}{[NH_4^+]} = \frac{1.8\times 10^{-5}\times 0.4}{0.1}$$

$$= 7.2\times 10^{-5} \text{ mol L}^{-1}$$

Example 8. *When* 0.100 *mole of ammonia,* NH_3, *is dissolved in sufficient water to make* 1.0 *L of solution, the solution is found to have a hydroxide ion concentration of* 1.34×10^{-3} *M. Calculate* K_b *for ammonia.*

Solution:

$$\begin{array}{lccc} & NH_3 & +\,H_2O \rightleftharpoons & NH_4^+ \\ \text{At equilibrium} & (0.100 - 1.34\times 10^{-3})\,M & & 1.34\times 10^{-3}\,M \\ & & & +\ OH^- \\ & = 0.09866\,M & & 1.34\times 10^{-3}\,M \end{array}$$

$$K_b = \frac{[NH_4^+][OH^-]}{[NH_3]} = \frac{1.34\times 10^{-3}\times 1.34\times 10^{-3}}{0.09866} = 1.8199\times 10^{-5}$$

Example 9. K_a *for HA is* 4.9×10^{-8}. *After making the necessary approximation, calculate for its decimolar solution*

(*a*) *% dissociation*

(*b*) H^+ *ion concentration.*

Solution: (a) For a weak electrolyte,

$$\alpha = \sqrt{\frac{K_a}{C}} = \sqrt{\frac{4.9\times 10^{-8}}{0.1}} = 7\times 10^{-4}$$

$$\%\,\text{dissociation} = 100\times\alpha = 100\times 7\times 10^{-4}$$
$$= 7\times 10^{-2}$$

(b) $$HA \rightleftharpoons H^+ + A^-$$
$$C(1-\alpha) \qquad C\alpha \qquad C\alpha$$
$$[H^+] = C\times\alpha = 0.1\times 7\times 10^{-4} = 7\times 10^{-5}\ \text{mol L}^{-1}$$

Example 10. *Nicotinic acid ($K_a = 1.4\times 10^{-5}$) is represented by the formula HNiC. Calculate its per cent dissociation in a solution which contains 0.10 mole of nicotinic acid per 2 litre of solution.* **(IIT 1993)**

Solution: Initial concentration of the nicotinic acid $= \frac{0.10}{2} = 0.05\ \text{mol L}^{-1}$

$$HNiC \rightleftharpoons H^+ + NiC^-$$
$$\text{Equilibrium conc.} \quad (0.05-x) \qquad x \qquad x$$

As x is very small, $(0.05-x)$ can be taken as 0.05

$$K_a = \frac{[H^+][NiC^-]}{[HNiC]} = \frac{x\times x}{0.05}$$

or $$x^2 = (0.05)\times(1.4\times 10^{-5})$$

or $$x = 0.83\times 10^{-3}\ \text{mol L}^{-1}$$

$$\%\,\text{dissociation} = \frac{0.83\times 10^{-3}}{0.05}\times 100 = 1.66$$

Alternative method: Let α be the degree of dissociation

$$HNiC \rightleftharpoons H^+ + NiC^-$$
$$\text{At equilibrium} \quad 0.05(1-\alpha) \qquad 0.05\alpha \qquad 0.05\alpha$$
$$K_a = \frac{0.05\alpha\times 0.05\alpha}{0.05(1-\alpha)}$$

As α is very small, $(1-\alpha)\longrightarrow 1$.

So, $$1.4\times 10^{-5} = 0.05\alpha^2$$

or $$\alpha = \sqrt{\frac{1.4\times 10^{-5}}{0.05}} = 1.67\times 10^{-2}$$

$$\text{Per cent dissociation} = 100\times\alpha = 100\times 1.67\times 10^{-2}$$
$$= 1.67$$

Example 11. *At 30°C, the degree of dissociation of 0.066 M HA is 0.0145. What would be the degree of dissociation of 0.02 M solution of the acid at the same temperature?*

Solution: Let the ionisation constant of the acid be K_a. Degree of dissociation at 0.066 M concentration = 0.0145.

Applying $$\alpha = \sqrt{\frac{K_a}{C}}$$

$$0.0145 = \sqrt{\frac{K_a}{0.066}} \qquad \text{... (i)}$$

Let the degree of dissociation of the acid at 0.02 M concentration be α_1.

$$\alpha_1 = \sqrt{\frac{K_a}{0.02}} \qquad \text{... (ii)}$$

Dividing eq. (ii) by eq. (i),

$$\frac{\alpha_1}{0.0145} = \sqrt{\frac{0.066}{0.02}} = 1.8166$$

or $$\alpha_1 = 0.0145\times 1.8166 = 0.0263$$

Example 12. *A solution contains 0.1 M H_2S and 0.3 M HCl. Calculate the concentration of S^{2-} and HS^- ions in solution. Given K_{a_1} and K_{a_2} for H_2S are 10^{-7} and 1.3×10^{-13} respectively.* **(IIT 1992)**

Solution: $$H_2S \rightleftharpoons H^+ + HS^-$$

$$K_{a_1} = \frac{[H^+][HS^-]}{[H_2S]} \qquad \text{... (i)}$$

Further $$HS^- = H^+ + S^{2-}$$

$$K_{a_2} = \frac{[H^+][S^{2-}]}{[HS^-]} \qquad \text{... (ii)}$$

Multiplying both the equations

$$K_{a_1}\times K_{a_2} = \frac{[H^+]^2[S^{2-}]}{[H_2S]}$$

Due to common ion, the ionisation of H_2S is suppressed and the $[H^+]$ in solution is due to the presence of 0.3 M HCl.

$$[S^{2-}] = \frac{K_{a_1}\times K_{a_2}[H_2S]}{[H^+]^2} = \frac{1.0\times 10^{-7}\times 1.3\times 10^{-13}\times(0.1)}{(0.3)^2}$$
$$= 1.44\times 10^{-20}\ M$$

Putting the value of $[S^{2-}]$ in eq. (ii),

$$1.3\times 10^{-13} = \frac{0.3\times 1.44\times 10^{-20}}{[HS^-]}$$

or $$[HS^-] = \frac{0.3\times 1.44\times 10^{-20}}{1.3\times 10^{-13}} = 3.3\times 10^{-8}\ M$$

Example 13. *What is the H^+ ion concentration of a solution known to contain 0.1g mole of CH_3COONH_4 in one litre of 0.1 M CH_3COOH? Assume effective ionisation of ammonium acetate is 80%. K_a for acetic acid is 1.8×10^{-5}.*

Solution: $$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$
$$(0.1-x) \qquad x \qquad x$$

$$K_a = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]}$$

The solution also contains CH_3COONH_4 which is 80% dissociated, *i.e.*, $\alpha = 0.8$. Thus, the acetate concentration provided by 0.1 M $CH_3COONH_4 = 0.1\times 0.8 = 0.08\,M$

Total $$[CH_3COO^-] = (0.08+x)\,M$$

So, $$K_a = \frac{(0.08+x)x}{(0.1-x)}$$

As x is very small, $(0.1-x)\longrightarrow 0.1$ and neglecting x^2,

$$K_a = \frac{0.08x}{0.1}$$

or $$1.8\times10^{-5}\times0.1=0.08x$$

or $$x=[H^+]=\frac{1.8\times10^{-5}\times0.1}{0.08}=2.25\times10^{-5}\ \text{mol L}^{-1}$$

Example 14. *Ostwald obtained the following table by determining the equivalent conductivities containing one gram equivalent of acetic acid in V litre. If the equivalent conductivity of acetic acid at infinite dilution be* 364, *show that the results are in agreement with Ostwald's law.*

Volume in litre (V)	*Equivalent conductivity*
8	4.34
64	12.09
128	16.99

Solution: Degree of dissociation, $\alpha=\frac{\Lambda_V}{\Lambda_\infty}$

(i) $$\alpha_1=\frac{4.34}{364}=0.0119$$

(ii) $$\alpha_2=\frac{12.09}{364}=0.0332$$

(iii) $$\alpha_3=\frac{16.99}{364}=0.0467$$

Now applying Ostwald's dilution law,

(i) $$K_a=\frac{\alpha_1^2}{V_1}=\frac{0.0119\times0.0119}{8}=1.77\times10^{-5}$$

(ii) $$K_a=\frac{\alpha_2^2}{V_2}=\frac{0.0332\times0.0332}{64}=1.72\times10^{-5}$$

(iii) $$K_a=\frac{\alpha_3^2}{V_3}=\frac{0.0467\times0.0467}{128}=1.70\times10^{-5}$$

The values of K_a are nearly the same which show the validity of Ostwald's dilution law.

Example 15. *Calculate the dissociation constant of* $H_2C_2O_4$ *(oxalic acid) if* 0.02 *M solution is 2% dissociated.*

Solution:
$$\underset{C(1-\alpha)}{H_2C_2O_4} \rightleftharpoons \underset{2C\alpha}{2H^+} + \underset{C\alpha}{C_2O_4^{2-}}$$

$$K_a=\frac{[H^+]^2[C_2O_4^{2-}]}{[H_2C_2O_4]}$$
$$=\frac{(2C\alpha)^2\times(C\alpha)}{C(1-\alpha)}$$
$$=\frac{4C^2\alpha^3}{1-\alpha}\quad[1-\alpha\to1\text{ as }\alpha\text{ is small}]$$
$$=4C^2\alpha^3$$
$$=4\times0.02\times0.02\times(0.02)^3$$
$$=1.28\times10^{-8}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. A monoprotic acid in 0.1 M solution ionizes to 0.001%. Its ionisation constant is:
(a) 1×10^{-3} (b) 1×10^{-6} (c) 1×10^{-8} (d) 1×10^{-11}
[Ans. (d)]
[Hint: $\alpha=\sqrt{\frac{K_a}{C}}$ or $K_a=C\alpha^2=0.1\times\left(\frac{0.001}{100}\right)^2$
$=1\times10^{-11}$]

2. The hydrogen ion concentration in mol/dm^3 in 0.2 M solution of weak acid, HA ($K_a=2\times10^{-5}$) is close to:
(a) 2×10^{-5} (b) 2×10^{-4} (c) 2×10^{-3} (d) 2×10^{-2}
[Ans. (c)]
[Hint: $[H_3O^+]=\sqrt{CK_a}=\sqrt{0.2\times2\times10^{-5}}=2\times10^{-3}$]

3. Autoprotolysis constant of NH_3 is:
(a) $[NH_4^+][NH_3]$ (b) $[NH_2^-][NH_3]$
(c) $[NH_4^+][NH_2^-]$ (d) $\frac{[NH_4^+]}{[NH_2^-]}$
[Ans. (c)]
[Hint: Autoprotolysis of NH_3 takes place as:
$$2NH_3 \rightleftharpoons NH_4^+ + NH_2^-$$
∴ Autoprotolysis constant $=[NH_4^+][NH_2^-]$]

4. The degree of ionization of an acid HA is 0.00001 at 0.1 M concentration. Its dissociation constant will be:
(a) 10^{-9} (b) 10^{-8} (c) 10^{-11} (d) 10^{-7}
[Ans. (c)]
[Hint: For monoprotic acid HA:
$K_a=C\alpha^2=0.1\times(10^{-5})^2=10^{-11}$]

5. The first and second dissociation constants of an acid, H_2A, are 1.0×10^{-5} and 5.0×10^{-10} respectively. The overall dissociation constant of the acid will be: **(AIEEE 2007)**
(a) 0.2×10^5 (b) 5.0×10^{-5}
(c) 5.0×10^{-15} (d) 5.0×10^{15}
[Ans. (c)]
[Hint: $K_a=K_{a_1}\times K_{a_2}$
$=1\times10^{-5}\times5\times10^{-10}$
$=5\times10^{-15}$]

10.4 SOLUBILITY PRODUCT

If to a given amount of solvent at a particular temperature, a solute is added gradually in increasing amounts, a stage is reached when some of the solute remains undissolved, no matter how long we wait or how vigorously we stir. The solution is then said to be saturated. **A solution which remains in contact with undissolved solute is said to be saturated.** At saturated stage, the quantity of the solute dissolved is always constant for the given amount of a particular solvent at a definite temperature.

In case, the solute is an electrolyte, its ionisation occurs in solution and degree of dissociation depends on the concentration of dissolved electrolyte at a particular temperature. Thus, in a saturated solution of an electrolyte two equilibria exist and can be represented as:

$$\underset{\text{Solid}}{AB} \rightleftharpoons \underset{\substack{\text{Unionised}\\(\text{Dissolved})}}{AB} \rightleftharpoons \underbrace{A^+ + B^-}_{\text{Ions}}$$

Applying the law of mass action to the ionic equilibrium,

$$\frac{[A^+][B^-]}{[AB]}=K$$

Since, the solution is saturated, the concentration of unionised molecules of the electrolyte is constant at a particular temperature, *i.e.*, $[AB]=K'=$ constant.

Hence, $[A^+][B^-]=K[AB]=KK'=K_s$ (constant)

K_s is termed as the solubility product. It is defined as **the product of the concentration of ions in a saturated solution of an electrolyte at a given temperature.**

Consider, in general, the electrolyte of the type A_xB_y which is dissociated as:

$$A_xB_y \rightleftharpoons xA^{y+} + yB^{x-}$$

Applying law of mass action,

$$\frac{[A^{y+}]^x[B^{x-}]^y}{[A_xB_y]}=K$$

When the solution is saturated,

$$[A_xB_y]=K' \text{ (constant)}$$

or $\quad [A^{y+}]^x[B^{x-}]^y=K[A_xB_y]=KK'=K_s$ (constant)

Thus, solubility product is defined as **the product of concentrations of the ions raised to a power equal to the number of times the ions occur in the equation representing the dissociation of the electrolyte at a given temperature when the solution is saturated.**

[**Note:** Solubility product is not the ionic product under all conditions but only when the solution is saturated.]

Different Expressions for Solubility Products

(i) Electrolyte of the type *AB*: Its ionisation is represented as:

$$AB \rightleftharpoons A^+ + B^-$$

Thus, $\quad K_s=[A^+][B^-]$

$$\text{AgCl} \rightleftharpoons \text{Ag}^+ + \text{Cl}^-; \quad K_s=[\text{Ag}^+][\text{Cl}^-]$$

$$\text{BaSO}_4 \rightleftharpoons \text{Ba}^{2+} + \text{SO}_4^{2-}; \quad K_s=[\text{Ba}^{2+}][\text{SO}_4^{2-}]$$

(ii) Electrolyte of the type *AB*$_2$: Its ionisation is represented as:

$$AB_2 \rightleftharpoons A^{2+} + 2B^-$$

Thus, $\quad K_s=[A^{2+}][B^-]^2$

$$\text{PbCl}_2 \rightleftharpoons \text{Pb}^{2+} + 2\text{Cl}^-; \quad K_s=[\text{Pb}^{2+}][\text{Cl}^-]^2$$

$$\text{CaF}_2 \rightleftharpoons \text{Ca}^{2+} + 2\text{F}^-; \quad K_s=[\text{Ca}^{2+}][\text{F}^-]^2$$

(iii) Electrolyte of the type *A*$_2$*B*: Its ionisation is represented as:

$$A_2B \rightleftharpoons 2A^+ + B^{2-}$$

Thus, $\quad K_s=[A^+]^2[B^{2-}]$

$$\text{Ag}_2\text{CrO}_4 \rightleftharpoons 2\text{Ag}^+ + \text{CrO}_4^{2-}; \quad K_s=[\text{Ag}^+]^2[\text{CrO}_4^{2-}]$$

$$\text{H}_2\text{S} \rightleftharpoons 2\text{H}^+ + \text{S}^{2-}; \quad K_s=[\text{H}^+]^2[\text{S}^{2-}]$$

(iv) Electrolyte of the type *A*$_2$*B*$_3$: Its ionisation is represented as:

$$A_2B_3 \rightleftharpoons 2A^{3+} + 3B^{2-}$$

Thus, $\quad K_s=[A^{3+}]^2[B^{2-}]^3$

$$\text{As}_2\text{S}_3 \rightleftharpoons 2\text{As}^{3+} + 3\text{S}^{2-}; \quad K_s=[\text{As}^{3+}]^2[\text{S}^{2-}]^3$$

$$\text{Sb}_2\text{S}_3 \rightleftharpoons 2\text{Sb}^{3+} + 3\text{S}^{2-}; \quad K_s=[\text{Sb}^{3+}]^2[\text{S}^{2-}]^3$$

(v) Electrolyte of the type *AB*$_3$: Its ionisation is represented as:

$$AB_3 \rightleftharpoons A^{3+} + 3B^-$$

Thus, $\quad K_s=[A^{3+}][B^-]^3$

$$\text{Fe(OH)}_3 \rightleftharpoons \text{Fe}^{3+} + 3\text{OH}^-; \quad K_s=[\text{Fe}^{3+}][\text{OH}^-]^3$$

$$\text{AlI}_3 \rightleftharpoons \text{Al}^{3+} + 3\text{I}^-; \quad K_s=[\text{Al}^{3+}][\text{I}^-]^3$$

Solubility product of a weak electrolyte: Let degree of ionisation of weak electrolyte A_mB_n be 'α'.

$$\begin{array}{llll} & A_mB_n & \rightleftharpoons mA^{n+} & + nB^{m-} \\ t=0 & S & 0 & 0 \\ t_{\text{eq}} & S-S\alpha & mS\alpha & nS\alpha \end{array}$$

$$K_{\text{sp}}=[A^{n+}]^m[B^{m-}]^n$$

$$=[mS\alpha]^m[nS\alpha]^n$$

$$K_{\text{sp}}=m^m n^n (S\alpha)^{m+n}$$

Criteria of precipitation of an electrolyte: A very useful conclusion is derived from the solubility product concept. No precipitation of the electrolyte occurs if the ionic product is less than the solubility product, *i.e.*, the solution has not reached the saturation stage.

Case I: When $K_{\text{ip}} < K_{\text{sp}}$, then solution is unsaturated in which more solute can be dissolved.

Case II: When $K_{\text{ip}} = K_{\text{sp}}$, then solution is saturated in which no more solute can be dissolved.

Case III: When $K_{\text{ip}} > K_{\text{sp}}$, then solution is supersaturated and precipitation takes place.

When the ionic product exceeds the solubility product, the equilibrium shifts towards left hand side, *i.e.*, increasing the concentration of undissociated molecules of the electrolyte. As the solvent can hold a fixed amount of electrolyte at a definite temperature, the excess of the electrolyte is thrown out from the solution as precipitate.

Thus, for the precipitation of an electrolyte, it is necessary that the ionic product must exceed its solubility product. For example, if equal volumes of 0.02 M AgNO_3 solution and 0.02 M K_2CrO_4 solution are mixed, the precipitation of Ag_2CrO_4 occurs as the ionic product exceeds the solubility product of Ag_2CrO_4 which is 2×10^{-12}.

In the resulting solution,

$$[\text{Ag}^+]=\frac{0.02}{2}=0.01=1\times10^{-2}\ M$$

and $\quad [\text{CrO}_4^{2-}]=\frac{0.02}{2}=0.01=1\times10^{-2}\ M$

Ionic product of $Ag_2CrO_4 = [Ag^+]^2[CrO_4^{2-}]$

$$= (1\times 10^{-2})^2\ (1\times 10^{-2})$$

$$= 1\times 10^{-6}$$

1×10^{-6} is higher than 2×10^{-12} and thus precipitation of Ag_2CrO_4 occurs.

Relationship between Solubility and Solubility Product

Salts like AgI, $BaSO_4$, $PbSO_4$, PbI_2, etc., are ordinarily considered insoluble but they do possess some solubility. These are sparingly soluble electrolytes. A saturated solution of sparingly soluble electrolyte contains a very small amount of the dissolved electrolyte. It is assumed that whole of the dissolved electrolyte is present in the form of ions, *i.e.*, it is completely dissociated.

The equilibrium for a saturated solution of any sparingly soluble salt may be expressed as:

$$A_xB_y \rightleftharpoons xA^{y+} + yB^{x-}$$

Thus, solubility product, $K_s = [A^{y+}]^x[B^{x-}]^y$

Let 'S' mol litre^{-1} be the solubility of the salt; then

$$A_xB_y \rightleftharpoons \underset{xS}{xA^{y+}} + \underset{yS}{yB^{x-}}$$

So, $$K_s = [xS]^x[yS]^y$$

$$= x^x\cdot y^y(S)^{x+y}$$

(i) 1 : 1 type salts: Examples: AgCl, AgI, $BaSO_4$, $PbSO_4$, etc.

Binary electrolyte: $AB \rightleftharpoons \underset{S}{A^+} + \underset{S}{B^-}$

Let solubility of AB be S mol litre^{-1}.

So, $$K_s = [A^+][B^-] = S\times S = S^2$$

or $$S = \sqrt{K_s}$$

(ii) 1 : 2 or 2 : 1 type salts: Examples: Ag_2CO_3, Ag_2CrO_4, $PbCl_2$, CaF_2, etc.

Ternary electrolyte: $AB_2 \rightleftharpoons \underset{S}{A^{2+}} + \underset{2S}{2B^-}$

Let solubility of AB_2 be S mol litre^{-1}.

So, $$K_s = [A^{2+}][B^-]^2 = S\times(2S)^2 = 4S^3$$

or $$S = \sqrt[3]{K_s/4}$$

$$A_2B \rightleftharpoons \underset{2S}{2A^+} + \underset{S}{B^{2-}}$$

Let S be the solubility of A_2B.

$$K_s = [A^+]^2[B^{2-}]$$

$$= (2S)^2(S) = 4S^3$$

or $$S = \sqrt[3]{K_s/4}$$

(iii) 1 : 3 type salts: Examples: AlI_3, $Fe(OH)_3$, $Cr(OH)_3$, $Al(OH)_3$, etc.

Quarternary electrolyte: $AB_3 \rightleftharpoons \underset{S}{A^{3+}} + \underset{3S}{3B^-}$

Let S mol litre^{-1} be the solubility of AB_3.

$$K_s = [A^{3+}][B^-]^3 = S\times(3S)^3 = 27S^4$$

or $$S = \sqrt[4]{K_s/27}$$

The presence of common ion affects the solubility of a salt. Let AB be a sparingly soluble salt in solution and $A'B$ be added to it. Let S and S' be the solubilities of the salt AB before and after addition of the electrolyte $A'B$. Let c be the concentration of $A'B$.

Before addition of $A'B$, $K_s = S^2$ ... (i)

After addition of $A'B$, the concentration of A^+ and B^- ions become S' and $(S'+c)$, respectively.

So, $$K_s = S'(S'+c) \quad \text{... (ii)}$$

Equating eqs. (i) and (ii),

$$S^2 = S'(S'+c)$$

Calculation of remaining concentration after precipitation: Sometimes an ion remains after precipitation if it is in excess. Remaining concentration can be determined, *e.g.*,

(i) $$[A^+]_{\text{left}} = \frac{K_{sp}[AB]}{[B^-]}$$

(ii) $$[Ca^{2+}]_{\text{left}} = \frac{K_{sp}[Ca(OH)_2]}{[OH^-]^2}$$

(iii) $$[A^{n+}]^m_{\text{left}} = \frac{K_{sp}[A_mB_n]}{[B^{m-}]^n}$$

Percentage precipitation of an ion

$$= \left[\frac{\text{Initial conc.} - \text{Left conc.}}{\text{Initial conc.}}\right]\times 100$$

Simultaneous Solubility

Solubility of two electrolytes having common ion; when they are dissolved in the same solution, is called **simultaneous solubility**, *e.g.*,

(i) Solubility of AgBr and AgSCN, when dissolved together.
(ii) Solubility of CaF_2 and SrF_2, when dissolved together.
(iii) Solubility of MgF_2 and CaF_2, when dissolved together.

Calculation of simultaneous solubility is divided into two cases:

Case I: When the two electrolytes are almost equally strong (having close solubility product), *e.g.*,

$$AgBr\ (K_{sp} = 5\times 10^{-13});\quad AgSCN\ (K_{sp} = 10^{-12})$$

(See example 26.)

Here, charge balancing concept is applied.

Charge of Ag^+ = Charge of Br^- + Charge of SCN^-

$$[Ag^+] = [Br^-] + [SCN^-]$$

$$(a+b) = a \qquad\qquad b$$

Case II: When solubility products of two electrolytes are not close, *i.e.*, they are not equally strong, *e.g.*,

CaF_2 ($K_{sp} = 3.4 \times 10^{-11}$); SrF_2 ($K_{sp} = 2.9 \times 10^{-9}$)

Most of fluoride ions come of stronger electrolyte.

SOME SOLVED EXAMPLES

Example 16. *The solubility product of silver chloride is 1.5625×10^{-10} at 25°C. Find its solubility in g L^{-1}.*

Solution: Let the solubility of AgCl be S mol litre^{-1}.

$$\underset{}{AgCl} \rightleftharpoons \underset{S}{Ag^+} + \underset{S}{Cl^-}$$

Hence, $S^2 = 1.5625 \times 10^{-10}$

or $S = 1.25 \times 10^{-5}$ mol L^{-1}

Molecular mass of AgCl = (108 + 35.5) = 143.5

So, Solubility in g litre^{-1} = Mol. mass × S

$= 143.5 \times 1.25 \times 10^{-5}$

$= 1.79 \times 10^{-3}$ g L^{-1}

Example 17. *The solubility of $PbSO_4$ in water is 0.038 g L^{-1} at 25°C. Calculate its solubility product at the same temperature.*

Solution: Solubility (S) of $PbSO_4$ in mol L^{-1},

$$= \frac{0.038}{\text{Mol. mass of } PbSO_4} = \frac{0.038}{303} = 1.254 \times 10^{-4}$$

The equilibrium is

$$PbSO_4 \rightleftharpoons \underset{S}{Pb^{2+}} + \underset{S}{SO_4^{2-}}$$

So, $K_s = [Pb^{2+}][SO_4^{2-}] = S \times S = S^2$

or $K_s = 1.254 \times 10^{-4} \times 1.254 \times 10^{-4} = 1.573 \times 10^{-8}$

Example 18. *The concentration of Ag^+ ion in a saturated solution of Ag_2CrO_4 at 20°C is 1.5×10^{-4} mol L^{-1}. Determine the solubility product of Ag_2CrO_4 at 20°C.*

Solution: The equilibrium is:

$$Ag_2CrO_4 \rightleftharpoons 2Ag^+ + CrO_4^{2-}$$

On the basis of this equation, the concentration of CrO_4^{2-} ions will be half of the concentration of Ag^+ ions.

Thus, $[Ag^+] = 1.5 \times 10^{-4}$ M and $[CrO_4^{2-}] = 0.75 \times 10^{-4}$ M

$K_s = [Ag^+]^2[CrO_4^{2-}] = (1.5 \times 10^{-4})^2\ (0.75 \times 10^{-4})$

$= 1.6875 \times 10^{-12}$

Example 19. *The solubility product of $BaSO_4$ is 1.5×10^{-9}. Find out the solubility in (i) pure water and (ii) 0.1 M $BaCl_2$ solution.*

Solution: The equilibrium is:

(i) $BaSO_4 \rightleftharpoons Ba^{2+} + SO_4^{2-}$

Let S be the solubility in mol litre^{-1}; then

$K_s = [Ba^{2+}][SO_4^{2-}] = S^2$

or $1.5 \times 10^{-9} = S^2$

So, $S = 3.87 \times 10^{-5}$ mol L^{-1}

(ii) Let S' be the solubility of $BaSO_4$ in 0.1 M $BaCl_2$ solution.

Total Ba^{2+} ions concentration = $(S' + c)$ mol L^{-1}

and SO_4^{2-} ions concentration = S' mol L^{-1}

So, $K_s = (S' + c)\,S' = (S' + 0.1)\,S'$

or $1.5 \times 10^{-9} = (S' + 0.1)\,S'$

or $(S')^2 + 0.1S' = 1.5 \times 10^{-9}$

Neglecting $(S')^2$,

$0.1S' = 1.5 \times 10^{-9}$

or $S' = 1.5 \times 10^{-8}$ mol L^{-1}

Example 20. *The solubility of $Mg(OH)_2$ in pure water is 9.57×10^{-3} g L^{-1}. Calculate its solubility in g L^{-1} in 0.02 M $Mg(NO_3)_2$ solution.*

Solution: Solubility of $Mg(OH)_2$ in pure water

$= 9.57 \times 10^{-3}$ g L^{-1}

$$= \frac{9.57 \times 10^{-3}}{\text{Mol. mass}} \text{ mol } L^{-1}$$

$$= \frac{9.57 \times 10^{-3}}{58} = 1.65 \times 10^{-4} \text{ mol } L^{-1}$$

Further, $Mg(OH)_2 \rightleftharpoons \underset{S}{Mg^{2+}} + \underset{2S}{2OH^-}$

$K_s = [Mg^{2+}][OH^-]^2 = S \times (2S)^2 = 4S^3 = 4 \times (1.65 \times 10^{-4})^3$

$= 17.9685 \times 10^{-12}$

Let S' be solubility of $Mg(OH)_2$ in presence of $Mg(NO_3)_2$

$[Mg^{2+}] = (S' + c) = (S' + 0.02)$

$[OH'] = 2S'$

So, $K_S = (S' + 0.02)(2S')^2$

$17.9685 \times 10^{-12} = 4(S')^2(S' + 0.02)$

$$\frac{17.9685 \times 10^{-12}}{4} = (S')^3 + 0.02(S')^2$$

[neglecting $(S')^3$]

$4.4921 \times 10^{-12} = 0.02(S')^2$

or $(S')^2 = \dfrac{4.4921}{0.02} \times 10^{-12}$

or $S' = 14.9868 \times 10^{-6}$ mol L^{-1}

Solubility of $Mg(OH)_2$ in g litre^{-1} = $S' \times M$

$= 14.9868 \times 10^{-6} \times 58$

$= 8.69 \times 10^{-4}$ g L^{-1}

Example 21. *The solubility product of lead iodide is 1.4×10^{-8}. Calculate its molar solubility in 0.1 M KI solution.*

Solution: Let the solubility of PbI_2 be S. Then,

$$\underset{S}{PbI_2} \rightleftharpoons \underset{S}{Pb^{2+}} + \underset{2S}{2I^-}$$

Potassium iodide is a strong electrolyte and is completely ionised. It shall provide I^- ion concentration = 0.1 M.

$$[Pb^{2+}] = S$$

$$[I^-] = (2S + 0.1)\,M$$

$$K_{sp} = [Pb^{2+}][I^-]^2$$

$$= S \times (2S + 0.1)^2$$

$$= S \times (4S^2 + 0.01 + 0.4S)$$

$$= 4S^3 + 0.01S + 0.4S^2$$

Neglecting S^3 and S^2,

$$1.4 \times 10^{-8} = 0.01S$$

or $$S = \frac{1.4 \times 10^{-8}}{0.01} = 1.4 \times 10^{-6} \text{ mol L}^{-1}$$

Example 22. *The solubility product of lead bromide is* 8×10^{-5}. *If the salt is 80% dissociated in saturated solution, find the solubility of the salt.*

Solution: Let S be the solubility of the salt.

Degree of dissociation of the salt = 0.8.

$$PbBr_2 \rightleftharpoons \underset{0.8S}{Pb^{2+}} + \underset{2 \times 0.8S}{2Br^-}$$

$$K_{sp} = [Pb^{2+}][Br^-]^2$$

$$= (0.8S) \times (1.6S)^2$$

$$= 2.048S^3$$

or $$S^3 = \frac{8 \times 10^{-5}}{2.048} = 3.906 \times 10^{-5}$$

$$S = \sqrt[3]{3.906 \times 10^{-5}} = 3.39 \times 10^{-2} \text{ mol L}^{-1}$$

Mol. mass of $PbBr_2 = 367$

Solubility of $PbBr_2 = 3.39 \times 10^{-2} \times 367 = 12.44 \text{ g L}^{-1}$

Example 23. *A solution has 0.05 M* Mg^{2+} *and 0.05 M* NH_3. *Calculate the concentration of* NH_4Cl *required to prevent the formation of* $Mg(OH)_2$ *in this solution.* K_{sp} *of* $Mg(OH)_2$ $= 9.0 \times 10^{-12}$ *and ionisation constant of* $NH_3 = 1.8 \times 10^{-5}$. **(IIT 1993)**

Solution: The maximum concentration of $[OH^-]$ ions that will precipitate $Mg(OH)_2$ is calculated by applying the equation

$$K_{sp} = [Mg^{2+}][OH^-]^2$$

$$[OH^-]^2 = \frac{K_{sp}}{[Mg^{2+}]} = \frac{9.0 \times 10^{-12}}{0.05} = 1.8 \times 10^{-10}$$

or $$[OH^-] = 1.34 \times 10^{-5}\,M$$

NH_3 is present in solution in the form of NH_4OH

$$\underset{0.05}{NH_3} + H_2O \rightleftharpoons \underset{0.05}{NH_4OH} \rightleftharpoons NH_4^+ + OH^-$$

The ionisation of NH_4OH is suppressed by the addition of NH_4Cl (Strong electrolyte).

$$K_{NH_3} = K_{NH_4OH} = \frac{[NH_4^+][OH^-]}{[NH_4OH]}$$

Whole of the concentration of NH_4^+ ions is provided by NH_4Cl.

$$[NH_4^+] = \frac{K_{NH_4OH} \times [NH_4OH]}{[OH^-]}$$

$$= \frac{1.8 \times 10^{-5} \times 0.05}{1.34 \times 10^{-5}} = 0.067\,M$$

i.e., $$[NH_4Cl] = 0.067\,M$$

Example 24. *The solubility product of* $Ag_2C_2O_4$ *at 25°C is* 1.29×10^{-11} $mol^3\ L^{-3}$. *A solution of* $K_2C_2O_4$ *containing 0.1520 mole in 500 mL of water is shaken with excess of* Ag_2CO_3 *till the following equilibrium is reached.*

$$Ag_2CO_3 + K_2C_2O_4 \rightleftharpoons Ag_2C_2O_4 + K_2CO_3$$

At equilibrium, the solution contains 0.0358 mole of K_2CO_3. *Assuming the degree of dissociation of* $K_2C_2O_4$ *and* K_2CO_3 *to be equal, calculate the solubility product of* Ag_2CO_3. **(IIT 1991)**

Solution:

	Ag_2CO_3 +	$K_2C_2O_4$	$\rightleftharpoons Ag_2C_2O_4$ +	K_2CO_3
Initial		0.1520 mole		0
At equilibrium		(0.1520 − 0.0358) = 0.1162 mole		0.0358 mole
Concentration		2 × 0.1162 = 0.2324 *M*		2 × 0.0358 = 0.0716 *M*

$$K_{sp}\ Ag_2C_2O_4 = [Ag^+]^2[C_2O_4^{2-}]$$

$$[Ag^+] = \left[\frac{K_{sp}\ Ag_2C_2O_4}{[C_2O_4^{2-}]}\right]^{1/2}$$

$$K_{sp} Ag_2CO_3 = [Ag^+]^2[CO_3^{2-}]$$

$$[Ag^+] = \left[\frac{K_{sp}\ Ag_2CO_3}{[CO_3^{2-}]}\right]^{1/2}$$

So, $$\left[\frac{K_{sp}\ Ag_2C_2O_4}{[C_2O_4^{2-}]}\right]^{1/2} = \left[\frac{K_{sp}\ Ag_2CO_3}{[CO_3^{2-}]}\right]^{1/2}$$

or $$K_{sp}\ Ag_2CO_3 = \frac{K_{sp}\ Ag_2C_2O_4 \times [CO_3^{2-}]}{[C_2O_4^{2-}]}$$

$$= K_{sp}\ Ag_2C_2O_4 \frac{[K_2CO_3]}{[K_2C_2O_4]}$$

$$= 1.29 \times 10^{-11} \times \frac{0.0716}{0.2324} = 3.97 \times 10^{-12} \text{ mol}^3 \text{ L}^{-3}$$

Example 25. *20 mL of 0.001 M* $AgNO_3$ *solution is added to 1 litre of 0.002 M* K_2CrO_4 *solution. Will there be any precipitation?* K_{sp} *of* Ag_2CrO_4 *is* 2.4×10^{-12}.

Solution: No. of moles of Ag^+ in 20 mL

$$= \frac{20}{1000} \times 0.001 = 2 \times 10^{-5}$$

No. of moles CrO_4^{2-} in one litre $= 0.002 = 2 \times 10^{-3}$

After mixing, total volume of the solution

$$= 1000 + 20 = 1020 \text{ mL} = 1.02 \text{ L}$$

$$[Ag^+] = \frac{2\times10^{-5}}{1.02} = 1.96\times10^{-5}$$

$$[CrO_4^{2-}] = \frac{2\times10^{-3}}{1.02} = 1.96\times10^{-3}$$

$$\text{Ionic product} = [Ag^+]^2[CrO_4^{2-}]$$

$$= (1.96\times10^{-5})^2\ (1.96\times10^{-3})$$

$$= 7.53\times10^{-13}$$

There will be no precipitation of Ag_2CrO_4 as ionic product is less than solubility product.

Example 26. *Calculate simultaneous solubility of AgCNS and AgBr in a solution of water.* K_{sp} *of AgCNS* $= 1\times10^{-12}$, K_{sp} *of AgBr* $= 5\times10^{-13}$.

Solution: Let the solubility of AgCNS and AgBr in water be a and b respectively.

$$AgCNS \rightleftharpoons \underset{a}{Ag^+} + \underset{a}{CNS^-}$$

$$AgBr \rightleftharpoons \underset{b}{Ag^+} + \underset{b}{Br^-}$$

$$[Ag^+] = a + b, [CNS^-] = a \quad \text{and} \quad [Br^-] = b$$

$$K_{sp} AgCNS = [Ag^+][CNS^-] = a(a+b)$$

$$1\times10^{-12} = a(a+b) \qquad \text{... (i)}$$

$$K_{sp}\ AgBr = [Ag^+][Br^-] = b(a+b)$$

$$5\times10^{-13} = b(a+b) \qquad \text{... (ii)}$$

Dividing eq. (i) by (ii),

$$\frac{1\times10^{-12}}{5\times10^{-13}} = \frac{a}{b}$$

$$2 = \frac{a}{b} \quad \text{or} \quad a = 2b$$

Putting the value of a in eq. (i),

$$6b^2 = 1\times10^{-12}$$

$$b^2 = \frac{1}{6}\times10^{-12}$$

$$b = 4.08\times10^{-7}\ \text{mol L}^{-1}$$

$$a = 2\times4.08\times10^{-7}$$

$$= 8.16\times10^{-7}\ \text{mol L}^{-1}$$

Example 27. *The* K_{sp} *of* $Ca(OH)_2$ *is* 4.42×10^{-5} *at* $25°C$. *500 mL of saturated solution of* $Ca(OH)_2$ *is mixed with equal volume of 0.4 M NaOH. How much* $Ca(OH)_2$ *in mg is precipitated?* (IIT 1992)

Solution: Let S be the solubility of $Ca(OH)_2$ in saturated solution.

$$Ca(OH)_2 \rightleftharpoons \underset{S}{Ca^{2+}} + \underset{2S}{2OH^-}$$

$$K_{sp}\ Ca(OH)_2 = [Ca^{2+}][OH^-]^2$$

$$4.42\times10^{-5} = S\times4S^2 = 4S^3$$

$$S = 0.0223\ \text{mol L}^{-1}$$

After mixing the two solutions, the total volume becomes 1 litre.

$$[Ca^{2+}] = \frac{0.0223}{1000}\times500 = 0.01115\ \text{mol L}^{-1}$$

$$[OH^-] = \underset{[\text{From } Ca(OH)_2]}{\frac{0.0223\times2\times500}{1000}} + \underset{(\text{From NaOH})}{\frac{0.4\times500}{1000}} = 0.2223\ \text{mol L}^{-1}$$

Under the high concentration of OH^- ions, some $Ca(OH)_2$ will be precipitated.

$$[Ca^{2+}]_{\text{left}}[OH^-]^2 = K_{sp}$$

$$[Ca^{2+}]_{\text{left}} = \frac{4.42\times10^{-5}}{(0.2223)^2} = 8.94\times10^{-4}\ \text{mol L}^{-1}$$

Moles of $Ca(OH)_2$ precipitated = Moles of Ca^{2+} precipitated

$$= [Ca^{2+}]_{\text{initial}} - [Ca^{2+}]_{\text{left}}$$

$$= 0.01115 - 8.94\times10^{-4}$$

$$= 111.5\times10^{-4} - 8.94\times10^{-4}$$

$$= 102.56\times10^{-4}\ M = 102.56\times10^{-4}\times74\ \text{g}$$

$$= 7589.44\times10^{-4}\ \text{g} = 758.944\ \text{mg}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

6. The solubility product of sparingly soluble salt Ag_2CrO_4 is 4×10^{-12}. The molar solubility of the salt is:

(a) 1×10^{-4} mol L^{-1} (b) 2×10^{-6} mol L^{-1}

(c) 1×10^{-5} mol L^{-1} (d) 2×10^{-12} mol L^{-1}

[Ans. (a)]

[Hint: $K_{sp} = [Ag^+]^2[CrO_4^{2-}]$

If solubility of Ag_2CrO_4 is 'S', then $[Ag^+] = 2S$ and $[CrO_4^{2-}] = S$.

$$K_{sp} = 4S^3$$

$$4\times10^{-12} = 4S^3$$

$$S = 1\times10^{-4}\ M]$$

7. The solubility of $PbSO_4$ at 25°C is 1.1×10^{-4} mol/L. Then its K_{sp} is:

(a) 1.21×10^{-8} (b) 12.1×10^{-6}

(c) 121×10^{-11} (d) 1.21×10^{-10}

[Ans. (a)]

[Hint: $PbSO_4$ is a binary electrolyte, hence its K_{sp} can be calculated as:

$$K_{sp} = S^2 = [1.1\times10^{-4}]^2 = 1.21\times10^{-8}]$$

8. The solubility of CaF_2 ($K_{sp} = 3.4\times10^{-11}$) in 0.1 M solution of NaF would be:

(a) $3.4\times10^{-12}\ M$ (b) $3.4\times10^{-10}\ M$

(c) $3.4\times10^{-9}\ M$ (d) $3.4\times10^{-13}\ M$

[Ans. (c)]

[Hint: $CaF_2 \rightleftharpoons \underset{x}{Ca^{2+}} + \underset{2x}{2F^-}$

$$NaF \longrightarrow \underset{0.1}{Na^+} + \underset{0.1}{F^-}$$

$$[Ca^{2+}] = x, \quad [F^-] = [2x + 0.1] \approx 0.1\,M$$

$$K_{sp} = [Ca^{2+}][F^-]^2$$

$$3.4 \times 10^{-11} = x(0.1)^2$$

$$x = 3.4 \times 10^{-9}\,M]$$

9. The solubility product of AgCl is 1.8×10^{-10}. Precipitation of AgCl will occur only when equal volumes of which of the following solutions are mixed ?

(a) $10^{-4}\,M\,Ag^+$ and $10^{-4}\,M\,Cl^-$

(b) $10^{-7}\,M\,Ag^+$ and $10^{-7}\,M\,Cl^-$

(c) $10^{-5}\,M\,Ag^+$ and $10^{-5}\,M\,Cl^-$

(d) $10^{-10}\,M\,Ag^+$ and $10^{-10}\,M\,Cl^-$

[**Ans.** (a)]

[**Hint:** After mixing,

$$[Ag^+] = \frac{1}{2} \times 10^{-4} = 5 \times 10^{-5}\,M$$

$$[Cl^-] = \frac{1}{2} \times 10^{-4} = 5 \times 10^{-5}\,M$$

$$K_{ip} = [Ag^+][Cl^-] = (5 \times 10^{-5})^2 = 2.5 \times 10^{-9}$$

Since, ionic product is greater than solubility product, hence precipitation will take place.]

10. If x mol L^{-1} is the solubility of $KAl(SO_4)_2$, then K_{sp} is equal to:

(a) x^3 (b) $4x^4$ (c) x^4 (d) $4x^3$

[**Ans.** (b)]

[**Hint:** $KAl(SO_4)_2 \longrightarrow \underset{x}{K^+} + \underset{x}{Al^{3+}} + \underset{2x}{2SO_4^{2-}}$

$$K_{sp} = [K^+][Al^{3+}][SO_4^{2-}]^2$$

$$= x \times x \times (2x)^2 = 4x^4]$$

11. For which of the following sparingly soluble salt, the solubility (S) and solubility product (K_{sp}) are related by the expression:

$$S = \left[\frac{K_{sp}}{4}\right]^{1/3}$$ **[PET (Kerala) 2006]**

(a) $BaSO_4$ (b) $Ca_3(PO_4)_2$ (c) Hg_2Cl_2 (d) Ag_3PO_4

(e) CuS

[**Ans.** (c)]

[**Hint:** $Hg_2Cl_2 \longrightarrow \underset{S}{Hg_2^{2+}} + \underset{2S}{2Cl^-}$ (with S under Hg_2Cl_2)

$$K_{sp} = [Hg_2^{2+}][Cl^-]^2 = [S][2S]^2 = 4S^3$$

$$S = \left[\frac{K_{sp}}{4}\right]^{1/3}]$$

12. The solubility of Sb_2S_3 in water is 1×10^{-5} mol/L at 298 K. What will be its solubility product? **[PMT (Raj.) 2006]**

(a) 108×10^{-25} (b) 1.0×10^{-25}

(c) 144×10^{-25} (d) 126×10^{-24}

[**Ans.** (a)]

[**Hint:** $\underset{S}{Sb_2S_3} \longrightarrow \underset{2S}{2Sb^{3+}} + \underset{3S}{3S^{2-}}$

$$K_{sp} = [Sb^{3+}]^2[S^{2-}]^3 = [2S]^2[3S]^3 = 108\,S^5$$

$$= 108 \times (10^{-5})^5 = 108 \times 10^{-25}]$$

Applications of Solubility Product

(i) Purification of common salt

Natural common salt consists of many insoluble and soluble impurities. Saturated solution of common salt is prepared and insoluble impurities are filtered off. Hydrogen chloride gas (HCl) is circulated through the saturated solution. HCl and NaCl dissociate into their respective ions as:

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

$$HCl \rightleftharpoons H^+ + Cl^-$$

The concentration of Cl^- ions increases considerably in solution due to ionisation of HCl. Hence, the ionic product $[Na^+][Cl^-]$ exceeds the solubility product of sodium chloride and, therefore, pure sodium chloride precipitates out from solution.

(ii) Salting out of soap

Soap is a sodium salt of higher fatty acids. From the solution, soap is precipitated by the addition of concentrated solution of sodium chloride. Soap and sodium chloride are present in the form of ions.

$$\underset{\text{Soap}}{C_nH_{2n+1}COONa} \rightleftharpoons C_nH_{2n+1}COO^- + Na^+$$

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

Thus, the concentration of Na^+ ions increases considerably on addition of NaCl solution. Hence, the ionic product $[C_nH_{2n+1}COO^-][Na^+]$ exceeds the solubility product of soap and, therefore, soap precipitates out from the solution.

(iii) Manufacture of sodium bicarbonate (baking soda)

In Solvay's soda process, CO_2 gas is passed through ammonical brine to precipitate out $NaHCO_3$.

$$NH_4OH + CO_2 \longrightarrow NH_4HCO_3$$

$$NH_4HCO_3 + NaCl \longrightarrow NaHCO_3 + NH_4Cl$$

$NaHCO_3$ is precipitated first because of its lower solubility product as compared to those of NH_4Cl, NH_4HCO_3 and NaCl.

Thus, baking soda ($NaHCO_3$) can be quantitatively estimated.

(iv) Application of solubility product in quantitative analysis

1. Estimation of barium as barium sulphate: H_2SO_4 as precipitating agent is added to the aqueous solution of $BaCl_2$.

$$BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl$$

Precipitation of $BaSO_4$ takes place when its ionic product exceeds solubility product. H_2SO_4 is added in slight excess to ensure complete precipitation. Large excess of H_2SO_4 is harmful for complex formation.

2. Estimation of silver as silver chloride: NaCl solution is added to the silver nitrate solution; slight excess of NaCl is added to ensure complete precipitation.

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$$

Again, precipitation of AgCl takes place when ionic product of AgCl exceeds its solubility product.

3. In a similar manner, we estimate lead as lead chromate, calcium as calcium oxalate, etc.

(v) Precipitation of the sulphides of group II and IV

Hydrogen sulphide is a weak electrolyte and is used for the precipitation of various sulphides of group II and IV in qualitative analysis.

It ionises to a small extent in water:

$$H_2S \rightleftharpoons 2H^+ + S^{2-}$$

Applying law of mass action,

$$K = \frac{[H^+]^2[S^{2-}]}{[H_2S]}$$

The concentration of S^{2-} ions can be decreased by increasing concentration of H^+ ions and it can be increased by decreasing concentration of H^+ ions. In group II, lower concentration of sulphide ions is required as the solubility products of the sulphides of group II are low while higher concentration of sulphide ions is required in group IV as the solubility products of the sulphides of group IV are high. The values of solubility products of various sulphides are given below:

	Metal sulphide	**Solubility product**
Group II	Bi_2S_3	1.6×10^{-72}
	HgS	4×10^{-54}
	CuS	1×10^{-44}
	PbS	5×10^{-29}
	CdS	1.4×10^{-28}
Group IV	CoS	3×10^{-26}
	NiS	1.4×10^{-24}
	ZnS	1.0×10^{-22}
	MnS	1.4×10^{-15}

The concentration of S^{2-} ions in group II is lowered by maintaining acidic medium. In the presence of HCl, the ionisation of H_2S is suppressed due to common ion effect. The concentration is so adjusted that only ionic products of the sulphides of group II exceed their solubility products and, therefore, get precipitated. However, CdS has somewhat higher value. For its precipitation, dilution of the solution is done which increases ionisation of H_2S and thereby increasing concentration of S^{2-} ions.

In group IV, higher concentration of S^{2-} ions is needed. This is done by changing the medium from acidic to alkaline. Ammonium hydroxide is added, the OH^- ions furnished by NH_4OH remove H^+ ions from solution in the form of water molecules as,

$$H^+ + OH^- \rightleftharpoons H_2O$$

More of the ionisation of H_2S occurs and, thus, concentration of S^{2-} ions increases. It becomes so high that ionic products of the sulphides of group IV exceed their solubility products and they get precipitated.

(vi) Precipitation of III group hydroxides

When NH_4OH is added in presence of NH_4Cl then precipitation of III group hydroxides takes place, *i.e.*, $Al(OH)_3$, $Fe(OH)_3$ and $Cr(OH)_3$ are precipitated. Solubility product of III group hydroxides is less than those of higher group hydroxides.

$$NH_4Cl \longrightarrow NH_4^+ + Cl^-$$

$$NH_4OH \rightleftharpoons NH_4^+ + OH^-$$

NH_4^+ ion furnished by NH_4Cl lowers the ionisation of NH_4OH and hence the concentration of hydroxide ion OH^-. At low concentration of hydroxide ion only III group hydroxides precipitate.

Fractional Precipitation

It is a technique of separating two or more ions from a solution by adding a reagent that precipitates first one ion and then the second.

Let us suppose 0.1 *M* Ba^{2+} and 0.1 *M* Sr^{2+} in aqueous solution. K_2CrO_4 is added as precipitating agent. K_{sp} of $BaCrO_4$ is 1.2×10^{-10} and K_{sp} of $SrCrO_4$ is 3.5×10^{-5}.

$[CrO_4^{2-}]$ concentration required to precipitate $BaCrO_4$

$$= \frac{K_{sp}}{[Ba^{2+}]} = \frac{1.2 \times 10^{-10}}{0.1} = 1.2 \times 10^{-9}$$

$BaCrO_4$ will precipitate first because it requires low concentration of CrO_4^{2-} ions. On addition of chromate ions, $BaCrO_4$ starts precipitating when chromate ion concentration reaches 1.2×10^{-9} *M*. When CrO_4^{2-} ion concentration reaches up to 3.5×10^{-4} *M*, then $SrCrO_4$ also starts precipitating.

Remaining concentration of Ba^{2+} when $SrCrO_4$ starts precipitation

$$= \frac{K_{sp}BaCrO_4}{[CrO_4^{2-}]} = \frac{1.2 \times 10^{-10}}{3.5 \times 10^{-4}} = 3.4 \times 10^{-7}\ M$$

$$\%\ \text{remaining concentration} = \frac{3.4 \times 10^{-7}}{0.1} \times 100$$

$$= 0.00034\%$$

Stability Constant

Let us consider dissociation of the ion $FeBr^+$.

$$FeBr^+ \rightleftharpoons Fe^{2+} + Br^-$$

Dissociation constant for above equilibria may be given as:

$$K_d = \frac{[Fe^{2+}][Br^-]}{[FeBr^+]}$$

Reciprocal of dissociation constant is called stability constant.

$$K_s = \frac{[FeBr^+]}{[Fe^{2+}][Br^-]}$$

Let us consider the formation of complex $K_2Cd(CN)_4$. Complex ion is $Cd(CN)_4^{2-}$ where oxidation state of central metal Cd^{2+} is (+2). Complexing process proceeds in four steps as:

$$Cd^{2+} + CN^- \rightleftharpoons CdCN^+; \qquad K_1 = \frac{[CdCN^+]}{[Cd^{2+}][CN^-]}$$

$$CdCN^+ + CN^- \rightleftharpoons Cd(CN)_2; \qquad K_2 = \frac{[Cd(CN)_2]}{[CdCN^+][CN^-]}$$

$$Cd(CN)_2 + CN^- \rightleftharpoons Cd(CN)_3^-; \qquad K_3 = \frac{[Cd(CN)_3^-]}{[Cd(CN)_2][CN^-]}$$

$$Cd(CN)_3^- + CN^- \rightleftharpoons Cd(CN)_4^{2-}; \qquad K_4 = \frac{[Cd(CN)_4^{2-}]}{[Cd(CN)_3^-][CN^-]}$$

Overall reaction may be given as:

$$Cd^{2+} + 4CN^- \rightleftharpoons [Cd(CN)_4^{2-}]; \qquad K_s = \frac{[Cd(CN)_4^{2-}]}{[Cd^{2+}][CN^-]^4}$$

Here, $K_s = K_1 K_2 K_3 K_4$

Significance of stability constant: Greater will be the value of stability constant more stable will be the complex.

Note: (a) If on addition of a common ion in a salt solution (sparingly soluble), formation of complex ion takes place, then ionisation increases, *i.e.*, equilibrium shifts towards right hand direction to maintain the value of K_{sp} constant. It means, addition of common ion in the case of complex formation increases the solubility of the sparingly soluble salt which is against the concept of common ion effect.

(b) When we add an electrolyte to another electrolyte solution having no common ion, then ionisation of the latter increases.

(c) For a given electrolyte solubility product is always constant at a particular temperature.

Solubility of Metal Hydroxides in Acid Medium

H^+ ion furnished by the medium affects the solubility of metal hydroxide, say $M(OH)_2$, because of neutralization of OH^- ion by H^+ ion.

$$M(OH)_2 \rightleftharpoons M^{2+} + 2OH^-$$

$$K_{sp} \text{ of } M(OH)_2 = [M^{2+}][OH^-]^2$$

$$[M^{2+}] = \frac{K_{sp}}{[OH^-]^2} \qquad \ldots \text{(i)}$$

$$[H^+][OH^-] = K_w = 10^{-14}$$

$$[OH^-]^2 = \frac{10^{-28}}{[H^+]^2} \qquad \ldots \text{(ii)}$$

From eqs. (i) and (ii), we have

$$[M^{2+}] = \frac{K_{sp}[H^+]^2}{10^{-28}}$$

10.5 ACIDS AND BASES

The earliest criteria for the characterisation of acids and bases were the experimentally observed properties of aqueous solutions. An acid* was defined as a substance whose water solution tastes sour, turns blue litmus red, neutralises bases and so on. A substance was a base if its aqueous solution tasted bitter, turns red litmus blue, neutralises acids and so on. **Faraday** termed acids, bases and salts as electrolytes and **Liebig** proposed that acids are compounds containing hydrogen that can be replaced by metals.

Different concepts have been put forth by different investigators to characterise acids and bases but the following are the three important modern concepts of acids and bases:

(1) Arrhenius concept

According to Arrhenius concept, **all substances which give H^+ ions when dissolved in water are called acids while those which ionise in water to furnish OH^- ions are called bases.**

$$HA \rightleftharpoons H^+ + A^- \qquad \text{(Acid)}$$

$$BOH \rightleftharpoons B^+ + OH^- \qquad \text{(Base)}$$

Thus, HCl is an acid because it gives H^+ ions in water. Similarly, NaOH is a base as it yields OH^- ions in water.

$$HCl \rightleftharpoons H^+ + Cl^-$$

$$NaOH \rightleftharpoons Na^+ + OH^-$$

Some acids and bases ionise almost completely in solutions and are called strong acids and bases. Others are dissociated to a limited extent in solutions and are termed weak acids and bases. HCl, HNO_3, H_2SO_4, $HClO_4$, etc., are examples of strong acids and NaOH, KOH, $(CH_3)_4NOH$ are strong bases. Every hydrogen compound cannot be regarded as an acid, *e.g.*, CH_4 is not an acid. Similarly, CH_3OH, C_2H_5OH, etc., have OH groups but they are not bases.

Actually free H^+ ions do not exist in water. They combine with solvent molecules, *i.e.*, have strong tendency to get hydrated.

$$HX + H_2O \rightleftharpoons \underset{\text{(Hydronium ion)}}{H_3O^+} + X^-$$

The proton in aqueous solution is generally represented as $H^+(aq.)$. It is now known that almost all the ions are hydrated to more or less extent and it is customary to put (*aq.*) after each ion.

The oxides of many non-metals react with water to form acids and are called acidic oxides or acid anhydrides.

$$CO_2 + H_2O \longrightarrow H_2CO_3 \rightleftharpoons 2H^+(aq.) + CO_3^{2-}(aq.)$$

$$N_2O_5 + H_2O \longrightarrow 2HNO_3 \rightleftharpoons 2H^+(aq.) + 2NO_3^-(aq.)$$

Many oxides of metals dissolve in water to form hydroxides. Such oxides are termed basic oxides.

$$Na_2O + H_2O \longrightarrow 2NaOH \rightleftharpoons 2Na^+(aq.) + 2OH^-(aq.)$$

The substance like NH_3 and N_2H_4 act as bases as they react with water to produce OH^- ions.

$$NH_3 + H_2O \longrightarrow NH_4OH \rightleftharpoons NH_4^+(aq.) + OH^-(aq.)$$

The reaction between an acid and a base is termed neutralisation. According to Arrhenius concept, the neutralisation in aqueous solution involves the reaction between H^+ and OH^- ions or hydronium and OH^- ions. This can be represented as

$$H_3O^+ + OH^- \rightleftharpoons 2H_2O$$

Limitations: (i) For the acidic or basic properties, the presence of water is absolutely necessary. Dry HCl shall not act as an acid. HCl is regarded as an acid only when dissolved in water and not in any other solvent.

(ii) The concept does not explain acidic and basic character of substances in non-aqueous solvents.

(iii) The neutralisation process is limited to those reactions which can occur in aqueous solutions only, although reactions involving salt formation do occur in the absence of solvent.

(iv) It cannot explain the acidic character of certain salts such as $AlCl_3$ in aqueous solution.

---

* Acid is a Latin word—*acidus*, meaning sour.

(v) An artificial explanation is required to explain the basic nature of NH_3 and metallic oxides and acidic nature of non-metal oxides.

(2) Bronsted-Lowry concept—The proton-donor-acceptor concept

In 1923, Bronsted and Lowry independently proposed a broader concept of acids and bases. According to Bronsted-Lowry concept **an acid is a substance (molecule or ion) that can donate proton, *i.e.*, a hydrogen ion, H^+, to some other substance and a base is a substance that can accept a proton from an acid.** More simply, an acid is a proton-donor (protogenic) and a base is a proton acceptor (protophilic). Consider the reaction,

$$HCl + H_2O \rightleftharpoons H_3O^+ + Cl^-$$

In this reaction, HCl acts as an acid because it donates a proton to the water molecule. Water, on the other hand, behaves as a base by accepting a proton from the acid.

The dissolution of ammonia in water may be represented as

$$NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$$

In this reaction, H_2O acts as an acid as it donates a proton to NH_3 molecule and NH_3 molecule behaves as a base as it accepts a proton.

When an acid loses a proton, the residual part of it has a tendency to regain a proton. Therefore, it behaves as a base.

$$\text{Acid} \rightleftharpoons H^+ + \text{Base}$$

The acid and base which differ by a proton are known to form a **conjugate pair.** Consider the following reaction:

$$CH_3COOH + H_2O \rightleftharpoons H_3O^+ + CH_3COO^-$$

It involves two conjugate pairs. The acid-base pairs are:

$$\underset{\text{Acid}}{CH_3COOH} \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} \underset{\text{Base}}{CH_3COO^-} \quad \text{and} \quad \underset{\text{Base}}{H_2O} \underset{-H^+}{\overset{+H^+}{\rightleftharpoons}} \underset{\text{Acid}}{H_3O^+}$$

Such pairs of substances which can be formed from one another by loss or gain of a proton are known as **conjugate acid-base pairs.**

If in the above reaction, the acid CH_3COOH is labelled acid$_1$ and its conjugate base, CH_3COO^- as base$_1$. H_2O is labelled as base$_2$ and its conjugate acid H_3O^+ as acid$_2$, the reaction can be written as:

$$\text{Acid}_1 + \text{Base}_2 \rightleftharpoons \text{Base}_1 + \text{Acid}_2$$

Thus, any acid-base reaction involves two conjugate pairs, *i.e.*, when an acid reacts with a base, another acid and base are formed. Some more examples are given below:

$$\text{Acid}_1 + \text{Base}_2 \rightleftharpoons \text{Acid}_2 + \text{Base}_1$$
$$H_2O + NH_3 \rightleftharpoons NH_4^+ + OH^-$$
$$HCN + H_2O \rightleftharpoons H_3O^+ + CN^-$$
$$HF + CH_3COOH \rightleftharpoons CH_3COOH_2^+ + F^-$$
$$CH_3COOH + NH_3 \rightleftharpoons NH_4^+ + CH_3COO^-$$
$$NH_3 + NH_3 \rightleftharpoons NH_4^+ + NH_2^-$$
$$H_2O + H_2O \rightleftharpoons H_3O^+ + OH^-$$
$$HCO_3^- + H_2O \rightleftharpoons H_3O^+ + CO_3^{2-}$$
$$NH_4^+ + H_2O \rightleftharpoons H_3O^+ + NH_3$$

Thus, every acid has its conjugate base and every base has its conjugate acid. It is further observed that strong acids have weak conjugate bases while weak acids have strong conjugate bases.

$$\underset{\text{Strong acid}}{HCl} \quad \underset{\text{Weak base}}{Cl^-} \quad \underset{\text{Weak acid}}{CH_3COOH} \quad \underset{\text{Strong base}}{CH_3COO^-}$$

There are certain molecules which have dual character of an acid and a base. These are called **amphiprotic** or **amphoteric.**

Examples are NH_3, H_2O, CH_3COOH, etc.

$$\underset{\text{Acid}}{H_2O} \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} \underset{\text{Base}}{OH^-} \qquad \underset{\text{Acid}}{NH_3} \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} \underset{\text{Base}}{NH_2^-}$$

$$\underset{\text{Base}}{H_2O} \underset{-H^+}{\overset{+H^+}{\rightleftharpoons}} \underset{\text{Acid}}{H_3O^+} \qquad \underset{\text{Base}}{NH_3} \underset{-H^+}{\overset{+H^+}{\rightleftharpoons}} \underset{\text{Acid}}{NH_4^+}$$

The strength of an acid depends upon its tendency to lose its proton and the strength of the base depends upon its tendency to gain the proton.

Acid-base chart containing some common conjugate acid-base pairs

Acid		Conjugate base	
$HClO_4$	(Perchloric acid)	ClO_4^-	(Perchlorate ion)
H_2SO_4	(Sulphuric acid)	HSO_4^-	(Hydrogen sulphate ion)
HCl	(Hydrogen chloride)	Cl^-	(Chloride ion)
HNO_3	(Nitric acid)	NO_3^-	(Nitrate ion)
H_3O^+	(Hydronium ion)	H_2O	(Water)
HSO_4^-	(Hydrogen sulphate ion)	SO_4^{2-}	(Sulphate ion)
H_3PO_4	(Ortho-phosphoric acid)	$H_2PO_4^-$	(Dihydrogen phosphate ion)
CH_3COOH	(Acetic acid)	CH_3COO^-	(Acetate ion)
H_2CO_3	(Carbonic acid)	HCO_3^-	(Hydrogen carbonate ion)
H_2S	(Hydrogen sulphide)	HS^-	(Hydrosulphide ion)
NH_4^+	(Ammonium ion)	NH_3	(Ammonia)
HCN	(Hydrogen cyanide)	CN^-	(Cyanide ion)
C_6H_5OH	(Phenol)	$C_6H_5O^-$	(Phenoxide ion)
H_2O	(Water)	OH^-	(Hydroxide ion)
C_2H_5OH	(Ethyl alcohol)	$C_2H_5O^-$	(Ethoxide ion)
NH_3	(Ammonia)	NH_2^-	(Amide ion)
CH_4	(Methane)	CH_3^-	(Methide ion)

↑ Increasing order of acid strength

Increasing order of basic strength ↓

In acid-base strength series, all acids above H_3O^+ in aqueous solution fall to the strength of H_3O^+. Similarly, the basic strength of bases below OH^- fall to the strength of OH^- in aqueous solution. This is known as **levelling effect.**

The strength of an acid also depends upon the solvent. The acids $HClO_4$, H_2SO_4, HCl and HNO_3 which have nearly the same strength in water will be in the order of $HClO_4 > H_2SO_4 > HCl > HNO_3$ in acetic acid, since, the proton accepting tendency of acetic acid is much weaker than water. So, the real strength of acids can be judged by solvents. On the basis of proton interaction, solvents can be classified into four types:

(i) Protophilic solvents: Solvents which have greater tendency to accept protons, *i.e.*, water, alcohol, liquid ammonia, etc.

(ii) Protogenic solvents: Solvents which have the tendency to produce protons, *i.e.*, water, liquid hydrogen chloride, glacial acetic acid, etc.

(iii) Amphiprotic solvents: Solvents which act both as protophilic or protogenic, *e.g.*, water, ammonia, ethyl alcohol, etc.

(iv) Aprotic solvents: Solvents which neither donate nor accept protons, *e.g.*, benzene, carbon tetrachloride, carbon disulphide, etc.

HCl acts as acid in H_2O, stronger acid in NH_3, weak acid in CH_3COOH, neutral in C_6H_6 and a weak base in HF.

$$\underset{\text{Base}}{HCl} + \underset{\text{Acid}}{HF} \longrightarrow \underset{\text{Acid}}{H_2Cl^+} + \underset{\text{Base}}{F^-}$$

Periodic Variations of Acidic and Basic Properties

(a) Hydracids of the elements of the same period: Consider the hydracids of the elements of II period, *viz.*, CH_4, NH_3, H_2O and HF. These hydrides become increasingly acidic as we move from CH_4 to HF. CH_4 has negligible acidic properties while HF is a fairly stronger acid. The increase in acidic nature is due to the fact that the stability of their conjugate bases increases in the order

$$CH_3^- < NH_2^- < OH^- < F^-$$

The increase in acidic properties is supported by the successive increase in the dissociation constant.

$$CH_4\ (=10^{-58}) < NH_3\ (=10^{-35}) < H_2O\ (=10^{-14}) < HF\ (=10^{-4})$$

(b) Hydracids of the elements of same group: (i) Hydrides of V group elements (NH_3, PH_3, AsH_3, SbH_3 and BiH_3) show basic character which decreases due to increase in size and decrease in electronegativity from N to Bi. There is a decrease in electron density in sp^3-hybrid orbital and thus electron donor capacity decreases.

(ii) Hydracids of VI group elements (H_2O, H_2S, H_2Se and H_2Te) act as weak acids. The strength increases in the order

$$H_2O < H_2S < H_2Se < H_2Te$$

The increasing acidic character reflects decreasing trend in the electron donor capacity of OH^-, HS^-, HSe^- or HTe^- ions.

(iii) Hydracids of VII group elements (HF, HCl, HBr and HI) show acidic nature which increases from HF to HI. This is explained by the fact that bond energies decrease. (H—F = 135 kcal/mol, HCl = 103, HBr = 88 and HI = 71 kcal/mol)

(c) Oxyacids: (i) The acidic character of oxyacids of the same element which is in different oxidation states increases with increase in oxidation number.

$$\overset{+1}{HClO} < \overset{+3}{HClO_2} < \overset{+5}{HClO_3} < \overset{+7}{HClO_4}$$

$$\overset{+4}{H_2SO_3} < \overset{+6}{H_2SO_4};\ \overset{+3}{HNO_2} < \overset{+5}{HNO_3}$$

But this rule fails in oxyacids of phosphorus.

$$H_3PO_2 > H_3PO_3 > H_3PO_4$$

(ii) The acidic character of the oxyacids of different elements which are in the same oxidation state decreases as the atomic number increases. This is due to increase in size and decrease in electronegativity.

$$HClO_4 > HBrO_4 > HIO_4$$

$$H_2SO_3 > H_2SeO_3$$

Limitations: There are number of acid-base reactions in which no proton transfer takes place, *e.g.*,

$$\underset{\text{Acid}_1}{SO_2} + \underset{\text{Base}_2}{SO_2} \rightleftharpoons \underset{\text{Acid}_2}{SO^{2+}} + \underset{\text{Base}_1}{SO_3^{2-}}$$

Thus, the protonic definition cannot be used to explain the reactions occurring in non-protonic solvents such as $COCl_2$, SO_2, N_2O_4, etc.

(3) Lewis concept

This concept was proposed by G.N. Lewis, in 1939. According to this concept, **a base is defined as a substance which can furnish a pair of electrons to form a coordinate bond whereas an acid is a substance which can accept a pair of electrons.** The acid is also known as electron acceptor or **electrophile** while the base is electron donor or **nucleophile.**

A simple example of an acid-base is the reaction of a proton with hydroxyl ion.

$$\underset{\text{Acid}}{H^+} + \underset{\text{Base}}{:\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}:H^-} = H:\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}:H$$

Some other examples are:

$$\underset{\text{Base}}{H_3N:} + \underset{\text{Acid}}{BF_3} = H_3N \rightarrow BF_3$$

$$\underset{\text{Acid}}{H^+} + \underset{\text{Base}}{:NH_3} = [H \leftarrow NH_3]^+$$

$$\underset{\text{Acid}}{BF_3} + \underset{\text{Base}}{[F]^-} = [F \rightarrow BF_3]^+$$

Lewis concept is more general than the Bronsted Lowry concept.

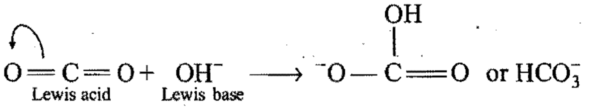
According to Lewis concept, the following species can act as Lewis acids:

(i) Molecules in which the central atom has incomplete octet: All compounds having central atom with less than 8 electrons are Lewis acids, *e.g.*, BF_3, BCl_3, $AlCl_3$, $MgCl_2$, $BeCl_2$, etc.

(ii) Simple cations: All cations are expected to act as Lewis acids since they are deficient in electrons. However, cations such as Na^+, K^+, Ca^{2+}, etc., have a very little tendency to accept electrons, while the cations like H^+, Ag^+, etc., have greater tendency to accept electrons and, therefore, act as Lewis acids.

(iii) Molecules in which the central atom has empty *d*-orbitals: The central atom of the halides such as SiX_4, GeX_4, $TiCl_4$, SnX_4, PX_3, PF_5, SF_4, SeF_4, $TeCl_4$, etc., have vacant *d*-orbitals. These can, therefore, accept an electron pair and act as Lewis acids.

(iv) Molecules having a multiple bond between atoms of dissimilar electronegativity: Typical examples of molecules falling in this class of Lewis acids are CO_2, SO_2 and SO_3. Under the influence of attacking Lewis base, one π-electron pair will be shifted towards the more negative atom.



$$\underset{\text{Lewis acid}}{O{=}C{=}O} + \underset{\text{Lewis base}}{OH^-} \longrightarrow {}^-O-\overset{\overset{\large OH}{|}}{C}{=}O \text{ or } HCO_3^-$$

The following species can act as Lewis bases:

(i) Neutral species having at least one lone pair of electrons: For example, ammonia, amines, alcohols, etc., act as Lewis bases because they contain a pair of electrons.

$$:NH_3, \quad -\ddot{N}H_2, \quad R-\underset{\cdot\cdot}{\ddot{O}}-H$$

(ii) Negatively charged species or anions: For example, chloride, cyanide, hydroxide ions, etc., act as Lewis bases.

$$CN^-, \quad Cl^-, \quad OH^-$$

It may be noted that all Bronsted bases are also Lewis bases but all Bronsted acids are not Lewis acids.

Limitations: Since, the strength of the Lewis acids and bases is found to depend on the type of reaction, it is not possible to arrange them in any order of their relative strength.

The choice of which definition of acids and bases one wishes to use in a particular instance depends largely on the sort of chemistry that is studied. But Arrhenius concept is perfectly satisfactory and simplest for dealing with reactions in aqueous solutions. It explains satisfactorily the strength of acids and bases in aqueous solutions, neutralisation, salt hydrolysis, etc.

10.6 RELATIVE STRENGTH OF ACIDS AND BASES

According to Arrhenius concept, an acid is a substance which furnishes H^+ ions when dissolved in water. All the acid properties on an acid are due to H^+ ions present in the solution.

The extent to which an acid property is given by an acid is a measure of its strength. The strength of the acid solution does not depend on its concentration but on the number of H^+ ions present. The concentration of H^+ ions depends on the ionisation of an acid in solution. On dilution, the ionisation increases and more of H^+ ions come to solution with the result that the strength of the acid increases. **Thus, strength of the acid increases on dilution while its concentration decreases.** At infinite dilution the dissociation of an acid is nearly complete and all acids are equally strong at infinite dilution.

The concentration of H^+ ions at all other dilutions of equimolar solutions of the acids may not be equal and depends on their degree of dissociation. Thus, to measure the relative strength of the two acids, the measurements of hydrogen ion concentration, *i.e.*, degree of dissociation is made of equinormal solutions of the two acids. Various methods are used for this purpose. Some are described below.

(i) The conductivity method: The degree of dissociation of a weak acid is equal to conductivity ratio $\frac{\Lambda}{\Lambda_\infty}$. Thus, the degrees of dissociation α_1 and α_2 for two equinormal acids are given by:

$$\text{For acid I,} \qquad \alpha_1 = \frac{\Lambda_1}{\Lambda_{\infty_1}}$$

and

$$\text{For acid II,} \qquad \alpha_2 = \frac{\Lambda_2}{\Lambda_{\infty_2}}$$

At infinite dilution, all weak electrolytes have almost the same value of Λ_∞; hence,

$$\Lambda_{\infty_1} = \Lambda_{\infty_2}$$

$$\frac{\text{Strength of acid I}}{\text{Strength of acid II}} = \frac{\alpha_1}{\alpha_2} = \frac{\Lambda_1}{\Lambda_2} = \frac{\dfrac{1000 \times \text{sp. cond. acid I}}{C}}{\dfrac{1000 \times \text{sp. cond. acid II}}{C}}$$

$$= \frac{\text{Sp. cond. acid I}}{\text{Sp. cond. acid II}}$$

The relative strength of two acids is, thus, equal to the ratio of their equivalent conductance or specific conductance of equinormal solutions which can be determined experimentally.

(ii) Comparing dissociation constants: Let K_1 and K_2 be the dissociation constants of two acids and let α_1 and α_2 be their degree of dissociation in equinormal solutions.

Applying Ostwald's dilution law, $\alpha_1 = \sqrt{\frac{K_1}{C}}$ and $\alpha_2 = \sqrt{\frac{K_2}{C}}$

$$\text{Thus,} \qquad \frac{\text{Strength of acid I}}{\text{Strength of acid II}} = \frac{\alpha_1}{\alpha_2} = \sqrt{\frac{K_1}{K_2}}$$

Dissociation constants of some weak acids are given in the table:

Acid-ionization constants at 25°C

Substance	Formula	K_a
Acetic acid	$HC_2H_3O_2$	1.7×10^{-5}
Benzoic acid	$HC_7H_5O_2$	6.3×10^{-5}
Boric acid	H_3BO_3	5.9×10^{-10}
Carbonic acid	H_2CO_3	4.3×10^{-7}
	HCO_3^-	4.8×10^{-11}
Cyanic acid	HOCN	3.5×10^{-4}

Substance	Formula	K_a
Formic acid	$HCHO_2$	1.7×10^{-4}
Hydrocyanic acid	HCN	4.9×10^{-10}
Hydrofluoric acid	HF	6.8×10^{-4}
Hydrogen sulphate ion	HSO_4^-	1.1×10^{-2}
Hydrogen sulphide	H_2S HS^-	8.9×10^{-8} 1.2×10^{-13}
Hypochlorous acid	$HClO$	3.5×10^{-8}
Nitrous acid	HNO_2	4.5×10^{-4}
Oxalic acid	$H_2C_2O_4$ $HC_2O_4^-$	5.6×10^{-2} 5.1×10^{-5}
Phosphoric acid	H_3PO_4 $H_2PO_4^-$ HPO_4^{2-}	6.9×10^{-3} 6.2×10^{-8} 4.8×10^{-13}
Phosphorous acid	H_2PHO_3 $HPHO_3^-$	1.6×10^{-2} 7.0×10^{-7}
Propionic acid	$HC_3H_5O_2$	1.3×10^{-5}
Pyruvic acid	$HC_3H_3O_3$	1.4×10^{-4}
Sulphurous acid	H_2SO_3 HSO_3^-	1.3×10^{-2} 6.3×10^{-8}

(iii) Thomson thermal method: In this method, heat of neutralisation of two acids is first determined separately with NaOH. Let it be 'x' and 'y' calorie. The one gram equivalent of each of the two acids is mixed and one gram equivalent of NaOH is added. Let the heat evolved in this case be 'z' calorie. The two acids will neutralise a fraction of the base proportional to their relative strength. Suppose n gram equivalent of NaOH is neutralised by acid I and the rest $(1-n)$ by acid II.

$$\text{Total heat evolved, } z = nx + (1-n)y$$

$$= nx + y - ny$$

or

$$z - y = n(x - y)$$

or

$$n = \frac{(z-y)}{(x-y)}$$

So,

$$\frac{\text{Strength of acid I}}{\text{Strength of acid II}} = \frac{n}{(1-n)} = \frac{\dfrac{(z-y)}{(x-y)}}{1 - \dfrac{(z-y)}{(x-y)}} = \frac{(z-y)}{(x-z)}$$

Relative strength of bases: A base is a substance which gives OH^- ions when dissolved in water. The strength of the base depends on OH^- ion concentration. The above methods can be used for measuring relative strengths of bases also. In the Thomson thermal method, the two bases and their mixtures will be neutralised by strong acid, say HCl.

The relative strengths of some of the acids are as follows:

(i) $HClO_4 > HBr > HCl > HNO_3 > H_2SO_4 > H_3O^+ > H_2SO_3 > H_2CO_3 > CH_3COOH$

(ii) $HClO_4 > HClO_3 > HClO_2 > HClO$

(iii) $HI > HBr > HCl > HF$

(iv) $HClO_3 > HBrO_3 > HIO_3$

(v) $CCl_3COOH > CHCl_2COOH > CH_2ClCOOH > CH_3COOH$

(vi) $HCOOH > CH_3COOH > C_2H_5COOH$

The relative strengths of some of the bases are as follows:

(i) $KOH > NaOH > Ca(OH)_2 > NH_4OH$

(ii) $(CH_3)_2NH > CH_3NH_2 > (CH_3)_3N > NH_3$

(iii) $(C_2H_5)_2NH > C_2H_5NH_2 > NH_3 > (C_2H_5)_3N$

(iv) $NaOH > NH_3 > H_2O$

(v) $NH_3 > NH_2 \cdot NH_2 > NH_2OH$

(vi) $NH_3 > C_5H_5N > C_6H_5NH_2$

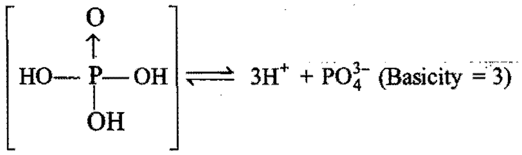
ILLUSTRATIONS OF OBJECTIVE QUESTIONS

13. Which one is correct statement? **(DCE 2007)**

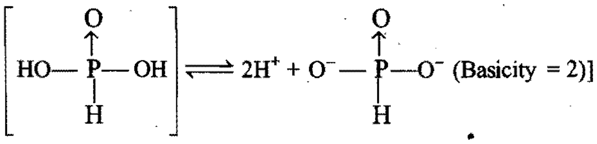
(a) Basicity of H_3PO_4 and H_3PO_3 are 3 and 3 respectively
(b) Acidity of H_3PO_4 and H_3PO_3 are 3 and 3 respectively
(c) Acidity of H_3PO_4 and H_3PO_3 are 3 and 2 respectively
(d) Basicity of H_3PO_4 and H_3PO_3 are 3 and 2 respectively

[Ans. (d)]

[Hint:



$$\left[HO-\overset{\overset{O}{\uparrow}}{\underset{\underset{OH}{|}}{P}}-OH\right] \rightleftharpoons 3H^+ + PO_4^{3-} \text{ (Basicity = 3)}$$



$$\left[HO-\overset{\overset{O}{\uparrow}}{\underset{\underset{H}{|}}{P}}-OH\right] \rightleftharpoons 2H^+ + O^- - \overset{\overset{O}{\uparrow}}{\underset{\underset{H}{|}}{P}}-O^- \text{ (Basicity = 2)]}$$

14. In the reaction,

$$HC_2O_4^- + PO_4^{3-} \rightleftharpoons HPO_4^{2-} + C_2O_4^{2-}$$

the Bronsted base are: **[PET (Raj.) 2004]**

(a) $PO_4^{3-}, C_2O_4^{2-}$ (b) PO_4^{3-}, HPO_4^{2-}
(c) $HC_2O_4^-, HPO_4^{2-}$ (d) $HC_2O_4^-, C_2O_4^{2-}$

[Ans. (a)]

[Hint: Acid − H^+ = Conjugate base]

15. Conjugate base of HCO_3^- is: **[PET (Raj.) 2005]**

(a) CO_2 (b) H_2CO_3 (c) H_2O (d) CO_3^{2-}

[Ans. (d)]

[Hint: Acid − H^+ = Conjugate base, $HCO_3^- - H^+ = CO_3^{2-}$]

16. Four species are listed below :

(i) HCO_3^- (ii) $H_3\overset{+}{O}$ (iii) HSO_4^- (iv) HSO_3F

Which one of the following is the correct sequence of their acid strength ? **(AIEEE 2008)**

(a) (iii) < (i) < (iv) < (ii) (b) (iv) < (ii) < (iii) < (i)
(c) (ii) < (iii) < (i) < (iv) (d) (i) < (iii) < (ii) < (iv)

[Ans. (d)]

[Hint : $HCO_3^- < HSO_4^- < H_3\overset{+}{O} < HSO_3F$

HSO_3F is super acid and it is most acidic. $H_3\overset{+}{O}$ is more acidic than anions because anions (HCO_3^-, HSO_4^-) do not release H^+ ion easily. HSO_4^- is more acidic than HCO_3^- because sulphur is more electronegative than carbon.]

17. Identify Bronsted-Lowry acids in the reaction given:

$$\underset{(A)}{[Al(H_2O)_6]^{3+}} + \underset{(B)}{HCO_3^-} \rightleftharpoons \underset{(C)}{[Al(H_2O)_5(OH^-)]^{2+}} + \underset{(D)}{H_2CO_3}$$

The correct answer is: [EAMCET (Med.) 2008]

(a) A, C (b) B, D (c) A, D (d) B, C

[**Ans.** (c)]

[**Hint :** $[Al(H_2O)_6]^{3+}$ and H_2CO_3 are proton donor or Bronsted acids]

18. Conjugate base of $H_2PO_4^-$ is: [Comed (Karnataka) 2008]

(a) HPO_4^{2-} (b) PO_4^{3-} (c) H_3PO_4 (d) HPO_4^-

[**Ans.** (a)]

[**Hint :** Acid – H^+ = Conjugate base

$H_2PO_4^- - H^+ = HPO_4^{2-}$]

10.7 ACID-BASE NEUTRALISATION—SALTS

When aqueous solutions of hydrochloric acid and sodium hydroxide are mixed in the proper proportion, a reaction takes place to form sodium chloride and water.

$$HCl(aq.) + NaOH(aq.) \rightleftharpoons \underset{\text{Sodium chloride}}{NaCl(aq.)} + H_2O(l)$$

Such a reaction is termed neutralisation because both acidic (H^+) and basic (OH^-) properties are eliminated during the reaction. The hydrogen ion, which is responsible for the acidic properties, has reacted with the hydroxyl ion which is responsible for the basic properties, producing neutral water. The Na^+ and Cl^- ions have undergone no chemical change and appear in the form of crystalline sodium chloride upon evaporation of the solution. Sodium chloride is an example of the class of compounds called **salts.**

$$H^+(aq.) + Cl^-(aq.) + Na^+(aq.) + OH^-(aq.)$$
$$\rightleftharpoons H_2O(l) + Na^+(aq.) + Cl^-(aq.)$$

or
$$H^+(aq.) + OH^-(aq.) \rightleftharpoons H_2O(l)$$

Thus, the neutralisation of a base with an acid involves the interaction between OH^- and H^+ ions.

Or

The reaction between an acid and a base to form salt and water is termed neutralisation.

The process of neutralisation does not produce the resulting solution always neutral; no doubt it involves the interaction of H^+ and OH^- ions. The nature of the resulting solution depends on the particular acid and a particular base involved in the reaction. The following examples illustrate this point when equivalent amounts of acids and bases are reacted in aqueous solution.

(i) A strong acid plus a strong base gives a neutral solution because both are completely ionised and the reaction goes to completion.

$$H^+ + Cl^- + Na^+ + OH^- \rightleftharpoons H_2O + Na^+ + Cl^-$$

(ii) A strong acid plus a weak base gives an acidic solution as the weak base is not completely ionised. The reaction does not go to completion and there is an excess of hydrogen ions in solution.

$$H^+ + Cl^- + NH_4OH \rightleftharpoons H_2O + NH_4^+ + Cl^-$$

(iii) A weak acid plus a strong base gives a basic solution as the weak acid is not completely ionised. The reaction does not go to completion and there is an excess of hydroxyl ions in solution.

$$CH_3COOH + Na^+ + OH^- \rightleftharpoons H_2O + CH_3COO^- + Na^+$$

(iv) A weak acid plus a weak base gives an acidic or a basic or a neutral solution depending on the relative strength of acid and base. In case, both have equal strength, the resulting solution is neutral in nature.

$$CH_3COOH + NH_4OH \rightleftharpoons H_2O + NH_4^+ + CH_3COO^-$$

Salts: Salts are regarded as compounds made up of positive and negative ions. The positive part comes from a base while negative part from an acid. Salts are ionic compounds. Salts may taste salty, sour, bitter, astringent or sweet or tasteless. Solutions of salts may be acidic, basic or neutral. Fused salts and aqueous solutions of salts conduct electricity and undergo electrolysis. The properties of salts in aqueous solutions are the properties of ions. The salts are generally crystalline solids.

The salts are classified into the following classes:

(i) Simple salts: The salt formed by the neutralisation process, *i.e.*, interaction between acid and base, is termed as simple salt. These are of three types:

(a) Normal salts: The salts formed by the loss of all possible protons (replaceable hydrogen atoms as H^+) are called normal salts. Such a salt does not contain either a replaceable hydrogen or a hydroxyl group.

Examples are: NaCl, $NaNO_3$, K_2SO_4, $Ca_3(PO_4)_2$, Na_3BO_3, Na_2HPO_3 (one H atom is not replaceable as H_3PO_3 is a dibasic acid), NaH_2PO_2 (both H atoms are not replaceable as H_3PO_2 is a monobasic acid), etc.

(b) Acid salts: Salts formed by incomplete neutralisation of poly-basic acids are called acid salts. Such salts still contain one or more replaceable hydrogen atoms. These salts when neutralised by bases form normal salts.

Examples are: $NaHCO_3$, $NaHSO_4$, NaH_2PO_4, Na_2HPO_4, etc.

(c) Basic salts: Salts formed by incomplete neutralisation of polyacidic bases are called basic salts. Such salts still contain one or more hydroxyl groups. These salts when neutralised by acids form normal salts.

Examples are: Zn(OH)Cl, Mg(OH)Cl, $Fe(OH)_2Cl$, $Bi(OH)_2Cl$, etc.

(ii) Double salts: The addition compounds formed by the combination of two simple salts are termed double salts. Such salts are stable in solid state only.

Examples are: Ferrous ammonium sulphate, $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$, Potash alum, $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ and other alums.

Properties: (a) When dissolved in water, it furnishes all the ions present in the simple salts from which it has been constituted.

(b) The solution of double salt shows the properties of the simple salts from which it has been constituted.

(iii) Complex salts: These are formed by combination of simple salts or molecular compounds. These are stable in solid state as well as in solutions.

$$\underbrace{FeSO_4 + 6KCN}_{\text{Simple salt}} \longrightarrow \underset{\text{Complex salt}}{K_4Fe(CN)_6} + K_2SO_4$$

$$\underset{\text{Simple salt}}{CoSO_4} + \underset{\text{Molecular compound}}{6NH_3} \longrightarrow \underset{\text{Complex salt}}{Co(NH_3)_6SO_4}$$

Properties: (a) On dissolving in water, it furnishes a complex ion.

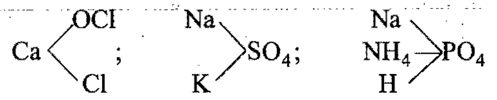
$$K_4Fe(CN)_6 \rightleftharpoons 4K^+ + \underset{\text{Complex ion}}{[Fe(CN)_6]^{4-}}$$

$$Cu(NH_3)_4SO_4 \rightleftharpoons \underset{\text{Complex ion}}{[Cu(NH_3)_4]^{2+}} + SO_4^{2-}$$

(b) The properties of the solution are different from the properties of the substances from which it has been constituted.

(iv) Mixed salts: The salt which furnishes more than one cation or more than one anion when dissolved in water is called a mixed salt.

Examples are:



Acidic, Basic and Amphoteric oxides

(i) Non-metal oxides are acidic, they dissolve in water to form acid. These oxides form salt with bases.

e.g., $\left.\begin{array}{l} SO_2, SO_3, P_4O_{10}, CO_2, NO_2, N_2O_5 \\ SiO_2, B_2O_3 \end{array}\right\}$ Non-metal oxides

Some Transition metal oxides are also acidic.

e.g., $CrO_3, MoO_3, WO_3, Mn_2O_7$

$$CO_2 + H_2O \longrightarrow H_2CO_3 \text{ (Carbonic acid)}$$

$$2NO_2 + H_2O \longrightarrow HNO_2 + HNO_3 \text{ (Nitrous and nitric acid)}$$

$$P_2O_5 + 3H_2O \longrightarrow \underset{\text{(Phosphoric acid)}}{2H_3PO_4}$$

$$NaOH + SO_3 \longrightarrow \underset{\text{Salt}}{NaHSO_4}$$

$$2KOH + CO_2 \longrightarrow \underset{\text{Salt}}{K_2CO_3} + H_2O$$

(ii) Usually, oxides of highly electropositive metals are basic. These oxides dissolve in water to form base and they form salt with acids.

e.g., $Na_2O, K_2O, MgO, CaO, Sc_2O_3, TiO_2, ZrO_2$

$$Na_2O + H_2O \longrightarrow \underset{\text{(Sodium hydroxide, a base)}}{2NaOH}$$

$$CaO + 2HCl \longrightarrow \underset{\text{Salt}}{CaCl_2} + H_2O$$

$$Mg + H_2SO_4 \longrightarrow \underset{\text{Salt}}{MgSO_4} + H_2O$$

(iii) Oxides of metalloids and less electropositive metals are amphoteric. These oxides form salt with both acids and bases.

e.g., $BeO, Al_2O_3, GeO, SnO, Sb_2O_3, PbO$

ZnO, Cr_2O_3

$$Al_2O_3 + 6HCl \longrightarrow 2AlCl_3 + 3H_2O$$

$$Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$$

10.8 IONIC PRODUCT OF WATER

Pure water is a very weak electrolyte and ionises according to the equation,

$$H_2O \rightleftharpoons H^+ + OH^-$$

Applying law of mass action at equilibrium, the value of dissociation constant, K comes to

$$K = \frac{[H^+][OH^-]}{[H_2O]}$$

or $$[H^+][OH^-] = K[H_2O]$$

Since, dissociation takes place to a very small extent, the concentration of undissociated water molecules, $[H_2O]$, may be regarded as constant. Thus, the product $K[H_2O]$ gives another constant which is designated as K_w. So,

$$[H^+][OH^-] = K_w$$

The constant, K_w, is termed as **ionic product of water.**

The product of concentrations of H^+ and OH^- ions in water at a particular temperature is known as ionic product of water. The value of K_w increases with the increase of temperature, *i.e.*, the concentration of H^+ and OH^- ions increases with increase in temperature.

Temperature (°C)	Value of K_w
0	0.11×10^{-14}
10	0.31×10^{-14}
25	1.00×10^{-14}
100	7.50×10^{-14}

The value of K_w at 25°C is 1×10^{-14}. Since, pure water is neutral in nature, H^+ ion concentration must be equal to OH^- ion concentration.

$$[H^+] = [OH^-] = x$$

or $$[H^+][OH^-] = x^2 = 1 \times 10^{-14}$$

or $$x = 1 \times 10^{-7}\ M$$

or $$[H^+] = [OH^-] = 1 \times 10^{-7} \text{ mol litre}^{-1}$$

This shows that at 25°C, in 1 litre only 10^{-7} mole of water is in ionic form out of a total of approximately 55.5 moles.

When an acid or a base is added to water, the ionic concentration product, $[H^+][OH^-]$, remains constant, *i.e.*, equal to K_w but concentrations of H^+ and OH^- ions do not remain equal. The addition of acid increases the hydrogen ion concentration while that of hydroxyl ion concentration decreases, *i.e.*,

$$[H^+] > [OH^-]; \qquad \text{(Acidic solution)}$$

Similarly, when a base is added, the OH^- ion concentration increases while H^+ ion concentration decreases,

i.e., $[OH^-] > [H^+]$; (Alkaline or basic solution)

In neutral solution, $[H^+] = [OH^-] = 1 \times 10^{-7}\ M$

In acidic solution, $[H^+] > [OH^-]$

or $\qquad [H^+] > 1 \times 10^{-7}\ M$

and $\qquad [OH^-] < 1 \times 10^{-7}\ M$

In alkaline solution, $\quad [OH^-] > [H^+]$

or $\qquad [OH^-] > 1 \times 10^{-7}\ M$

and $\qquad [H^+] < 1 \times 10^{-7}\ M$

Thus, if the hydrogen ion concentration is more than $1 \times 10^{-7}\ M$, the solution will be acidic in nature and if less than $1 \times 10^{-7}\ M$, the solution will be alkaline.

$[H^+] = 10^{-0} \quad 10^{-1} \quad 10^{-2} \quad 10^{-3} \quad 10^{-4} \quad 10^{-5} \quad 10^{-6}$ (Acidic)
$[H^+] = \qquad 10^{-7}$ (Neutral)
$[H^+] = 10^{-14} \quad 10^{-13} \quad 10^{-12} \quad 10^{-11} \quad 10^{-10} \quad 10^{-9} \quad 10^{-8}$ (Alkaline)

We shall have the following table if OH $^-$ ion concentration is taken into account:

$[OH^-] = 10^{-14} \quad 10^{-13} \quad 10^{-12} \quad 10^{-11} \quad 10^{-10} \quad 10^{-9} \quad 10^{-8}$ (Acidic)
$[OH^-] = \qquad 10^{-7}$ (Neutral)
$[OH^-] = 10^{-0} \quad 10^{-1} \quad 10^{-2} \quad 10^{-3} \quad 10^{-4} \quad 10^{-5} \quad 10^{-6}$ (Alkaline)

It is, thus, concluded that every aqueous solution, whether acidic, neutral or alkaline contains both H $^+$ and OH $^-$ ions. The product of their concentrations is always constant, equal to 1×10^{-14} at 25° C. If one increases, the other decreases accordingly so that the product remains 1×10^{-14} at 25° C.

If $[H^+] = 10^{-2}\ M$, then $[OH^-] = 10^{-12}\ M$; the product, $[H^+][OH^-] = 10^{-2} \times 10^{-12} = 10^{-14}$; the solution is acidic.

If $[H^+] = 10^{-10}\ M$, then $[OH^-] = 10^{-4}\ M$; the product, $[H^+][OH^-] = 10^{-10} \times 10^{-4} = 10^{-14}$; the solution is alkaline.

10.9 HYDROGEN ION CONCENTRATION—pH SCALE

It is clear from the above discussion that nature of the solution (acidic, alkaline or neutral) can be represented in terms of either hydrogen ion concentration or hydroxyl ion concentration but it is convenient to express acidity or alkalinity of a solution by referring to the concentration of hydrogen ions only. Since, H $^+$ ion concentration can vary within a wide range from 1 mol per litre to about 1.0×10^{-14} mol per litre, a logarithmic notation has been devised by **Sorensen**, in 1909, to simplify the expression of these quantities. The notation used is termed as the pH scale.

The hydrogen ion concentrations are expressed in terms of the numerical value of negative power to which 10 must be raised. This numerical value of negative power was termed as pH, *i.e.*,

$$[H^+] = 10^{-pH}$$

or $\quad \log [H^+] = \log 10^{-pH} = -pH \log 10 = -pH$

or $\quad pH = -\log [H^+]$

or $\quad pH = \log \dfrac{1}{[H^+]}$

pH of a solution is, thus, defined as **the negative logarithm of the concentration (in mol per litre) of hydrogen ions which it contains** or pH of the solution is the **logarithm of the reciprocal of H $^+$ ion concentration.**

Just as pH indicates the hydrogen ion concentration, the pOH represents the hydroxyl ion concentration, *i.e.*,

$$pOH = -\log [OH^-]$$

Considering the relationship,

$$[H^+][OH^-] = K_w = 1 \times 10^{-14}$$

Taking log on both sides, we have

$$\log [H^+] + \log [OH^-] = \log K_w = \log (1 \times 10^{-14})$$

or $\quad -\log [H^+] - \log [OH^-] = -\log K_w = -\log (1 \times 10^{-14})$

or $\quad pH + pOH = pK_w^* = 14$

i.e., sum of pH and pOH is equal to 14 in any aqueous solution at 25° C. The above discussion can be summarised in the following manner:

	$[H^+]$	$[OH^-]$	pH	pOH
Acidic solution	$> 10^{-7}$	$< 10^{-7}$	< 7	> 7
Neutral solution	10^{-7}	10^{-7}	7	7
Basic solution	$< 10^{-7}$	$> 10^{-7}$	> 7	< 7

$[H^+]$	$[OH^-]$	pH	pOH	Nature of solution
10^0	10^{-14}	0	14	Strongly acidic
10^{-2}	10^{-12}	2	12	Acidic
10^{-5}	10^{-9}	5	9	Weakly acidic
10^{-7}	10^{-7}	7	7	Neutral
10^{-9}	10^{-5}	9	5	Weakly basic
10^{-11}	10^{-3}	11	3	Basic
10^{-14}	10^0	14	0	Strongly basic

The following table shows the pH range for a few common substances:

Substance	pH range	Substance	pH range
Gastric contents	1.0 – 3.0	Milk (cow)	6.3 – 6.6
Soft drinks	2.0 – 4.0	Saliva (human)	6.5 – 7.5
Lemons	2.2 – 2.4	Blood plasma (human)	7.3 – 7.5
Vinegar	2.4 – 3.4	Milk of magnesia	10.5
Apples	2.9 – 3.3	Seawater	8.5
Urine (human)	4.8 – 8.4		

***pK* value:** *p* stands for negative logarithm. Just as H $^+$ and OH $^-$ ion concentrations range over many negative powers of 10, it is convenient to express them as pH or pOH, the dissociation constant (K) values also range over many negative powers of 10 and it is convenient to write them as pK. Thus, pK is the negative logarithm of dissociation constant.

$$pK_a = -\log K_a \qquad \text{and} \qquad pK_b = -\log K_b$$

Weak acids have higher pK_a values. Similarly, weak bases have higher pK_b values.

Any method which can measure the concentration of H^+ ions or OH^- ions in a solution can serve for finding pH value.

Limitations of pH Scale: (i) pH values of the solutions do not give us immediate idea of the relative strengths of the solutions. A solution of pH = 1 has a hydrogen ion concentration 100 times that of a solution of pH = 3 (not three times). A 4×10^{-5} N HCl is twice concentrated of a 2×10^{-5} N HCl solution, but the pH values of these solutions are 4.40 and 4.70 (not double).

(ii) pH value of zero is obtained in 1 N solution of strong acid. In case the concentration is 2 N, 3 N, 10 N, etc. The respective pH values will be negative.

(iii) A solution of an acid having very low concentration, say 10^{-8} N, cannot have pH 8, as shown by pH formula, but the actual pH value will be less than 7.

[**Note:** (i) Normality of strong acid $= [H_3O^+]$

Normality of strong base $= [OH^-]$

$$\therefore \quad pH = -\log[N] \quad \text{for strong acids}$$

$$pOH = -\log[N] \quad \text{for strong bases}$$

(ii) Sometimes, pH of acid comes more than 7 and that of base comes less than 7. It shows that the solution is very dilute; in such cases, H^+ or OH^- contribution from water is also considered, *e.g.*, in 10^{-8} N HCl,

$$[H^+]_{\text{Total}} = [10^{-8}]_{\text{Acid}} + [10^{-7}]_{\text{Water}}$$

$$= 11\times10^{-8}\ M = 1.1\times10^{-7}\ M$$

(iii) **pH of mixture:** Let one litre of an acidic solution of pH 2 be mixed with two litre of other acidic solution of pH 3. The resultant pH of the mixture can be evaluated in the following way:

Sample-1	**Sample-2**
pH = 2	pH = 3
$[H^+] = 10^{-2}\ M$	$[H^+] = 10^{-3}\ M$
$V = 1$ litre	$V = 2$ litre

$$M_1V_1 + M_2V_2 = M_R(V_1+V_2)$$

$$10^{-2}\times1 + 10^{-3}\times2 = M_R(1+2)$$

$$\frac{12\times10^{-3}}{3} = M_R$$

$4\times10^{-3} = M_R$ (Here, M_R = **Resultant molarity**)

$$pH = -\log(4\times10^{-3})$$

(iv) Total concentration of $[H^+]$ or $[H_3^+O]$ in a mixture of **weak acid** and a **strong acid**

$$= \frac{C_2 + \sqrt{C_2^2 + 4K_aC_1}}{2}$$

where, C_1 is the concentration of weak acid (in mol litre^{-1}) having dissociation constant K_a and C_2 is the concentration of strong acid.

(v) Let us consider mixture of two weak acids HA and HB.

$$HA \rightleftharpoons H^+ + A^-$$

$$HB \rightleftharpoons H^+ + B^-$$

On applying charge balance

$$[H^+] = [A^-] + [B^-] + [OH^-]$$

$$= \frac{K_a[HA]}{[H^+]} + \frac{K_b[HB]}{[H^+]} + \frac{K_w}{[H^+]}$$

$$[H^+] = \sqrt{K_a[HA] + K_b[HB] + K_w}$$

$$= \sqrt{CK_a + CK_b + K_w}$$

(vi) Let us consider mixture of two weak bases AOH and BOH with dissociation constant K_1, K_2 and concentration C_1, C_2 respectively

$$[OH^-] = \sqrt{C_1K_1 + C_2K_2 + K_w}$$

10.10 pH OF WEAK ACIDS AND BASES

Weak acids and bases are not completely ionised; an equilibrium is found to have been established between ions and unionised molecules. Let us consider a weak acid of basicity 'n'.

$$\begin{array}{lcccc} & AH_n & \rightleftharpoons & A^{n-} & + \ nH^+ \\ t=0 & C & & 0 & 0 \\ t_{eq} & C(1-\alpha) & & C\alpha & nC\alpha \end{array}$$

$$[H^+] = nC\alpha; \quad \therefore \quad pH = -\log_{10}[nC\alpha] \qquad \dots \text{(i)}$$

For monobasic acid, $n = 1$

$$pH = -\log_{10}[C\alpha] \qquad \dots \text{(ii)}$$

Dissociation constant of acid K_a may be calculated as:

$$K_a = \frac{[A^{n-}][H^+]^n}{[AH_n]} = \frac{[C\alpha][nC\alpha]^n}{C(1-\alpha)}$$

$$= \frac{\alpha[nC\alpha]^n}{(1-\alpha)} \qquad [\text{for weak acids, } \alpha \ll 1$$

$$\therefore (1-\alpha) \approx 1]$$

$$= \alpha[nC\alpha]^n$$

$$nCK_a = nC\alpha[nC\alpha]^n = [nC\alpha]^{(n+1)}$$

$$[nC\alpha] = [nCK_a]^{1/(n+1)}$$

$$[H^+] = [nCK_a]^{1/(n+1)}$$

$$\therefore \quad pH = -\frac{1}{(n+1)}\log_{10}(nCK_a) \qquad \dots \text{(iii)}$$

For monobasic acid, $n = 1$

$$pH = -\log_{10}\sqrt{CK_a} \qquad \dots \text{(iv)}$$

Since, $K_a = \alpha[nC\alpha]^n$

$$\frac{K_a}{\alpha} = (nC\alpha)^n$$

$$[nC\alpha] = \left[\frac{K_a}{\alpha}\right]^{1/n} = [H^+]$$

$$pH = -\frac{1}{n}\log_{10}\left(\frac{K_a}{\alpha}\right) \qquad \dots \text{(v)}$$

For $n = 1$,

$$pH = -\log_{10}\left(\frac{K_a}{\alpha}\right) \qquad \dots \text{(vi)}$$

SOME SOLVED EXAMPLES

Example 28. *The hydrogen ion concentration of a solution is 0.001 M. What will be the hydroxyl ion concentration of solution?*

Solution: We know that, $[H^+][OH^-] = 1.0 \times 10^{-14}$

Given that, $[H^+] = 0.001\,M = 10^{-3}\,M$

So, $$[OH^-] = \frac{1.0 \times 10^{-14}}{[H^+]} = \frac{1 \times 10^{-14}}{10^{-3}} = 10^{-11}\,M$$

Example 29. *What is the pH of the following solutions?*

(a) 10^{-3} *M HCl (b)* 0.0001*M NaOH (c)* 0.0001*M* H_2SO_4

Solution: HCl is a strong electrolyte and is completely ionised.

$$HCl \rightleftharpoons H^+ + Cl^-$$

So, $$[H^+] = 10^{-3}\,M$$

$$pH = -\log[H^+] = -\log(10^{-3}) = 3$$

(b) NaOH is a strong electrolyte and is completely ionised.

$$NaOH \rightleftharpoons Na^+ + OH^-$$

So, $$[OH^+] = 0.0001\,M = 10^{-4}\,M$$

$$pOH = -\log(10^{-4}) = 4$$

As $pH + pOH = 14$

So, $pH + 4 = 14$ or $pH = 10$

Alternative method: $[OH^-] = 10^{-4}\,M$

We know that, $[H^+][OH^-] = 1.0 \times 10^{-14}$

So, $$[H^+] = \frac{1.0 \times 10^{-14}}{10^{-4}} = 10^{-10}\,M$$

$$pH = -\log[H^+] = -\log(10^{-10}) = 10$$

(c) H_2SO_4 is a strong electrolyte and is ionised completely.

$$H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$$

One molecule of H_2SO_4 furnishes $2H^+$ ions.

So, $$[H^+] = 2 \times 10^{-4}\,M$$

$$pH = -\log[H^+]$$
$$= -\log(2 \times 10^{-4}) = 3.70$$

Example 30. *Calculate the pH of the following solutions assuming complete dissociation:*

(a) 0.365 *g* L^{-1} *HCl solution*

(b) 0.001*M* *Ba(OH)*$_2$ *solution.*

Solution: (a) Mole. mass of HCl = 36.5

$$\text{Concentration of HCl} = \frac{0.365}{36.5} = 1.0 \times 10^{-2}\ \text{mol L}^{-1}$$

HCl is a strong electrolyte and is completely ionised.

So, $[H^+] = 1 \times 10^{-2}$ mol L^{-1}

$$pH = -\log[H^+] = -\log(1 \times 10^{-2}) = 2$$

(b) $Ba(OH)_2$ is a strong electrolyte and is completely ionised

$$Ba(OH)_2 \rightleftharpoons Ba^{2+} + 2OH^-$$

One molecule on dissociation furnishes 2 OH^- ions.

So, $$[OH^-] = 2 \times 10^{-3}\,M$$

$$pOH = -\log[OH^-]$$
$$= -\log(2 \times 10^{-3}) = 2.7$$

We know that, $pH + pOH = 14$

So, $$pH = (14 - 2.7) = 11.3$$

Example 31. *Find the pH of a* 0.002*N acetic acid solution, if it is 2.3% ionised at a given dilution.*

Solution: Degree of dissociation, $\alpha = \frac{2.3}{100} = 0.023$

Concentration of acetic acid, $C = 0.002\,M$

The equilibrium is,

$$\underset{C(1-\alpha)}{CH_3COOH} \rightleftharpoons \underset{C\alpha}{CH_3COO^-} + \underset{C\alpha}{H^+}$$

So, $$[H^+] = C\alpha = 0.002 \times 0.023$$
$$= 4.6 \times 10^{-5}\,M$$

$$pH = -\log[H^+]$$
$$= -\log(4.6 \times 10^{-5}) = 4.3372$$

Example 32. *Calculate the pH value of a solution obtained by mixing 50 mL of 0.2 N HCl with 50 mL of 0.1 N NaOH.*

Solution: Number of milli-equivalents of the acid

$$= 50 \times 0.2 = 10$$

Number of milli-equivalents of the base

$$= 50 \times 0.1 = 5$$

Number of milli-equivalents of the acid left after the addition of base

$$= (10 - 5) = 5$$

Total volume of the solution = 50 + 50 = 100 mL

Thus, 5 milli-equivalents of the acid are present in 100 mL of solution.

or 50 milli-equivalents of the acid are present in one litre of solution.

or 0.05 equivalents of the acid are present in one litre of solution.

The acid is monobasic and completely ionised in solution.

$$0.05\,N\ HCl = 0.05\,M\ HCl$$

So, $$[H^+] = 0.05\,M$$

$$pH = -\log[H^+] = -\log 5 \times 10^{-2} = -[\log 5.0 + \log 10^{-2}]$$
$$= -[0.70 - 2] = 1.3$$

Example 33. *What will be the pH of a solution obtained by mixing 800 mL of 0.05 N sodium hydroxide and 200 mL of 0.1 N HCl, assuming the complete ionisation of the acid and the base?*

Solution: Number of milli-equivalents of NaOH

$$= 800 \times 0.05 = 40$$

Number of milli-equivalents of HCl = 200 × 0.1 = 20

Number of milli-equivalents of NaOH left after the addition of HCl

$$= (40 - 20) = 20$$

Total volume $= (200 + 800)$ mL $= 1000$ mL $= 1$ litre

20 milli-equivalents or 0.02 equivalents of NaOH are present in one litre, *i.e.*,

0.02 N NaOH $= 0.02$ M NaOH (Mono-acidic) and the base is completely ionised.

So, $[OH^-] = 0.02\,M$

or $[OH^-] = 2 \times 10^{-2}\ M$

$$pOH = -\log\,(2 \times 10^{-2}) = 1.7$$

We know that, $pH + pOH = 14$

So, $pH = (14 - 1.7) = 12.3$

Example 34. *What is the hydrogen ion concentration of a solution (i) whose pH is* 12, *(ii) whose pH is* 5.6*?*

Solution:

(i) $pH = -\log\,[H^+]$

or $\log\,[H^+] = -pH = -12$

$$[H^+] = 10^{-12}\ M$$

(ii) $pH = -\log\,[H^+]$

or $\log\,[H^+] = -5.6$

or $[H^+] = 10^{-5.6} = 10^{-6} \times 10^{0.4} = 2.5 \times 10^{-6}\ M$

Example 35. *How many moles of calcium hydroxide must be dissolved to produce* 250 *mL of an aqueous solution of pH* 10.65*? Assume the complete ionisation.*

Solution: We know that,

$$pH + pOH = 14$$

So, $pOH = (14 - 10.65) = 3.35$

$$[OH^-] = 10^{-3.35} = 10^{-4} \times 10^{0.65}$$

$$= 4.47 \times 10^{-4}\ M$$

One molecule of $Ca(OH)_2$ furnishes 2 OH^- ions.

Hence, concentration of

$$Ca(OH)_2 = \frac{4.47 \times 10^{-4}}{2} = 2.235 \times 10^{-4}\ M$$

$$\text{No. of moles in 250 mL} = \frac{2.235 \times 10^{-4}}{4} = 5.58 \times 10^{-5}$$

Example 36. *The pH of* $0.1\,M$ *hydrocyanic acid solution is* 5.2. *What is the value of* K_a *for hydrocyanic acid?*

Solution: $pH = -\log\,[H^+]$

or $\log\,[H^+] = -pH = -5.2$

$$[H^+] = 10^{-5.2} = 10^{-6} \times 10^{0.8}$$

$$= 6.3 \times 10^{-6}\ M$$

$$\text{'}\alpha\text{', degree of dissociation} = \frac{[H^+]}{C} = \frac{6.3 \times 10^{-6}}{0.1} = 6.3 \times 10^{-5}$$

According to Ostwald's formula for weak electrolyte,

$$K_a = \alpha^2 C = 6.3 \times 10^{-5} \times 6.3 \times 10^{-5} \times 0.1$$

$$= 3.69 \times 10^{-10}$$

Example 37. *Calculate the pH of the following solutions:*
(i) 1.0×10^{-8} *M HCl,* *(ii)* 1.0×10^{-8} *M NaOH*

Solution: (i) The neutral water has $[H^+] = 1 \times 10^{-7}\ M$

By adding $1.0 \times 10^{-8}\ M$ HCl, a concentration of $1.0 \times 10^{-8}\ M$ H^+ ions has increased in solution.

Thus, total $[H^+] = (1 \times 10^{-7} + 1 \times 10^{-8})\,M$

$$= (1 \times 10^{-7} + 0.1 \times 10^{-7})\,M$$

$$= 1.1 \times 10^{-7}\ M$$

$$pH = -\log\,(1.1 \times 10^{-7}) = -[\log 1.1 + \log 10^{-7}]$$

$$= -[0.0414 - 7.0] = 6.9586$$

(i) The neutral water has $[OH^-] = 1 \times 10^{-7}\ M$

By adding $1.0 \times 10^{-8}\ M$ NaOH, a concentration of $1.0 \times 10^{-8}\ M$ OH^- ions has increased in solution.

Thus, total $[OH^-] = (1 \times 10^{-7} + 1.0 \times 10^{-8})\,M$

$$= 1.1 \times 10^{-7}\ M$$

$$pOH = -\log 1.1 \times 10^{-7}$$

$$= 6.9586$$

$$pH = (14 - pOH) = (14 - 6.9586) = 7.0414$$

Example 38. *Calculate the* S^{2-} *ion concentration in a saturated solution* $(0.1\,M)$ *of* H_2S *whose pH was adjusted to* 2 *by the addition of HCl.* $(K_a = 1.1 \times 10^{-21})$

Solution: $H_2S \rightleftharpoons 2H^+ + S^{2-}$

$$K_a = \frac{[H^+]^2\,[S^{2-}]}{[H_2S]}$$

or $$[S^{2-}] = \frac{K_a\,[H_2S]}{[H^+]^2}$$

$pH = 2$; So, $[H^+] = 1 \times 10^{-2}\ M$

H_2S is a weak electrolyte, So, $[H_2S] = 0.1\,M$

So, $$[S^{2-}] = \frac{1.1 \times 10^{-21} \times 0.1}{1 \times 10^{-2} \times 1 \times 10^{-2}} = 1.1 \times 10^{-18}\ M$$

Example 39. *What is the hydrogen ion concentration of* 0.1 *N* CH_3COOH *solution? The ionisation constant of* CH_3COOH *is* 1.8×10^{-5}. *What is the pH of the solution?*

(IIT 1993)

Solution: Let the degree of dissociation be 'α'.

CH_3COOH is a weak electrolyte; thus,

$$\alpha^2 C = K_a$$

$$\alpha^2 \times 0.1 = 1.8 \times 10^{-5}$$

or $\alpha = 1.34 \times 10^{-2}$

$$[H^+] = \alpha \cdot C = 1.34 \times 10^{-2} \times 0.1 = 1.34 \times 10^{-3}\ M$$

$$pH = -\log\,[H^+] = -\log 1.34 \times 10^{-3} = 2.8729$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

19. At 90°C, pure water has $[H_3O^+] = 10^{-6}\ M$. What is the value of K_w at this temperature? **[CBSE (Med.) 2006]**

(a) 10^{-6} (b) 10^{-12} (c) 10^{-13} (d) 10^{-14}

[Ans. (b)]

[Hint: $[H_3O^+] = [OH^-] = 10^{-6}\ M$

$\therefore \quad K_w = [H_3O^+][OH^-] = 10^{-12}$]

20. The pH of 0.5 M aqueous solution of HF ($K_a = 2 \times 10^{-4}$) is:

(a) 2 (b) 4 (c) 6 (d) 10

[Ans. (a)]

[Hint: $[H^+] = \sqrt{CK_a} = \sqrt{0.5 \times 2 \times 10^{-4}} = 10^{-2}\ M$

$pH = -\log_{10}[H^+] = -\log 10^{-2} = 2$]

21. The hydroxyl ion concentration in a solution having pH value 3 will be:

(a) $10^{-11}\ M$ (b) $10^{-7}\ M$ (c) $10^{-3}\ M$ (d) $10^{-14}\ M$

[Ans. (a)]

[Hint: $pH + pOH = 14$

$pOH = 14 - pH = 14 - 3 = 11$

$[OH^-] = 10^{-pOH} = 10^{-11}\ M$]

22. A 50 mL solution of pH = 1 is mixed with a 50 mL solution of pH = 2. The pH of the mixture will be nearly:

(a) 0.76 (b) 1.26 (c) 1.76 (d) 2.26

[Ans. (b)]

[Hint: $pH = 1, [H^+] = 10^{-1}\ M$

$pH = 2, [H^+] = 10^{-2}\ M$

$M_1V_1 + M_2V_2 = M_R(V_1 + V_2)$

$10^{-1} \times 50 + 10^{-2} \times 50 = M_R \times 100$

$M_R = 5.5 \times 10^{-2}\ M$

(Resultant molarity of H^+ ions)

$pH = -\log 5.5 \times 10^{-2} = 1.26$]

23. The pH of a solution obtained by mixing 50 mL of 0.4 N HCl and 50 mL of 0.2 N NaOH is:

(a) –log 2 (b) – log 0.2 (c) 1 (d) 2

[Ans. (c)]

[Hint: $N_1V_{1\,\text{acid}} - N_2V_{2\,\text{base}} = N_R(V_1 + V_2)$

$0.4 \times 50 - 0.2 \times 50 = N_R \times 100$

$N_R = 0.1$

$\therefore \quad [H^+] = 0.1\ M$

$pH = -\log[H^+] = -\log 0.1 = 1$]

24. What will be the pH value of 0.05 M $Ba(OH)_2$ solution? **[PMT (Raj.) 2006]**

(a) 12 (b) 13 (c) 1 (d) 12.96

[Ans. (b)]

[Hint: $\underset{0.05\ M}{Ba(OH)_2} \longrightarrow Ba^{2+} + \underset{\substack{2 \times 0.05\ M \\ = 0.1\ M}}{2OH^-}$

$pOH = -\log[OH^-] = -\log 0.1 = 1$

$pH = 14 - 1 = 13$]

25. Equal volumes of three acid solutions of pH 3, 4 and 5 are mixed in a vessel. What will be the H^+ ion concentration in the mixture? **[CBSE (PMT) 2008]**

(a) $3.7 \times 10^{-3} M$ (b) $1.11 \times 10^{-3} M$

(c) $1.11 \times 10^{-4} M$ (d) $3.7 \times 10^{-4} M$

[Ans. (d)]

[Hint: $[H^+] = 10^{-3} M$, $[H^+] = 10^{-4}\ M$, $[H^+] = 10^{-5}\ M$ for the given acids.

$M_{mix}V_{mix} = M_1V_1 + M_2V_2 + M_3V_3$

$M_{mix} \times 3 = 10^{-3} \times 1 + 10^{-4} \times 1 + 10^{-5} \times 1$

$$M_{mix} = \frac{10^{-5}[100 + 10 + 1]}{3} = \frac{111 \times 10^{-5}}{3} = 37 \times 10^{-5}\ M$$

$= 3.7 \times 10^{-4}\ M$]

10.11 BUFFER SOLUTIONS

For several purposes, we need solutions which should have constant pH. Many reactions, particularly the biochemical reactions, are to be carried out at a constant pH. But it is observed that solutions and even pure water (pH = 7) cannot retain the constant pH for long. If the solution comes in contact with air, it will absorb CO_2 and becomes more acidic. If the solution is stored in a glass bottle, alkaline impurities dissolve from glass and the solution becomes alkaline.

A solution whose pH is not altered to any great extent by the addition of small quantities of either an acid (H^+ ions) or a base (OH^- ions) is called the **buffer solution.** It can also be defined as a solution of **reserve acidity** or **alkalinity** which resists change of pH upon the addition of small amount of acid or alkali.

General Characteristics of a Buffer Solution

(i) It has a definite pH, *i.e.*, it has reserve acidity or alkalinity.

(ii) Its pH does not change on standing for long.

(iii) Its pH does not change on dilution.

(iv) Its pH is slightly changed by the addition of small quantity of an acid or a base.

Buffer solutions can be obtained:

(i) by mixing a weak acid with its salt with a strong base, *e.g.*,
  (a) $CH_3COOH + CH_3COONa$
  (b) Boric acid + Borax
  (c) Phthalic acid + Potassium acid phthalate

(ii) by mixing a weak base with its salt with a strong acid, *e.g.*,
  (a) $NH_4OH + NH_4Cl$
  (b) Glycine + Glycine hydrochloride

(iii) by a solution of ampholyte. The ampholytes or amphoteric electrolytes are the substances which show properties of both an acid and a base. Proteins and amino acids are the examples of such electrolytes.

(iv) by a mixture of an acid salt and a normal salt of a polybasic acid, *e.g.*, $Na_2HPO_4 + Na_3PO_4$ or a salt of weak acid and a weak base, such as CH_3COONH_4.

The first and second type are also called acidic and basic buffers respectively.

Explanation of Buffer Action

(i) Acidic buffer: Consider the case of the solution of acetic acid containing sodium acetate. Acetic acid is feebly ionised while sodium acetate is almost completely ionised. The mixture thus contains CH_3COOH molecules, CH_3COO^- ions, Na^+ ions, H^+ ions and OH^- ions. Thus, we have the following equilibria in solution:

$$CH_3COOH \rightleftharpoons H^+ + CH_3COO^- \quad \text{(Feebly ionised)}$$

$$CH_3COONa \rightleftharpoons Na^+ + CH_3COO^- \quad \text{(Completely ionised)}$$

$$H_2O \rightleftharpoons H^+ + OH^- \quad \text{(Very feebly ionised)}$$

When a drop of strong acid, say HCl, is added, the H^+ ions furnished by HCl combine with CH_3COO^- ions to form feebly ionised CH_3COOH whose ionisation is further suppressed due to common ion effect. Thus, there will be a very slight effect in the overall H^+ ion concentration or pH value.

When a drop of NaOH is added, it will react with free acid to form undissociated water molecules.

$$CH_3COOH + OH^- \rightleftharpoons CH_3COO^- + H_2O$$

Thus, OH^- ions furnished by a base are removed and pH of the solution is practically unaltered.

(ii) Basic buffer: Consider the case of the solution containing NH_4OH and its salt NH_4Cl. The solution will have NH_4OH molecule, NH_4^+ ions, Cl^- ions, OH^- ions and H^+ ions.

$$NH_4OH \rightleftharpoons NH_4^+ + OH^- \quad \text{(Feebly ionised)}$$

$$NH_4Cl \rightleftharpoons NH_4^+ + Cl^- \quad \text{(Completely ionised)}$$

$$H_2O \rightleftharpoons H^+ + OH^- \quad \text{(Very feebly ionised)}$$

When a drop of NaOH is added, the added OH^- ions combine with NH_4^+ ions to form feebly ionised NH_4OH whose ionisation is further suppressed due to common ion effect. Thus, pH is not disturbed considerably.

$$NH_4^+ + \underset{\text{(From strong base)}}{\underset{\uparrow}{OH^-}} \rightleftharpoons NH_4OH$$

When a drop of HCl is added, the added H^+ ions combine with NH_4OH to form undissociated water molecules.

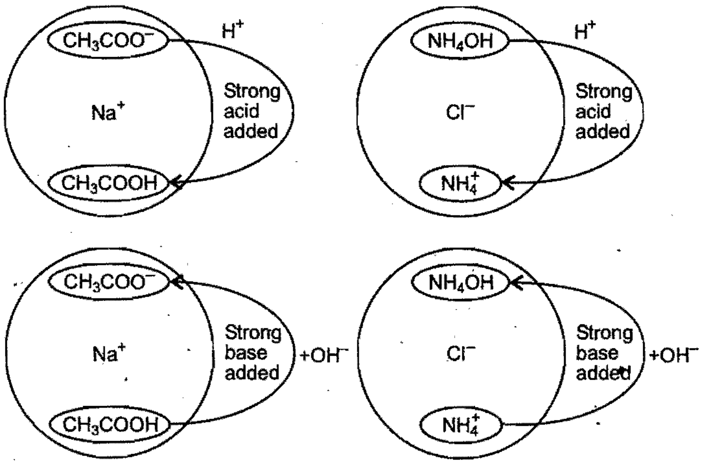
$$NH_4OH + \underset{\text{(From strong acid)}}{\underset{\uparrow}{H^+}} \rightleftharpoons NH_4^+ + H_2O$$

Thus, pH of the buffer is practically unaffected.

Diagramatic Representation of Buffer Action

Acid Buffer $(CH_3COOH + CH_3COONa)$

Base Buffer $(NH_4OH + NH_4Cl)$



Henderson's Equation (pH of a buffer)

(i) Acidic buffer: It consists of a mixture of weak acid and its salt (strong electrolyte). The ionisation of the weak acid, HA, can be shown by the equation,

$$HA \rightleftharpoons H^+ + A^-$$

Applying law of mass action,

$$K_a = \frac{[H^+][A^-]}{[HA]} \quad \text{... (i)}$$

or

$$[H^+] = K_a \frac{[HA]}{[A^-]} \quad \text{... (ii)}$$

It can be assumed that concentration of A^- ions from complete ionisation of the salt BA is too large to be compared with concentration of A^- ions from the acid HA.

$$BA \rightleftharpoons B^+ + A^-$$

Thus, $[HA]$ = Initial concentration of the acid as it is feebly ionised in presence of common ion

and $[A^-]$ = Initial concentration of the salt as it is completely ionised.

So, $$[H^+] = K_a \cdot \frac{[\text{Acid}]}{[\text{Salt}]} \quad \text{... (iii)}$$

Taking logarithm and reversing sign,

$$-\log [H^+] = -\log K_a - \log \frac{[\text{Acid}]}{[\text{Salt}]}$$

or $$\text{pH} = \log \frac{[\text{Salt}]}{[\text{Acid}]} - \log K_a$$

or $$\text{pH} = \text{p}K_a + \log \frac{[\text{Salt}]}{[\text{Acid}]} \quad \text{... (iv)}$$

This is known as **Henderson's equation.**

When $\frac{[\text{Salt}]}{[\text{Acid}]} = 10$, then

$$\text{pH} = 1 + \text{p}K_a$$

and when $\frac{[\text{Salt}]}{[\text{Acid}]} = \frac{1}{10}$, then

$$\text{pH} = \text{p}K_a - 1$$

So, weak acid may be used for preparing buffer solutions having pH values lying within the ranges $\text{p}K_a + 1$ and $\text{p}K_a - 1$. The acetic acid has a $\text{p}K_a$ of about 4.8; it may, therefore, be used for making buffer solutions with pH values lying roughly within the range 3.8 to 5.8.

(ii) Basic buffer: It consists of a weak base and its salt with strong acid. Ionisation of a weak base, BOH, can be represented by the equation,

$$B\text{OH} \rightleftharpoons B^+ + \text{OH}^-$$

Applying law of mass action,

$$K_b = \frac{[B^+][\text{OH}^-]}{[B\text{OH}]} \qquad \text{... (i)}$$

or

$$[\text{OH}^-] = K_b \frac{[B\text{OH}]}{[B^+]} \qquad \text{... (ii)}$$

As the salt is completely ionised, it can be assumed that whole of B^+ ion concentration comes from the salt and contribution of weak base to B^+ ions can be ignored.

$$BA \rightleftharpoons B^+ + A^- \quad \text{(Completely ionised)}$$

So,

$$[\text{OH}^-] = K_b \frac{[\text{Base}]}{[\text{Salt}]} \qquad \text{... (iii)}$$

or

$$\text{pOH} = \log \frac{[\text{Salt}]}{[\text{Base}]} - \log K_b$$

or

$$\text{pOH} = \text{p}K_b + \log \frac{[\text{Salt}]}{[\text{Base}]} \qquad \text{... (iv)}$$

Knowing pOH, pH can be calculated by the application of the formula,

$$\text{pH} + \text{pOH} = 14$$

Buffer capacity: The property of a buffer solution to resist alteration in its pH value is known as **buffer capacity.** It has been found that if the ratio $\frac{[\text{Salt}]}{[\text{Acid}]}$ or $\frac{[\text{Salt}]}{[\text{Base}]}$ is unity, the pH of a particular buffer does not change at all. Buffer capacity is defined quantitatively as **number of moles of acid or base added in one litre of solution as to change the pH by unity,** *i.e.*,

Buffer capacity

$$(\phi) = \frac{\text{No. of moles of acid or base added to 1 litre}}{\text{Change in pH}}$$

or

$$\phi = \frac{\partial b}{\partial(\text{pH})}$$

where, $\partial b \longrightarrow$ number of moles of acid or base added to 1 litre solution and $\partial(\text{pH}) \longrightarrow$ change in pH.

Buffer capacity is maximum:

(i) When [Salt] = [Acid], *i.e.*, $\text{pH} = \text{p}K_a$ for acid buffer

(ii) When [Salt] = [Base], *i.e.*, $\text{pOH} = \text{p}K_b$ for base buffer under above conditions, the buffer is called efficient.

Utility of Buffer Solutions in Analytical Chemistry

Buffers are used:

(i) To determine the pH with the help of indicators.

(ii) For the removal of phosphate ion in the qualitative inorganic analysis after second group using $CH_3COOH + CH_3COONa$ buffer.

(iii) For the precipitation of lead chromate quantitatively in gravimetric analysis, the buffer, $CH_3COOH + CH_3COONa$, is used.

(iv) For precipitation of hydroxides of third group of qualitative analysis, a buffer, $NH_4Cl + NH_4OH$, is used.

(v) A buffer solution of NH_4Cl, NH_4OH and $(NH_4)_2CO_3$ is used for precipitation of carbonates of fifth group in qualitative inorganic analysis.

(vi) The pH of intracellular fluid, blood is naturally maintained. This maintenance of pH is essential to sustain life because, enzyme catalysis is pH sensitive process. The normal pH of blood plasma is 7.4. Following two buffers in the blood help to maintain pH (7.4):

(a) Buffer of carbonic acid (H_2CO_3 and $NaHCO_3$)

(b) Buffer of phosphoric acid ($H_2PO_4^-$, HPO_4^{2-})

Buffers are used in industrial processes such as manufacture of paper, dyes, inks, paints, drugs, etc. Buffers are also employed in agriculture, dairy products and preservation of various types of foods and fruits.

SOME SOLVED EXAMPLES

Example 40. *The pH of a buffer is 4.745. When 0.01 mole of NaOH is added to 1 litre of it, the pH changes to 4.832, calculate its buffer capacity.*

Solution: From definition,

$$\text{Buffer capacity } (\phi) = \frac{\partial b}{\partial[\text{pH}]}$$

$$\partial(\text{pH}) = (4.832 - 4.745) = 0.087; \quad \partial b = 0.01$$

Substituting given values,

$$\phi = \frac{0.01}{0.087} = 0.115$$

Example 41. *Suppose it is required to make a buffer solution of pH = 4, using acetic acid and sodium acetate. How much of sodium acetate is to be added to 1 litre of N/10 acetic acid?*

Dissociation constant of acetic acid $= 1.8 \times 10^{-5}$.

Solution: Applying Henderson's equation,

$$\text{pH} = \log \frac{[\text{Salt}]}{[\text{Acid}]} - \log K_a$$

$$4 = \log[\text{Salt}] - \log(0.1) - \log 1.8 \times 10^{-5}$$

So, $\log[\text{Salt}] = (4 - 1 - 5 + 0.2552) = \bar{2}.2552$

$$[\text{Salt}] = 0.018 \text{ g mol L}^{-1}$$

The molecular mass of $CH_3COONa = 82$

$$\text{Amount of salt} = 0.018 \times 82 = 1.476 \text{ g}$$

Example 42. *What is the pH of the solution when 0.2 mole of hydrochloric acid is added to one litre of a solution containing 1M acetic acid and acetate ion? Assume that the total volume is one litre.* (K_a *for* $CH_3COOH = 1.8 \times 10^{-5}$)

Solution: On adding HCl, the free hydrogen ions will combine with CH_3COO^- ions to form CH_3COOH. Thus, the concentration of acetic acid increases while that of CH_3COO^- ions decreases.

$$[CH_3COOH] = (0.2 + 1) = 1.2 \text{ mol litre}^{-1}$$

$$[\text{Salt}] = (1 - 0.2) = 0.8 \text{ mol litre}^{-1}$$

Applying Henderson's equation,

$$\text{pH} = \log \frac{[\text{Salt}]}{[\text{Acid}]} - \log K_a$$

$$= \log \frac{0.8}{1.2} - \log 1.8 \times 10^{-5}$$

$$= \log 2 - \log 3 - \log 1.8 \times 10^{-5} = 4.5687$$

Example 43. *20 mL of 0.2 M sodium hydroxide is added to 50 mL of 0.2 M acetic acid to give 70 mL of the solution. What is the pH of the solution? Calculate the additional volume of 0.2 M NaOH required to make the pH of solution 4.74. The ionisation constant of acetic acid is* 1.8×10^{-5}.

Solution: No. of moles of NaOH in

$$20 \text{ mL} = \frac{0.2}{1000} \times 20 = 0.004$$

$$\text{No. of moles of acetic acid in } 50 \text{ mL} = \frac{0.2}{1000} \times 50 = 0.01$$

When NaOH is added, CH_3COONa is formed.

$$\underset{1 \text{ mole}}{CH_3COOH} + \underset{1 \text{ mole}}{NaOH} \rightleftharpoons \underset{1 \text{ mole}}{CH_3COONa} + \underset{1 \text{ mole}}{H_2O}$$

No. of moles of CH_3COONa in 70 mL solution = 0.004

No. of moles of CH_3COOH in 70 mL solution

$$= (0.01 - 0.004) = 0.006$$

Applying Henderson's equation,

$$\text{pH} = \log \frac{[\text{Salt}]}{[\text{Acid}]} - \log K_a$$

$$= \log \frac{0.004}{0.006} - \log 1.8 \times 10^{-5} = 4.5687$$

On further addition of NaOH, the pH becomes 4.74.

$$\text{pH} = \log \frac{[\text{Salt}]}{[\text{Acid}]} - \log K_a$$

$$= \log \frac{[\text{Salt}]}{[\text{Acid}]} - \log 1.8 \times 10^{-5}$$

$$\text{or } \log \frac{[\text{Salt}]}{[\text{Acid}]} = \text{pH} + \log 1.8 \times 10^{-5} = (4.74 - 4.7448) = -0.0048$$

So,
$$\log \frac{[\text{Salt}]}{[\text{Acid}]} = \bar{1}.9952$$

$$\frac{[\text{Salt}]}{[\text{Acid}]} = 0.9891$$

Let 'x' moles of NaOH be added.

$$[\text{Salt}] = (0.004 + x) \text{ mole}$$

$$[\text{Acid}] = (0.006 - x) \text{ mole}$$

$$\frac{[\text{Salt}]}{[\text{Acid}]} = \frac{0.004 + x}{0.006 - x} = 0.9891$$

or
$$0.004 + x = 0.9891 \times 0.006 - 0.9891x$$

$$x = 0.000972 \text{ mole}$$

Volume of 0.2 M NaOH solution having 0.000972 mole

$$= \frac{1000}{0.2} \times 0.000972 = 4.86 \text{ mL}$$

Example 44. *Calculate the pH of the buffer solution containing 0.15 mole of NH_4OH and 0.25 mole of NH_4Cl. K_b for NH_4OH is* 1.98×10^{-5}.

Solution: Applying the equation,

$$\text{pOH} = \log \frac{[\text{Salt}]}{[\text{Base}]} - \log K_b$$

$$= \log \frac{0.25}{0.15} - \log 1.8 \times 10^{-5}$$

$$= \log 5 - \log 3 - \log 1.8 \times 10^{-5}$$

$$= 0.6989 - 0.4771 + 4.7448 = 4.966$$

$$\text{pH} = (14 - 4.966) = 9.034$$

Example 45. *What volume of 0.10 M sodium formate solution should be added to 50 mL of 0.05 M formic acid to produce a buffer solution of pH 4.0? pK_a for formic acid is 3.80.* (IIT 1990)

Solution: Let x mL of 0.10 M sodium formate be added.

$$\text{No. of moles in } x \text{ mL of } 0.10 \, M \text{ sodium formate} = \frac{0.10}{1000} \times x$$

$$\text{No. of moles in } 50 \text{ mL of } 0.05 \, M \text{ formic acid} = \frac{0.05}{1000} \times 50$$

$$\frac{[\text{Sod. formate}]}{[\text{Formic acid}]} = \frac{\frac{0.10 \times x}{1000}}{\frac{0.05 \times 50}{1000}} = \frac{0.10x}{2.5} = 0.04x$$

Applying the equation,

$$\text{pH} = \log \frac{[\text{Salt}]}{[\text{Acid}]} + \text{p}K_a$$

$$4.0 = \log 0.04x + 3.8$$

or
$$x = 39.6 \text{ mL}$$

Example 46. *How many gram moles of HCl will be required to prepare one litre of a buffer solution (containing NaCN and HCN) of pH 8.5 using 0.01 g formula mass of NaCN? K_a for HCN* $= 4.1 \times 10^{-10}$.

Solution: Let a mole of HCl be added. It will combine with NaCN to form HCN.

$$\underset{a}{NaCN} + \underset{a}{HCl} \longrightarrow NaCl + \underset{a}{HCN}$$

$$[NaCN] = (0.01 - a)$$

$$[HCN] = a$$

Applying the equation,

$$\text{pH} = \log \frac{[NaCN]}{[HCN]} - \log K_a$$

$$8.5 = \log \frac{0.01 - a}{a} - \log 4.1 \times 10^{-10}$$

So, $$\log \frac{(0.01 - a)}{a} = 8.5 + 0.6127 - 10.0 = \bar{1}.1127$$

$$\frac{(0.01 - a)}{a} = 0.1296$$

or $$a = \frac{0.01}{1.1296} = 0.0089 \text{ mole}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

26. The pH of a solution that is 0.1 M NaA and 0.1 M HA $(K_a = 1 \times 10^{-6})$ would be:

(a) 5 (b) 6 (c) 3 (d) 7

[Ans. (b)]

[Hint: $$\text{pH} = \text{p}K_a + \log \frac{[\text{Salt}]}{[\text{Acid}]} = -\log K_a + \log \frac{[\text{Salt}]}{[\text{Acid}]}$$

$$= -\log 10^{-6} + \log \frac{0.1}{0.1} = 6]$$

27. pK_a for acetic acid is 4.74. What should be the ratio of concentrations of acetic acid and acetate ions to have a solution with pH 5.74?

(a) 1 : 10 (b) 10 : 1 (c) 1 : 1 (d) 2 : 1

[Ans. (a)]

[Hint: $$\text{pH} = \text{p}K_a + \log \frac{[\text{Acetate ion}]}{[\text{Acetic acid}]}$$

$$5.74 = 4.74 + \log \frac{[\text{Acetate ion}]}{[\text{Acetic acid}]}$$

$$[\text{Acetic acid}] : [\text{Acetate}] = 1 : 10]$$

28. What is the pH of the buffer solution containing 0.15 mol of NH_4OH and 0.25 mol of NH_4Cl? K_b for NH_4OH is 1.98×10^{-5}:

(a) 10 (b) 9 (c) 9.2 (d) 10.2

[Ans. (b)]

[Hint: $$14 - \text{pH} = \text{p}K_b + \log \frac{[\text{Salt}]}{[\text{Base}]}$$

$$= -\log(1.98 \times 10^{-5}) + \log\left(\frac{0.25}{0.15}\right)$$

$$\text{pH} \approx 9]$$

29. The pH of a buffer solution of 0.1 M CH_3COOH and 0.1 M CH_3COONa is .... $(\text{p}K_a = 4.745)$.

(a) 4.745 (b) 3.745 (c) 5.745 (d) 3.255

[Ans. (a)]

[Hint: $$\text{pH} = \text{p}K_a + \log \frac{[CH_3COONa]}{[CH_3COOH]}$$

$$= 4.745 + \log \frac{0.1}{0.1} = 4.745]$$

30. The pH of a buffer solution prepared by adding 10 mL of 0.1 M CH_3COOH and 20 mL of 0.1 M sodium acetate will be: (Given: pK_a of CH_3COOH = 4.74)

(a) 4.05 (b) 3.04 (c) 5.04 (d) 3.05

[Ans. (c)]

[Hint:

$$\text{Number of moles of } CH_3COOH = \frac{MV}{1000} = \frac{0.1 \times 10}{1000} = 0.001$$

$$\text{Number of moles of } CH_3COONa = \frac{MV}{1000} = \frac{0.1 \times 20}{1000} = 0.002$$

$$\text{pH} = \text{p}K_a + \log \frac{[\text{Salt}]}{[\text{Acid}]}$$

$$= 4.74 + \log\left[\frac{0.002}{0.001}\right] = 5.04]$$

31. 40 mL of 0.1 M ammonium hydroxide is mixed with 20 mL of 0.1 M HCl. What is the pH of the mixture? (pK_b of ammonia solution is 4.74.) (AIIMS 2006)

(a) 4.74 (b) 2.26 (c) 9.26 (d) 5

[Ans. (c)]

[Hint: Since, ammonium hydroxide is 50% neutralised, hence

$$[\text{Salt}] = [\text{Base}]$$

$$\text{pOH} = \text{p}K_b + \log_{10} \frac{[\text{Salt}]}{[\text{Base}]} = 4.74 + \log_{10} 1 = 4.74$$

$$\text{pH} = 14 - 4.74 = 9.26]$$

32. The pK_a of a weak acid (HA) is 4.5. The pOH of an aqueous buffered solution of HA, in which 50% of the acid is ionised, is: (AIEEE 2007)

(a) 7.0 (b) 4.5 (c) 2.5 (d) 9.5

[Ans. (d)]

[Hint: $$\text{pH} = \text{p}K_a + \log_{10} \frac{[A^-]}{[HA]}$$

Since, acid is 50% ionised, hence $[A^-] = [HA]$

or $$\text{pH} = \text{p}K_a + \log 1$$

$$= 4.5$$

$$\text{pOH} = 14 - 4.5 = 9.5]$$

33. pK_a value of acetic acid is 4.75. If the buffer solution contains 0.125 M acetic acid and 0.25 M sodium acetate, the pH of buffer solution is : [Comed (Karnataka) 2008]

(a) 5.05 (b) 5.5 (c) 4.9 (d) 5.75

[Ans. (a)]

[Hint : $$\text{pH} = \text{p}K_a + \log \frac{[\text{Salt}]}{[\text{Acid}]}$$

$$= 4.75 + \log \frac{0.25}{0.125}$$

$$= 5.05]$$

Example 47. *The dissociation constants for HCOOH and CH_3COOH are 2.1×10^{-4} and 1.8×10^{-5} respectively. Calculate the relative strengths of the acids.*

Solution: The strength of the acid is directly proportional to the square root of the dissociation constant.

$$\text{Strength of the acid} \propto \sqrt{\text{dissociation constant}}$$

Hence, $$\frac{\text{Strength of HCOOH}}{\text{Strength of } CH_3COOH} = \sqrt{\frac{K_{HCOOH}}{K_{CH_3COOH}}}$$

$$= \sqrt{\frac{2.1 \times 10^{-4}}{1.8 \times 10^{-5}}} = 3.415$$

Example 48. *Freshly precipitated aluminium and magnesium hydroxides are stirred vigorously in a buffer solution containing 0.05 mol L^{-1} of NH_4OH and 0.25 mol L^{-1} of NH_4Cl. Calculate the concentration of aluminium and magnesium ions in solution.*

$$K_{sp}\ Al(OH)_3 = 6\times10^{-32};\ K_b\ NH_4OH = 1.8\times10^{-5}$$

$$K_{sp}\ Mg(OH)_2 = 6\times10^{-10}$$

Solution: $$\text{pOH} = \log\frac{[\text{Salt}]}{[\text{Base}]} - \log K_b$$

$$-\log[\text{OH}^-] = \log\frac{0.25}{0.05} - \log 1.8\times10^{-5}$$

or $$\log[\text{OH}^-] = \log\frac{1.8\times10^{-5}}{5}$$

$$[\text{OH}^-] = 0.36\times10^{-5}\ \text{mol L}^{-1}$$

$$[\text{Al}^{3+}] = \frac{K_{sp}\ \text{Al(OH)}_3}{[\text{OH}^-]^3} = \frac{6\times10^{-32}}{(0.36\times10^{-5})^3} = 1.29\times10^{-10}\ \text{mol L}^{-1}$$

$$[\text{Mg}^{2+}] = \frac{K_{sp}\ \text{Mg(OH)}_2}{[\text{OH}^-]^2} = \frac{6\times10^{-10}}{(0.36\times10^{-5})^2} = 46.3\ \text{mol L}^{-1}$$

Example 49. *Calculate the pH at which $Mg(OH)_2$ begins to precipitate from a solution containing 0.10 M Mg^{2+} ions.* (*K_{sp} $Mg(OH)_2 = 1.0\times10^{-11}$*) **(IIT 1992)**

Solution: $K_{sp}\ \text{Mg(OH)}_2 = 1.0\times10^{-11} = [\text{Mg}^{2+}][\text{OH}^-]^2$

$$= (0.10)[\text{OH}^-]^2$$

or $$[\text{OH}^-]^2 = \frac{1.0\times10^{-11}}{0.10} = 1\times10^{-10}$$

or $$[\text{OH}^-] = 1\times10^{-5}$$

$$[\text{H}^+] = \frac{1\times10^{-14}}{1\times10^{-5}} = 1\times10^{-9}$$

$$\text{pH} = -\log[\text{H}^+] = -\log(1\times10^{-9}) = 9.0$$

Example 50. *An aqueous solution of metal bromide, MBr_2 (0.05 M) is saturated with H_2S. What is the minimum pH at which MS will precipitate? K_{sp} for $MS = 6.0\times10^{-21}$, conc. of saturated $H_2S = 0.1 M$.*

$K_1 = 10^{-7}$ and $K_2 = 1.3\times10^{-13}$ for H_2S **(IIT 1993)**

Solution: The minimum concentration of S^{2-} ions required to precipitate MS is,

$$[\text{S}^{2-}] = \frac{K_{sp}\ M\text{S}}{[M^{2+}]} = \frac{6.0\times10^{-21}}{0.05} = 1.2\times10^{-19}\ M$$

H_2S ionises in solution in two steps:

$$\text{H}_2\text{S} \rightleftharpoons \text{H}^+ + \text{HS}^-;\ K_1 = 10^{-7}$$

$$\text{HS}^- \rightleftharpoons \text{H}^+ + \text{S}^{2-};\ K_2 = 1.3\times10^{-13}$$

$$\frac{[\text{H}^+][\text{HS}^-]}{[\text{H}_2\text{S}]} = K_1 \quad \text{and} \quad \frac{[\text{H}^+][\text{S}^{2-}]}{[\text{HS}^-]} = K_2$$

Hence, $$K_1K_2 = \frac{[\text{H}^+]^2[\text{S}^{2-}]}{[\text{H}_2\text{S}]}$$

or $$[\text{H}^+]^2 = \frac{K_1K_2[\text{H}_2\text{S}]}{[\text{S}^{2-}]} = \frac{10^{-7}\times1.3\times10^{-13}\times0.1}{1.2\times10^{-19}}$$

$$= 1.08\times10^{-2}$$

So, $$[\text{H}^+] = 1.04\times10^{-1}$$

$$\text{pH} = -\log[\text{H}^+] = -\log(1.04\times10^{-1}) = 0.98$$

Example 51. *The pH of blood stream is maintained by a proper balance of H_2CO_3 and $NaHCO_3$ concentrations. What volume of 5 M $NaHCO_3$ solution should be mixed with a 10 mL sample of blood which is 2 M in H_2CO_3, in order to maintain a pH of 7.47? K_a for H_2CO_3 in blood is 7.8×10^{-7}.* **(IIT 1993)**

Solution: Let V mL of 5 M NaHCO_3 solution be mixed.

$$\text{Total volume} = (V + 10)\ \text{mL}$$

Conc. of H_2CO_3 and NaHCO_3 in the solution becomes

$$[\text{NaHCO}_3] = \frac{5\times V}{(V+10)}M$$

and $$[\text{H}_2\text{CO}_3] = \frac{2\times10}{(V+10)}M$$

Now applying Henderson's equation,

$$\text{pH} = -\log K_a + \log\frac{[\text{NaHCO}_3]}{[\text{H}_2\text{CO}_3]}$$

$$7.4 = -\log 7.8\times10^{-7} + \log\frac{5\times V}{(V+10)}\times\frac{(V+10)}{2\times10}$$

$$= -\log 7.8\times10^{-7} + \log\frac{V}{4}$$

or $$\log\frac{V}{4} = 7.4 + \log 7.8\times10^{-7}$$

$$V = 78.32\ \text{mL}$$

Example 52. *The pH of 0.05 M aqueous solution of diethylamine is 12. Calculate its K_b.* **(IIT 1993)**

Solution: We know that, $\text{pH} + \text{pOH} = 14$

or $$\text{pOH} = 14 - \text{pH} = 14 - 12 = 2$$

So, $$[\text{OH}^-] = 10^{-2}$$

$$\begin{array}{lcccc} & (\text{C}_2\text{H}_5)_2\text{NH} + \text{H}_2\text{O} & \rightleftharpoons & (\text{C}_2\text{H}_5)_2\text{NH}_2^+ & + \ \text{OH}^- \\ \text{At equilibrium} & (0.05 - x) & & x & x \\ & (0.05 - 0.01) & & 0.01 & 0.01 \end{array}$$

$$K_b = \frac{[(\text{C}_2\text{H}_5)_2\text{NH}_2^+][\text{OH}^-]}{[(\text{C}_2\text{H}_5)_2\text{NH}]} = \frac{0.01\times0.01}{0.04} = 2.5\times10^{-3}$$

Example 53. *100 mL of HCl gas at 25°C and 740 mm pressure were dissolved in one litre of water. Calculate the pH of solution. Given, vapour pressure of H_2O at 25° C is 23.7 mm.*

Solution: Given, $V = 100\ \text{mL} = 0.1\ \text{L}$

$$P = \left(\frac{740 - 23.7}{760}\right)\text{atm} = 0.9425\ \text{atm}$$

$$R = 0.0821$$

$$T = (25 + 273)\ \text{K} = 298\ \text{K}$$

Applying, $$PV = nRT$$

or $$n = \frac{PV}{RT} = \frac{0.9425 \times 0.1}{0.0821 \times 298} = 3.85 \times 10^{-3} \text{ mol}$$

$$\text{Molarity} = \frac{n}{V} = \frac{3.85 \times 10^{-3}}{1} = 3.85 \times 10^{-3}\ M$$

HCl is a strong electrolyte. It is completely dissociated.

So, $$[\text{H}^+] = 3.85 \times 10^{-3}\ M$$

$$\text{pH} = -\log[\text{H}^+] = -\log 3.85 \times 10^{-3} = 2.4146$$

Example 54. *Calculate the* $[Cl^-]$, $[Na^+]$, $[H^+]$, $[OH^-]$ *and pH of the resulting solution obtained by mixing 50 mL of 0.6 N HCl and 50 mL of 0.3 N NaOH.*

Solution:	HCl +	NaOH $\longrightarrow$	NaCl +	H_2O
Milli-equivalents before reaction	50×0.6 = 30	50×0.3 = 15	0	0
Milli-equivalents after reaction	$(30 - 15)$ = 15	0	15	15

$$\text{Total volume} = 50 + 50 = 100 \text{ mL}$$

$$[\text{Cl}^-] = \frac{15+15}{100} = 0.3\,M$$

$$[\text{Na}^+] = \frac{15}{100} = 0.15\,M$$

$$[\text{H}^+] = \frac{15}{100} = 0.15\,M$$

$$[\text{OH}^-] = \frac{10^{-14}}{0.15} = 6.6 \times 10^{-14}$$

$$\text{pH} = -\log[\text{H}^+] = -\log 0.15 = 0.8239$$

Example 55. *What is the pH of a 1.0 M solution of acetic acid? To what volume of one litre of this solution be diluted so that the pH of the resulting solution will be twice the original value? Given,* $K_a = 1.8 \times 10^{-5}$. **(IIT 1990)**

Solution: We know that degree of dissociation,

$$\alpha = \sqrt{\frac{K_a}{C}}$$

$$= \sqrt{\frac{1.8 \times 10^{-5}}{1}}$$

$$= 4.2426 \times 10^{-3}$$

$$[\text{H}^+] = C \times \alpha = 1 \times 4.2426 \times 10^{-3}$$

$$= 4.2426 \times 10^{-3} \text{ mol L}^{-1}$$

$$\text{pH} = -\log[\text{H}^+] = -\log 4.2426 \times 10^{-3} = 2.3724$$

So, pH of the acetic acid solution after dilution = 2 × 2.3724

= 4.7448

$$\text{New } [\text{H}^+] = 10^{-4.7448} = 1.8 \times 10^{-5}$$

Let the new concentration be C_0.

$$\underset{\text{At equilibrium } C_0 - 1.8\times10^{-5}}{\text{CH}_3\text{COOH}} \rightleftharpoons \underset{1.8\times10^{-5}}{\text{H}^+} + \underset{1.8\times10^{-5}}{\text{CH}_3\text{COO}^-}$$

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = \frac{1.8 \times 10^{-5} \times 1.8 \times 10^{-5}}{(C_0 - 1.8 \times 10^{-5})} = 1.8 \times 10^{-5}$$

So, $$C_0 = 3.6 \times 10^{-5}$$

Let the new volume be V litre

$$1 \times 1 = 3.6 \times 10^{-5} \times V$$

$$V = \frac{1}{3.6 \times 10^{-5}} = 2.78 \times 10^4 \text{ litre}$$

Example 56. *Calculate the change in pH of one litre buffer solution containing 0.10 mole each of* NH_3 *and* NH_4Cl *upon addition of* (i) 0.02 *mole of dissolved gaseous HCl,* (ii) 0.02 *mole of dissolved NaOH.*

Assume no change in volume (K_b *for* $NH_3 = 1.8 \times 10^{-5}$). **(IIT 1992)**

Solution: pOH of NH_3 and NH_4Cl buffer

$$= -\log K_b + \log \frac{[\text{Salt}]}{[\text{Base}]}$$

$$= -\log 1.8 \times 10^{-5} + \log \frac{0.1}{0.1} = 4.75$$

$$\text{pH} = (14 - 4.75) = 9.25$$

First case: $$\text{NH}_3 + \text{HCl} \longrightarrow \text{NH}_4\text{Cl}$$

$$[\text{Salt}] = (0.1 + 0.02) = 0.12\,M$$

$$[\text{Base}] = (0.1 - 0.02) = 0.08\,M$$

$$\text{pOH} = -\log K_b + \log \frac{0.12}{0.08}$$

$$= 4.75 + 0.176 = 4.926$$

$$\text{pH} = (14 - 4.926) = 9.074$$

$$\Delta\text{pH} = (9.25 - 9.074) = 0.176 \text{ pH unit}$$

Second case: $$\text{NH}_4\text{Cl} + \text{NaOH} \longrightarrow \text{NH}_3 + \text{NaCl}$$

$$[\text{Salt}] = (0.1 - 0.02) = 0.08\,M$$

$$[\text{Base}] = (0.1 + 0.02) = 0.12\,M$$

$$\text{pOH} = -\log K_b + \log \frac{0.08}{0.12}$$

$$= (4.75 - 0.176) = 4.576$$

$$\text{pH} = (14 - 4.574) = 9.426$$

$$\Delta\text{pH} = (9.426 - 9.25) = 0.176 \text{ pH unit}$$

Example 57. *Saccharin* ($K_a = 2 \times 10^{-12}$) *is a weak acid represented by formula HSac. A* 4×10^{-4} *mole amount of saccharin is dissolved in 200* cm^3 *water of pH* = 3. *Assuming no change in volume, calculate the concentration of* Sac^- *ions in the resulting solution at equilibrium.* **(IIT 1994)**

Solution: Concentration of saccharin

$$= \frac{4 \times 10^{-4}}{200} \times 1000 = 2 \times 10^{-3} \text{ mol L}^{-1}$$

$$[\text{H}^+] = 10^{-\text{pH}} = 10^{-3} \text{ mol L}^{-1}$$

$$\underset{[(2\times10^{-3})-x]}{\text{HSac}} \rightleftharpoons \underset{(10^{-3}+x)}{\text{H}^+} + \text{Sac}^-$$

$$K_a = \frac{[\text{H}^+][\text{Sac}^-]}{[\text{HSac}]} = \frac{(10^{-3}+x)[\text{Sac}^-]}{[2\times10^{-3}-x]}$$

$$[\text{Sac}^-] = \frac{2\times10^{-12}\times(2\times10^{-3}-x)}{(10^{-3}+x)}$$

Since, x is very small, it can be neglected.

$$[\text{Sac}^-] = \frac{2\times10^{-12}\times2\times10^{-3}}{10^{-3}} = 4\times10^{-12}\ \text{mol L}^{-1}$$

Example 58. *An aqueous solution contains 10% ammonia by mass and has a density 0.99 g cm^{-3}. Calculate hydroxyl and hydrogen ion concentration in this solution. (K_a for $NH_4^+ \approx 5.0\times10^{-10}\ M$)* (IIT 1995)

Solution: Mass of 1 litre solution $= 1000\times0.99$ g

$= 990$ g

NH_3 present in 990 g solution $= 99$ g

1 litre solution contains $= \frac{99}{17} = 5.8$ mole

$$\text{NH}_3 + \text{H}_2\text{O} \rightleftharpoons \text{NH}_4^+ + \text{OH}^-$$

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{x\times x}{(5.8-x)} \approx \frac{x^2}{5.8}$$

$$K_b = \frac{K_w}{K_a} = \frac{10^{-14}}{5.0\times10^{-10}} = 2\times10^{-5}$$

So, $$2\times10^{-5} = \frac{x^2}{5.8}$$

$$x^2 = 2\times10^{-5}\times5.8$$

$$x = 1.078\times10^{-2}\ \text{mol L}^{-1}$$

$$[\text{OH}^-] = x = 1.078\times10^{-2}\ M$$

$$[\text{H}^+] = \frac{10^{-14}}{1.078\times10^{-2}} = 9.27\times10^{-13}\ M$$

Example 59. 0.15 *mole of pyridium chloride has been added into* 500 *cm*^{3} *of* 0.2 *M pyridine solution. Calculate pH and hydroxyl ion concentration in the resulting solution assuming no change in volume.*

(K_b for pyridine $= 1.5\times10^{-9}\ M$) (IIT 1995)

Solution: Concentration of pyridium chloride

$= 0.15\times2 = 0.3\ M$

$$\text{pOH} = \log\frac{[\text{Salt}]}{[\text{Base}]} - \log K_b$$

$$= \log\frac{0.3}{0.2} - \log 1.5\times10^{-9}$$

$$= 9$$

$$[\text{OH}^-] = 10^{-\text{pOH}} = 10^{-9}$$

$$\text{pH} = (14-\text{pOH}) = (14-9) = 5$$

Example 60. *How many moles of acetic acid and sodium acetate each should be dissolved to prepare one litre of* 0.063 *molar buffer solution of pH* 4.5*?*

(K_a for $CH_3COOH = 1.8\times10^{-5}$)

Solution: Applying Henderson's equation,

$$\text{pH} = \log\frac{[\text{Salt}]}{[\text{Acid}]} - \log K_a$$

$$\log\frac{[\text{Salt}]}{[\text{Acid}]} = 4.5 + \log 1.8\times10^{-5} = -0.2447$$

$$\frac{[\text{Salt}]}{[\text{Acid}]} = \text{antilog}\ (-0.2447) = 0.5692$$

$$[\text{Salt}] = 0.5692\times[\text{Acid}]$$

Given: $[\text{Acid}] + [\text{Salt}] = 0.063$

$$[\text{Acid}] = \frac{0.063}{1.5692} = 0.040\ \text{mol L}^{-1}$$

$$[\text{Salt}] = (0.063-0.040) = 0.023\ \text{mol L}^{-1}$$

10.12 SALT HYDROLYSIS

Pure water is a weak electrolyte and neutral in nature, *i.e.*, H^+ ion concentration is exactly equal to OH^- ion concentration

$$[\text{H}^+] = [\text{OH}^-]$$

When this condition is disturbed by decreasing the concentration of either of the two ions, the neutral nature changes into acidic or basic. When $[H^+] > [OH^-]$, the water becomes acidic and when $[H^+] < [OH^-]$, the water acquires basic nature. This is exactly the change which occurs during the phenomenon known as **salt hydrolysis.** It is defined as **a reaction in which the cation or anion or both of a salt react with water to produce acidity or alkalinity.**

Salts are strong electrolytes. When dissolved in water, they dissociate almost completely into ions. In some salts, cations are more reactive in comparison to anions and these react with water to produce H^+ ions. Thus, the solution acquires acidic nature.

$$M^+ + \text{H}_2\text{O} \rightleftharpoons \underset{\text{Weak base}}{M\text{OH}} + \text{H}^+$$

In other salts, anions may be more reactive in comparison to cations and these react with water to produce OH^- ions. Thus, the solution becomes basic.

$$A^- + \text{H}_2\text{O} \rightleftharpoons \underset{\text{Weak acid}}{\text{H}A} + \text{OH}^-$$

The process of hydrolysis is actually the reverse of neutralisation.

$$\text{Salt} + \text{Water} \rightleftharpoons \text{Acid} + \text{Base}$$

If acid is stronger than base, the solution is acidic and in case base is stronger than acid, the solution is alkaline. When both the acid and the base are either strong or weak, the solution is generally neutral in nature.

As the nature of the cation or the anion of the salt determines whether its solution will be acidic or basic, it is proper to divide the salts into four categories.

(i) Salt of a strong acid and a weak base.
Examples: $FeCl_3, CuCl_2, AlCl_3, NH_4Cl, CuSO_4$, etc.

(ii) Salt of a strong base and a weak acid.
Examples: $CH_3COONa, NaCN, NaHCO_3, Na_2CO_3$, etc.

(iii) Salt of a weak acid and a weak base.
Examples: $CH_3COONH_4, (NH_4)_2CO_3, NH_4HCO_3$, etc.

(iv) Salt of a strong acid and a strong base.
Examples: $NaCl, K_2SO_4, NaNO_3, NaBr$, etc.

1. Salt of a strong acid and a weak base

The solution of such a salt is acidic in nature. The cation of the salt which has come from weak base is reactive. It reacts with water to form a weak base and H^+ ions.

$$B^+ + H_2O \rightleftharpoons \underset{\text{Weak base}}{BOH} + H^+$$

Consider, for example, NH_4Cl. It ionises in water completely into NH_4^+ and Cl^- ions. NH_4^+ ions react with water to form a weak base (NH_4OH) and H^+ ions.

$$\underset{C(1-x)}{NH_4^+} + H_2O \rightleftharpoons \underset{Cx}{NH_4OH} + \underset{Cx}{H^+}$$

Thus, hydrogen ion concentration increases and the solution becomes acidic.

Applying law of mass action,

$$K_h = \frac{[H^+][NH_4OH]}{[NH_4^+]} = \frac{Cx \cdot Cx}{C(1-x)} = \frac{x^2C}{(1-x)} \qquad \text{... (i)}$$

where, C is the concentration of salt and x the degree of hydrolysis.

Other equilibria which exist in solution are

$$NH_4OH \rightleftharpoons NH_4^+ + OH^-, \; K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]} \qquad \text{... (ii)}$$

$$H_2O \rightleftharpoons H^+ + OH^-, \; K_w = [H^+][OH^-] \qquad \text{... (iii)}$$

From eqs. (ii) and (iii),

$$\frac{K_w}{K_b} = \frac{[H^+][NH_4OH]}{[NH_4^+]} = K_h \qquad \text{... (iv)}$$

$$[H^+] = \frac{K_h[NH_4^+]}{[NH_4OH]} = \frac{K_w}{K_b} \times \frac{[NH_4^+]}{[NH_4OH]}$$

$$\log [H^+] = \log K_w - \log K_b + \log \frac{[\text{Salt}]}{[\text{Base}]}$$

$$-\text{pH} = -\text{p}K_w + \text{p}K_b + \log \frac{[\text{Salt}]}{[\text{Base}]}$$

$$\text{p}K_w - \text{pH} = \text{p}K_b + \log \frac{[\text{Salt}]}{[\text{Base}]}$$

$$\text{pOH} = \text{p}K_b + \log \frac{[\text{Salt}]}{[\text{Base}]}$$

Relation between Hydrolysis Constant and Degree of Hydrolysis

The extent to which hydrolysis proceeds is expressed as degree of hydrolysis and is defined as the fraction of one mole of the salt that is hydrolysed when the equilibrium has been attained. It is generally expressed as h or x.

$$h = \frac{\text{Amount of salt hydrolysed}}{\text{Total salt taken}}$$

Considering again eq. (i),

$$K_h = \frac{x^2C}{(1-x)} \quad \text{or} \quad K_h = \frac{h^2C}{(1-h)}$$

When h is very small $(1-h) \longrightarrow 1$,

$$h^2 = K_h \times \frac{1}{C}$$

or

$$h = \sqrt{\frac{K_h}{C}}$$

$$= \sqrt{\frac{K_w}{K_b \times C}}$$

$$[H^+] = h \times C = \sqrt{\frac{C \times K_w}{K_b}}$$

$$\log [H^+] = \frac{1}{2}\log K_w + \frac{1}{2}\log C - \frac{1}{2}\log K_b$$

$$\text{pH} = \frac{1}{2}\text{p}K_w - \frac{1}{2}\log C - \frac{1}{2}\text{p}K_b$$

$$= 7 - \frac{1}{2}\text{p}K_b - \frac{1}{2}\log C$$

2. Salt of a weak acid and a strong base

The solution of such a salt is basic in nature. The anion of the salt is reactive. It reacts with water to form a weak acid and OH^- ions.

$$A^- + H_2O \rightleftharpoons \underset{\text{Weak acid}}{HA} + OH^-$$

Consider, for example, the salt CH_3COONa. It ionises in water completely to give CH_3COO^- and Na^+ ions. CH_3COO^- ions react with water to form a weak acid, CH_3COOH and OH^- ions.

$$\underset{C(1-x)}{CH_3COO^-} + H_2O \rightleftharpoons \underset{Cx}{CH_3COOH} + \underset{Cx}{OH^-}$$

Thus, OH^- ion concentration increases, the solution becomes alkaline.

Applying law of mass action,

$$K_h = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} = \frac{Cx \times Cx}{C(1-x)} = \frac{Cx^2}{(1-x)} \qquad \text{... (i)}$$

Other equilibria present in the solution are:

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+, K_a = \frac{[CH_3COO^-][H^+]}{[CH_3COOH]} \qquad \text{... (ii)}$$

$$H_2O \rightleftharpoons H^+ + OH^-, K_w = [H^+][OH^-] \qquad \text{... (iii)}$$

From eqs. (ii) and (iii),

$$\frac{K_w}{K_a}=\frac{[CH_3COOH][OH^-]}{[CH_3COO^-]}=K_h \qquad \text{... (iv)}$$

$$[OH^-]=\frac{K_h[CH_3COO^-]}{[CH_3COOH]}=\frac{K_w}{K_a}\frac{[CH_3COO^-]}{[CH_3COOH]}$$

$$\log[OH^-]=\log K_w-\log K_a+\log\frac{[Salt]}{[Acid]}$$

$$-pOH=-pK_w+pK_a+\log\frac{[Salt]}{[Acid]}$$

$$pK_w-pOH=pK_a+\log\frac{[Salt]}{[Acid]}$$

$$pH=pK_a+\log\frac{[Salt]}{[Acid]}$$

Considering eq. (i) again,

$$K_h=\frac{Cx^2}{(1-x)} \text{ or } K_h=\frac{Ch^2}{(1-h)}$$

When h is very small, $(1-h)\longrightarrow 1$

or $$h^2=\frac{K_h}{C}$$

or $$h=\sqrt{\frac{K_h}{C}}$$

$$[OH^-]=h\times C=\sqrt{CK_h}=\sqrt{\frac{C\times K_w}{K_a}}$$

$$[H^+]=\frac{K_w}{[OH^-]}$$

$$=\frac{K_w}{\sqrt{\frac{C\times K_w}{K_a}}}=\sqrt{\frac{K_a\times K_w}{C}}$$

$$-\log[H^+]=-\frac{1}{2}\log K_w-\frac{1}{2}\log K_a+\frac{1}{2}\log C$$

$$pH=\frac{1}{2}pK_w+\frac{1}{2}pK_a+\frac{1}{2}\log C$$

$$=7+\frac{1}{2}pK_a+\frac{1}{2}\log C$$

3. Salt of a weak acid and a weak base

Maximum hydrolysis occurs in the case of such a salt as both the cation and anion are reactive and react with water to produce H^+ and OH^- ions. The solution is generally neutral but it can be either slightly acidic or slightly alkaline if both the reactions take place with slightly different rates. Consider, for example, the salt CH_3COONH_4. It gives CH_3COO^- and NH_4^+ ions in solution. Both react with water.

$$\underset{\text{Weak base}}{NH_4^+ + H_2O \rightleftharpoons NH_4OH} + H^+$$

$$\underset{\text{Weak acid}}{CH_3COO^- + H_2O \rightleftharpoons CH_3COOH} + OH^-$$

Both the reactions occur with same speeds. The solution is neutral.

$$\text{or } \underset{C(1-h)}{CH_3COO^-} + \underset{C(1-h)}{NH_4^+} + H_2O \rightleftharpoons \underset{Ch}{CH_3COOH} + \underset{Ch}{NH_4OH}$$

$$K_h=\frac{[CH_3COOH][NH_4OH]}{[CH_3COO^-][NH_4^+]}$$

Other equilibria which exist in solution are:

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+, K_a=\frac{[CH_3COO^-][H^+]}{[CH_3COOH]} \qquad \text{... (i)}$$

$$NH_4OH \rightleftharpoons NH_4^+ + OH^-, \quad K_b=\frac{[NH_4^+][OH^-]}{[NH_4OH]} \qquad \text{... (ii)}$$

$$H_2O \rightleftharpoons H^+ + OH^-, \quad K_w=[H^+][OH^-] \qquad \text{... (iii)}$$

From eqs. (i), (ii) and (iii),

$$K_h=\frac{K_w}{K_a\cdot K_b}=\frac{[CH_3COOH][NH_4OH]}{[CH_3COO^-][NH_4^+]} \qquad \text{... (iv)}$$

Let C be the concentration and h be the degree of hydrolysis

$$K_h=\frac{h^2}{(1-h)^2}$$

When h is small, $(1-h)\longrightarrow 1$,

$$K_h=h^2$$

$$h=\sqrt{K_h}=\sqrt{\frac{K_w}{K_a\times K_b}}$$

$$[H^+]=K_a\times h$$

$$=K_a\times\sqrt{\frac{K_w}{K_a\times K_b}}$$

$$=\sqrt{\frac{K_a\times K_w}{K_b}}$$

$$-\log[H^+]=-\frac{1}{2}\log K_a-\frac{1}{2}\log K_w+\frac{1}{2}\log K_b$$

$$pH=\frac{1}{2}pK_a+\frac{1}{2}pK_w-\frac{1}{2}pK_b$$

$$=7+\frac{1}{2}pK_a-\frac{1}{2}pK_b$$

When $pK_a=pK_b$, pH = 7, *i.e.*, solution will be neutral in nature.

When $pK_a>pK_b$, the solution will be alkaline as the acid will be slightly weaker than base and pH value will be more than 7. In case $pK_a<pK_b$, the solution will be acidic as the acid is relatively stronger than base and pH will be less than 7.

4. Salt of a strong acid and a strong base

Such a salt, say NaCl, does not undergo hydrolysis as both the ions are not reactive. The solution is thus, neutral in nature.

5. Hydrolysis of amphiprotic anion

Let us consider hydrolysis of amphiprotic anion only, *i.e.*, when counter cation is not hydrolysed example of some salts of this category are $NaHCO_3$, $NaHS$, Na_2HPO_4, NaH_2PO_4.

$$\text{(i) } H_3PO_4 \rightleftharpoons H_2PO_4^- + H^+; \quad K_{a_1} = \frac{[H_2PO_4^-][H^+]}{[H_3PO_4]}$$

$$\text{(ii) } H_2PO_4^- \rightleftharpoons HPO_4^{2-} + H^+; \quad K_{a_2} = \frac{[HPO_4^{2-}][H^+]}{[H_2PO_4^-]}$$

$$\text{(iii) } HPO_4^{2-} \rightleftharpoons PO_4^{3-} + H^+; \quad K_{a_3} = \frac{[PO_4^{3-}][H^+]}{[HPO_4^{2-}]}$$

Here, $H_2PO_4^-$ and HPO_4^{2-} are amphiprotic anions, pH after their hydrolysis can be calculated as,

$$\text{pH of } H_2PO_4^- \text{ in aqueous medium} = \frac{pK_{a_1} + pK_{a_2}}{2}$$

$$\text{pH of } HPO_4^{2-} \text{ in aqueous medium} = \frac{pK_{a_2} + pK_{a_3}}{2}$$

Here, $\mathbf{HPO_4^{2-}}$ is conjugate base of $\mathbf{H_2PO_4^-}$ and $\mathbf{H_3PO_4}$ is conjugate acid of $\mathbf{H_2PO_4^-}$.

Similarly, $\mathbf{PO_4^{3-}}$ is conjugate base of $\mathbf{HPO_4^{2-}}$ and $\mathbf{HPO_4^{2-}}$ is conjugate acid of $\mathbf{PO_4^{3-}}$.

(iv) Let us consider amphiprotic bicarbonate anion.

$$\underset{\text{Acid}}{HCO_3^{2-}} + H_2O \rightleftharpoons \underset{\text{Conjugate base}}{CO_3^{2-}} + H_3^+O \quad \text{(Ionization)}$$

$$\underset{\text{Base}}{HCO_3^-} + H_2O \rightleftharpoons \underset{\text{Conjugate acid}}{H_2CO_3} + OH^- \quad \text{(Hydrolysis)}$$

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-; \quad K_{a_1} = \frac{[H^+][HCO_3^-]}{[H_2CO_3]}$$

$$HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}; \quad K_{a_2} = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]}$$

pH of HCO_3^- ion after hydrolysis in aqueous medium

$$= \frac{pK_{a_1} + pK_{a_2}}{2}$$

(v) Let us consider the hydrolysis of amphiprotic anion along with cation, *e.g.*, NH_4HCO_3, NH_4HS.

In above examples both cations and anions are derived from weak base and weak acids respectively, hence both will undergo hydrolysis in aqueous medium.

When these salts are dissolved in water, $[H_3O^+]$ concentration can be determined as,

$$[H_3O^+] = \sqrt{K_{a_1}\left[\frac{K_w}{K_b} + K_{a_2}\right]}$$

$$pH = -\log\sqrt{K_{a_1}\left[\frac{K_w}{K_b} + K_{a_2}\right]}$$

Table 10.1 Hydrolysis at a Glance

Salt	Nature	Degree	Hydrolysis Constant	pH
1. NaCl (Strong acid + Strong base)	Neutral	No hydrolysis	—	—
2. CH_3COONa (Weak acid + Strong base)	Basic	$h = \sqrt{\frac{K_w}{CK_a}}$	$K_h = \frac{K_w}{K_a}$	$pH = \frac{1}{2}[pK_w + pK_a + \log C]$
3. NH_4Cl (Strong acid + Weak base)	Acidic	$h = \sqrt{\frac{K_w}{CK_b}}$	$K_h = \frac{K_w}{K_b}$	$pH = \frac{1}{2}[pK_w - pK_b - \log C]$
4. CH_3COONH_4 (Weak acid + Weak base)	*	$h = \sqrt{\frac{K_w}{K_a \times K_b}}$	$K_h = \frac{K_w}{K_a \times K_b}$	$pH = \frac{1}{2}[pK_w + pK_a - pK_b]$

*In the case of salt of weak acid and weak base, nature of medium after hydrolysis is decided in the following manner:

(i) If $K_a = K_b$, the medium will be neutral.

(ii) If $K_a > K_b$, the medium will be acidic.

(iii) If $K_a < K_b$, the medium will be basic.

The degree of hydrolysis of salts of weak acids and weak bases is unaffected by dilution because there is no concentration term in the expression of degree of hydrolysis.

[**Note:** Degree of hydrolysis always increases with increase in temperature because at elevated temperature increase in K_w is greater as compared to K_a and K_b.]

SOME SOLVED EXAMPLES

Example 61. *Calculate the degree of hydrolysis and pH of 0.1 M sodium acetate solution. Hydrolysis constant of sodium acetate is* 5.6×10^{-10}.

Solution: $\underset{0.1(1-h)}{CH_3COO^-} + H_2O \rightleftharpoons \underset{(0.1 \times h)}{CH_3COOH} + \underset{(0.1 \times h)}{OH^-}$

$$K_h = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} = \frac{(0.1 \times h)(0.1 \times h)}{0.1(1-h)};$$

$$\because h \text{ is small } (1-h) \longrightarrow 1$$

$$5.6 \times 10^{-10} = 0.1 \times h^2$$

or
$$h^2 = \frac{5.6 \times 10^{-10}}{0.1} = 56 \times 10^{-10}$$

$$h = 7.48 \times 10^{-5}$$

$$[OH^-] = Ch = 0.1 \times 7.48 \times 10^{-5} = 7.48 \times 10^{-6}\ M$$

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{7.48 \times 10^{-6}} = 1.33 \times 10^{-9}\ M$$

$$pH = -\log[H^+] = -\log(1.33 \times 10^{-9}) = 8.88$$

Example 62. *When 0.2 M acetic acid is neutralised with 0.2 M NaOH in 0.5 litre of water the resulting solution is slightly alkaline. Calculate the pH of the resulting solution.* K_a *for* $CH_3COOH = 1.8 \times 10^{-5}$.

Solution: 0.2 M acetic acid will form 0.2 M CH_3COONa in 0.5 litre of water. Hence, concentration of sodium acetate, $[CH_3COONa] = 0.1\,\text{mol L}^{-1}$.

$$\underset{C(1-x)}{CH_3COO^-} + H_2O \rightleftharpoons \underset{Cx}{CH_3COOH} + \underset{Cx}{OH^-}$$

$$K_h = \frac{Cx^2}{(1-x)} = Cx^2 \qquad (1-x) \longrightarrow 1$$

$$K_h = \frac{K_w}{K_a} = \frac{1\times10^{-14}}{1.8\times10^{-5}} = 5.5\times10^{-10}$$

So, $K_h = Cx^2 = 5.5\times10^{-10}$

or $x^2 = \dfrac{5.5\times10^{-10}}{0.1} = 55\times10^{-10}$

or $x = 7.42\times10^{-5}$

$$[OH^-] = Cx = 7.42\times10^{-5}\times0.1 = 7.42\times10^{-6}\ M$$

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{1\times10^{-14}}{7.42\times10^{-6}} = 1.3477\times10^{-9}\ M$$

$$pH = -\log[H^+] = -\log(1.3477\times10^{-9}) = 8.87$$

Example 63. *Calculate the hydrolysis constant for NH_4Cl, pH value and $[OH^-]$ in 0.1 M NH_4Cl solution.*
$(K_{NH_4OH} = 1.75\times10^{-5}, K_w = 1\times10^{-14})$

Solution: We know that, $K_h = \dfrac{K_w}{K_b}$

So, $K_h = \dfrac{1\times10^{-14}}{1.75\times10^{-5}} = 5.7\times10^{-10}$

Hydrolysis of NH_4Cl can be represented as,

$$\underset{C(1-x)}{NH_4^+} + H_2O \rightleftharpoons \underset{Cx}{NH_4OH} + \underset{Cx}{H^+}$$

Thus, $K_h = \dfrac{Cx^2}{(1-x)}$

Neglecting 'x' in denominator,

$$x^2 = \frac{K_h}{C} = \frac{5.7\times10^{-10}}{0.1} = 57\times10^{-10}$$

or $x = 7.55\times10^{-5}$

$$[H^+] = Cx = 0.1\times7.55\times10^{-5} = 7.55\times10^{-6}\ M$$

$$pH = -\log[H^+] = -\log(7.55\times10^{-6}) = 5.12$$

Again, $[OH^-] = \dfrac{K_w}{[H^+]} = \dfrac{1\times10^{-14}}{7.55\times10^{-6}} = 1.32\times10^{-9}\ M$

Example 64. *Calculate the pH at the equivalence point when a solution of 0.1M acetic acid is titrated with a solution of 0.1M sodium hydroxide.*
K_a for acetic acid $= 1.9\times10^{-5}$ **(IIT 1990)**

Solution: Concentration of sodium acetate $= \dfrac{0.1}{2} = 0.05\ M$ as equal volumes of the acid and the base will be used.

The equilibrium is,

$$\underset{C(1-x)}{CH_3COO^-} + H_2O \rightleftharpoons \underset{Cx}{CH_3COOH} + \underset{Cx}{OH^-}$$

where, x is the degree of hydrolysis, and

$$K_h = \frac{Cx^2}{(1-x)}$$

We know that,

$$K_h = \frac{K_w}{K_a} = \frac{1\times10^{-14}}{1.9\times10^{-5}} = 5.26\times10^{-10}$$

So, $K_h = Cx^2$ as $(1-x) \longrightarrow 1$

$5.26\times10^{-10} = 0.05\times x^2$

or $x^2 = \dfrac{5.26\times10^{-10}}{0.05} = 1.05\times10^{-8}$

or $x = 1.025\times10^{-4}$

$$[OH^-] = Cx = 1.025\times10^{-4}\times0.05 = 5.125\times10^{-6}\ M$$

$$[H^+] = \frac{1\times10^{-14}}{5.125\times10^{-6}} = 1.95\times10^{-9}\ M$$

$$pH = -\log[H^+] = -\log(1.95\times10^{-9}) = 8.71$$

Example 65. *Calculate the amount of ammonium chloride required to dissolve in 500 mL water to have pH = 4.5. (K_b for NH_4OH is 1.8×10^{-5})*

Solution: $[H^+] = 10^{-pH} = 10^{-4.5} = 10^{-5}$ antilog 0.5
$= 3.162\times10^{-5}\ M$

Let C be the concentration of NH_4Cl

$$\underset{C(1-h)}{NH_4^+} + H_2O \rightleftharpoons \underset{Ch}{NH_4OH} + \underset{Ch}{H^+}$$

If h is small, then

$$K_h = Ch^2 \qquad \left[K_h = \frac{K_w}{K_b} = \frac{10^{-14}}{1.8\times10^{-5}} = 5.5\times10^{-10}\right]$$

$$h = \frac{K_h}{Ch} = \frac{K_h}{[H^+]}$$

$$= \frac{5.5\times10^{-10}}{3.162\times10^{-5}} = 1.739\times10^{-5}$$

$$Ch = [H^+]$$

$$C = \frac{[H^+]}{h} = \frac{3.162\times10^{-5}}{1.739\times10^{-5}} = 1.8\ \text{mol L}^{-1}$$

500 mL of water contains $= \dfrac{1.8}{2} = 0.9$ mole

Mass in g $= 0.9\times53.5 = 48.15$ g

Example 66. *Calcium lactate is a salt of a weak organic acid and represented as $Ca(Lac)_2$. A saturated solution of*

$Ca(Lac)_2$ contains 0.13 *mole of this salt in* 0.50 *litre solution. The pOH of this solution is* 5.60. *Assuming a complete dissociation of salt, calculate* K_a *of the lactic acid.* **(IIT 1991)**

Solution:

$$\underset{0.13\times 2\,M}{\mathrm{Ca(Lac)_2}} \rightleftharpoons \mathrm{Ca^{2+}} + \underset{2\times 2\times 0.13\,M}{2\mathrm{Lac^-}}$$

$$\text{At equilibrium}\quad \underset{(0.52-x)}{\mathrm{Lac^-}} + \mathrm{H_2O} \rightleftharpoons \underset{x}{\mathrm{HLac}} + \underset{x}{\mathrm{OH^-}}$$

$$K_h = \frac{x^2}{(0.52-x)} = \frac{x^2}{0.52} \text{ as } x \text{ is small}$$

$$[\mathrm{OH^-}] = 10^{-5.6} = 2.51\times 10^{-6} = x$$

$$K_h = \frac{2.51\times 10^{-6}\times 2.51\times 10^{-6}}{0.52} = 12.12\times 10^{-12}$$

$$K_a = \frac{K_w}{K_h} = \frac{10^{-14}}{12.12\times 10^{-12}} = 8.26\times 10^{-4}$$

Example 67. K_a *for butyric acid is* 2×10^{-5}. *Calculate pH and hydroxyl ion concentration of* 0.2 *M aqueous solution of sodium butyrate.* **(IIT 1994)**

Solution: Butyrate ion hydrolysis in solution into butyric acid and OH^- ions. Let x mole of butyrate ion be hydrolysed.

$$\underset{(0.2-x)}{\mathrm{C_3H_7COO^-}} + \mathrm{H_2O} \rightleftharpoons \underset{x}{\mathrm{C_3H_7COOH}} + \underset{x}{\mathrm{OH^-}}$$

$$K_h = \frac{x^2}{(0.2-x)} = \frac{x^2}{0.2} \quad (x \text{ being small is neglected as compared to } 0.2)$$

So,

$$K_h = \frac{K_w}{K_a}$$

$$\frac{K_w}{K_a} = \frac{x^2}{0.2}$$

$$\frac{10^{-14}}{2\times 10^{-5}} = \frac{x^2}{0.2}$$

or

$$x^2 = 10^{-10} \text{ or } x = 10^{-5} \text{ mol L}^{-1}$$

$$[\mathrm{OH^-}] = 10^{-5}\,M$$

$$[\mathrm{H^+}] = \frac{10^{-14}}{10^{-5}} = 10^{-9}\,M$$

$$\mathrm{pH} = -\log[10^{-9}] = 9$$

Example 68. *Calculate the pH of an aqueous solution of* $1.0M$ *ammonium formate assuming complete dissociation.* pK_a *for formic acid* $= 3.8$ *and* pK_b *of ammonia* $= 4.8$. **(IIT 1995)**

Solution: Ammonium formate is a salt of weak acid and weak base. Hence,

$$\mathrm{pH} = 7 + \frac{1}{2}\mathrm{p}K_a - \frac{1}{2}\mathrm{p}K_b$$

$$= 7 + (1/2)\times 3.8 - (1/2)\times 4.8$$

$$= 7 + 1.9 - 2.4$$

$$= 6.5$$

Example 69. *A certain weak acid has* $K_a = 1.0\times 10^{-4}$. *Calculate the equilibrium constant for its reaction with a strong base.* **(IIT 1991)**

Solution:

$$\underset{\text{Weak}}{\mathrm{H}A} + \underset{\text{Strong}}{B\mathrm{OH}} \rightleftharpoons BA + \mathrm{H_2O}$$

$$\mathrm{H}A + B^+ + \mathrm{OH^-} \rightleftharpoons B^+ + A^- + \mathrm{H_2O}$$

or

$$\mathrm{H}A + \mathrm{OH^-} \rightleftharpoons A^- + \mathrm{H_2O}$$

$$K = \frac{[A^-]}{[\mathrm{H}A][\mathrm{OH^-}]}$$

In the above reaction,

$$K_h = \frac{[\mathrm{H}A][\mathrm{OH^-}]}{[A^-]}$$

So,

$$K = \frac{1}{K_h}$$

We know that,

$$K_h = \frac{K_w}{K_a} = \frac{10^{-14}}{1.0\times 10^{-4}} = 10^{-10}$$

$$K = \frac{1}{10^{-10}} = 10^{10}$$

Example 70. *Calculate for* 0.01 *N solution of sodium acetate:*

(a) Hydrolysis constant, (b) degree of hydrolysis, (c) pH.
(Given, $K_a = 1.9\times 10^{-5}$*)* **(MLNR 1991)**

Solution: $K_h = \dfrac{K_w}{K_a} = \dfrac{10^{-14}}{1.9\times 10^{-5}} = 5.26\times 10^{-10}$

$$h = \sqrt{\frac{K_h}{C}} = \sqrt{\frac{5.26\times 10^{-10}}{0.01}} = 2.29\times 10^{-4}$$

$$\mathrm{CH_3COO^-} + \mathrm{H_2O} \rightleftharpoons \mathrm{CH_3COOH} + \underset{Ch}{\mathrm{OH^-}}$$

$$[\mathrm{OH^-}] = C\times h = 0.01\times 2.29\times 10^{-4}$$

$$= 2.29\times 10^{-6}\,M$$

$$[\mathrm{H^+}] = \frac{K_w}{[\mathrm{OH^-}]} = \frac{10^{-14}}{2.29\times 10^{-6}} = 4.37\times 10^{-9}\,M$$

$$\mathrm{pH} = -\log[\mathrm{H^+}] = -\log(4.37\times 10^{-9}) = 8.36$$

Example 71. H_2CO_3 *ionises as,*

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-;\quad K_1 = 4.3\times 10^{-7}$$

$$HCO_3^- \rightleftharpoons H^+ + CO_3^{2-};\quad K_2 = 5.6\times 10^{-11}$$

Calculate the degree of hydrolysis and pH value of 0.12 *M* Na_2CO_3 *solution.*

Solution: $\mathrm{Na_2CO_3}$ is a salt of strong base and weak acid. Thus, $\mathrm{CO_3^{2-}}$ ion is hydrolysed.

$$\underset{0.12(1-h)}{\mathrm{CO_3^{2-}}} + \mathrm{H_2O} \rightleftharpoons \underset{0.12h}{\mathrm{HCO_3^-}} + \underset{0.12h}{\mathrm{OH^-}}$$

$$K_h = h^2 C$$

or $$h^2 = \frac{K_h}{C} = \frac{K_h}{0.12}$$

We know that, $$K_h = \frac{K_w}{K_a} = \frac{K_w}{K_2} = \frac{10^{-14}}{5.6\times10^{-11}} = 1.7857\times10^{-4}$$

So, $$h^2 = \frac{1.7857\times10^{-4}}{0.12} = 14.88\times10^{-4}$$

$$h = 3.85\times10^{-2}$$

$$[OH^-] = C\times h = 0.12\times3.85\times10^{-2}$$

$$= 0.462\times10^{-2} = 4.62\times10^{-3}$$

$$[H^+] = \frac{10^{-14}}{4.62\times10^{-3}} = 2.164\times10^{-12}\ M$$

$$pH = -\log[H^+] = -\log(2.164\times10^{-12}) = 11.665$$

Example 72. *How much must a 0.2 M solution of sodium acetate be diluted at 25°C in order to double the degree of hydrolysis?*

Solution: Let h be the initial degree of hydrolysis

$$K_h = Ch^2 = 0.2\times h^2 \quad \text{... (i)}$$

Let the concentration be C_1 when degree of hydrolysis is $2h$.

$$K_h = C_1(2h)^2 \quad \text{... (ii)}$$

Dividing both the equations,

$$1 = \frac{0.2\times(h^2)}{4C_1\times(h)^2}$$

$$C_1 = \frac{0.2}{4} = 0.05\,M$$

Applying, $$M_1V_1 = M_2V_2$$

$$0.2V_1 = 0.05\times V_2$$

$$V_2 = \frac{0.2}{0.05}V_1 = 4V_1$$

The solution be diluted four times.

Example 73. *Calculate change in pH upon ten-fold dilution of the following solutions:*

(a) 0.1 HCl (b) 0.1 M acetic acid (c) 0.1 M NH_4Cl

$$K_a\ CH_3COOH = 1.8\times10^{-5},\quad K_b\ NH_3 = 1.8\times10^{-5}$$

Solution: (a) HCl is a strong acid. It is completely ionised in solution.

$$HCl \rightleftharpoons H^+ + Cl^-$$

$$[H^+] = 0.1 = 10^{-1}$$

$$pH = -\log[H^+] = -\log(10^{-1}) = 1$$

After dilution, $$[H^+] = 0.01 = 10^{-2}\ M$$

$$pH = -\log[H^+] = -\log 10^{-2} = 2$$

pH change from 1 to 2.

(b) $$\underset{(0.1-x)}{CH_3COOH} \rightleftharpoons \underset{x}{CH_3COO^-} + \underset{x}{H^+}$$

(CH_3COOH is a weak acid)

$$\frac{x^2}{0.1} = 1.8\times10^{-5} \text{ or } x^2 = 1.8\times10^{-6} \text{ or } x = 1.34\times10^{-3}$$

$$pH = -\log x = -\log(1.34\times10^{-3}) = 2.87$$

After dilution,

$$\frac{x_1^2}{0.01} = 1.8\times10^{-5} \text{ or } x_1^2 = 18\times10^{-8} \text{ or } x_1 = 4.24\times10^{-4}\ M$$

$$pH = -\log x = -\log 4.24\times10^{-4} = 3.37$$

pH change from 2.87 to 3.37.

(c) NH_4Cl is a salt of weak base and strong acid.

$$\underset{(0.1-h)}{NH_4^+} + H_2O \rightleftharpoons \underset{h}{NH_4OH} + \underset{h}{H^+}$$

$$\frac{h^2}{0.1} = K_h \quad\text{or}\quad h^2 = 0.1\times K_h$$

$$\left[K_h = \frac{K_w}{K_b} = \frac{10^{-14}}{1.8\times10^{-5}} = 5.55\times10^{-10}\right]$$

$$= 0.1\times5.55\times10^{-10}$$

$$h = 7.45\times10^{-6} = [H^+]$$

$$pH = -\log(7.45\times10^{-6}) = 5.128$$

After dilution, $$h^2 = 0.01\times K_h = 0.01\times5.55\times10^{-10}$$

$$h = 2.35\times10^{-6}$$

$$pH = -\log 2.35\times10^{-6} = 5.627$$

pH change from 5.128 to 5.627.

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

34. The pH of a solution obtained by mixing 100 mL of 0.2 M CH_3COOH with 100 mL of 0.2 M NaOH would be: (Given: pK_a for CH_3COOH = 4.74)

(a) 4.74 (b) 8.87 (c) 9.10 (d) 8.57

[Ans. (b)]

[Hint: Concentration of salt formed will be 0.1 M.

$$CH_3COOH + NaOH \rightleftharpoons CH_3COONa + H_2O$$

$$pH = \frac{1}{2}[pK_w + pK_a + \log C]$$

$$= \frac{1}{2}[14 + 4.74 - 1] = 8.87\ ]$$

35. The pH of 0.02 M $NH_4Cl(aq.)$ (pK_b = 4.73) is equal to:

(a) 3.78 (b) 4.73 (c) 5.48 (d) 7.00

[Ans. (c)]

[Hint: $$pH = \frac{1}{2}[pK_w - pK_b - \log C]$$

$$= \frac{1}{2}[14 - 4.73 - \log 0.02]$$

$$= \frac{1}{2}[14 - 4.73 + 1.698] = 5.48\ ]$$

36. pH of 0.05 M $(CH_3COO)_2Ca$ (pK_a = 4.74) is:

(a) 8.72 (b) 8.87 (c) 7 (d) 1.30

[Ans. (b)]

[Hint: $[CH_3COO^-] = 2\times0.05 = 0.1$

$$pH = \frac{1}{2}[pK_w + pK_a + \log C]$$

$$= \frac{1}{2}[14 + 4.74 + \log 0.1]$$

$$= \frac{1}{2}[14 + 4.74 - 1] = 8.87\ ]$$

37. The degree of hydrolysis of which of the following salt is independent of the concentration of salt solution?

(a) CH_3COONa (b) NH_4Cl
(c) CH_3COONH_4 (d) NaCl

[Ans. (c)]

[Hint: It is the salt of weak acid and weak base, hence its degree of hydrolysis will be independent of concentration.

$$h = \sqrt{\frac{K_w}{K_a \times K_b}}\ ]$$

38. The pH of 1 *M* $PO_4^{3-}(aq.)$ solution will be: (given pK_b of $PO_4^{3-} = 1.62$)

(a) 1.62 (b) 12.38 (c) 13.19 (d) 7

[Ans. (c)]

[Hint: $pK_a = 14 - pK_b = 14 - 1.62 = 12.38$

$$pH = \frac{1}{2}[\ pK_w + pK_a + \log C\ ]$$

$$= \frac{1}{2}[14 + 12.38 + 0] = 13.19\ ]$$

39. For the following equilibrium:

$$NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$$

calculate the equilibrium constant, if for the equilibrium,

$$NH_4^+ + H_2O \rightleftharpoons NH_4OH + H^+$$

the equilibrium constant is 5.5×10^{-10}.

(a) 1.8×10^{-4} (b) 1.8×10^{-5} (c) 1.8×10^{-6} (d) 1.8×10^{-7}

[Ans. (b)]

[Hint: $K_w = K_a \times K_b$

$$10^{-14} = 5.5 \times 10^{-10} \times K_b$$

$$K_b = 1.8 \times 10^{-5}\ ]$$

40. Which of the following expressions is not applicable on the hydrolysis equilibrium? [PET (Raj.) 2004]

$$CN^- + H_2O \rightleftharpoons HCN + OH^-$$

(a) $K_h = \frac{K_w}{K_a(HCN)}$ (b) $h = \sqrt{\frac{K_h}{C}}$

(c) $pH = \frac{1}{2}pK_a(HCN)$ (d) $(H^+) = \sqrt{\frac{K_w \times K_a}{C}}$

[Ans. (c)]

[Hint: For the salt of weak acid and strong base:

$$pH = \frac{1}{2}[pK_w + pK_a - \log C\ ]$$

41. The pK_a of weak acid H*A* is 4.80 and the pK_b of a weak base *B*OH is 4.78. The pH of an aqueous solution of corresponding salt *BA* will be : (AIEEE 2008)

(a) 9.22 (b) 9.58 (c) 4.79 (d) 7.01

[Ans. (d)]

[Hint: $pH = \frac{1}{2}[pK_w + pK_a - pK_b]$

$$= \frac{1}{2}[14 + 4.8 - 4.78] = 7.01\ ]$$

10.13 THEORY OF INDICATORS

An indicator is a substance which is used to determine the end point in a titration. In acid-base titrations, organic substances (weak acids or weak bases) are generally used as indicators. They change their colour within a certain pH range. The colour change and the pH range of some common indicators are tabulated below:

Indicator	pH range	Colour change
Methyl orange	3.2 – 4.5	Pink to yellow
Methyl red	4.4 – 6.5	Red to yellow
Litmus	5.5 – 7.5	Red to blue
Phenol red	6.8 – 8.4	Yellow to red
Phenolphthalein	8.3 – 10.5	Colourless to pink

Theory of acid-base indicators: Two theories have been proposed to explain the change of colour of acid-base indicators with change in pH.

1. Ostwald's theory: According to this theory:

(a) The colour change is due to ionisation of the acid-base indicator. The unionised form has different colour than the ionised form.

(b) The ionisation of the indicator is largely affected in acids and bases as it is either a weak acid or a weak base. In case, the indicator is a weak acid, its ionisation is very much low in acids due to common H^+ ions while it is fairly ionised in alkalies. Similarly, if the indicator is a weak base, its ionisation is large in acids and low in alkalies due to common OH^- ions.

Considering two important indicators phenolphthalein (a weak acid) and methyl orange (a weak base), Ostwald's theory can be illustrated as follows:

Phenolphthalein: It can be represented as HPh. It ionises in solution to a small extent as:

$$\underset{\text{Colourless}}{HPh} \rightleftharpoons H^+ + \underset{\text{Pink}}{Ph^-}$$

Applying law of mass action,

$$K = \frac{[H^+][Ph^-]}{[HPh]}$$

The undissociated molecules of phenolphthalein are colourless while Ph^- ions are pink in colour. In presence of an acid, the ionisation of HPh is practically negligible as the equilibrium shifts to left hand side due to high concentration of H^+ ions. Thus, the solution would remain colourless. On addition of alkali, hydrogen ions are removed by OH^- ions in the form of water molecules and the equilibrium shifts to right hand side. Thus, the concentration of Ph^- ions increases in solution and they impart pink colour to the solution.

Let us derive Henderson's equation for an indicator

$$\underset{\text{'Acid form'}}{HIn} + H_2O \rightleftharpoons H_3^+O + \underset{\text{'Base form'}}{In^-}$$

Conjugate acid-base pair

$$K_{In} = \frac{[In^-][H_3^+O]}{[HIn]}; (K_{In} = \text{Ionization constant of indicator})$$

$$[H_3^+O] = K_{In} \times \frac{[HIn]}{[In^-]}$$

$$pH = -\log_{10}[H_3^+O] = -\log_{10}[K_{In}] - \log_{10}\frac{[HIn]}{[In^-]}$$

$$pH = pK_{In} + \log_{10}\frac{[In^-]}{[HIn]} \text{ (Henderson's equation for indicator)}$$

At equivalence point;

$$[In^-] = [HIn] \quad \text{and} \quad pH = pK_{In}$$

Methyl orange: It is a very weak base and can be represented as MeOH. It is ionised in solution to give Me^+ and OH^- ions.

$$\underset{\text{Yellow}}{MeOH} \rightleftharpoons \underset{\text{Red}}{Me^+} + OH^-$$

Applying law of mass action,

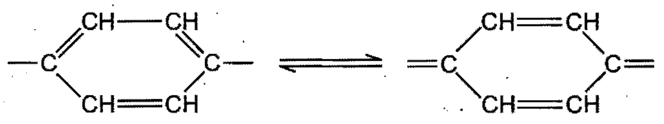
$$K = \frac{[Me^+][OH^-]}{[MeOH]}$$

In presence of an acid, OH^- ions are removed in the form of water molecules and the above equilibrium shifts to right hand side. Thus, sufficient Me^+ ions are produced which impart red colour to the solution. On addition of alkali, the concentration of OH^- ions increases in the solution and the equilibrium shifts to left hand side, *i.e.*, the ionisation of MeOH is practically negligible. Thus, the solution acquires the colour of unionised methyl orange molecules, *i.e.*, yellow.

This theory also explains the reason why phenolphthalein is not a suitable indicator for titrating a weak base against strong acid. The OH^- ions furnished by a weak base are not sufficient to shift the equilibrium towards right hand side considerably, *i.e.*, pH is not reached to 8.3. Thus, the solution does not attain pink colour. Similarly, it can be explained why methyl orange is not a suitable indicator for the titration of weak acid with strong base.

2. Quinonoid theory: According to this theory:

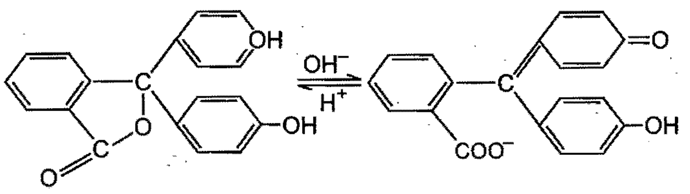
(a) The acid-base indicators exist in two tautomeric forms having different structures. Two forms are in equilibrium. One form is termed **benzenoid form** and the other **quinonoid form.**



(b) The two forms have different colours. The colour change is due to the interconversion of one tautomeric form into other.

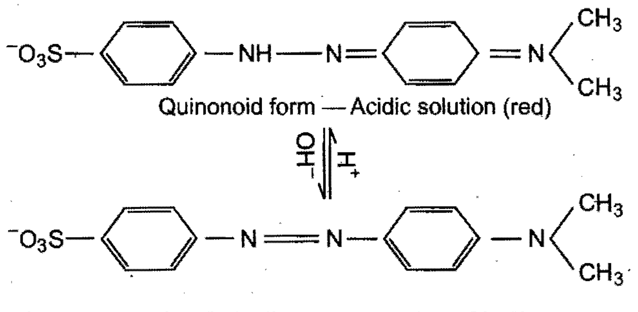
(c) One form mainly exists in acidic medium and the other in alkaline medium.

Thus, during titration the medium changes from acidic to alkaline or *vice-versa*. The change in pH converts one tautomeric form into other and thus, the colour change occurs.



Phenolphthalein has benzenoid form in acidic medium and thus, it is colourless while it has quinonoid form in alkaline medium which has pink colour.

Methyl orange has quinonoid form in acidic solution and benzenoid form in alkaline solution. The colour of benzenoid form is yellow while that of quinonoid form is red.

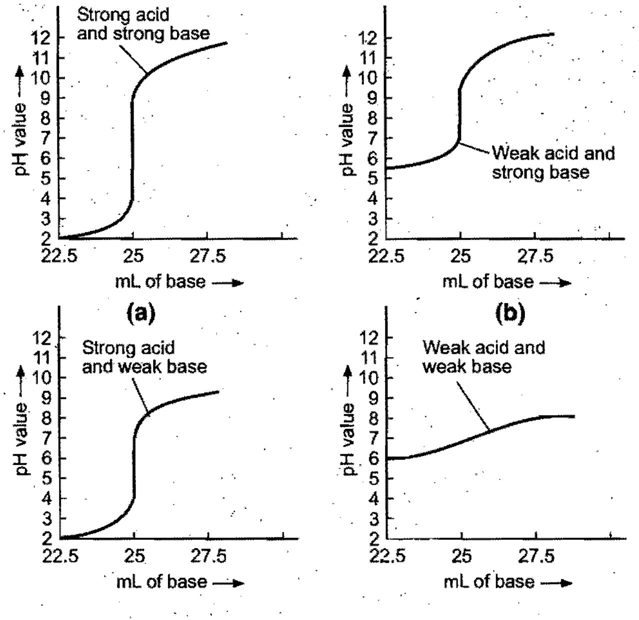


Selection of suitable indicator or choice of indicator

The neutralisation reactions are of the following four types:

(i) A strong acid *versus* a strong base. [Fig. 10.1 (a)]
(ii) A weak acid *versus* a strong base. [Fig. 10.1 (b)]
(iii) A strong acid *versus* a weak base. [Fig. 10.1 (c)]
(iv) A weak acid *versus* a weak base. [Fig. 10.1 (d)]

In order to choose a suitable indicator, it is necessary to understand the pH changes in the above four types of titrations. The change in pH in the vicinity of the equivalence point is most important for this purpose. The curve obtained by plotting pH as ordinate against the volume of alkali added as abscissa is known as neutralisation or titration curve. The titration curves of the above four types of neutralisation reactions are shown in Fig. 10.1 (a), 10.1 (b), 10.1 (c) and 10.1 (d).



(a) (b)

(c) (d)

Fig. 10.1

In each case 25 mL of the acid (*N*/10) has been titrated against a standard solution of a base (*N*/10). Each curve becomes almost vertical for some distance [except curve Fig. 10.1 (d)] and then bends away again. This region of abrupt change in pH indicates the equivalence point. For a particular titration, the indicator should be so selected that it changes its colour within vertical distance of the curve.

(i) Strong acid *vs.* strong base: pH curve of strong acid (say HCl) and strong base (say NaOH) is vertical over almost the pH range 4–10. So, the indicators phenolphthalein (pH range 8.3 to 10.5), methyl red (pH range 4.4–6.5) and methyl orange (pH range 3.2–4.5) are suitable for such a titration.

(ii) Weak acid *vs.* strong base: pH curve of weak acid (say CH_3COOH or oxalic acid) and strong base (say NaOH) is vertical over the approximate pH range 7 to 11. So, phenolphthalein is the suitable indicator for such a titration.

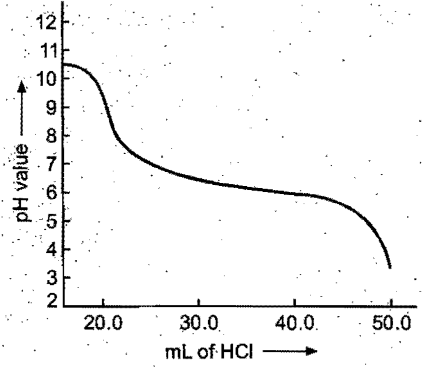


Fig. 10.2

(iii) Strong acid *vs.* weak base: pH curve of strong acid (say HCl or H_2SO_4 or HNO_3) with a weak base (say NH_4OH) is vertical over the pH range of 4 to 7. So, the indicators methyl red and methyl orange are suitable for such a titration.

(iv) Weak acid *vs.* weak base: pH curve of weak acid and weak base indicates that there is no vertical part and hence, no suitable indicator can be used for such a titration.

Titration of soluble carbonate with strong acid.

pH curve of sodium carbonate with HCl shows two inflection points (Fig. 10.2). First inflection point (pH = 8.5) indicates conversion of carbonate into bicarbonate.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$

As the inflection point lies in the pH range 8 to 10, phenolphthalein can be used to indicate the above conversion. The second inflection point (pH = 4.3) indicates the following reaction:

$$NaHCO_3 + HCl \longrightarrow NaCl + CO_2 + H_2O$$

As the point lies between 3 to 5, methyl orange can be used.

MISCELLANEOUS NUMERICAL EXAMPLES

Example 1. *Ionisation constant of NH_4^+ in water is 5.6×10^{-10} at 25°C. The rate constant for reaction of NH_4^+ and OH^- to form NH_3 and H_2O at 25°C is 3.4×10^{10} litre mol^{-1} sec^{-1}. Calculate rate constant for proton transfer from water to NH_3.* **(IIT 1996)**

Solution: $NH_3 + H_2O \underset{k_b}{\overset{k_f}{\rightleftharpoons}} NH_4^+ + OH^-; k_b = 3.4 \times 10^{10}$

$$NH_4^+ + H_2O \rightleftharpoons NH_4OH + H^+; k_a = 5.6 \times 10^{-10}$$

$$K_{Base} = \frac{k_f}{k_b} = \frac{K_w}{K_{Acid}} \quad \text{... (i)}$$

$$K_{Acid} \times K_{Base} = K_w \quad \text{... (ii)}$$

$$\therefore \quad \frac{k_f}{3.4 \times 10^{10}} = \frac{10^{-14}}{5.6 \times 10^{-10}}$$

$$k_f = 6.07 \times 10^5$$

Example 2. *K_a for the acid ionisation constant of Fe^{3+} to $Fe(OH)_2^{2+}$ and H^+ is 6.5×10^{-3}. What is the maximum pH value which could be used so that at least 95% of total Fe^{3+} ion in solution exists free?*

Solution: $Fe^{3+} + H_2O \rightleftharpoons Fe(OH)^{2+} + H^+$

$$K = \frac{[Fe(OH)_2]^{2+}[H^+]}{[Fe^{3+}]} = \frac{\frac{5}{100} \times [H^+]}{95/100} = 6.5 \times 10^{-3}$$

$$[H^+] = 0.12\,M$$

$$pH = -\log 0.12 = 0.91$$

Example 3. *K_a for ascorbic acid (HAsc) is 5×10^{-5}. Calculate the hydrogen ion concentration and percentage hydrolysis in an aqueous solution in which the concentration of Asc^- ions is 0.02 M.* **(IIT 1997)**

Solution:

$$\text{Degree of hydrolysis 'h'} = \sqrt{\frac{K_w}{CK_a}}$$

$$= \sqrt{\frac{10^{-14}}{0.02 \times 5 \times 10^{-5}}} = 10^{-4}$$

$$\% \text{ hydrolysis} = 0.01$$

$$pH = \frac{1}{2}[pK_w + pK_a + \log C]$$

$$= \frac{1}{2}[14 + (-\log 5 \times 10^{-5}) + \log 0.02]$$

$$pH = 8.3$$

$$[H^+] = 5 \times 10^{-9}\,M$$

Example 4. *Determine the number of moles of AgI which may be dissolved in 1 litre of 1 M CN^- solution K_{sp} for AgI and K_c for $Ag(CN)_2^-$ are $1.2 \times 10^{-17}\,M^2$ and $7.1 \times 10^{19}\,M^{-2}$ respectively.* **(IIT 1998)**

Solution: $\mathrm{AgI}(s) \rightleftharpoons \mathrm{Ag}^+ + \mathrm{I}^-$

$$K_{sp} = [\mathrm{Ag}^+][\mathrm{I}^-] = 1.2 \times 10^{-17}$$

$$\mathrm{Ag}^+ + 2\mathrm{CN}^- \rightleftharpoons [\mathrm{Ag(CN)}_2]^-$$

$$K_f = \frac{[\mathrm{Ag(CN)}_2^-]}{[\mathrm{Ag}^+][\mathrm{CN}^-]^2} = 7.1 \times 10^{19}$$

$$K_{\mathrm{eq}} = K_{sp} \times K_f$$

$$= \frac{[\mathrm{Ag(CN)}_2^-][\mathrm{I}^-]}{[\mathrm{CN}^-]^2} = 1.2 \times 10^{-7} \times 7.1 \times 10^{19}$$

$$= 8.52 \times 10^2$$

Let us consider the following equilibrium:

$$\begin{array}{lcccc} & \mathrm{AgI}(s) + & 2\mathrm{CN}^- \rightleftharpoons & [\mathrm{Ag(CN)}_2^-] + & \mathrm{I}^- \\ t=0 & & 1 & 0 & 0 \\ t_{eq} & & 1-2x & x & x \end{array}$$

Let 'x' moles of AgI be dissolved in CN^- solution.

Then,

$$\mathrm{AgI} + 2\mathrm{CN}^- \rightleftharpoons \mathrm{Ag(CN)}_2^- + \mathrm{I}^-$$

$$K_{\mathrm{eq}} = 8.5 \times 10^2 = \frac{x \times x}{(1-2x)^2}$$

$$\frac{x}{1-2x} = 29.2$$

$$x = 0.49 \text{ mole}$$

Example 5. *Given* $Ag(NH_3)_2^+ \rightleftharpoons Ag^+ + 2NH_3$, $K_c = 6.2 \times 10^{-8}$ *and* K_{sp} *of AgCl is* 1.8×10^{-10} *at* $298\,K$. *Calculate concentration of the complex in* $1\,M$ *aqueous ammonia.* (IIT 1998)

Solution: $\mathrm{AgCl} \rightleftharpoons \mathrm{Ag}^+ + \mathrm{Cl}^-$

On adding ammonia solution, complex formation takes place.

$$\underset{(x-y)}{\mathrm{Ag}^+} + \underset{1}{2\mathrm{NH}_3} \rightleftharpoons \underset{y}{[\mathrm{Ag(NH}_3)_2]^+} \qquad \text{. . . (i)}$$

where, x = solubility of AgCl in NH_3

y = amount of complex formed

$$K_{sp} \text{ of AgCl} = [\mathrm{Ag}^+][\mathrm{Cl}^-]$$

$$1.8 \times 10^{-10} = (x-y) \times x \qquad \text{... (ii)}$$

$$K_c \text{ for equation (i)} = \frac{[\mathrm{Ag(NH}_3)_2]^+}{[\mathrm{Ag}^+][\mathrm{NH}_3]^2}$$

$$\frac{1}{6.2 \times 10^{-8}} = \frac{y}{(x-y)1} \qquad \text{... (iii)}$$

On solving equations (ii) and (iii), we get

$$y = 0.0539\,M$$

Example 6. *An aqueous solution of aniline of concentration 0.24 is prepared. What concentration of sodium hydroxide is needed in this solution so that anilinium ion concentration remains at* 1×10^{-8} *M?* K_a *for* $C_6H_5NH_3^+$ *is* 2.4×10^{-5} *M.* (IIT 1996)

Solution: $\mathrm{C_6H_5NH_2} + \mathrm{H_2O} \rightleftharpoons \mathrm{C_6H_5NH_3^+} + \mathrm{OH}^-$

Thus, $$K_b = \frac{[\mathrm{C_6H_5NH_3^+}][\mathrm{OH}^-]}{[\mathrm{C_6H_5NH_2}]} \qquad \text{... (i)}$$

Also K_b for

$$\mathrm{C_6H_5NH_2} = \frac{K_w}{K_a \text{ for } \mathrm{C_6H_5NH_3^+}} = \frac{10^{-14}}{2.4 \times 10^{-5}} \qquad \text{... (ii)}$$

Since, dissociation of $\mathrm{C_6H_5NH_2}$ occurs in presence of NaOH and thus dissociation of $\mathrm{C_6H_5NH_2}$ will be suppressed.

Thus, $[\mathrm{OH}^-] = ?$; $[\mathrm{C_6H_5NH_2}] = 0.24$; $[\mathrm{C_6H_5NH_3^+}] = 10^{-8}$

Therefore, $$\frac{10^{-14}}{2.4 \times 10^{-5}} = \frac{10^{-8} \times [\mathrm{OH}^-]}{0.24}$$

$$\therefore \quad [\mathrm{OH}^-] = \frac{0.24 \times 10^{-14}}{2.4 \times 10^{-5} \times 10^{-8}} = 0.01$$

$$\therefore \quad [\mathrm{NaOH}] = 0.01\,M$$

Example 7. *A solution contains* 0.05 *mol litre*$^{-1}$ *of* Ba^{2+} *ions and* 0.002 *mol litre*$^{-1}$ *of* Ag^+ *ions. The metals are to be precipitated by addition of chromate ions,* CrO_4^{2-}. *Which ion precipitates first? What percentage of this ion remain in the solution when the second ion begins to precipitate?*

$K_{sp}\ Ag_2CrO_4 = 3 \times 10^{-12}$, $\quad K_{sp}\ BaCrO_4 = 1 \times 10^{-10}$

Solution: $\mathrm{CrO_4^{2-}}$ ion concentration required for precipitation:

For $\mathrm{BaCrO_4}$:

$$[\mathrm{CrO_4^{2-}}] = \frac{K_{sp}\ \mathrm{BaCrO_4}}{[\mathrm{Ba}^{2+}]} = \frac{10^{-10}}{0.05} = 20 \times 10^{-10}\,M$$

For $\mathrm{Ag_2CrO_4}$:

$$[\mathrm{CrO_4^{2-}}] = \frac{K_{sp}\ \mathrm{Ag_2CrO_4}}{[\mathrm{Ag}^+]^2} = \frac{3 \times 10^{-12}}{[0.002]^2} = 0.75 \times 10^{-6}\,M$$

Ba^{2+} will be precipitated first because it requires low concentration of $\mathrm{CrO_4^{2-}}$. Remaining conc. of Ba^{2+} when Ag^+ will start precipitation.

$$[\mathrm{Ba}^{2+}]_{\text{Remaining}} = \frac{K_{sp}\ \mathrm{BaCrO_4}}{[\mathrm{CrO_4^{2-}}]} = \frac{10^{-10}}{0.75 \times 10^{-6}} = 1.33 \times 10^{-4}\,M$$

$$\%\text{of remaining } \mathrm{Ba}^{2+} = \frac{1.33 \times 10^{-4}}{0.05} \times 100 = 0.26\%$$

Example 8. *Calculate pH change which results when* 50 *mL of* 0.1 *M* HNO_3 *is added to each of the following at* 25° *C:*

(*a*) 1.00 *litre of pure water.*

(*b*) 1.00 *litre of a solution containing acetic acid and sodium acetate each of* 0.1 *M concentration.*

Solution:

(a) Molarity after dilution $= M_2$

$$M_1V_1 = M_2V_2$$

$$0.1 \times 50 = M_2 \times 1050$$

$$M_2 = 0.00476$$

$$\text{pH} = -\log(0.00476) = 2.322$$

Change in pH of water $= 7 - 2.322 = 4.68$

(b) $$\text{pH} = \text{p}K_a + \log\frac{[\text{Salt}]}{[\text{Acid}]}$$

$$= 4.7447 + \log\frac{0.1}{0.1} = 4.7447$$

Moles of HNO_3 added $= \frac{0.1}{1000} \times 50 = 5 \times 10^{-3}$; it will convert sodium acetate to acetic acid.

$$\text{pH} = 4.7447 + \log\left[\frac{0.1 - 5\times10^{-3}}{0.1 + 5\times10^{-3}}\right] = 4.70123$$

Change in $\text{pH} = 4.7447 - 4.70123 = 0.043$

Example 9. *A certain monoprotic acid (weak) serves as indicator. Assuming that colour change is seen when 1/3rd of the indicator has been converted to ions and that at end point the pH of solution is 6, what is the value of pK_{In}?*

Solution: $\text{HIn} \rightleftharpoons \text{H}^+ + \text{In}^-$ (Ionization equilibrium of indicator)

$$\text{pH} = \text{p}K_{\text{In}} + \log_{10}\frac{[\text{In}^-]}{[\text{HIn}]}$$

$$6 = \text{p}K_{\text{In}} + \log_{10}\left[\frac{0.33}{0.67}\right] \quad \text{(1/3rd conversion)}$$

$$\text{p}K_{\text{In}} = 6.307$$

Example 10. *What is the minimum pH of a solution 0.10 M in Mg^{2+} from which $Mg(OH)_2$ will not precipitate? K_{sp} $Mg(OH)_2 = 1.2\times10^{-11}\ M^3$.*

Solution: Given that,

$$K_{sp}\ \text{Mg(OH)}_2 = [\text{Mg}^{2+}][\text{OH}^-]^2$$

$$1.2\times10^{-11} = [0.1][\text{OH}^-]^2$$

$$[\text{OH}^-]^2 = 1.2\times10^{-10}$$

$$[\text{OH}^-] = 1.0954\times10^{-5}\ M$$

$$\text{pOH} = -\log_{10}(1.0954\times10^{-5}) = 4.96$$

$$\text{pH} = 14 - 4.96 = 9.04$$

Thus, at 9.04 pH, precipitation will not take place.

Example 11. *What is the pH of 10^{-7} mol litre^{-1} HCl at 25° C?*

Solution: $$[\text{H}^+] = [\text{H}^+]_{\text{Acid}} + [\text{H}^+]_{\text{Water}}$$

$$= 10^{-7} + 10^{-7} = 2\times10^{-7}\ M$$

$$\text{pH} = -\log(2\times10^{-7}) = 6.70$$

Example 12. *A solution contains 0.1 M Cl^- and 0.001 M CrO_4^{2-}. If solid $AgNO_3$ is gradually added to this solution, which will precipitate first, AgCl or Ag_2CrO_4? Assume that the addition causes no change in volume. Given $K_{sp}\ AgCl = 1.7\times10^{-10}M^2$ and $K_{sp} Ag_2CrO_4 = 1.79\times10^{-12}M^3$.*

What per cent of Cl^- remains in the solution when CrO_4^{2-} starts precipitating?

Solution: Ag^+ ion concentration required for precipitation:

For AgCl:

$$[\text{Ag}^+] = \frac{K_{sp}\ \text{AgCl}}{[\text{Cl}^-]} = \frac{1.7\times10^{-10}}{0.1} = 1.7\times10^{-9}M$$

For Ag_2CrO_4:

$$[\text{Ag}^+]^2 = \frac{K_{sp}\ \text{Ag}_2\text{CrO}_4}{[\text{CrO}_4^{2-}]} = \frac{1.79\times10^{-12}}{[0.001]}$$

$$[\text{Ag}^+] = [1.79\times10^{-9}\ \text{M}^2]^{1/2}$$

$$= 4.23\times10^{-5}M$$

AgCl will precipitate first because it requires low conc. of Ag^+.

$$\text{Remaining conc. of } [\text{Cl}^-] = \frac{K_{sp} \text{ of AgCl}}{[\text{Ag}^+]}$$

$$= \frac{1.7\times10^{-10}}{4.23\times10^{-5}} = 4.01\times10^{-6}M$$

$$\%\ \text{Remaining conc. of } [\text{Cl}^-] = \frac{4.01\times10^{-6}}{0.1}\times100 = 4\times10^{-3}\%$$

Example 13. *25 mL of 0.1 mol dm^{-3} aqueous pyridine ($K_b = 1.7\times10^{-9}$ mol dm^{-3}) is titrated with 0.1 mol dm^{-3} hydrochloric acid. Calculate the pH initially, at equivalence and after 30 cm^3 hydrochloric acid have been added.*

Solution: For salt of weak base and strong acid:

$$\text{pH} = \frac{1}{2}[\text{p}K_w - \text{p}K_b - \log C]$$

$$\text{p}K_w = 14;\quad \text{p}K_b = -\log_{10} 1.7\times10^{-9} = 8.769;\quad C = 0.05$$

$$\text{pH} = \frac{1}{2}[14 - 8.769 + 1.30102] = 3.27 \quad \text{(pH at equivalence)}$$

5 cc 0.1 M HCl will be considered for pH.

$$\text{Mole of HCl remaining} = \frac{0.1}{1000}\times5 = 5\times10^{-4}$$

$$\text{New molarity} = \frac{5\times10^{-4}}{55}\times1000 = 0.00909\,M$$

$$\text{pH} = -\log[0.00909] = 2.04$$

Example 14. *If very small amount of phenolphthalein is added to 0.15 mol litre^{-1} solution of sodium benzoate, what fraction of the indicator will exist in the coloured form? State any assumption that you make.*

$$K_a\ (\text{Benzoic acid}) = 6.2\times10^{-5},\ K_w\ (H_2O) = 1\times10^{-14},$$

$$K_{In}\ (\text{Phenolphthalein}) = 3.16\times10^{-10}$$

Solution: Formula for pH of salt hydrolysis:

$$pH = \frac{1}{2}[pK_w + pK_a + \log C]$$

$$= \frac{1}{2}[14 - \log_{10} 6.2 \times 10^{-5} + \log 0.15]$$

$$= 8.6918$$

Formula for pH of indicator:

$$pH = pK_{In} + \log_{10}\frac{[In^-]}{[HIn]}$$

$$8.6918 = -\log_{10}(3.16 \times 10^{-10}) + \log_{10}\frac{[In^-]}{[HIn]}$$

$0.16 = [In^-]/[HIn] =$ Fraction of indicator in coloured form.

Example 15. *How much NH_3 must be added to 0.004 M Ag^+ solution to prevent the precipitation of AgCl when (Cl^-) reaches 0.001 M? K_{sp} for AgCl is 1.8×10^{-10} and K for $Ag(NH_3)_2^+$ is 5.9×10^{-8}.*

Solution:

$$[Ag^+] = \frac{K_{sp}}{[Cl^-]} = \frac{1.8 \times 10^{-10}}{0.001} = 1.8 \times 10^{-7}\ M$$

NH_3 is added to keep the conc. of Ag^+ below $1.8 \times 10^{-7}\ M$ to prevent precipitation.

$[Ag(NH_3)_2]^+$ at above limiting condition

$$= 0.004 - 1.8 \times 10^{-7} \approx 0.004\ M$$

$$[Ag(NH_3)_2]^+ \rightleftharpoons Ag^+ + 2NH_3$$

$$K_d = \frac{[Ag^+][NH_3]^2}{[Ag(NH_3)_2]^+}$$

$$5.9 \times 10^{-8} = \frac{[1.8 \times 10^{-7}][NH_3]^2}{[0.004]}$$

$$[NH_3] = 0.036\ M$$

$$[NH_3]_{Total} = [NH_3]_{Free} + [NH_3]_{Complexed}$$

$$= 0.036 + 2 \times 0.004 = 0.044 \text{ mol/litre}$$

Example 16. *Calculate the percentage error in hydronium ion concentration made by neglecting ionization of water in 10^{-6} M NaOH.*

Solution: $[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-6}} = 10^{-8}\ M$

[Neglecting ionization of water]

Consider ionization of water.

$$[H_3O^+] = y \quad [OH^-] = (y + 10^{-6})$$

$$[H_3O^+][OH^-] = K_w = 10^{-14}$$

$$y[y + 10^{-6}] = 10^{-14}$$

$$y^2 + 10^{-6}y - 10^{-14} = 0$$

On solving for y, $y = 9.9 \times 10^{-9}$

$$\%\text{ error} = \frac{10^{-8} - 9.9 \times 10^{-9}}{9.9 \times 10^{-9}} \times 100 = 1\%$$

Example 17. *Determine the silver ion concentration in a 0.2 M solution of $[Ag(NH_3)_2]NO_3$.*

$$Ag(NH_3)_2^+ \rightleftharpoons Ag^+ + 2NH_3$$

$$K_{diss.} = \frac{[Ag^+][NH_3]^2}{[Ag(NH_3)_2^+]} = 6.8 \times 10^{-8}$$

Solution: Let concentration of Ag^+ at equilibrium be 'C' M.

$\therefore$ $[NH_3] = 2C\ M$

$$K = \frac{[Ag^+][NH_3]^2}{[Ag(NH_3)_2^+]}$$

$$6.8 \times 10^{-8} = \frac{C \times 4C^2}{0.2}$$

$$C = 0.0015\ M$$

Example 18. *The solubility of silver acetate in pure water at 25° C is 8.35 g litre^{-1} and 61.8 g litre^{-1} in an acid solution of pH = 3. Calculate:*

(i) K_{sp} of silver acetate and

(ii) dissociation constant of acetic acid.

Solution: (i) CH_3COOAg (mw) = 167

$$S = \frac{8.35}{167} \text{ mol / litre} = 0.05\ M$$

$$K_{sp} = S^2 = (0.05)^2 = 2.5 \times 10^{-4}\ M$$

(ii) Use expression of salt hydrolysis to calculate K_a.

$$pH = \frac{1}{2}[pK_w + pK_a + \log C]$$

$$K_a = 1.8 \times 10^{-5}$$

Example 19. *How many moles of NH_3 must be added to 1 litre of a 0.1 M $AgNO_3$ to reduce Ag^+ concentration to 2×10^{-7} M?*

$$Ag(NH_3)_2^+ \rightleftharpoons Ag^+ + 2NH_3$$

$$K_{diss.} = \frac{[Ag^+][NH_3]^2}{[Ag(NH_3)_2^+]} = 6.8 \times 10^{-8}$$

Solution: $[Ag(NH_3)_2]^+ \approx 0.1\ M$

$$[Ag^+] = 2 \times 10^{-7}$$

$$K = \frac{[Ag^+][NH_3]^2}{[Ag(NH_3)_2]^+}$$

$$6.8 \times 10^{-8} = \frac{2 \times 10^{-7}[NH_3]^2}{0.1}$$

$$[NH_3] = 0.184\ M$$

It is the concentration of free NH_3.

$$[NH_3]_{Total} = [NH_3]_{Free} + [NH_3]_{Complexed}$$

$$= 0.184 + 2 \times 0.1 = 0.384\ M$$

Example 20. *A buffer of pH 8.50 is prepared from 0.02 mole of KCN. The desired volume of buffer solution is to be 1* *litre. How will you make this buffer by using HCl? What is the change after addition of* 0.5×10^{-4} *mole HCl to* $100\ cm^3$ *and same amount of NaOH in* $100\ cm^3$ *of buffer?* (K_a *HCN* $= 6.2 \times 10^{-10}$)

Solution:

$$\underset{(0.02-x)}{\text{KCN}} + \underset{x}{\text{HCl}} \longrightarrow \underset{x}{\text{KCl}} + \underset{x}{\text{HCN}}$$

$$\text{pH} = \text{p}K_a + \log \frac{[\text{Salt}]}{[\text{Acid}]}$$

$$8.50 = -\log(6.2 \times 10^{-10}) + \log_{10}\left[\frac{0.02-x}{x}\right]$$

$$8.50 = 9.2076 + \log_{10}\left[\frac{0.02-x}{x}\right]$$

$$x = 0.01672$$

(Buffer is prepared by adding 0.01672 mole of HCl in salt KCN.)

Calculation of pH change when HCl is added:

Moles of HCl added in 1 litre buffer $= 0.5 \times 10^{-3}$

HCl will convert more salt into acid.

$$\text{pH} = 9.2076 + \log_{10}\frac{0.00382 - 0.5 \times 10^{-3}}{0.01672 + 0.5 \times 10^{-3}} = 9.4156$$

pH change $= 9.4156 - 8.50 = 0.9156$

Example 21. *What* (H_3O^+) *must be maintained in a saturated* H_2S *solution to precipitate* Pb^{2+}, *but not* Zn^{2+} *from a solution in which each ion is present at a concentration of* $0.01M$? (K_{sp} $H_2S = 1.1 \times 10^{-22}$ *and* K_{sp} *ZnS* $= 1.0 \times 10^{-21}$) **(IIT 2000)**

Solution:

$$K_{sp}\ \text{ZnS} = [\text{Zn}^{2+}][\text{S}^{2-}] = 1.0 \times 10^{-21}$$

or $$0.01 \times [\text{S}^{2-}] = 1.0 \times 10^{-21}$$

or $$[\text{S}^{2-}] = 1.0 \times 10^{-19}$$

To start precipitation of ZnS, the required concentration of sulphide ions is 1.0×10^{-19}.

$$K_{sp}\ \text{H}_2\text{S} = [\text{H}^+]^2[\text{S}^{2-}] = 1.1 \times 10^{-22}$$

or $$[\text{H}^+]^2 = \frac{1.1 \times 10^{-22}}{1.0 \times 10^{-19}} = 1.1 \times 10^{-3}$$

or $$[\text{H}^+] = 0.0331M$$

Thus, the hydrogen ion concentration higher than 0.0331 M will reduce the concentration of sulphide ions which will not allow the precipitation of Zn^{2+} ions as ZnS and under this condition only PbS precipitation occurs.

Example 22. *The average concentration of* SO_2 *in the atmosphere over a city on a certain day is 10 ppm, when the average temperature is 298 K. Given that the solubility of* SO_2 *in water at 298 K is 1.3653 mol litre*$^{-1}$ *and the* pK_a *of* H_2SO_3 *is 1.92, estimate the pH of rain on that day.* **(IIT 2000)**

Solution:

$$\text{p}K_a = 1.92$$

$$K_a = \text{antilog}(-1.92) = 0.012$$

$$\begin{array}{llll} & \text{H}_2\text{SO}_3 & \rightleftharpoons\ 2\text{H}^+ & +\ \text{SO}_3^{2-} \\ t=0 & C & 0 & 0 \\ t_{eq} & C - C\alpha & 2C\alpha & C\alpha \end{array}$$

$$K_a = \frac{[\text{H}^+]^2[\text{SO}_3^{2-}]}{[\text{H}_2\text{SO}_3]}$$

$$0.012 = \frac{(2C\alpha)^2 \times C\alpha}{C(1-\alpha)} = \frac{4C^2\alpha^3}{(1-\alpha)} \approx 4C^2\alpha^3$$

$$0.012 = 4 \times (1.3653)^2 \times \alpha^3$$

or $$\alpha = 0.117$$

$$[\text{H}^+] = 2C\alpha = 2 \times 1.3653 \times 0.117 = 0.3194$$

$$\text{pH} = -\log_{10}(0.3194) = 0.495$$

Example 23. 0.16 *g of* N_2H_4 *are dissolved in water and the total volume made up to* 500 *mL. Calculate the percentage of* N_2H_4 *that has reacted with water at this dilution. The* K_b *for* N_2H_4 *is* 4.0×10^{-6} *M.* **(IIT 1998)**

Solution: Concentration of N_2H_4,

$$[\text{N}_2\text{H}_4] = \frac{0.16}{32} \times \frac{1000}{500} = 0.01M$$

$$\begin{array}{lllll} & \text{N}_2\text{H}_4 & +\ \text{H}_2\text{O} \rightleftharpoons & \text{N}_2\text{H}_5^+ & +\ \text{OH}^- \\ \text{At equilibrium} & 1-\alpha & & \alpha & \alpha \end{array}$$

$$K_b = C\alpha^2 \text{ or } \alpha^2 = \frac{K_b}{C} = \frac{4.0 \times 10^{-6}}{0.01} = 4 \times 10^{-4}$$

or $$\alpha = 2 \times 10^{-2}$$

i.e., 2%

Example 24. *What will be the resultant pH when* 200 *mL of an aqueous solution of HCl* (*pH* = 2) *is mixed with* 300 *mL of an aqueous solution of NaOH* (*pH* = 12)? **(IIT 1998)**

Solution: pH of HCl = 2 $\therefore [\text{HCl}] = 10^{-2}\ M$

pH of NaOH = 12 $\therefore [\text{NaOH}] = 10^{-2}\ M$

$$\begin{array}{llll} & \text{HCl} & +\ \text{NaOH} \rightleftharpoons & \text{NaCl} + \text{H}_2\text{O} \\ \text{meq after reaction} & 0 & 100 \times 10^{-2} & \\ & & = 1 & \end{array}$$

$$[\text{OH}^-] \text{ after reaction} = \frac{1}{500} = 2 \times 10^{-3}\ M$$

$$\text{pOH} = -\log[\text{OH}^-] = -\log 2 \times 10^{-3} = 2.7$$

$$\therefore \quad \text{pH} = 14 - 2.7 = 11.3$$

Example 25. 500 *mL of* 0.2 *M aqueous solution of acetic acid is mixed with* 500 *mL of* 0.2 *M HCl at* 25°*C.*

(*a*) *Calculate the degree of dissociation of acetic acid in the resulting solution and pH of the solution.*

(*b*) *If* 6 *g of NaOH is added to the above solution, determine final pH. Assume there is no change in volume on mixing.* K_a *for acetic acid is* 1.75×10^{-5} *M.* **(IIT 2002)**

Solution: (a) Conc. of HCl and CH_3COOH after mixing will be 0.1 M.

$$\begin{array}{lllll} & \text{CH}_3\text{COOH} & \rightleftharpoons \text{CH}_3\text{COO}^- & +\ \text{H}^+ & \\ t=0 & 0.1 & 0 & 0.1 & \text{(from HCl)} \\ t_{eq} & 0.1 - x & x & (0.1 + x) & \end{array}$$

$$K_a = \frac{[\text{CH}_3\text{COO}^-][\text{H}^+]}{[\text{CH}_3\text{COOH}]}$$

$$1.75\times10^{-5}=\frac{x\times(0.1+x)}{(0.1-x)}$$

On approximation, $x\approx1.75\times10^{-5}$

$$[\mathrm{H^+}]=0.1+x\approx0.1\,M$$

$$\mathrm{pH}=-\log[0.1]=1$$

Degree of dissociation of acetic acid $=\dfrac{1.75\times10^{-5}}{0.1}=1.75\times10^{-4}$

(b) Number of moles of NaOH added $=\dfrac{6}{40}=0.15$

$$\begin{array}{lcccccc} & CH_3COOH & + HCl & + NaOH & \rightleftharpoons CH_3COONa & + NaCl & + H_2O \\ t=0 & 0.1 & 0.1 & 0.15 & 0 & 0 & 0 \\ t_{eq} & 0.05 & 0 & 0 & 0.05 & 0 & 0 \end{array}$$

$$\mathrm{pH}=\mathrm{p}K_a+\log\frac{[\text{Salt}]}{[\text{Acid}]}$$

$$=-\log1.75\times10^{-5}+\log\frac{0.05}{0.05}=4.757$$

Example 26. *Will the pH of water be same at 4°C and 25°C? Explain.* (IIT 2003)

Solution: We know that,

$$K_w=[\mathrm{H^+}][\mathrm{OH^-}]$$

At 25°C, $[\mathrm{H^+}]=[\mathrm{OH^-}]=1.01\times10^{-7}\,M$

$$\mathrm{pH}=-\log_{10}[\mathrm{H^+}]=-\log_{10}[10^{-7}]=7$$

At 4°C, ionization of water will be less than that at 25°C.

∴ at 25° C $K_w=[\mathrm{H^+}][\mathrm{OH^-}]$ will be less than 10^{-14}. Thus, pH of water will be more than 7 at 4°C.

Example 27. *0.1 M NaOH is titrated with 0.1 M HA till the end point; K_a for HA is 5.6×10^{-6} and degree of hydrolysis is less compared to 1. Calculate pH of the resulting solution at the end point.* (IIT 2004)

Solution: Neutralization of *HA* with NaOH may be given as,

$$HA+\mathrm{NaOH}\longrightarrow\mathrm{Na}A+\mathrm{H_2O}$$

Concentration of salt will be $\dfrac{0.1}{2}M$, *i.e.*, 0.05 *M*, since volume will be double. pH of the salt after hydrolysis may be calculated as,

$$\mathrm{pH}=\frac{1}{2}[\mathrm{p}K_w+\mathrm{p}K_a+\log C]\qquad\text{... (i)}$$

$$\mathrm{p}K_w=14$$

$$\mathrm{p}K_a=-\log K_a=-\log(5.6\times10^{-6})=5.2518$$

$$\log C=\log0.05=-1.3010$$

Substituting the values of $\mathrm{p}K_w$, $\mathrm{p}K_a$ and $\log C$ in eq. (i) we get,

$$\mathrm{pH}=\frac{1}{2}[14+5.2518-1.3010]=8.9754$$

Example 28. *A solution of acetic acid is 1% ionised. Determine the molar concentration of acetic acid. (ionization constant for acetic acid $=1.8\times10^{-5}$)* [BCECE (Mains) 2006]

Solution: $CH_3COOH\rightleftharpoons CH_3COO^-+H^+$

$$\begin{array}{lccc} t_0 & C & 0 & 0 \\ t_{eq.} & C-C\alpha & C\alpha & C\alpha \end{array}$$

$$K_a=\frac{[CH_3COO^-][H^+]}{[CH_3COOH]}=\frac{C\alpha\times C\alpha}{C-C\alpha}$$

$$=\frac{C\alpha^2}{1-\alpha}\qquad\left(\alpha=\frac{1}{100}=0.01\right)$$

$$1.8\times10^{-5}=\frac{C\times(0.01)^2}{1-0.01}$$

$$1.8\times10^{-5}\approx C\times10^{-4}$$

$$C=0.18\,M$$

Example 29. *A mixture of H_2O and solid AgCl shaken to obtain saturated solution. The solid is filtered and to 100 mL of filtrate, 100 mL of 0.03 M NaBr is added, will a precipitate be formed?* [BCECE (Mains) 2006]

$$K_{sp}\ AgCl=10^{-10},\ K_{sp}\ AgBr=5\times10^{-13}$$

Solution: Let solubility of AgCl is '*S*'

$$\therefore\quad K_{sp}\ \mathrm{AgCl}=S^2$$

$$S=\sqrt{K_{sp}}$$

$$=\sqrt{10^{-10}}=10^{-5}$$

When, 100 mL of both AgCl and NaBr are mixed then, concentration of $\mathrm{Ag^+}$ and $\mathrm{Br^-}$ will be:

$$[\mathrm{Ag^+}]=\frac{100\times10^{-5}}{200}=0.5\times10^{-5}M$$

$$[\mathrm{Br^-}]=\frac{100\times0.03}{200}=0.015\,M$$

Ionic product of AgBr $=0.5\times10^{-5}\times0.015$

$$=7.5\times10^{-8}$$

Since, ionic product of AgBr is greater than its solubility product, hence AgBr will be precipitated.

SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. Strong and weak electrolytes: Electrolytes which ionise almost completely when dissolved in water are termed strong electrolytes while those electrolytes which ionise to small extent are termed as weak electrolytes. The degree of ionisation and electrical conductivity of strong electrolytes have high values while weak electrolytes possess small values. NaOH, HCl, H_2SO_4, $BaCl_2$, KCl, etc., are strong electrolytes while NH_4OH, CH_3COOH, $(NH_4)_2CO_3$, HCN, etc., are weak electrolytes.

Degree of ionisation

$$= \frac{\text{Number of molecules of the electrolyte dissociated into ions}}{\text{Total number of molecules of the electrolyte dissolved}}$$

2. Ostwald's dilution law: A dynamic equilibrium exists between ions and unionised molecules of the electrolyte in solution and law of mass action can be applied to this equilibrium also. Consider a binary electrolyte AB.

$$\begin{array}{lccc} & AB & \rightleftharpoons & A^+ + B^- \\ \text{Initial concentration} & C & & 0 \quad\; 0 \\ \text{Conc. at equilibrium} & C(1-\alpha) & & C\alpha \quad C\alpha \end{array}$$

where, α is the degree of dissociation

$$K = \frac{[A^+][B^-]}{[AB]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)} = \frac{C \times \alpha^2}{(1-\alpha)}$$

K is termed ionisation constant. For a weak electrolyte, the value of α is very small in comparison to 1. Thus, $1-\alpha \to 1$.

$$K = C\alpha^2 \quad \text{or} \quad \alpha = \sqrt{\frac{K}{C}} \quad \text{or} \quad \alpha = \sqrt{KV}$$

Where, V is the volume containing one mole of electrolyte.

The degree of dissociation of a weak electrolyte is proportional to the square root of dilution. It increases as V increases and approaches to one at high dilution.

This law holds good for weak electrolytes. In the case of acids, ionisation constant is represented as K_a and in case of bases K_b. Polybasic acids ionise stepwise and each step has its own ionisation constant.

For example, H_3PO_4 ionises in three steps:

Step I: $H_3PO_4 \rightleftharpoons H^+ + H_2PO_4^-$; $K_1 = \dfrac{[H^+][H_2PO_4^-]}{[H_3PO_4]}$

Step II: $H_2PO_4^- \rightleftharpoons H^+ + HPO_4^{2-}$; $K_2 = \dfrac{[H^+][HPO_4^{2-}]}{[H_2PO_4^-]}$

Step III: $HPO_4^{2-} \rightleftharpoons H^+ + PO_4^{3-}$; $K_3 = \dfrac{[H^+][PO_4^{3-}]}{[HPO_4^{2-}]}$

$$H_3PO_4 \rightleftharpoons 3H^+ + PO_4^{3-}$$

$$K = K_1 \times K_2 \times K_3$$

Generally, $K_1 > K_2 > K_3$

3. Common ion effect: The degree of dissociation of a weak electrolyte is suppressed by the presence of another electrolyte (strong) containing a common ion. As a result of common ion effect, the concentration of the ion not in common in two electrolytes decreases.

4. Solubility product: In a saturated solution of an electrolyte, two equilibria exist in solution. It can be represented as:

$$\underset{\text{Solid}}{AB} \rightleftharpoons \underset{\substack{\text{Unionised}\\ \text{(dissolved)}}}{AB} \rightleftharpoons \underbrace{A^+ + B^-}_{\text{Ions}}$$

$$K = \frac{[A^+][B^-]}{[AB]}$$

In saturated solution, the value of $[AB]$ is fixed at a definite temperature.

Thus, $K[AB] = [A^+][B^-] = K_s$ (constant)

K_s is termed solubility product. For a general equation,

$$A_xB_y \rightleftharpoons xA^{y+} + yB^{x-}$$

$$K_s = [A^{y+}]^x[B^{x-}]^y$$

Thus, solubility product is defined as the product of concentrations of ions raised to a power equal to the number of times the ions occur in the equation representing the dissociation of the electrolyte at a given temperature when the solution is saturated.

For the precipitation of an electrolyte, it is necessary that the ionic product must exceed its solubility product.

Relationship between solubility and solubility product: Salts like AgI, $PbSO_4$, $BaSO_4$, PbI_2, etc., which are considered to be insoluble do possess solubility. It is assumed that whole of the dissolved electrolyte is present in the form of ions.

$$A_x \times B_y = \underset{xS}{xA^{y+}} + \underset{yS}{yB^{x-}}$$

Let 'S' mol per litre be solubility of the salt; then

$$K_s = [A^{y+}]^x[B^{x-}]^y$$

$$= (xS)^x(yS)^y$$

$$= x^x y^y (S)^{x+y}$$

(a) 1 : 1 type salts such as AgCl, AgI, $BaSO_4$, $PbSO_4$, etc.

$$K_s = S^2 \quad \text{or} \quad S = \sqrt{K_s}$$

(b) 1 : 2 or 2 : 1 type salts such as Ag_2CO_3, Ag_2CrO_4, PbI_2, CaF_2, etc.

$$K_s = S \times (2S)^2 = 4S^3$$

$$S = \sqrt[3]{\frac{K_s}{4}}$$

(c) 1 : 3 type salts such as AlI_3, $Fe(OH)_3$, etc.

$$K_s = S \times (3S)^3 = 27S^4$$

$$S = \sqrt[4]{\frac{K_s}{27}}$$

The presence of common ion affects the solubility of salt. Let C be the concentration of strong electrolyte containing common ion and new solubility of salt be S'. For an electrolyte, AB,

$$S^2 = K_s = S'(S'+C)$$

Applications of Solubility Product and Common ion Effect

(i) Purification of common salt.
(ii) Salting out of soap.
(iii) Precipitation of the sulphides of group (II) and (IV).
(iv) Precipitation of the hydroxides of group (III).
(v) Using excess of precipitating agent in gravimetric estimations.
(vi) Predicting precipitation in ionic reactions.

5. Acids and Bases: Three important concepts are:

(i) Arrhenius concept: All substances which furnish H^+ ions when dissolved in water are called acids while those which ionise in water to furnish OH^- ions are called bases. Actually free H^+ ions do not exist in water. They combine with water to form hydronium ions (H_3O^+). The reaction between an acid and a base is termed as neutralisation.

All aqueous solutions contain both H^+ and OH^- ions. However, their relative amounts are different in different solutions.

$H^+ > OH^-$ —solution will be acidic
$H^+ < OH^-$ —solution will be basic
$H^+ = OH^-$ —solution will be neutral

(ii) Bronsted-Lowry concept: Any molecule, cation or anion, which provides proton to any other substance is known as an acid and any molecule, cation or anion, which can accept proton from any other substance is known as base. Conjugate acid-base pairs are formed by the loss or gain of a proton.

$$\underset{\text{Acid}}{CH_3COOH} \underset{+H^+}{\overset{-H^+}{\rightleftharpoons}} \underset{\text{Base}}{CH_3COO^-}$$

$$\underset{\text{Base}}{NH_3} \underset{-H^+}{\overset{+H^+}{\rightleftharpoons}} \underset{\text{Acid}}{NH_4^+}$$

In a conjugate pair, if acid is strong, the base will be weak and *vice-versa*. The substances which possess dual nature are termed amphiprotic such as H_2O and NH_3. The acid-base reaction involves two conjugate pairs.

$$\underbrace{\mathrm{Acid}_1 + \underbrace{\mathrm{Base}_2 \rightleftharpoons \mathrm{Acid}_2}_{\text{Conjugate pair}} + \mathrm{Base}_1}_{\text{Conjugate pair}}$$

This concept fails to explain reactions between non-protic acids and bases.

(iii) Lewis concept: A base is defined as a substance which can furnish a pair of electrons to form a coordinate bond whereas an acid is a substance which can accept a pair of electrons, *i.e.*, base is a **nucleophile** and acid is an **electrophile.** All Lewis bases are Bronsted bases but all Lewis acids are not Bronsted acids. All simple cations, molecules whose central atom has incomplete octet, the molecules in which central atom can expand its valence cell and molecules having multiple bonds between atoms of different electronegativities can act as Lewis acids. All simple anions and molecules having one or more lone pairs of electrons can act as Lewis bases.

Arrhenius concept is most simple and explains satisfactorily reactions in aqueous solutions.

6. Relative strength of acids and bases: The extent to which an acid property is given by an acid is a measure of its strength. The strength of the acid solution does not depend on its concentration but on the number of H^+ ions present. On dilution, as the number of H^+ ions increases, the strength of an acid also increases. At infinite dilution, all acids are almost completely ionised and, therefore, tend to be equally strong. The concentration of H^+ ions at all other dilutions of equimolar solutions of the acids may not be equal and depends on their degree of dissociation. The relative strength is generally compared in terms of degree of dissociation of equimolar solutions.

$$\frac{\text{Strength of acid I}}{\text{Strength of acid II}} = \frac{\alpha_1}{\alpha_2} = \sqrt{\frac{K_{a_1}}{K_{a_2}}}$$

The strength of the base depends upon OH^- ion concentration.

$$\frac{\text{Strength of base I}}{\text{Strength of base II}} = \frac{\alpha_1}{\alpha_2} = \sqrt{\frac{K_{b_1}}{K_{b_2}}}$$

7. Neutralisation: The neutralisation is the interaction of H^+ ions furnished by an acid and OH^- ions furnished by a base or a reaction between acid and base to form salt and water is termed neutralisation.

Salts are regarded as compounds made up of positive and negative ions. The positive part comes from a base and negative part comes from an acid. The salts are generally crystalline solids. These are classified into the following classes:

(i) Simple salts: The salts formed by neutralisation process are of three types:

(a) **Normal salts** are salts formed by the replacement of all replaceable hydrogen atoms at H^+ ions. Examples are NaCl, KNO_3, $CuSO_4$, $FeSO_4$, etc.

(b) **Acid salts** are formed by incomplete neutralisation of polybasic acids. Examples are $NaHCO_3$, $NaHSO_4$, Na_2HPO_4, etc.

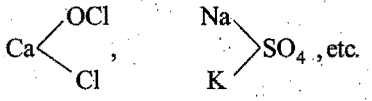
(c) **Basic salts** are salts formed by incomplete neutralisation of polyacidic bases. Examples are: Zn(OH)Cl, Mg(OH)Cl, $Fe(OH)_2Cl$, etc.

(ii) Double salts are the addition compounds formed by combination of two or more simple salts. Such salts are stable in solid state only. Examples are $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$, $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, etc. These salts when dissolved in water furnish all the ions present in simple salts.

(iii) Complex salts are the salts formed by combination of simple salts or molecular compounds. These are stable in solid state. On dissolving in water, they furnish at least one complex ion.

Examples are $K_4Fe(CN)_6$, $[Cu(NH_3)_4]SO_4$, etc.

(iv) Mixed salts furnish more than one cation or more than one anion when dissolved in water. Examples are:



$$\mathrm{Ca}\begin{matrix}\mathrm{OCl}\\ \mathrm{Cl}\end{matrix}, \quad \begin{matrix}\mathrm{Na}\\ \mathrm{K}\end{matrix}\mathrm{SO_4}, \text{ etc.}$$

8. Ionic product of water: Pure water is a weak electrolyte and is very slightly dissociated into hydrogen and hydroxyl ions.

$$H_2O \rightleftharpoons H^+ + OH^-$$

$$K = \frac{[H^+][OH^-]}{[H_2O]}$$

$[H_2O]$ can be taken as constant.

$$K[H_2O] = [H^+][OH^-] = K_w$$

K_w is constant and known as ionic product of water. Its value is 1×10^{-14} at 25°C. The value increases with increases of temperature. Since, water is neutral, $[H^+]=[OH^-]$

or $$[H^+]=[OH^-]=10^{-7}$$

When $[H^+]>[OH^-]$, the solution is acidic.

Similarly, when $[H^+]<[OH^-]$, the solution is basic in nature. Every aqueous solution, whether acidic, neutral or basic, contains both H^+ and OH^- ions. The product of their concentrations is always 1×10^{-14} at 25° C. If one increases, the other decreases.

$$[H^+]=\frac{K_w}{[OH^-]} \quad \text{and} \quad [OH^-]=\frac{K_w}{[H^+]}$$

9. pH scale: This has been devised by Sorensen in 1909. The negative logarithm of the concentration of hydrogen ions is termed the pH of the solution.

$$pH=-\log[H^+]=\log\frac{1}{[H^+]}$$

pH is thus logarithm of the reciprocal of hydrogen ion concentration.

Similarly, $$pOH=-\log[OH^-]=\log\frac{1}{[OH^-]}$$

$$pH+pOH=14$$

Limitations of pH scale: pH values do not give any immediate idea about the relative strengths of the solution. pH value is zero for 1 *N* solution of strong acid. In case of 2 *N*, 3 *N*, 4 *N*, etc., solutions, pH values are negative. A solution of an acid having very low concentration, say 10^{-8} *N*, cannot have pH 8 as shown by pH formula but the actual pH value will be less than 7.

10. Hydrolysis: It is the interaction of ions of a salt with water to give acidic, basic or neutral solution. It is found in the salts of weak acids and strong bases, in salts of strong acids and weak bases and in salts of weak acids and weak bases. The process of hydrolysis is actually the reverse of neutralisation.

$$\text{Salt} + \text{Water} \rightleftharpoons \text{Acid} + \text{Base}$$

If acid is stronger than base, the solution is acidic and in case base is stronger than acid, the solution is alkaline. When both acid and base are either strong or weak, the solution is generally neutral in nature.

Salt of a strong acid and a weak base: The solution of such a salt is acidic in nature. The cation of the salt is reactive and reacts with water.

$$\underset{C(1-h)}{B^+} + H_2O \rightleftharpoons \underset{\substack{Ch \\ \text{Weak base}}}{BOH} + \underset{Ch}{H^+}$$

The extent to which hydrolysis proceeds is expressed as degree of hydrolysis. It is denoted as *h* or *x*.

$$h=\frac{\text{Amount of salt hydrolysed}}{\text{Total salt taken}}$$

Let *C* be the concentration of salt and *h* be the degree of hydrolysis.

$$K_h=\frac{[BOH][H^+]}{[B^+]}=\frac{Ch\times Ch}{C(1-h)}=\frac{Ch^2}{(1-h)}\approx Ch^2 \quad (\text{if } h \text{ is small})$$

$$K_h=\frac{K_w}{K_b}$$

$$h=\sqrt{\frac{K_h}{C}}=\sqrt{\frac{K_w}{C\times K_b}}$$

$$=hC=[H^+]=\frac{\sqrt{C\times K_w}}{K_b}$$

$$pH=\tfrac{1}{2}pK_w-\tfrac{1}{2}pK_b-\tfrac{1}{2}\log C$$

11. Summary pH of mixtures of acids and bases:

Let '*x*' meq of acid (H*A*) and '*y*' meq of base (*B*OH) be mixed.

$$\text{meq}=NV\ \text{mL};\ N=M\times\text{acidity or basicity}$$

Case I. Strong acid and strong base

(a) When $x=y$, then there will be complete neutralisation; the solution will then be neutral with pH = 7.

(b) When $x>y$, then acid will remain after neutralisation.

$$\text{meq of remaining acid}=(x-y)$$

$$N_a=\frac{(x-y)}{V\ \text{mL}}$$

$$[H^+]_{\text{Strong acid}}=N_a=\frac{(x-y)}{V\ \text{mL}}$$

$$pH=-\log_{10}\left[\frac{x-y}{V\ \text{mL}}\right]$$

(c) When $y>x$, then base will remain after neutralization.

$$\text{meq of remaining base}=(y-x)$$

$$N_b=\frac{(y-x)}{V\ \text{mL}}$$

$$[OH^-]_{\text{Strong base}}=N_b=\frac{(y-x)}{V\ \text{mL}}$$

$$pOH=-\log_{10}\left[\frac{(y-x)}{V\ \text{mL}}\right]; \qquad pH=14-pOH$$

Case II. Strong base and weak acid

(a) If $x=y$, then after complete neutralisation there will be salt of weak acid and strong base. There will be hydrolysis; pH after hydrolysis may be calculated as:

$$pH=\frac{1}{2}[pK_w+pK_a+\log_{10}C]$$

C = Conc. of salt in mol litre^{-1}.

(b) If $x>y$, then weak acid will be in excess.

$$\text{Weak acid}=(x-y)\ \text{meq}$$

$$\text{Salt}=y\ \text{meq}$$

The resultant solution will be acid buffer; its pH may be calculated as:

$$pH=pK_a+\log\frac{[\text{Salt}]}{[\text{Acid}]}$$

Conc. should be taken in mol litre^{-1}.

(c) When $y > x$, then excess of strong base will remain after neutralisation. Remaining base $= (y - x)$ meq

$$\underset{\text{Strong}}{N_b} = \frac{(y-x)}{V \text{ mL}} = [\text{OH}^-]$$

$$\text{pOH} = -\log_{10}\left[\frac{y-x}{V \text{ mL}}\right]$$

Case III. Strong acid and weak base

(a) When $x = y$, there will be salt formation after complete neutralisation. Salt of weak base and strong base will undergo hydrolysis. pH after hydrolysis may be calculated as:

$$\text{pH} = \frac{1}{2}[\text{p}K_w - \text{p}K_a - \log_{10} C]$$

$C =$ Conc. of salt in mol litre^{-1}.

(b) When $x > y$, then strong acid will remain after neutralisation.

Remaining acid $= (x - y)$ meq

$$\underset{\text{Strong}}{N_a} = \frac{(x-y)}{V \text{ mL}} = [\text{H}^+]$$

$$\text{pH} = -\log_{10}\left[\frac{x-y}{V \text{ mL}}\right]$$

(c) When $y > x$, then weak base will remain after salt formation; the resultant mixture will be, therefore, base buffer.

$$14 - \text{pH} = \text{pOH} = \text{p}K_b + \log_{10}\frac{[\text{Salt}]}{[\text{Base}]}$$

Remaining base $= (y - x)$ meq

Salt $= x$ meq

Salt and base conc. should be taken in mol litre^{-1}.

Case IV. Weak acid and weak base

(a) When $x = y$, there will complete neutralisation forming salt of weak acid and weak base. pH after salt hydrolysis may be calculated as:

$$\text{pH} = \frac{1}{2}[\text{p}K_w + \text{p}K_a - \text{p}K_b]$$

(b) When $x > y$, weak acid will remain after neutralisation; the mixture of weak acid and salt behaves as acid buffer.

(c) When $y > x$, then weak base will remain after salt formation; the mixture thus behaves as base buffer.

12. Acid-base indicators: In acid-base titrations, organic substances (weak acids or weak bases) are generally used as indicators. They change their colours within a certain pH range.

Methyl orange	pH range 3.2 – 4.5	Pink to yellow
Methyl red	pH range 4.4 – 6.5	Red to yellow
Phenolphthalein	pH range 8.3 –10.5	Colourless to pink

Two theories have been proposed to explain the change of colour of these acid-base indicators. These theories are:

(a) Ostwald's theory (b) Quinonoid theory

The suitable indicators for the following titrations are:

(i) Strong acid *versus* strong base—Phenolphthalein, methyl red and methyl orange.

(ii) Weak acid *versus* strong base—Phenolphthalein.

(iii) Strong acid *versus* weak base—Methyl red and methyl orange.

Questions

1. (a) Mention conjugate base of each of the following:
HS^-, H_3O^+, $H_2PO_4^-$, HSO_4^-, HF, CH_3COOH, C_6H_5OH, $HClO_4$, NH_4^+

(b) Mention the conjugate acid of each of the following:
OH^-, CH_3COO^-, Cl^-, CO_3^{2-}, $H_2PO_4^-$, CH_3NH_2, CH_3COOH, NH_2^-

(c) Which of the following behave both as Bronsted acids as well as Bronsted bases?
$H_2O, HCO_3^-, H_2SO_4, H_3PO_4, HS^-, NH_3$

(d) Which is stronger acid in each of the following pairs?
HCl, HI; H_2CO_3, H_2SO_4; H_2O, H_2S; C_6H_5OH, C_2H_5OH; Na^+, K^+

(e) Which is stronger base in each of the following pairs?
OH^-, Cl^-; OH^-, NH_2^-; OH^-, CH_3COO^-; CH_3COO^-, Cl^-; NH_3, CH_3NH_2

(f) Classify the following into acids and bases according to Lewis concept:
S^{2-}, H^+, OH^-, BF_3, Ni^{2+}, NF_3, $AlCl_3$, $SnCl_4$, NH_3, $(CH_3)_2O$

2. Predict whether the following substances will give acidic, basic or neutral solution?

(i)	K_2CO_3	(ii)	NaCl	(iii)	$FeCl_3$
(iv)	$CuSO_4$	(v)	$AlCl_3$	(vi)	NH_4Cl
(vii)	CH_3COONH_4	(viii)	NaCN	(ix)	Na_2S
(x)	$Na_2B_4O_7$				

3. [A] Match the List-I with List-II:

List-I (Salt)	List-II (pH)
(a) Salt of strong acid and strong base	(p) $\frac{1}{2}[pK_w + pK_a - pK_b]$
(b) Salt of weak acid and strong base	(q) $\frac{1}{2}[pK_w + pK_a + \log C]$
(c) Salt of weak base and strong acid	(r) $\frac{1}{2}[pK_w - pK_b - \log C]$
(d) Salt of weak acid and weak base	(s) $\frac{1}{2}pK_w$

[B] Match the List-I with List-II:

List-I (Indicator)	List-II (pH range)
(a) Phenolphthalein	(p) 4.2 – 6.3
(b) Litmus	(q) 3.1 – 4.4
(c) Methyl red	(r) 8.3–10.0
(d) Methyl orange	(s) 5.0–8.0

[C] Match the List-I with List-II:

List-I	List-II
(a) Lewis acid	(p) PH_3
(b) Lewis base	(q) $[Al(H_2O)_5OH]^{2+}$
(c) Conjugate acid	(r) $(CH_3)_3B$
(d) Conjugate base	(s) H_3O^+

4. **Matrix-Matching Problems (For IIT Aspirants):**

[A] Match the List-I with List-II:

List-I	List-II
(a) H_3PO_4	(p) Monobasic
(b) H_3PO_3	(q) Dibasic
(c) H_3PO_2	(r) Tribasic
(d) H_3BO_3	(s) sp^3-hybrid state

[B] Match the List-I with List-II:

List-I (Indicator)	List-II (Types of titration)
(a) Phenolphthalein	(p) NaOH + HCl
(b) Phenol red	(q) $H_2SO_4 + NH_4OH$
(c) Bromo cresol green	(r) $CH_3COOH + NH_4OH$
(d) Methyl orange	(s) $KOH + H_2SO_4$

[C] Match the acid/base in List-I with their nature in List-II:

List-I	List-II
(a) HSO_4^-	(p) Lewis acid
(b) BF_3	(q) Lewis base
(c) NH_3	(r) Bronsted acid
(d) OH^-	(s) Bronsted base

[**Note:** Consider the normal behaviour of species.]

[D] Match the Column-I with Column-II:

Column-I (Salt)	Column-II (Solubility product)
(a) Zirconium phosphate	(p) $27S^4$
(b) Aluminium phosphate	(q) $108S^5$
(c) Calcium phosphate	(r) $6912S^7$
(d) Sodium phosphate	(s) S^2

[E] Match the Column-I with Column-II:

Column-I (Salt)	Column-II (Nature of hydrolysis)
(a) NH_4CN	(p) Only cation hydrolysis
(b) CH_3COONa	(q) Only anion hydrolysis
(c) $NaClO_4$	(r) Both cation and anion hydrolysis
(d) $Fe(NO_3)_2$	(s) No hydrolysis

[F] Match the Column-I with Column-II:

Column-I (Titration)	Column-II (Indicator used)
(a) Strong acid versus strong base	(p) Methyl orange (3 – 4.4)
(b) Weak acid versus strong base	(q) Methyl red (4.3 – 6.3)
(c) Strong acid versus weak base	(r) Phenolphthalein (8–10)
(d) Weak acid versus weak base.	(s) No suitable indicator

Answers

1. (a) S^{2-}, H_2O, HPO_4^{2-}, SO_4^{2-}, F^-, CH_3COO , C_6H_5O , ClO_4^-, NH_3

(b) H_2O, CH_3COOH, HCl, HCO_3^-, H_3PO_4, $CH_3NH_3^+$, $CH_3COOH_2^+$, NH_3

(c) H_2O, HCO_3^-, HS^- and NH_3 behave both as acids and bases.

(d) HI > HCl; $H_2SO_4 > H_2CO_3$; $H_2S > H_2O$;
$C_6H_5OH > C_2H_5OH$; $Na^+ > K^+$

(e) $OH^- > Cl$; $NH_2^- > OH^-$; $OH^- > CH_3COO^-$;
$CH_3COO^- > Cl^-$; $CH_3NH_2 > NH_3$

(f) Lewis acids: H^+, BF_3, Ni^{2+}, $AlCl_3$, $SnCl_4$
Lewis bases: S^{2-}, OH^-, NF_3, NH_3, $(CH_3)_2O$

2. Acidic: $FeCl_3$, $CuSO_4$, $AlCl_3$, NH_4Cl
Basic: K_2CO_3, NaCN, Na_2S, $Na_2B_4O_7$
Neutral: NaCl, CH_3COONH_4

3. [A] (a–s), (b–q), (c–r), (d–p)
[B] (a–r), (b–s), (c–p), (d–q)
[C] (a–r), (b–p), (c–s), (d–q)

4. [A] (a–r, s), (b–q, s), (c–p, s), (d–p)
[B] (a—p, s), (b–r), (c–q), (d–p, s, q)
[C] (a–r, s), (b–p), (c–q, s), (d–q, s)
[D] (a–r), (b–s), (c–q), (d–p)
[E] (a–r), (b–q), (c–s), (d–p)
[F] (a–p, q, r), (b–r), (c–p, q), (d–s)

• PRACTICE PROBLEMS •

1. Calculate the degree of ionisation of 0.1 *M* acetic acid. The dissociation constant of acetic acid is 1.8×10^{-5}.
[Ans. $\alpha = 1.34 \times 10^{-2}$]

2. Calculate the concentration of OH^- ions of 0.01 *M* NH_4OH solution. The equilibrium constant of NH_4OH is 1.8×10^{-5}.
[Ans. 4.24×10^{-4} mol L^{-1}]

3. At 15° C, 0.05 *N* solution of a weak monobasic acid is 3.5% ionised. Calculate the ionisation constant of acid.
[Ans. 6.125×10^{-5}]

4. 0.02 *M* solution of NH_4OH is 3% dissociated. Calculate the dissociation constant of NH_4OH.
[Ans. 1.8×10^{-5}]

5. A solution contains 0.4 *M* CH_3COOH and 0.2 *M* CH_3COONa. Calculate the concentration of H^+ ions. The ionisation constant of acetic acid is 1.8×10^{-5}.
[Ans. 3.6×10^{-5} mol L^{-1}]

6. The dissociation constant of hydrocyanic acid (HCN) is 4×10^{-8}. Calculate the H^+ ion concentration of 0.01 *M* HCN solution.
[2×10^{-5} mol L^{-1}]

7. The degree of dissociation of a weak electrolyte in 0.1 *M* aqueous solution is 0.0114 at 298 K. Calculate the degree of dissociation of the same electrolyte at 298 K in 0.001 *M* solution.
[Ans. 0.114]

8. Calculate K_a for a dibasic acid if its concentration is 0.05 *N* and hydrogen ion concentration is 1×10^{-3} mol L^{-1}.
[Ans. 2×10^{-8}]
[Hint: Conc.= 0.025 *M*, $[H^+] = 2C \times \alpha = 1 \times 10^{-3}$,
i.e., $\alpha = 0.02$, $K_a = 4 \times C^2 \times \alpha^3$]

9. K_a for $HC_2H_3O_2$ is 1.8×10^{-5}. What concentration of the acid must be taken so that it is 1% dissociated?
[Ans. 0.18 mol L^{-1}]

10. Calculate the degree of ionisation and hydroxyl ion concentration in 0.2 *M* NH_3 solution. ($K_b = 1.85 \times 10^{-5}$ at 298 K)
[Ans. $\alpha = 0.962 \times 10^{-2}$, $[OH^-] = 1.924 \times 10^{-3}$ *M*]

11. The dissociation constant of acetic acid at 18° C is 1.8×10^{-5}. Calculate the pH of 0.1 *N* and 0.001 *N* solution of acetic acid.
[Ans. 2.873, 3.726]

12. Calculate the approximate pH of 0.1 *M* aqueous H_2S solution. K_1 and K_2 for H_2S are 1.0×10^{-7} and 1.3×10^{-13} respectively at 25° C.

[**Ans.** pH = 4]

[**Hint:** Second dissociation constant is very small. H^+ ion concentration mainly depends on the first dissociation constant.

$$H_2S \overset{K_1}{\rightleftharpoons} H^+ + HS^-]$$

13. The pH of a soft drink is 4.4. Calculate $[H_3O^+]$ and $[OH^-]$ of the drink.

[**Ans.** 3.98×10^{-5} mol L^{-1}, 2.5×10^{-10} mol L^{-1}]

14. Calculate the pH of a 0.001 *M* solution of $Sr(OH)_2$ assuming it to be completely ionised.

[**Ans.** 11.301]

[**Hint:** $Sr(OH)_2 \rightleftharpoons Sr^{2+} + 2OH^-$;

$[OH^-] = 2 \times 0.001 = 0.002$ *M*]

15. The value of K_w is 9.55×10^{-14} at a certain temperature. Calculate the pH of water at this temperature.

[**Ans.** 6.51]

[**Hint:** $K_w = [H^+][OH^-]$, So, $[H^+] = \sqrt{K_w}$]

16. 9.8 g of H_2SO_4 is present in 500 mL of the solution. Calculate the pH of the solution.

[**Ans.** 0.3979]

17. The pH of a 0.1 *M* solution of an organic acid is 4.0. Calculate the dissociation constant of the acid.

[**Ans.** 1×10^{-7}]

18. Calculate $[H_3O^+]$, $[OH^-]$ and pH of 0.2 *M* solution of HCN. ($K_a = 7.2 \times 10^{-10}$)

[**Ans.** $[H_3O^+] = 1.2 \times 10^{-5}$ mol L^{-1}, $[OH^-] = 8.33 \times 10^{-10}$ mol L^{-1}, pH = 4.92]

19. Calculate pH of 0.002 *M* CH_3COOH if it is 2.3% ionised at this concentration.

[**Ans.** 4.34]

20. Calculate the pH of the solution obtained by mixing 150 mL of 0.2 *M* HCl and 150 mL of 0.1 *M* NaOH.

[**Ans.** 1.30]

21. pH of a 0.1 *M* HCN solution is 5.2. What is the value of K_a for the acid?

[**Ans.** 3.97×10^{-10}]

22. The pH of a solution of $B(OH)_2$ is 10.6. Calculate the solubility and solubility product of hydroxide.

[**Hint:** pOH = 3.4, $[OH^-] = 3.98 \times 10^{-4}$ mol L^{-1}

Solubility = $\frac{1}{2}[OH^-] = 1.99 \times 10^{-4}$ mol L^{-1}

$K_{sp} = [B^+][OH^-]^2 = 3.15 \times 10^{-11}$]

23. Calculate the pH of a solution:

(i) containing 2 g of sodium hydroxide in one litre;

(ii) made by mixing 50 mL of 0.01 *M* $Ba(OH)_2$ solution with 50 mL water.

[**Ans.** (i) pH = 12.7, (ii) pH = 12]

24. What happens to the pH of 500 mL of a solution that is 0.1 molar in sodium acetate and 0.1 molar in acetic acid when 10 mL of 0.1 *M* sodium hydroxide is added?

[**Ans.** pH = 4.7447 and pH will increase]

25. What ratio of acetic acid to sodium acetate concentration is needed to achieve a buffer whose pH is 5.70? The dissociation constant of acetic acid is 1.8×10^{-5}.

[**Ans.** 1 : 9]

26. Find the concentration of H^+, HCO_3^- and CO_3^{2-} in a 0.01 *M* solution of carbonic acid if the pH of the solution is 4.18, $K_1 = 4.45 \times 10^{-7}$, $K_2 = 4.69 \times 10^{-11}$.

[**Ans.** $[H^+] = 6.61 \times 10^{-5}$ *M*, $[HCO_3^-] = 6.73 \times 10^{-5}$ *M*,

$[CO_3^{2-}] = 4.78 \times 10^{-11}$ mol L^{-1}]

[**Hint.** $K_1 = \dfrac{[H^+][HCO_3^-]}{[H_2CO_3]} = 4.45 \times 10^{-7}$

$$K_2 = \frac{[H^+][CO_3^{2-}]}{[HCO_3^-]} = 4.69 \times 10^{-11}$$

$$[H^+] = 6.61 \times 10^{-5}\,M,\ [H_2CO_3] = 0.01\,M$$

$$[HCO_3^-] = 6.73 \times 10^{-5}\,M,\ [CO_3^{2-}] = 4.78 \times 10^{-11} \text{ mol } L^{-1}]$$

27. What will be the pH value of a solution of 500 mL containing 5 g acetic acid and 7.2 g of sodium acetate? $K_a = 1.8 \times 10^{-5}$ at 25° C.

[**Ans.** 4.82]

28. The concentration of HCN and NaCN in a solution is 0.01 *M* each. Calculate the concentration of hydrogen and hydroxyl ions if the dissociation constant of HCN is 7.2×10^{-10}. **(IIT 1991)**

[**Ans.** $[H^+] = 7.2 \times 10^{-10}$ *M*; $[OH^-] = 1.4 \times 10^{-7}$ *M*]

[**Hint:** $\text{pH} = \log \dfrac{[\text{Salt}]}{[\text{Acid}]} - \log K_a = -\log [H^+]$]

29. A buffer solution of pH = 9 is to be prepared by mixing NH_4Cl and NH_4OH. Calculate the number of moles of NH_4Cl that should be added to one litre of 1.0 *M* NH_4OH solution. ($K_b = 1.8 \times 10^{-5}$) **(MLNR 1991)**

[**Ans.** 1.8 mole]

30. Calculate the amount of $(NH_4)_2SO_4$ which must be added to 500 mL of 0.200 *M* NH_3 to yield a solution of pH 9.35. (K_b for $NH_3 = 1.78 \times 10^{-5}$) **(MLNR 1992)**

[**Ans.** 10.494 g]

31. Calculate the pH of the buffer containing 1.0 mol L^{-1} of weak acid H*A* and 0.1 mol L^{-1} of its sodium salt Na*A* assuming K_a to be 10^{-6}. **(Dhanbad 1993)**

[**Ans.** pH = 5]

32. Calculate K_b for a base whose 0.1 *M* solution has pH of 10.5.

[**Ans.** 10^{-6}]

33. What is the maximum pH of a solution 0.10 *M* in Mg^{2+} from which $Mg(OH)_2$ will not precipitate? Given, $K_{sp}[Mg(OH)_2] = 1.2 \times 10^{-11}$.

[**Ans.** pH = 9.4]

34. A solution of HCl has a pH = 5. If one mL of it is diluted to 1 litre, what will be the pH of the resulting solution?

[**Ans.** pH = 6.9586]

[**Hint:** pH = 5, $[H^+] = 10^{-5}\,M$. After dilution $= \frac{10^{-5}}{1000} = 10^{-8}\,M$

$$[H^+] = 10^{-8} + 10^{-7}$$
$$= 1.1 \times 10^{-7}$$
$$pH = -\log[H^+] = -\log 1.1 \times 10^{-7} = 6.9586]$$

35. Calculate the pH of the solution obtained by mixing 10 mL of 0.1 M HCl and 40 mL of 0.2 M H_2SO_4.

[**Ans.** pH = 0.4685]

[**Hint:** $[H^+] = \frac{10 \times 0.1 + 40 \times 0.4}{50} = 0.34]$

36. The degree of dissociation of a weak electrolyte in 0.1 M aqueous solution is 0.0114 at 298 K. Calculate the degree of dissociation of the same electrolyte at 298 K in 0.001 M solution.

[**Ans.** 0.114]

[**Hint:** α is proportional to $\sqrt{\frac{1}{C}}$.

$$\frac{\alpha}{\alpha'} = \sqrt{\frac{C'}{C}} = \sqrt{\frac{0.001}{0.1}} = 0.1$$
$$\alpha' = \frac{\alpha}{0.1} = \frac{0.0114}{0.1} = 0.114\,]$$

37. The degree of dissociation of water is 1.8×10^{-9} at 298 K. Calculate the ionisation constant and ionic product of water at 298 K.

[**Hint:** $H_2O \rightleftharpoons H^+ + OH^-$, $[H_2O] = \frac{1000}{18} = 55.56\ \text{mol L}^{-1}$,

$$[H^+] = [OH^-] = C \times \alpha = 55.56 \times 1.8 \times 10^{-9}$$
$$K_a = \frac{[H^+][OH^-]}{[H_2O]} = \frac{55.56 \times 1.8 \times 10^{-9} \times 55.56 \times 1.8 \times 10^{-9}}{55.56}$$
$$= 1.8 \times 10^{-16}$$
$$K_w = [H^+][OH^-] = (55.56 \times 1.8 \times 10^{-9})^2 = 1 \times 10^{-14}\,]$$

38. One litre of a buffer solution is prepared by dissolving 0.6 mole of NH_3 and 0.4 mole of NH_4Cl. What is the pH of the solution? For NH_3, $K_b = 1.8 \times 10^{-5}$.

(i) What is the pH of the buffer after addition of 0.1 mole of HCl?

(ii) What is the pH of the buffer after addition of 0.1 mole of NaOH?

[**Ans.** 9.4314 (i) 9.2553 (ii) 9.6233]

39. One litre of a buffer contains 40 g of NH_4Cl and 20 g of NH_3. Calculate the pH of the solution. $K_b(NH_3) = 1.8 \times 10^{-5}$ at 298 K.

[**Ans.** 9.452]

40. A buffer solution is prepared by mixing 50 mL of 0.5 molar ammonia solution, 40 mL of 0.4 molar NH_4Cl solution and 10 mL of distilled water. Calculate the pH of the buffer. $K_b(NH_3) = 1.8 \times 10^{-8}$ at 298 K.

[**Ans.** 9.45]

[**Hint:** Total volume = 50 + 40 + 10 = 100 mL

$$\text{Molarity of } NH_3 = \frac{0.5 \times 50}{100} = 0.25;$$
$$\text{Molarity of } NH_4Cl = \frac{0.4 \times 40}{100} = 0.16]$$

41. pK_a value of acetic acid is 4.76 at room temperature. How will you obtain buffers of 4.40 and 5.40 pH values from acetic acid and sodium acetate?

[**Ans.** $\frac{\text{Acetate}}{\text{Acid}} = 0.4365$ and $\frac{\text{Acetate}}{\text{Acid}} = 4.364]$

42. Calculate the ratio of pH of a solution containing 1 mole of CH_3COONa + 1 mole of HCl per litre and of the other solution containing 1 mole of CH_3COONa + 1 mole of CH_3COOH per litre.

[**Hint:** 1st case: $CH_3COONa + HCl \longrightarrow \underset{\text{1 mole}}{CH_3COOH} + NaCl$

$$pH_1 = -\frac{1}{2}\log K_a$$

2nd case: $pH_2 = -\log K_a + \log\frac{[\text{Salt}]}{[\text{Acid}]} = -\log K_a$

$$\frac{pH_1}{pH_2} = \frac{1}{2}\,]$$

43. Calculate the composition of an acidic buffer solution $(HA + NaA)$ of total molarity 0.29 having pH = 4.4 and $K_a = 1.8 \times 10^{-5}$.

[**Ans.** [Salt] = 0.09 M; [Acid] = 0.20 M]

[**Hint:** $pH = -\log K_a + \log\frac{[\text{Salt}]}{[\text{Acid}]}$

$$= -\log K_a + \log\frac{a}{(0.29 - a)}\,]$$

44. Calculate the pH of a solution obtained by mixing 100 mL of an acid of pH = 3 and 400 mL solution of pH = 1.

[**Ans.** 1.096]

45. The solubility product of AgCl in water is 1.5×10^{-10}. Calculate its solubility in 0.01 M NaCl aqueous solution. (IIT 1995)

[**Ans.** 1.5×10^{-8} mol L^{-1}]

46. Calculate the pH of a 0.02 M aqueous solution of NH_4Cl? Given, $pK_{NH_4OH} = 4.73$.

[**Ans.** 3.78]

47. Determine the pH value of 0.1 M aqueous solution of ammonium cyanide ($pK_a = 9.04$, $pK_b = 4.73$).

[**Ans.** 9.15]

48. Calculate the pH of a 0.2 M solution of strychnine hydrochloride. ($K_b = 1 \times 10^{-7}$)

[**Ans.** 3.8494]

49. The dissociation constants of acetic acid and aniline are 1.8×10^{-5} and 4.2×10^{-10} respectively. What is the degree of hydrolysis of aqueous aniline acetate? What is the pH of the solution?

[**Ans.** 0.5348, pH = 4.684]

50. A weak acid HA after treatment with 12 mL of 0.1 M strong base has a pH of 5. At the end point, the volume of the same base required is 26.6 mL. Calculate the K_a of the acid.

[**Ans.** 8.219×10^{-6}]

[**Hint:** Applying $\underset{\text{Acid}}{M_1V_1} = \underset{\text{Base}}{M_2V_2}$

$$= 26.6 \times 0.1$$

$$= 2.66 \text{ meq.}$$

$$\begin{array}{lcccc} & HA & + BOH & \rightleftharpoons BA & + H_2O \\ & 2.66 & 1.2 & 0 & 0 \\ \text{After the reaction} & 1.46 & 0 & 1.2 & 1.2 \end{array}$$

Applying Henderson's equation,

$$pH = \log \frac{[\text{Salt}]}{[\text{Acid}]} - pK_a \text{]}$$

51. K_a for HCN is 1.4×10^{-9}. Calculate for 0.01 N KCN solution:

(a) degree of hydrolysis

(b) $[OH^-]$ and $[CN^-]$

(c) pH

[**Ans.** (a) 2.67×10^{-2} (b) 2.67×10^{-4}, 9.73×10^{-3} (c) 10.4265]

52. What is the H^+ ion concentration in ammonium acetate solution?

$K_a = 1.8 \times 10^{-5}$, $K_b = 1.8 \times 10^{-5}$ and $K_w = 1.0 \times 10^{-14}$

[**Ans.** 1.0×10^{-7}]

53. A 40 mL sample of 0.1 M solution of nitric acid is added to 20 mL of 0.3 M aqueous ammonia. What is the pH of the resulting solution? Given, K_b for ammonia $= 1.8 \times 10^{-5}$.

[**Ans.** 8.95]

54. Calculate the pH of 0.1 M solution of NH_4OCN. K_b for NH_3 is 1.75×10^{-5} and K_a for HOCN is 3.3×10^{-4}.

[**Ans.** 6.36]

55. Which of the two solutions 0.1 M HCN ($K_a = 4 \times 10^{-10}$) and 0.1 M HF ($K_a = 6.7 \times 10^{-4}$) will have greater degree of ionisation and to what extent?

[**Ans.** HF will have greater degree of dissociation.

$$\frac{\alpha\,(\text{HF})}{\alpha\,(\text{HCN})} = 1294\text{]}$$

56. Calculate the pH of a solution prepared by mixing 100.0 mL of 0.4 M HCl with 100.0 mL of 0.4 M NH_3. Hydrolysis constant of ammonium chloride is 5.6×10^{-10}.

[**Ans.** pH = 4.96]

57. Calculate the per cent hydrolysis in 0.003 M aqueous solution of NaOCN.

(K_a for HOCN $= 3.33 \times 10^{-4}$ M) (IIT 1996)

[**Ans.** 0.01%]

58. What is the $[OH^-]$ in a 0.01 M solution of aniline hydrochloride? K_b for aniline is 4.0×10^{-10}.

[**Ans.** 2.0×10^{-11} M]

[**Hint:** $\underset{(0.01-x)}{C_6H_5NH_3^+} + H_2O \rightleftharpoons \underset{x}{C_6H_5NH_2} + \underset{x}{H_3O^+}$]

59. Calculate the pH of 1.0×10^{-3} M sodium phenolate $NaOC_6H_5$. K_a for C_6H_5OH is 1×10^{-10}.

[**Ans.** pH = 10.43]

[**Hint:** $\underset{(0.001-x)}{C_6H_5O^-} + H_2O \rightleftharpoons \underset{x}{C_6H_5OH} + \underset{x}{OH^-}$

$$K_h = \frac{K_w}{K_a} = 1 \times 10^{-4} = \frac{x^2}{(0.001 - x)}$$

$$x^2 + 1 \times 10^{-4}x - 1 \times 10^{-7} = 0, x = 2.7 \times 10^{-4}, pOH = 3.57]$$

60. The dissociation constants of *m*-nitrobenzoic acid and acetic acid are 36.0×10^{-5} and 1.8×10^{-5} respectively. What are their relative strengths?

[**Ans.** 4.47 : 1]

61. Calculate the degree of hydrolysis of 0.10 solution of KCN. Dissociation constant of HCN $= 7.2 \times 10^{-10}$ at 25° C and $K_w = 1.0 \times 10^{-14}$.

[**Ans.** 1.18×10^{-2}]

62. An aqueous solution of aniline of concentration 0.24 M is prepared. What concentration of sodium hydroxide is needed in this solution so that anilinium ion concentration remains at 1×10^{-8} M?

(K_a for $C_6H_5NH_3^+ = 2.4 \times 10^{-5}$ M) (IIT 1996)

[**Ans.** 0.01 M]

63. What is the pH of a 0.50 M aqueous NaCN solution? pK_b of CN^- is 4.70. (IIT 1996)

[**Ans.** pH = 11.5]

64. Calculate the pH of an aqueous solution of 1 M ammonium formate, assuming complete dissociation.

($pK_a = 3.8$, $pK_b = 4.8$) (IIT 1995)

[**Ans.** 6.5]

[**Hint:** Use; $pH = \frac{1}{2}[pK_w - pK_b + pK_a]$]

65. Calculate the hydrolysis constant of the salt containing NO_2^- ions. Given, K_a for $HNO_2 = 4.5 \times 10^{-10}$. (MLNR 1996)

[**Ans.** 2.2×10^{-5}]

66. Aniline is an amine that is used to manufacture dyes. It is isolated as aniline hydrochloride $[C_6H_5NH_3]Cl$, a salt of aniline and HCl. Calculate the pH of 0.233 M solution of aniline.

[K_b = (aniline) $= 4.6 \times 10^{-10}$]

[**Ans.** 2.64]

67. Calculate the pH of a 0.1 M solution of $AlCl_3$ that dissolves to give hydrated aluminium ion $[Al(H_2O)_6]^{3+}$ in solution. ($K_a = 1.4 \times 10^{-5}$)

[**Ans.** 2.92]

[**Hint:** Consider the equilibrium:

$$[Al(H_2O)_6]^{3+} + H_2O \rightleftharpoons H_3O^+ + [Al(H_2O)_5(OH)]^{2+}\text{]}$$

68. Calculate the amount of NH_3 and NH_4Cl required to prepare a buffer solution of pH, when total concentration of buffering reagents is 0.6 mol litre^{-1}, pK_b for $NH_3 = 4.7$, $\log_{10} 2 = 0.30$. (IIT 1997)

[**Ans.** [Salt] = 0.4 M, [Base] = 0.2 M]

69. The solubility product of AgCl in water is 1.5×10^{-10} at 18° C. Calculate its solubility at the same temperature.

[**Ans.** 1.75×10^{-3} g L^{-1}]

70. The solubility product of AgBr is 4×10^{-13} and the concentration of Ag^+ ions in it is 1×10^{-6} mol L^{-1}. What is concentration of Br^- ions?
[**Ans.** 4×10^{-7} mol L^{-1}]

71. A sample of hard water contains 0.005 mole of $CaCl_2$ per litre. What is the minimum concentration of Na_2SO_4 which must be exceeded for removing calcium ions from this water solution? The solubility product of $CaSO_4$ is 2.4×10^{-5}.
[**Ans.** 4.8×10^{-3} mol L^{-1}]

72. Solubility of AgCl at 20° C is 1.435×10^{-5} g L^{-1}. Calculate the solubility product of AgCl.
[**Ans.** 1×10^{-14}]

73. Given, that the solubility product of radium sulphate ($RaSO_4$) is 4×10^{-11}. Calculate its solubility in:
(a) pure water.
(b) 0.10 *M* Na_2SO_4. **(Dhanbad 1992)**
[**Ans.** (a) 6.32×10^{-6} mol L^{-1} (b) 4×10^{-10} mol L^{-1}]

74. Calculate the solubility of AgCl in 0.20 *M* $AgNO_3$. K_{sp} AgCl is 1×10^{-10}.
[**Ans.** 5×10^{-10} mol L^{-1}]

75. The values of K_{sp} for sparingly soluble *AB* and MB_2 are each equal to 4.0×10^{-18}. Which salt is more soluble?
[**Ans.** Solubility $AB = 2 \times 10^{-9}$; Solubility $MB_2 = 1.0 \times 10^{-6}$; MB_2 is more soluble]

76. The solubility of $CaSO_4$ at 25° C is 2.036 g L^{-1} and degree of dissociation of the saturated solution at this temperature is 52.25%. Compute K_{sp} for $CaSO_4$. (Mol. mass of $CaSO_4$ = 136)
[**Ans.** 6.12×10^{-5}]

77. The concentration of the Ag^+ ion in a saturated solution of Ag_2CrO_4 at 20° C is 1.5×10^{-4} mol L^{-1}. Compute the solubility product constant of Ag_2CrO_4 at 20° C.
[**Ans.** 1.7×10^{-12}]

78. K_{sp} AgCl is 2.8×10^{-10} at 25° C. Calculate the solubility of AgCl in (a) pure water (b) 0.1 *M* $AgNO_3$ (c) 0.1 *M* KCl and (d) 0.1 *M* KNO_3. **(MLNR 1994)**
[**Ans.** (a) 1.673×10^{-3} mol L^{-1} (b) 2.8×10^{-9} mol L^{-1} (c) 2.8×10^{-9} mol L^{-1} (d) No common ion is present, so treat it like water 2.8×10^{-9} mol L^{-1}]

79. A solution is saturated with respect to strontium fluoride and strontium carbonate. The fluoride ion concentration in the solution is found to be 3.7×10^{-2} mol L^{-1}. What is the value of $[CO_3^{2-}]$?
K_{sp} $SrF_2 = 7.9 \times 10^{-10}$ and K_{sp} $SrCO_3 = 7.0 \times 10^{-10}$
[**Ans.** 1.2×10^{-3} mol L^{-1}]
[**Hint:** $\frac{K_{sp}\ SrCO_3}{K_{sp}\ SrF_2} = \frac{[Sr^{2+}][CO_3^{2-}]}{[Sr^{2+}][F^-]^2} = \frac{[CO_3^{2-}]}{[F^-]^2}$]

80. A solution contains 0.01 mol L^{-1} of each Pb^{2+} and Zn^{2+} ions. The solution is saturated with H_2S when $[S^{2-}]$ is 1.0×10^{-14} mol L^{-1}. Predict which one of the two ions will be precipitated from the solution? K_{sp} PbS = 2.4×10^{-27} and K_{sp} ZnS = 1.0×10^{-21}.
[**Ans.** Both the ions will be precipitated as ionic products exceed the solubility products of both the sulphides.]

81. An acid type indicator, HIn, differs in colour from its conjugate base In^-. The human eye is sensitive to colour differences only when the ratio $[In^-]/[HIn]$ is greater than 10 or smaller than 0.1. What should be the minimum change in pH of solution to observe a complete colour change? $(K_a = 10^{-5})$ **(IIT 1997)**
[**Ans.** 2]
[**Hint:** For calculation of pH we can use following relation:

$$pH = pK_a + \log \frac{[In^-]}{[HIn]}$$

(i) $pH = 5 + \log_{10} 10 = 6$
(ii) $pH = 5 + \log_{10} 0.1 = 4$
Thus, minimum pH change will be 2.]

82. A sample of AgCl was treated with 5 mL of 1.5 *M* Na_2CO_3 solution to give Ag_2CO_3. The remaining solution contained 0.0026 g Cl^- per litre. Calculate the solubility product of AgCl. (K_{sp} $Ag_2CO_3 = 8.2 \times 10^{-12}$) **(IIT 1997)**
[**Ans.** K_{sp} AgCl = 1.71×10^{-10}]

83. Calculate the simultaneous solubility of CaF_2 and SrF_2. K_{sp} for the two salts are 4×10^{-11} and 2.8×10^{-9} respectively.
[**Ans.** 1.25×10^{-5} and 8.75×10^{-4}]

84. The solubility product of $Fe(OH)_3$ is 1×10^{-36}. What is the minimum concentration of OH^- ions required to precipitate $Fe(OH)_3$ from 0.001 *M* solution of $FeCl_3$?
[**Ans.** 1×10^{-11} mol L^{-1}]

85. The solubility product of AgCl is 1.5×10^{-10}. Predict whether there will be any precipitation by mixing 50 mL of 0.01 *M* NaCl and 50 mL of 0.01 *M* $AgNO_3$ solution.
[**Ans.** Since, ionic product (2.5×10^{-5}) is greater than solubility product, precipitation will occur.]

86. A solution containing 0.1 *M* Zn^{2+} and 0.01 *M* Cu^{2+} is saturated with H_2S. The S^{2-} concentration is 8.1×10^{-31} *M*. Will ZnS or CuS precipitate?
K_{sp}ZnS = 3.0×10^{-23} and K_{sp}CuS = 8.0×10^{-34}
[**Ans.** CuS precipitates]

87. The precipitate of M_2S_3 is obtained on mixing equal volumes of solutions S_1 having $[M^{3+}] = 4 \times 10^{-5}$ *M* and S_2 having $[S^{2-}] = 2 \times 10^{-3}$ *M*. Calculate its solubility product.
[**Ans.** 4×10^{-17}]
[**Hint:** Let 1 litre of both S_1 and S_2 be mixed; then their concentration in mixture will become half $(M_1V_1 = M_2V_2)$.

$$[M^{3+}] = 2 \times 10^{-4}\ M; [S^{2-}] = 1 \times 10^{-3}$$

$$K_{sp}M_2S_3 = [M^{3+}]^2[S^{2-}]^3$$

$$= [2 \times 10^{-4}]^2[1 \times 10^{-3}]^3 = 4 \times 10^{-17}\ M^5]$$

88. Solubility products (K_{sp}) of two salts *AB* and A_2C are same where, '*A*' is mono cation and *B* and *C* are anions. Calculate the ratio of their solubilities.
[**Ans.** $(16\ K_{sp})^{1/3}$]

[**Hint:** Use; $K_{sp}\ AB = x^2$

$K_{sp}\ A_2C = 4y^3$]

89. Calculate the pH of a solution having 0.1 *M* formic acid and 0.2 *M* HCl. Also find the concentration of all the anions present in the solution.

[**Ans.** pH = 0.6989, $[\text{OH}^-] = 5\times10^{-14}$]

90. Calculate the accurate pH of 5×10^{-3} *M* formic acid solution. K_a (HCOOH) = 2×10^{-4}.

[**Ans.** pH = 3.043]

[**Hint:** Use the quadratic equation:

$$[\text{H}^+]^2 + K_a[\text{H}^+] - CK_a = 0$$

$$[\text{H}^+] = \frac{-K_a + \sqrt{K_a^2 + 4CK_a}}{2} = 9.05\times10^{-4}$$

(On substituting the values of C and K_a)

$$\text{pH} = -\log_{10}[\text{H}^+]$$

$$= -\log_{10}[9.05\times10^{-4}]$$

$$= 3.043]$$

91. Calculate the accurate pH of 5×10^{-6} *M* pyridine solution. K_b(pyridine) = 1.5×10^{-9}.

[**Ans.** 7.1215]

[**Hint:** Use; $[\text{OH}^-]^2 = CK_b + K_w$

$$[\text{OH}^-] = \sqrt{5\times10^{-6}\times1.5\times10^{-9} + 10^{-14}}$$

$$= \sqrt{1.75\times10^{-14}}$$

$$\text{pOH} = -\log[\text{OH}^-]$$

$$= -\log\sqrt{1.75\times10^{-14}} = 6.8785$$

$$\text{pH} = 7.1215]$$

92. Ionic product of water (K_w) at two different temperatures 25°C and 50°C are 1.08×10^{-14} and 5.474×10^{-14} respectively. Assuming ΔH of any reaction to be independent of temperature, calculate enthalpy of neutralisation of strong acid with strong base.

[**Ans.** 12.5 kcal]

[**Hint:** Use $\log\dfrac{K_{w_2}}{K_{w_1}} = \dfrac{\Delta H}{2.303\,R}\left(\dfrac{1}{T_1} - \dfrac{1}{T_2}\right)$]

93. The solubility product of PbI_2 is 7.47×10^{-9} at 15°C and 1.39×10^{-8} at 25°C. Calculate the molar heat of solution of PbI_2.

[**Ans.** 44.318 kJ/mol]

[**Hint:** $\log\dfrac{(K_{sp})_2}{(K_{sp})_1} = \dfrac{\Delta H}{2.303R}\left(\dfrac{1}{T_1} - \dfrac{1}{T_2}\right)$

$$\log\frac{[1.39\times10^{-8}]}{[7.47\times10^{-9}]} = \frac{\Delta H}{2.303\times8.314}\left(\frac{1}{288} - \frac{1}{298}\right)$$

$$\Delta H = 44318.4\ \text{J} = 44.318\ \text{kJ/mol}]$$

94. Given, a solution of acetic acid. How many times of the acid concentration, acetate salt should be added to obtain a solution with pH = 7?

K_a for dissociation of $\text{CH}_3\text{COOH} = 1.8\times10^{-5}$.

[BCECE (Mains) 2007]

[**Ans.** 1.799×10^2]

OBJECTIVE QUESTIONS

Set–1: Questions with single correct answer

1. A certain weak acid has a dissociation constant of 1×10^{-4}. The equilibrium for its reaction with a strong base is:

(a) 1×10^{-4} (b) 1×10^{-10} (c) 1×10^{10} (d) 1×10^{14}

[**Hint:** $K_h = \dfrac{K_w}{K_a} = \dfrac{1\times10^{-14}}{1\times10^{-4}} = 1\times10^{-10}$;

$$K_{eq} = \frac{1}{K_h} = 1\times10^{10}]$$

2. Which one of the following formulae represents Ostwald's dilution law for a binary electrolyte whose degree of dissociation is 'α' and concentration C?

(a) $K = \dfrac{(1-\alpha)C}{\alpha}$ (b) $K = \dfrac{\alpha^2 C}{(1-\alpha)}$

(c) $K = \dfrac{(1-\alpha)C}{\alpha^2}$ (d) $K = \dfrac{\alpha^2}{(1-\alpha)C}$

3. Which of the following is the correct quadratic form of the Ostwald's dilution law equation? **[CET (J& 2009]**

(a) $\alpha^2C + \alpha K - K = 0$ (b) $\alpha^2C - \alpha K - K = 0$

(c) $\alpha^2C - \alpha K + K = 0$ (d) $\alpha^2C + \alpha K + K = 0$

[**Hint:** According to Ostwald's dilution law :

$$K = \frac{C\alpha^2}{1-\alpha}$$

or $C\alpha^2 + K\alpha - K = 0$]

4. A monoprotic acid in 1.00 *M* solution is 0.001% ionised. The dissociation constant of acid is:

(a) 1.0×10^{-3} (b) 1.0×10^{-6}

(c) 1.0×10^{-8} (d) 1.0×10^{-10}

5. Formic acid is 4.5% dissociated in a 0.1 *N* solution at 20°C. The ionisation constant of formic acid is:

(a) 21×10^{-4} (b) 21

(c) 0.21×10^{-4} (d) 2.1×10^{-4}

6. The fraction of total molecules which is ionised in a solution of an electrolyte is known as:

(a) molecular velocity

(b) order of reaction

(c) degree of ionisation

(d) mole fraction of the electrolyte

97. One litre of water contains 10^{-7} mole of H^+ ions. Degree of ionisation of water is:
(a) $1.8 \times 10^{-7}\%$ (b) $0.8 \times 10^{-9}\%$
(c) $3.6 \times 10^{-9}\%$ (d) $3.6 \times 10^{-7}\%$
[**Hint:** Since, 1 litre of water contains 1000/18 mole, degree of ionisation $= 10^{-7} / \frac{1000}{18}$]

98. The degree of dissociation in a weak electrolyte increases:
(a) on increasing pressure (b) on decreasing dilution
(c) on increasing dilution (d) on increasing concentration

99. Which of the following is the weakest base?
(a) NaOH (b) $Ca(OH)_2$
(c) NH_4OH (d) KOH

100. Acetic acid is a weak electrolyte because:
(a) its molecular mass is high
(b) it is a covalent compound
(c) it is highly unstable
(d) it does not dissociate much or its ionisation is very small

101. When NH_4Cl is added to NH_4OH solution, the dissociation of ammonium hydroxide is reduced. It is due to: [PMT (MP) 1993]
(a) common ion effect (b) hydrolysis
(c) oxidation (d) reduction

102. The addition of HCl will not suppress the ionisation of: [PMT (MP) 1993]
(a) acetic acid (b) sulphuric acid
(c) H_2S (d) benzoic acid

103. H_2S in presence of HCl precipitates second group radicals but not fourth group radicals because:
(a) HCl activates H_2S
(b) HCl decreases concentration of sulphide ions
(c) HCl increases concentration of sulphide ions
(d) sulphides of IV group are unstable in HCl

104. The solubility product of a salt *AB* is 1×10^{-8}. In a solution, in which concentration of *A* is 10^{-3} *M*, *AB* will precipitate when the concentration of *B* will be: [PET (MP) 1990]
(a) 10^{-7} *M* (b) 10^{-4} *M* (c) 10^{-5} *M* (d) 10^{-6} *M*

105. The solubility product of $BaSO_4$ is 1.5×10^{-9}. The precipitation in a 0.01 *M* Ba^{2+} ions solution will start on adding H_2SO_4 of concentration:
(a) 10^{-9} *M* (b) 10^{-8} *M*
(c) 10^{-7} *M* (d) 10^{-6} *M*

106. Solubility product of $BaCl_2$ is 4×10^{-9}. Its solubility would be: [UGET (Manipal) 2006]
(a) 1×10^{-27} (b) 1×10^{-3} (c) 1×10^{-7} (d) 1×10^{-2}

107. Which pair will show common ion effect? [PMT (MP) 1990]
(a) $BaCl_2 + Ba(NO_3)_2$ (b) NaCl + HCl
(c) $NH_4OH + NH_4Cl$ (d) AgCN + KCN

108. What is the correct representation of solubility product of Ag_2CrO_4?
(a) $[Ag^+]^2[CrO_4^{2-}]$ (b) $[Ag^+][CrO_4^{2-}]$
(c) $[2Ag^+][CrO_4^{2-}]$ (d) $[2Ag^+]^2[CrO_4^{2-}]$

109. Solubility product of silver bromide 5×10^{-13}. The quantity of potassium bromide (molar mass taken as 120 g mol^{-1}) to be added to 1 litre of 0.05 M solution of silver nitrate to start the precipitation of AgBr is : (AIEEE 2010)
(a) 6.2×10^{-5} g (b) 5.0×10^{-8} g
(c) 1.2×10^{-10} g (d) 1.2×10^{-9} g

110. When equal volumes of the following solutions are mixed, precipitation of AgCl ($K_{sp} = 1.8 \times 10^{-10}$) will occur only with: [AMU (PMT) 2009]
(a) 10^{-4} *M* $Ag^+ + 10^{-4}$ *M* Cl^-
(b) 10^{-5} *M* $Ag^+ + 10^{-5}$ *M* Cl^-
(c) 10^{-6} *M* $Ag^+ + 10^{-6}$ *M* Cl^-
(d) 10^{-10} *M* $Ag^+ + 10^{-10}$ *M* Cl^-

111. Buffering action of a mixture of CH_3COOH and CH_3COONa is maximum when the ratio of salt to acid is equal to:
(a) 1.0 (b) 100.0 (c) 10.0 (d) 0.1

112. Which hydroxide will have lowest value of solubility product at normal temperature (25°C)? (IIT 1990)
(a) $Mg(OH)_2$ (b) $Ca(OH)_2$
(c) $Ba(OH)_2$ (d) $Be(OH)_2$

113. The solubility of $Al(OH)_3$ is '*S*' g mol L^{-1}. Its solubility product is:
(a) S^2 (b) S^3 (c) $27S^4$ (d) $27S^3$

114. The solubility products of $Al(OH)_3$ and $Zn(OH)_2$ are 8.5×10^{-23} and 1.8×10^{-14} at room temperature. If the solution contains Al^{3+} and Zn^{2+} ions, the ion first precipitated by adding NH_4OH is:
(a) Al^{3+} (b) Zn^{2+}
(c) both (d) none of these

115. The solubility product of $CaSO_4$ is 2.4×10^{-5}. When 100 mL of 0.01 *M* $CaCl_2$ and 100 mL of 0.02 *M* Na_2SO_4 are mixed, then:
(a) Na_2SO_4 will precipitate (b) both will precipitate
(c) $CaSO_4$ will precipitate (d) none will precipitate

116. The solubility of AgCl in a solution of common salt is lower than in water. This is due to:
(a) salt effect (b) lowering of solubility effect
(c) common ion effect (d) complex formation

117. The solubility products of AgCl and AgI are 1.1×10^{-10} and 1.6×10^{-16} respectively. If $AgNO_3$ is added drop by drop to the solution containing both chloride and iodide ions, the salt precipitated first is:
(a) AgI (b) $AgNO_3$
(c) AgCl (d) both AgI and AgCl

118. Why is pure NaCl precipitated when HCl gas is passed in saturated solution of NaCl? [PET (MP) 1993]
(a) Impurities dissolve in HCl
(b) The value of $[Na^+]$ and $[Cl^-]$ product becomes smaller than K_{sp} of NaCl
(c) The value of $[Na^+]$ and $[Cl^-]$ product becomes higher than K_{sp} of NaCl
(d) HCl dissolves in water

119. On passing a current of HCl gas in saturated solution of NaCl, the solubility of NaCl:

(a) increases (b) decreases
(c) remains unchanged (d) NaCl decomposes

30. In a saturated solution of electrolytes, the ionic products of their concentration are constant at a particular temperature. This constant for an electrolyte is known as:
(a) ionic product (b) ionisation constant
(c) dissociation constant (d) solubility product

31. On addition of ammonium chloride to a solution of NH_4OH:
(a) dissociation of NH_4OH increases
(b) concentration of OH^- decreases
(c) concentration of OH^- increases
(d) concentration of both NH_4^+ and OH^- increases

32. The solubility product of a salt A_2B is 4×10^{-9}. Its solubility would be: [IIT 1990]
(a) 4×10^{-2} *M* (b) 2×10^{-4} *M*
(c) 1×10^{-4} *M* (d) 1×10^{-3} *M*

33. If the concentration of CrO_4^{2-} ions in a saturated solution of silver chromate is 2×10^{-4}, solubility product of silver chromate will be: [PET (MP) 1992]
(a) 4×10^{-8} (b) 8×10^{-12}
(c) 16×10^{-12} (d) 32×10^{-12}

34. 50% neutralisation of a solution of formic acid ($K_a = 2 \times 10^{-4}$) with NaOH would result in a solution having a hydrogen ion concentration of:
(a) 2×10^{-4} (b) 3.7 (c) 2.7 (d) 1.85

35. The solubility product of $BaCl_2$ is 4×10^{-9}. Its solubility in mol L^{-1} would be:
(a) 1×10^{-3} (b) 1×10^{-9}
(c) 4×10^{-27} (d) 1×10^{-27}

36. Addition of conc. HCl to saturated $BaCl_2$ solution precipitate $BaCl_2$ because: [BHU (Screening) 2010]
(a) at constant temperature the product $[Ba^{2+}][Cl^-]^2$ remains constant in a saturated solution
(b) ionic product of $[Ba^{2+}][Cl^-]$ remains constant in a saturated solution
(c) of common ion effect
(d) it follows Le-Chatelier's principle

37. How many grams of CaC_2O_4 will dissolve in distilled water to make one litre of saturated solution? ($K_{sp} = 2.5 \times 10^{-9}$ and its molecular mass is 128) [PMT (MP) 1993]
(a) 0.0064 g (b) 0.0128 g (c) 0.0032 g (d) 0.0640 g

38. On the addition of a solution containing CrO_4^{2-} ions to the solution of Ba^{2+}, Sr^{2+} and Ca^{2+} ions, the precipitate obtained first will be of: [PET (MP) 1993]
(a) $CaCrO_4$ (b) $SrCrO_4$
(c) $BaCrO_4$ (d) a mixture of all the three

39. Ostwald's dilution law is applicable in the case of the solution of:
(a) NaCl (b) NaOH (c) H_2SO_4 (d) CH_3COOH

40. What will be the solubility of AgCl in a 0.1 *M* NaCl solution? (K_{sp} AgCl $= 1.20 \times 10^{-10}$) [PMT (MP) 1992]
(a) 0.1 *M* (b) 1.2×10^{-4} *M*
(c) 1.2×10^{-9} *M* (d) 1.2×10^{-10} *M*

41. Which of the following metal sulphides has maximum solubility in water?
(a) CdS ($K_{sp} = 36 \times 10^{-30}$) (b) FeS ($K_{sp} = 11 \times 10^{-20}$)
(c) HgS ($K_{sp} = 32 \times 10^{-54}$) (d) ZnS ($K_{sp} = 11 \times 10^{-22}$)

42. The ionisation constant of acetic acid is 1.8×10^{-5}. The concentration at which it will be dissociated to 2%, is:
(a) 1 *M* (b) 0.045 *M* (c) 0.018 *M* (d) 0.45 *M*

43. The solubility of $PbSO_4$ in 0.01 *M* Na_2SO_4 solution is: (K_{sp} for $PbSO_4 = 1.25 \times 10^{-9}$)
(a) 1.25×10^{-7} mol L^{-1} (b) 1.25×10^{-9} mol L^{-1}
(c) 1.25×10^{-10} mol L^{-1} (d) 1.25×10^{-18} mol L^{-1}

44. The value of K_{sp} for $HgCl_2$ is 4×10^{-15}. The concentration of Cl^- ion in its aqueous solution at saturation point is:
(a) 1×10^{-5} *M* (b) 4×10^{-15} *M*
(c) 8×10^{-15} *M* (d) 2×10^{-5} *M*

45. If the solubility of $PbBr_2$ is '*S*' gram mol per litre, considering 80% ionisation, its ionic product is:
(a) $2S^3$ (b) $4S^2$ (c) $4S^3$ (d) $2S^4$

46. If the solubility of M_3N_2 is '*S*' g mol L^{-1}, its solubility product is:
(a) $2S^3$ (b) $8S^4$ (c) $108S^5$ (d) $27S^3$

47. At 30 °C, the solubility of Ag_2CO_3 ($K_{sp} = 8 \times 10^{-12}$) would be greatest in one litre of:
(a) 0.05 *M* Na_2CO_3 (b) 0.05 *M* $AgNO_3$
(c) pure water (d) 0.05 *M* NH_3

48. The following equilibrium exists in aqueous solution;

$$CH_3COOH \rightleftharpoons H^+ + CH_3COO^-$$

If dilute HCl is added:
(a) the equilibrium constant will increase
(b) the equilibrium constant will decrease
(c) acetate ion concentration will increase
(d) acetate ion concentration will decrease

49. According to Arrhenius concept, base is a substance that:
(a) gives H^+ ions in solution
(b) gives OH^- ions in solution
(c) accepts electrons
(d) donates electrons

50. According to Bronsted-Lowry concept an acid is a substance which:
(a) accepts proton (b) gives an electron pair
(c) gives proton (d) combines with H_3O^+ ions

51. According to Lewis concept, a base is a substance which:
(a) donates an electron pair (b) accepts an electron pair
(c) produces hydronium ions (d) combines with OH^- ions

52. The strength of the acid depends on the:
(a) number of hydrogen atoms present in the molecule
(b) oxygen content
(c) density
(d) concentration of hydrogen ions furnished by ionisation

53. Cl^- ion is the conjugate base of:
(a) HCl (b) HOCl (c) $HClO_3$ (d) $HClO_4$

54. Which one of the following is the strongest acid?
(a) CH_3COOH (b) $CH_2ClCOOH$
(c) $CHCl_2COOH$ (d) CCl_3COOH

55. Number of H^+ ions present in 250 mL of lemon juice of pH = 3 is: **[PMT (Kerala) 2008]**
(a) 1.506×10^{22} (b) 1.506×10^{23}
(c) 1.506×10^{20} (d) 3.012×10^{21}
(e) 2.008×10^{23}
[**Hint:** $[H^+] = 10^{-3}\,M$

$$\text{Number of moles of } H^+ \text{ ions in 250 mL} = \frac{10^{-3}}{4} \times 6.023 \times 10^{23}$$
$$= 1.506 \times 10^{20}\,]$$

56. Conjugate acid of OH^- base is:
(a) H_2 (b) H_2O (c) H^+ (d) H_3O^+

57. Which among the following qualifies as a Lewis acid?
(a) NaF (b) NaCl (c) BF_3 (d) $MgCl_2$

58. Which of the following will qualify as Lewis base?
(a) BCl_3 (b) CH_4 (c) Cl_2 (d) NH_3

59. NH_4^+ ion in an aqueous solution will behave as:
(a) a base (b) an acid
(c) both acid and base (d) neutral

60. In the dissociation of bicarbonate ion, the conjugate base involved is:
(a) CO_3^{2-} (b) CO_2 (c) H_2CO_3 (d) CO

61. Which one of the following is an acidic salt?
(a) $NaHSO_4$ (b) Na_2SO_4 (c) Na_2SO_3 (d) Na_2SO_4

62. The conjugate acid of NH_2^- is:
(a) NH_4^+ (b) NH_3 (c) NH_2OH (d) N_2H_4

63. The correct increasing order of strengths of following acids is:
(a) $H_2SO_4, CH_3COOH, H_2CO_3$
(b) $CH_3COOH, H_2SO_4, H_2CO_3$
(c) $H_2CO_3, CH_3COOH, H_2SO_4$
(d) $CH_3COOH, H_2CO_3, H_2SO_4$

64. The decreasing order of strength of following bases is:
(a) Cl^-, CH_3COO^-, NH_3 (b) CH_3COO^-, NH_3, Cl^-
(c) CH_3COO^-, Cl^-, NH_3 (d) NH_3, CH_3COO^-, Cl^-

65. Which one of the following does not act as a Bronsted acid?
(a) NH_4^+ (b) HCO_3^- (c) HSO_3^- (d) CH_3COO^-

66. Of the given anions, the strongest Bronsted base is:
(a) ClO^- (b) ClO_2^- (c) ClO_3^- (d) ClO_4^-

67. The compound that is not a Lewis acid is:
(a) $BaCl_2$ (b) $AlCl_3$ (c) BCl_3 (d) $SnCl_4$

68. The dissociation constants of two acids HA_1 and HA_2 are 3.0×10^{-4} and 1.8×10^{-5} respectively. The relative strengths of the acids will be:
(a) 1 : 4 (b) 4 : 1 (c) 1 : 16 (d) 16 : 1

69. In the acid-base relation;
$$HCl + CH_3COOH \rightleftharpoons Cl^- + CH_3COOH_2^+,$$
the conjugate acid of acetic acid is:
(a) Cl^- (b) HCl
(c) $CH_3COOH_2^+$ (d) H_3O^+

70. The numerical value of negative power to which 10 must be raised in order to express hydrogen ion concentration, is equal to:
(a) strength of the solution
(b) pH of the solution
(c) degree of hydrolysis
(d) solubility product of the electrolyte

71. Which one of the following solutions will have pH close to unity? **[IIT 1992; PMT(Kerala) 2008]**
(a) 100 mL of *M*/10 HCl + 100 mL of *M*/10 NaOH
(b) 55 mL of *M*/10 HCl + 45 mL of *M*/10 NaOH
(c) 10 mL of *M*/10 HCl + 90 mL of *M*/10 NaOH
(d) 75 mL of *M*/5 HCl + 25 mL of *M*/5 NaOH
(e) 50 mL of *M*/5 HCl + 50 mL of *M*/5 NaOH
[**Hint:** $M_{\text{mix}} V_{\text{mix}} = M_{\text{HCl}} V_{\text{HCl}} + M_{\text{NaOH}} V_{\text{NaOH}}$

$$M_{\text{mix}}(100) = \frac{1}{5} \times 75 + \frac{1}{5} \times 25 = 20$$
$$M_{\text{mix}} = 0.2$$
$$[H^+] = 0.2\,M$$
$$\text{pH} = -\log 0.2 = 0.7 \approx \text{close to unity}]$$

72. 0.1 *M* acetic acid solution is titrated against 0.1 *M* NaOH solution. What would be the difference in pH between 1/4 and 3/4 stages of neutralisation of acid?
(a) 2 log 3/4 (b) 2 log 1/4 (c) log 1/3 (d) 2 log 3

73. The pK_a of acetylsalicylic acid (aspirin) is 3.5. The pH of gastric juice in human stomach is about 2–3 and the pH in the small intestine is about 8. Aspirin will be:
(a) unionised in the small intestine and in the stomach
(b) completely ionised in the small intestine and in the stomach
(c) ionised in the stomach and almost unionised in the small intestine
(d) ionised in the small intestine and almost unionised in the stomach

74. When 10^{-6} mole of a monobasic strong acid is dissolved in one litre of solvent, the pH of the solution is:
(a) 6 (b) 7
(c) less than 6 (d) more than 7

75. When pH of a solution is 2, the hydrogen ion concentration in mol litre^{-1} is:
(a) 1×10^{-12} (b) 1×10^{-2} (c) 1×10^{-7} (d) 1×10^{-4}

76. At 90°C, pure water has $[H_3O^+] = 10^{-6}$ mol litre^{-1}. The value of K_w at 90°C is: **(MLNR 1990)**
(a) 10^{-6} (b) 10^{-12} (c) 10^{-14} (d) 10^{-8}

77. The pH of 10^{-8} molar solution of HCl in water is: **(CPMT 1990; MLNR 1992)**
(a) 8 (b) –8
(c) between 7 and 8 (d) between 6 and 7

78. When pH of 0.001 *M* solution of HCl is:
(a) 1.0 (b) 3 (c) 4.0 (d) 5.0

79. The pH of a solution containing 0.1 *N* NaOH solution is:
(a) 1 (b) 10^{-1} (c) 13 (d) 10^{-13}

80. When 0.4 g of NaOH is dissolved in one litre of solution, the pH of the solution is:
(a) 12 (b) 2 (c) 6 (d) 10

81. The pH of an aqueous solution of a 0.1 M solution of a weak monoprotic acid which is 1% ionised is:
(a) 1 (b) 2 (c) 3 (d) 11

82. The pH of a 0.002 N acetic acid solution if it is 2.3% ionised at this dilution is: ($\log 4.6 = 0.6628$)
(a) 4.3372 (b) 0.4337 (c) 3.4337 (d) 0.6628

83. 0.1 M HCl and 0.1 M H_2SO_4 each of volume 2 mL are mixed and the volume is made up to 6 mL by adding 2 mL of 0.01 N NaCl solution. The pH of the resulting mixture is:
(a) 1.17 (b) 1.0
(c) 0.3 (d) $\log 2 - \log 3$

[**Hint:** Number of millimoles of $H^+ = 0.1 \times 2 + 0.1 \times 2 \times 2 = 0.6$

Concentration of $[H^+] = \frac{0.6}{6} = 0.1$ M

$$pH = -\log[H^+]$$
$$= -\log 0.1 = 1]$$

84. The pH and pOH of 0.1 M aqueous solution of HNO_3 are:
(a) 0, 14 (b) 14, 0 (c) 13, 1 (d) 1, 13

85. The pH of a neutral solution at 50° C is: ($K_w = 10^{-13.26}$ at 50° C)
(a) 7 (b) 6.0 (c) 7.23 (d) 6.63

86. The pH of 0.005 molar aqueous solution of sulphuric acid is approximately:
(a) 0.005 (b) 1 (c) 0.1 (d) 2.0

87. 20 mL of 0.1 N HCl is mixed with 20 mL of 0.1 N KOH solution; the pH of the solution will be:
(a) 0 (b) 2 (c) 7 (d) 9

88. When the pH changes from 4 to 2, the hydrogen ion concentration will increase by a factor:
(a) 2 (b) 1/2 (c) 10^2 (d) $10^{0.5}$

89. 100 mL of 0.2 N HCl is added to 100 mL of 0.18 N NaOH and the whole volume is made one litre. The pH of the resulting solution is:
(a) 1 (b) 2 (c) 3 (d) 4

90. 10 mL of 0.1 N HCl is added to 990 mL solution of NaCl. The pH of the resulting solution is:
(a) zero (b) 3 (c) 7 (d) 10

91. Solutions with reserve acidity and alkalinity are called:
(a) isohydric solutions (b) true solutions
(c) normal solutions (d) buffer solutions

92. A solution which is resistant to changes of pH on dilution, or addition of small amounts of an acid or a base is known as:
(a) buffer solution (b) true solution
(c) isohydric solution (d) ideal solution

93. Which of the following is a buffer solution?
(a) $CH_3COOH + CH_3COONa$
(b) NaCl + NaOH
(c) $HCl + NH_4Cl$
(d) $CH_3COOH + HCl$

94. The hydrogen ion concentration of a buffer solution consisting of a weak acid and its sodium salt is given by:
(a) $[H^+] = K_a \frac{[\text{Acid}]}{[\text{Salt}]}$ (b) $[H^+] = K_a\,[\text{Salt}]$
(c) $[H^+] = K_a\,[\text{Acid}]$ (d) $[H^+] = K_a \frac{[\text{Salt}]}{[\text{Acid}]}$

95. When a buffer solution of CH_3COOH and CH_3COONa is diluted with water:
(a) CH_3COO^- ion concentration increases
(b) $[H^+]$ ion concentration increases
(c) OH^- ion concentration increases
(d) H^+ ion concentration does not change

96. In a buffer solution consisting of a weak acid and its salt, the ratio of concentration of salt to acid is increased tenfold; then the pH of the solution will:
(a) increase by one (b) increase tenfold
(c) decrease by one (d) decrease tenfold

97. Acetic acid and propionic acid have K_a values 1.75×10^{-5} and 1.3×10^{-5} respectively at a certain temperature. An equimolar solution of a mixture of the two acids is partially neutralised by NaOH. How is the ratio of the contents of acetate and propionate ions related to the K_a values and the molarity?
(a) $\left[\frac{\alpha}{1-\alpha}\right] = \frac{1.75}{1.3} \times \left[\frac{\beta}{1-\beta}\right]$, where, α and β are ionised fractions of the acids
(b) The ratio is unrelated to the K_a values
(c) The ratio is unrelated to the molarity
(d) The ratio is unrelated to the pH of the solution

98. A weak acid of dissociation constant 10^{-5} is being titrated with aqueous NaOH solution. The pH at the point of one-third neutralisation of the acid will be: **[JEE (WB) 2010]**
(a) $5 + \log 2 - \log 3$ (b) $5 - \log 2$
(c) $5 - \log 3$ (d) $5 - \log 6$

[**Hint :** $pK_a = -\log 10^{-5} = 5$

$$pH = pK_a + \log\frac{[\text{salt}]}{[\text{acid}]}$$
$$= 5 + \log\frac{1/3}{2/3} = 5 - \log 2]$$

99. Which of the following salts when dissolved in water will hydrolyse?
(a) NaCl (b) KCl (c) NH_4Cl (d) Na_2SO_4

100. The aqueous solution of $AlCl_3$ is acidic due to:
(a) cation hydrolysis
(b) anion hydrolysis
(c) hydrolysis of both the ions
(d) dissociation

101. A certain buffer solution contains equal concentration of X^- and H_X. The K_b for X^- is 10^{-10}. The pH of the buffer is:
(a) 4 (b) 7 (c) 10 (d) 14

102. An acidic buffer solution can be prepared by mixing the solutions of:
(a) sodium acetate and acetic acid
(b) ammonium chloride and ammonium hydroxide
(c) sulphuric acid and sodium hydroxide
(d) sodium chloride and sodium hydroxide

103. The compound whose aqueous solution has highest pH, is:
(a) NaCl (b) NH_4Cl
(c) CH_3COONH_4 (d) Na_2CO_3

104. The compound whose 0.1 *M* solution basic, is:
(a) ammonium chloride (b) ammonium acetate
(c) ammonium sulphate (d) sodium acetate

105. Aqueous solution of copper sulphate:
(a) turns blue litmus red
(b) turns red litmus blue
(c) does not affect litmus
(d) affects both red and blue litmus

106. When an equivalent of a strong acid is added to one equivalent of a weak base, the resulting solution will be:
(a) neutral (b) acidic
(c) alkaline (d) coloured

107. Indicators used in acid-base titrations are:
(a) strong organic acids
(b) strong organic bases
(c) weak organic acids or weak organic bases
(d) non-electrolytes

108. For the titration between oxalic acid and sodium hydroxide, the indicator used is:
(a) potassium permanganate (b) phenolphthalein
(c) litmus (d) methyl orange

109. Phenolphthalein gives a pink colour in alkaline medium due to the fact that:
(a) it is a coloured compound
(b) it ionises to give coloured ions
(c) it is decomposed by alkali
(d) it forms a complex compound with alkali

110. Which is the best choice for weak base-strong acid titration ? [JEE (Orissa) 2008]
(a) Methyl red (b) Litmus
(c) Phenol red (d) Phenolphthalein

111. Water is:
(a) a base (b) an acid
(c) non-electrolyte (d) an amphiprotic molecule

112. An aqueous solution, whose pH is zero, is:
(a) alkaline (b) neutral
(c) acidic (d) amphoteric

113. 0.1 *N* solution of Na_2CO_3 is being titrated with 0.1 *N* HCl. The best indicator to be used is:
(a) potassium ferricyanide (b) phenolphthalein
(c) methyl red (d) litmus

114. In the reaction, $AlCl_3 + Cl^- = AlCl_4^-$, $AlCl_3$ can be classified as:
(a) a base (b) an acid
(c) a salt (d) none of these

115. Sulphuric acid is a dibasic acid. Hence, it forms:
(a) acidic salt (b) basic and acidic salt
(c) acidic and normal salt (d) double salt

116. The buffer solutions play an important role in:
(a) increasing the pH value (b) decreasing the pH value
(c) keeping the pH constant (d) none of these

117. Which of the following will occur if 1.0 *M* solution of a weak acid is diluted to 0.01 *M* at constant temperature? (AIIMS 1993)
(a) $[H^+]$ will decrease to 0.01 *M*
(b) pH will decrease by 2 units
(c) K_a will increase
(d) Percentage ionisation will increase

118. Which one of the following indicators works in the pH range 8 – 9.8?
(a) Litmus (b) Phenolphthalein
(c) Methyl red (d) Methyl orange

119. What is $[OH^-]$ in the final solution prepared by mixing 20 mL of 0.05 *M* HCl with 30 mL of 0.10 *M* $Ba(OH)_2$? [CBSE (PMT) 2009]
(a) 0.12 *M* (b) 0.10 *M*
(c) 0.40 *M* (d) 0.005 *M*

[**Hint :** $n_{H^+} = \frac{MV}{1000} = \frac{0.05\times 20}{1000} = 10^{-3}$ mol

$$n_{OH^-} = 2\times n_{Ba(OH)_2}$$
$$= 2\times\frac{MV}{1000} = 2\times\frac{0.1\times 30}{1000} = 6\times 10^{-3}\text{ mol}$$

Remaining moles of OH^- after neutralization
$$= 6\times 10^{-3} - 10^{-3}$$
$$= 5\times 10^{-3}\text{ mol}$$

Conc. of $[OH^-] = \frac{n_{OH^-}}{V}\times 1000 = \frac{5\times 10^{-3}}{50}\times 1000 = 0.1M$]

120. The following reaction is known to occur in the human body;
$$CO_2 + H_2O \rightleftharpoons H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$
If CO_2 escapes from the system:
(a) pH will decrease
(b) H^+ ion concentration will decrease
(c) H_2CO_3 concentration will be unaltered
(d) the forward reaction will be promoted

121. The pH of human blood is about:
(a) 5.2 (b) 6.3 (c) 7.4 (d) 8.3

122. The dissociation constants of acids H*A*, H*B*, H*C* and H*D* are 2.6×10^{-3}, 5.3×10^{-9}, 1.1×10^{-2} and 7.5×10^{-5} respectively. The weakest acid amongst these acids is:
(a) H*A* (b) H*B* (c) H*C* (d) H*D*

123. The addition of sodium carbonate in pure water causes:
(a) an increase in the hydrogen ion concentration
(b) a decrease in hydroxyl ion concentration
(c) no change in pH
(d) an increase in pH

124. The best indicator for titrating HCl against NH_4OH is:
(a) litmus (b) phenolphthalein
(c) phenol red (d) methyl orange

125. A buffer solution is used in:
(a) preparation of potash alum
(b) the removal of PO_4^{3-} ions
(c) increasing the pH value of a solution
(d) precipitation of $Cr(OH)_3$ from $CrCl_3$

126. A certain weak acid has a dissociation constant of 1.0×10^{-4}. The equilibrium constant for its reaction with a strong base is:
(a) 1.0×10^{-4} (b) 1.0×10^{-10}
(c) 1.0×10^{10} (d) 1.0×10^{-14}

[**Hint:** $HA + BOH \rightleftharpoons BA + H_2O$. The equilibrium constt. $= 1/K_h$ and $K_h = K_w/K_a$]

127. Which one of the following statements is correct?
(a) CH_3COOH is a weak acid
(b) NH_4Cl gives an alkaline solution in water
(c) CH_3COONa gives an acidic solution in water
(d) NH_4OH is a strong base

128. In the hydrolytic equilibrium $A^- + H_2O \rightleftharpoons HA + OH^-$ $K_a = 1.0 \times 10^{-5}$. The degree of hydrolysis of 0.001 M solution of the salt is:
(a) 10^{-3} (b) 10^{-4} (c) 10^{-5} (d) 10^{-6}

129. The pH of an aqueous solution of 0.1 M solution of the salt of a weak base ($K_b = 1.0 \times 10^{-5}$) and a strong acid is:
(a) 4.5 (b) 5.0 (c) 5.5 (d) 6.0

[Hint: First calculate degree of hydrolysis;

$$\alpha^2 C = K_h, K_h = (K_w / K_b), [H^+] = \alpha C]$$

130. The pH of the solution obtained by mixing equal volumes of solution of pH = 5 and pH = 3 of the same electrolyte is:
(a) 3.3 (b) 4.0 (c) 4.5 (d) 2.0

[Hint: $[H^+] = \frac{10^{-3} + 10^{-5}}{2} = \frac{100 \times 10^{-5} + 10^{-5}}{2} = 50.5 \times 10^{-5}$]

131. pK_a values of four acids are given below at 25°C. The strongest acid is: [PMT (MP) 1990]
(a) 2.0 (b) 2.5 (c) 3.0 (d) 4.0

132. The ionisation constant of NH_4^+ in water is 5.6×10^{-10} at 25°C. The rate constant of the reaction of NH_4^+ and OH^- to form NH_3 and H_2O at 25°C is 3.4×10^{10} L mol^{-1} s^{-1}. The rate constant for proton transfer from water to NH_3 is:
(a) 6.07×10^5 s^{-1} (b) 6.07×10^{-10} s^{-1}
(c) 6.07×10^{-5} s^{-1} (d) 6.07×10^{10} s^{-1}

133. The pH of a soft drink is 3.82. The hydrogen ion concentration will be: (given a antilog 0.18 = 1.5) [PET (MP) 1990]
(a) 1.96×10^{-2} mol lit^{-1} (b) 1.96×10^{-5} mol lit^{-1}
(c) 1.5×10^{-4} mol lit^{-1} (d) 1.5×10^{-2} mol lit^{-1}

134. 100 mL of 0.1 M HCl is mixed with 100 mL of 0.01 M HCl. The pH of the resulting solution is:
(a) 2.0 (b) 1.0
(c) 1.26 (d) none of these

135. How many times has a solution of pH 2 higher acidity than a solution of pH 6?
(a) 10,000 (b) 12
(c) 400 (d) 4

136. For a concentrated solution of a weak electrolyte A_xB_y of concentration 'C', the degree of dissociation 'α' is given as: [PET (Kerala) 2008]

(a) $\alpha = \sqrt{K_{eq.}/C(x+y)}$ (b) $\alpha = \sqrt{\frac{C K_{eq.}}{xy}}$

(c) $\alpha = \left[\frac{K_{eq.}}{(C^{x+y-1} x^x y^y)}\right]^{1/x+y}$

(d) $\alpha = \frac{K_{eq.}}{Cxy}$, (e) $\alpha = \frac{K_{eq.}}{C^{xy}}$

[Hint: $A_xB_y \rightleftharpoons xA^{y+} + yB^{x-}$

$$\begin{array}{llll} t_0 & C & 0 & 0 \\ t_{eq.} & C(1-\alpha) & xC\alpha & yC\alpha \end{array}$$

$$K_{eq.} = \frac{(xC\alpha)^x (yC\alpha)^y}{C(1-\alpha)}$$

$$\approx \frac{(xC\alpha)^x (yC\alpha)^y}{C} \quad \because (1-\alpha) \approx 1$$

$$\alpha = \left[\frac{K_{eq.}}{C^{x+y-1} x^x y^y}\right]^{1/x+y}$$]

137. The following equilibrium is established when hydrogen chloride is dissolved in acetic acid;

$$HCl + CH_3COOH \rightleftharpoons Cl^- + CH_3COOH_2^+$$

The set that characterises the conjugate acid-base pairs is: (IIT 1992)
(a) (HCl, CH_3COOH) and ($CH_3COOH_2^+$, Cl^-)
(b) (HCl, $HC_3COOH_2^+$) and (CH_3COOH, Cl^-)
(c) ($CH_3COOH_2^+$, HCl) and (Cl^-, CH_3COOH)
(d) (HCl, Cl^-) and ($CH_3COOH_2^+$, CH_3COOH)

138. The pH of a 10^{-10} M NaOH solution is: [PMT (Uttarakhand) 2006]
(a) 10 (b) 7.01 (c) 6.99 (d) 4

139. Which of the following is strongest Lewis base?
(a) CH_3^- (b) Ag^+ (c) NH_3 (d) H_2

140. If the solubility of lithium sodium hexafluoro aluminate, $Li_3Na_3(AlF_6)_2$ is 'S' mol L^{-1}, its solubility product is equal to: (CPMT 1992)
(a) S^8 (b) $12S^3$ (c) $18S^3$ (d) $2916S^8$

141. Given that the dissociation constant for water is $K_w = 1 \times 10^{-14}$ mol^2 L^{-2}. The pH of a 0.001 molar KOH solution is: (MLNR 1991)
(a) 10^{-11} (b) 10^{-3} (c) 3 (d) 11

142. Which one of the following solutions will have the highest pH value? (CPMT 1992)
(a) 0.01 M NaOH (b) 0.02 M CH_3COONa
(c) 0.10 M $NaHCO_3$ (d) 0.10 M H_2SO_4

143. In the titration of NH_4OH with HCl, the indicator which cannot be used is:
(a) phenolphthalein
(b) methyl orange
(c) methyl red
(d) both methyl orange and methyl red

144. pH of the buffer containing 0.6 g of acetic acid and 8.2 g of sodium acetate in 1 litre of water is: (pK_a of acetic acid = 4.5)
(a) 7.5 (b) 4.5 (c) 5.5 (d) 6.5

145. At 25°C, the dissociation constants of CH_3COOH and NH_4OH in aqueous solution are almost the same. The pH of a solution of 0.01 N CH_3COOH is 4.0 at 25°C. The pH of 0.01 N NH_4OH solution at the same temperature would be: (IIT 1990)
(a) 3.0 (b) 4.0
(c) 10.0 (d) 10.5

[Hint: $[H^+]$ in CH_3COOH soln. = 10^{-4};
Similarly $[OH^-]$ in NH_4OH soln. = 10^{-4};

So, $[H^+] = \frac{K_w}{[OH^-]} = \frac{10^{-14}}{10^{-4}} = 10^{-10}$]

146. The dissociation constant of acetic acid is 1.8×10^{-5} and that of ammonium hydroxide is also 1.8×10^{-5} at 25°C. Hence, an aqueous solution of ammonium acetate is:
(a) acidic (b) basic
(c) neutral (d) slightly acidic

147. The concentration of OH^- ions in neutral solution is:
(a) 1×10^{-14} g ions/litre (b) 1×10^{14} g ions/litre
(c) 1×10^{7} g ions/litre (d) 1×10^{-7} g ions/litre

148. 10^{-6} M NaOH is diluted by 100 times. The pH of diluted base is: **[PMT (Pb.) 1993]**
(a) between 6 and 7 (b) between 10 and 11
(c) between 7 and 8 (d) between 5 and 6

149. Ionic dissociation of acetic acid is represented as:

$$CH_3COOH + H_2O \rightleftharpoons CH_3COO^- + H_3O^+$$

According to Lowry and Bronsted, the reaction possesses: **[CEE (Bihar) 1992]**
(a) an acid and three bases (b) two acids and two bases
(c) an acid and a base (d) three acids and a base

150. The concept of an acid as an acceptor of a pair of electrons was introduced by:
(a) Lowry (b) Bronsted (c) Arrhenius (d) Lewis

151. The ionic product of water will increase if:
(a) pressure is decreased (b) H^+ ions are added
(c) OH^- ions are added (d) temperature is increased

152. One litre of a buffer solution containing 0.01 M NH_4Cl and 0.1 M NH_4OH having pK_b of 5 has pH of:
(a) 10 (b) 9 (c) 4 (d) 6

153. An aqueous solution of ferric chloride would be:
(a) acidic (b) neutral (c) basic (d) amphoteric

154. An acid solution of pH 6 is diluted hundred times. The pH of the solution becomes:
(a) 6 (b) 6.95 (c) 4 (d) 8

155. The pH of a solution is 5.0. To this solution sufficient acid is added to decrease the pH to 2.0. The increase in hydrogen ion concentration is: **(CPMT 1990)**
(a) 100 times (b) 10 times (c) 1000 times (d) 2.5 times

156. Conjugate base of HPO_4^{2-} is: **[PMT (MP) 1991]**
(a) PO_4^{3-} (b) $H_2PO_4^-$
(c) H_3PO_4 (d) H_4PO_3

157. The pH of a solution is 2. Its pH is to be changed to 4. Then the H^+ ion concentration of original solution has to be:
(a) halved (b) doubled
(c) increased 100 times (d) decreased 100 times

158. The pH value of 0.1 mol/litre HCl is approximately 1. The approximate pH value of 0.05 mol/litre H_2SO_4 is most likely to be:
(a) 0.05 (b) 0.5
(c) 1 (d) 2

159. The aqueous solution of a salt is alkaline. This shows that the salt is made from: **[PMT (MP) 1991]**
(a) a weak acid and a weak base
(b) a weak acid and a strong base
(c) a strong acid and a strong base
(d) a strong acid and a weak base

160. A semi-normal solution of sodium acetate in water has $[H^+]$:
(a) less than 10^{-7} M (b) greater than 10^{-7} M
(c) equal to 10^{-7} M (d) none of these

161. The most important buffer in the blood consists of:
(a) HCl and Cl^- (b) H_2CO_3 and HCO_3^-
(c) H_2CO_3 and Cl^- (d) HCl and HCO_3^-

162. The pH of a buffer solution containing 25 mL of 1 M CH_3COONa and 25 mL of 1 M CH_3COOH will be appreciably affected by 5 mL of:
(a) 1 M CH_3COOH (b) 5 M HCl
(c) 5 M CH_3COOH (d) 1 M NH_4OH

163. 50 mL of 2 N acetic acid mixed with 10 mL of 1 N sodium acetate solution will have an approximate pH:
(a) 7 (b) 6 (c) 5 (d) 4

164. The solution of which salt in water is acidic?
(a) $Na_2B_4O_7$ (b) $NaHCO_3$ (c) KCl (d) $FeCl_3$

165. Which of the following expressions is not true?
(a) $[H^+] = [OH^-] = \sqrt{K_w}$ for a neutral solution
(b) $[H^+] > \sqrt{K_w}$ and $[OH^-] < \sqrt{K_w}$ for an acidic solution
(c) $[H^+] < \sqrt{K_w}$ and $[OH^-] > \sqrt{K_w}$ for an alkaline solution
(d) $[H^+] = [OH^-] = 10^{-7}$ M for a neutral solution at all temperatures

166. Ammonia gas dissolves in water to give NH_4OH. In this reaction water acts as: **[PMT (MP) 1990]**
(a) an acid (b) a base
(c) a salt (d) a conjugate base

167. What is the decreasing order of strength of the bases OH^-, NH_2^-, $H—C{=}C^-$ and $CH_3CH_2^-$? **(IIT 1993)**
(a) $CH_3CH_2^- > NH_2^- > H—C{\equiv}C^- > OH^-$
(b) $H—C{\equiv}C^- > CH_3—CH_2^- > NH_2^- > OH^-$
(c) $OH^- > NH_2^- > H—C{\equiv}C^- > CH_3CH_2^-$
(d) $NH_2^- > H—C{\equiv}C^- > OH^- > CH_3CH_2^-$

168. The best explanation for the solubility of MnS in dil. HCl is that: **(MLNR 1993)**
(a) solubility product of $MnCl_2$ is less than that of MnS
(b) concentration of Mn^{2+} is lowered by the formation of complex ions
(c) concentration of sulphide ions is lowered by oxidation to free sulphur
(d) concentration of sulphide ions is lowered by the formation of weak acid H_2S

169. The correct order of increasing $[H_3O^+]$ in the following aqueous solution is: **(MLNR 1993; AFMC 2009)**
(a) 0.001 M H_2S < 0.01 M H_2SO_4 < 0.01 M NaCl < 0.01 M $NaNO_2$
(b) 0.01 M NaCl < 0.01 M $NaNO_2$ < 0.01 M H_2S < 0.01 M H_2SO_4
(c) 0.01 M $NaNO_2$ < 0.01 M NaCl < 0.01 M H_2S < 0.01 M H_2SO_4
(d) 0.01 M H_2S < 0.01 M NaCl < 0.01 M $NaNO_2$ < 0.01 M H_2SO_4

170. Which of the following statements/relationships is not correct?
(a) Upon hydrolysis salt of strong base and weak acid gives a solution with pH > 7
(b) $\text{pH} = \log \dfrac{1}{[\text{H}^+]}$
(c) Only at 25° C, the pH of pure water is 7
(d) The value of $\text{p}K_w$ at 25°C is 7

171. Fear and excitement generally cause one to breathe rapidly and it results in the decrease of CO_2 concentration in blood. In what way will it change the pH of the blood? **(IIT 1993)**
(a) pH will decrease (b) pH will increase
(c) No change (d) pH will adjust to 7

172. Nucleophiles are:
(a) Lewis acids (b) Lewis bases
(c) Bronsted acids (d) none of these

173. Electrophiles are:
(a) Lewis acids (b) Lewis bases
(c) Bronsted acids (d) Bronsted bases

174. K_h (hydrolysis constant) of ammonium benzoate can be calculated by the formula:
(a) $\sqrt{\dfrac{K_w}{K_a C}}$ (b) $\sqrt{\dfrac{K_w}{K_a \times K_b}}$ (c) $\sqrt{\dfrac{K_w}{K_b \times C}}$ (d) $\sqrt{\dfrac{K_h}{C}}$

175. The pH of a neutral water is 6.5. Then the temperature of water: **[PET (Kerala) 2007]**
(a) is 25°C
(b) is more than 25°C
(c) is less than 25°C
(d) can be more or less than 25°C
(e) cannot be predicted

176. The buffer capacity of buffer containing acid with $\text{p}K_a = 4.0$ is highest when its pH is equal to:
(a) 6.0 (b) 5.0
(c) 4.0 (d) 3.0

177. K_{sp} (AgCl) > K_{sp} (AgBr) > K_{sp} (AgI). This means that:
(a) AgCl is more ionised than AgBr and AgI
(b) both AgBr and AgI are less soluble than AgCl
(c) AgI is most soluble
(d) AgBr is more soluble than AgCl but less soluble than AgI

178. In the hydrolytic equilibrium;

$$B^+ + H_2O \rightleftharpoons BOH + H^+$$

$K_b = 1 \times 10^{-5}$. The hydrolysis constant is:
(a) 10^{-5} (b) 10^{-19} (c) 10^{-10} (d) 10^{-9}

179. The solution of a salt of a weak acid and weak base will have pH: ($K_b = 1.0 \times 10^{-6}$ and $K_a = 1.0 \times 10^{-4}$)
(a) 7.0 (b) 8.0
(c) 6 (d) 4.0

180. 0.1 *N* solution of sodium acetate will have pH: ($\text{p}K_a = 4.57$)
(a) 8.78 (b) 11.57
(c) 4.57 (d) 7.0

181. The following acids have been arranged in the order of decreasing acid strength. Identify the correct order: **(IIT 1996)**
ClOH (I) BrOH (II) IOH (III)
(a) I > II > III (b) II > I > III
(c) III > II > I (d) I > III > II

182. Which of the following statements is correct?
(a) $\text{p}K_w$ increases with increase of temperature
(b) $\text{p}K_w$ decreases with increase of temperature
(c) $\text{p}K_w = 14$ at all temperatures
(d) $\text{p}K_w = \text{pH}$ at all temperatures

183. For a concentrated solution of a weak electrolyte A_x and B_y, the degree of dissociation is given as:
(a) $\alpha = \sqrt{K_{eq}/c(x+y)}$
(b) $\alpha = \sqrt{K_{eq}c/(xy)}$
(c) $\alpha = (K_{eq}/c^{x+y-1}\, x^x y^y)^{1/(x+y)}$
(d) $\alpha = \sqrt{K_{eq}/xyc}$

184. A solution is saturated with respect to $SrCO_3$ and SrF_2. The $[CO_3^{2-}]$ was found to be $1.2 \times 10^{-3}\ M$. The concentration of F^- in the solution would be:
(a) $1.3 \times 10^{-3}\ M$ (b) $2.6 \times 10^{-2}\ M$
(c) $3.7 \times 10^{-2}\ M$ (d) $5.8 \times 10^{-7}\ M$
(Given: K_{sp} $SrCO_3 = 7.0 \times 10^{-10}\ M^2$,
$K_{sp}(SrF_2) = 7.9 \times 10^{-10}\ M^3$)

185. The solubility of sparingly soluble electrolyte $M_m A_a$ in water is given by the expression:
(a) $S = \left[\dfrac{K_{sp}}{m^m a^a}\right]^{m+a}$ (b) $S = \left[\dfrac{K_{sp}}{m^m a^a}\right]^{1/(m+a)}$
(c) $S = \left[\dfrac{K_{sp}}{m^a a^m}\right]^{m+a}$ (d) $S = \left[\dfrac{K_{sp}}{m^a a^m}\right]^{1/(m+a)}$

186. The solubility of mercurous chloride in water will be given as:
(a) $S = K_{sp}$ (b) $S = K_{sp}/4$
(c) $S = (K_{sp}/4)^{1/2}$ (d) $S = (K_{sp}/4)^{1/3}$

187. In the titration of acetic acid *versus* sodium hydroxide, the pH of the solution at equivalence point (when temperature is 25°C) is:
(a) about 5.5 (b) about 6.5
(c) about 7 (d) about 8.5

188. When K_2O is added to water, the solution is basic because it contains a significant concentration of:
(a) K^+ (b) OH^-
(c) O^{3-} (d) O_2^{2-}

189. The blood buffers are most often involved in stabilizing the pH in presence of metabolically produced:
(a) acids (b) bases
(c) salts (d) none of these

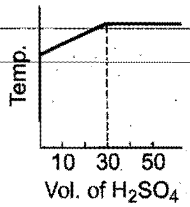
190. The colour of $CuCr_2O_7$ solution in water is green because:
(a) Cu^{2+} ion is green
(b) $Cr_2O_7^{2-}$ ions are green
(c) both the ions are green
(d) Cu^{2+} ion is blue and $Cr_2O_7^{2-}$ ion is yellow

191. An acid with molecular formula $C_7H_6O_3$ forms three types of sodium salts, *i.e.*, $C_7H_5O_3Na$, $C_7H_4O_3Na_2$ and $C_7H_3O_3Na_3$. The basicity of the acid is:
(a) one (b) two (c) three (d) four

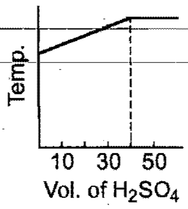
192. If the salts M_2X, QY_2 and PZ_3 have the same solubilities, their K_{sp} values are related as:
(a) $K_{sp}(M_2X) = K_{sp}(QY_2) < K_{sp}(PZ_3)$
(b) $K_{sp}(M_2X) > K_{sp}(QY_2) = K_{sp}(PZ_3)$
(c) $K_{sp}(M_2X) = K_{sp}(QY_2) = K_{sp}(PZ_3)$
(d) $K_{sp}(M_2X) > K_{sp}(QY_2) > K_{sp}(PZ_3)$

193. In an experiment to determine the enthalpy of neutralization of sodium hydroxide with sulphuric acid, $50\,cm^3$ of 0.4 *M* sodium hydroxide were titrated thermometrically with 0.25 *M* sulphuric acid. Which of the following plots gives the correct representation?

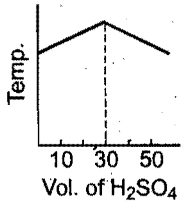
(a)



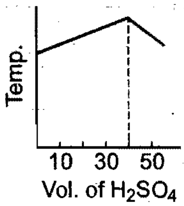
(b)



(c)



(d)



194. K_{sp} of CuS, Ag_2S and HgS are 10^{-31}, 10^{-44} and 10^{-54} respectively. Select the correct order for their solubility in water: (CBSE 1997)
(a) $Ag_2S > HgS > CuS$ (b) $HgS > CuS > Ag_2S$
(c) $HgS > Ag_2S > CuS$ (d) $Ag_2S > CuS > HgS$
[**Hint:** Solubility of Ag_2S ($4S^3 = K_{sp}$) and for CuS and HgS ($S^2 = K_{sp}$).]

195. If the K_b value in the hydrolysis reaction,

$$B^+ + H_2O \rightleftharpoons BOH + H^+$$

is 1.0×10^{-6}, then the hydrolysis constant of the salt would be: (IIT 1998)
(a) 1.0×10^{-6} (b) 1.0×10^{-7} (c) 1×10^{-8} (d) 1.0×10^{-9}

196. The concentration of $[H^+]$ and $[OH^-]$ of a 0.1 *M* aqueous solution of 2% ionised weak acid is: (ionic product of water $= 1 \times 10^{-14}$) (CBSE 1999)
(a) 0.2×10^{-3} *M* and 5×10^{-11} *M*
(b) 1×10^{-3} *M* and 3×10^{-11} *M*
(c) 2×10^{-3} *M* and 5×10^{-12} *M*
(d) 3×10^{-2} *M* and 4×10^{-13} *M*
[**Hint:** $[H^+] = C \times \alpha = 0.1 \times 0.02 = 2 \times 10^{-3}\,M$;
$[OH^-] = \dfrac{K_w}{[H^+]}$]

197. The pH value of decinormal solution of NH_4OH, which is 20% ionised, is: (CBSE [illegible])
(a) 13.30 (b) 14.70 (c) 12.30 (d) 12.95
[**Hint:** $[OH^-] = 0.1 \times 0.2 = 2 \times 10^{-3}$;
$pOH = 1.7\ pH = 14 - pOH$]

198. The pH of 0.1 *M* solution of the following salts increases in the order of: (IIT 1999)
(a) $NaCl < NH_4Cl < NaCN < HCl$
(b) $HCl < NH_4Cl < NaCl < NaCN$
(c) $NaCN < NH_4Cl < NaCl < HCl$
(d) $HCl < NaCl < NaCN < NH_4Cl$

199. A physician wishes to prepare a buffer solution at pH = 3.58 that efficiently resists a change in pH yet contains only small concentration of buffering agents. Which one of the following weak acids together with its sodium salt would be best to use? (CBSE 1997)
(a) *m*-chlorobenzoic acid ($pK_a = 3.98$)
(b) *p*-chlorobenzoic acid ($pK_a = 4.41$)
(c) 2,5-dihydroxybenzoic acid ($pK_a = 2.97$)
(d) Acetoacetic acid ($pK_a = 3.58$)

200. Which one does not give a buffer solution?
(a) Ammonia and sodium hydroxide in water
(b) Sodium acetate and acetic acid in water
(c) Ammonia and ammonium chloride in water
(d) Sodium acetate and hydrochloric acid in water

201. Conjugate base of $[Al(H_2O)_3(OH)_3]$ is:
(a) $[Al(H_2O)_3(OH)_2]^+$ (b) $[Al(H_2O)_3(OH)_2O]^-$
(c) $[Al(H_2O)_3(OH)_3]^-$ (d) $[Al(H_2O)_2(OH)_4]^-$

202. The solubility of calcium phosphate in water is *x* mol h^{-1} at 25°C. Its solubility product is equal to: [illegible] 1995
(a) $108x^2$ (b) $36x^3$
(c) $36x^5$ (d) $108x^5$

203. K_{sp} values for silver bromide, silver chloride and silver iodide are $5 \times 10^{-13}\ mol^2\ dm^{-6}$, $2 \times 10^{-10}\ mol^2\ dm^{-6}$ and $8 \times 10^{-17}\ mol^2\ dm^{-6}$ respectively. The order of solubility of these silver salts is : [illegible]
(a) AgCl > AgBr > AgI (b) AgI > AgBr > AgCl
(c) AgCl > AgI > AgBr (d) AgI > AgCl > AgBr

204. In the reaction,

$$I_2 + I^- \longrightarrow I_3^-$$

the Lewis base is: [illegible]
(a) I_2 (b) I^-
(c) I_3^- (d) none of these

205. Which of the following on reaction with H_2S does not produce metallic sulphide? (AIIMS [illegible])
(a) $CdCl_2$ (b) $ZnCl_2$ (c) $CoCl_2$ (d) $CuCl_2$

206. A buffer solution of pH = 9 can be prepared by mixing: (CPMT 2000)
(a) CH_3COONa and CH_3COOH
(b) NaCl and NaOH
(c) NH_4Cl and NH_4OH
(d) KH_2PO_4 and K_2HPO_4

207. Which of the following is the strongest Lewis base? [PMT (MP) [illegible]]
(a) CH_3^- (b) NH_2^- (c) OH^- (d) F^-

208. The monobasic acid among the following is : **(ISAT 2010)**

(a) H_3PO_3 (b) $H_2S_2O_7$
(c) H_3PO_2 (d) $H_4P_2O_7$

209. To Ag_2CrO_4 solution over its own precipitate, CrO_4^{2-} ions are added. This results in: **[MEE (Kerala) 2000]**

(a) increase in Ag^+ concentration
(b) decrease in Ag^+ concentration
(c) increase in solubility product
(d) shifting of Ag^+ ions from the precipitate into the solution

210. Aluminium chloride is: **(KCET 2000)**

(a) Bronsted Lowry acid (b) Arrhenius acid
(c) Lewis acid (d) Lewis base

211. A 50 mL solution of pH = 1 is mixed with a 50 mL solution of pH = 2. The pH of the mixture will be nearly: **[IAS (Prelim.) 1995]**

(a) 0.76 (b) 1.26 (c) 1.76 (d) 2.26

212. The $[Ag^+]$ in a saturated solution of Ag_2CrO_4 is $1.5 \times 10^{-4}\ M$. What is the solubility product of Ag_2CrO_4? **(SCRA 2009)**

(a) $3.375 \times 10^{-12} M^3$ (b) $1.6875 \times 10^{-10} M^3$
(c) $1.6875 \times 10^{-11} M^3$ (d) $1.6875 \times 10^{-12} M^3$

[**Hint :** $Ag_2CrO_4 \longrightarrow 2Ag^+ + CrO_4^{2-}$

$[Ag^+] = 1.5 \times 10^{-4}\ M \quad \therefore [CrO_4^{2-}] = 0.75 \times 10^{-4}\ M$

$K_{sp} = [Ag^+]^2[CrO_4^{2-}]$

$= [1.5 \times 10^{-4}]^2[0.75 \times 10^{-4}]$

$= 1.6875 \times 10^{-12} M^3$]

213. The pH of a buffer containing equal molar concentrations of a weak base and its chloride (K_b for weak base $= 2 \times 10^{-5}$, log 2 = 0.3) is:

(a) 5 (b) 9 (c) 4.7 (d) 9.3

214. The solubility product (K_{sp}) of AgCl is 1.8×10^{-10}. Precipitation of AgCl will occur only when equal volumes of solutions of: **[IAS (Prelim.) 1997; PET (MP) 2007]**

(a) $10^{-4}\ M\ Ag^+$ and $10^{-4}\ M\ Cl^-$ are mixed
(b) $10^{-7}\ M\ Ag^+$ and $10^{-7}\ M\ Cl^-$ are mixed
(c) $10^{-5}\ M\ Ag^+$ and $10^{-5}\ M\ Cl^-$ are mixed
(d) $10^{-10}\ M\ Ag^+$ and $10^{-10}\ M\ Cl^-$ are mixed

215. Solid $Ba(NO_3)_2$ is gradually dissolved in a $1 \times 10^{-4}\ M\ Na_2CO_3$ solution. At what concentration of Ba^{2+} will a precipitate begin to form ? (K_{sp} for $BaCO_3 = 5.1 \times 10^{-9}$) **(AIEEE 2009)**

(a) $4.1 \times 10^{-5}\ M$ (b) $5.1 \times 10^{-5}\ M$
(c) $8.1 \times 10^{-8}\ M$ (d) $8.1 \times 10^{-7}\ M$

216. How many gram of CaC_2O_4 will dissolve in distilled water to make one litre of unsaturated solution of it? (K_{sp} for $CaC_2O_4 = 2.5 \times 10^{-9}$ mol^2 lit^{-2}) **[PMT (MP) [illegible]]**

(a) 0.0064 g (b) 0.1028 g (c) 0.1280 g (d) 0.2056 g

217. When CO_2 dissolves in water, the following equilibrium is established,

$$CO_2 + 2H_2O \rightleftharpoons H_3O^+ + HCO_3^-$$

for which the equilibrium constant is 3.8×10^{-7} and pH = 6.0. The ratio of $[HCO_3^-]$ to $[CO_2]$ would be:

(a) 3.8×10^{-13} (b) 3.8×10^{-1} (c) 6.0 (d) 13.4

218. pH of a buffer solution decreases by 0.02 units when 0.12 g of acetic acid is added to 250 mL of a buffer solution of acetic acid and potassium acetate at 27°C. The buffer capacity of the solution is: **(EAMCET 2009)**

(a) 0.1 (b) 10 (c) 1 (d) 0.4

219. The dissociation constants of monobasic acids A, B, C and D are 6×10^{-4}, 5×10^{-5}, 3.6×10^{-6} and 7×10^{-10} respectively. The pH values of their 0.1 molar aqueous solutions are in the order:

(a) $A < B < C < D$ (b) $A > B > C > D$
(c) $A = B = C = D$ (d) $A > B < C > D$

220. If the equilibrium constant of the reaction of weak acid HA with strong base is 10^9, then pH in 0.1 M NaA is:

(a) 5 (b) 9 (c) 7 (d) 8

221. If the freezing point of 0.1 molal HA ($aq.$) is – 0.2046°C, then pH of the solution is: $[K_f\ (H_2O) = 1.86°\ mol^{-1}\ kg]$

~~(a) 1 (b) 2 (c) 1.3 (d) 1.7~~

222. ~~% ionisation of weak acid can be calculated as:~~

(a) $100\sqrt{\dfrac{K_a}{c}}$ (b) $\dfrac{100}{1 + 10^{(pK_a - pH)}}$
(c) both correct (d) none is correct

223. Assuming complete ionisation which will have maximum pH?

(a) 0.01 M NH_4Cl (b) 0.01 M $(NH_4)_2SO_4$
(c) 0.01 M $(NH_4)_3PO_4$ (d) equal

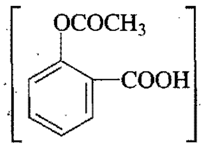
224. $H_2O + H_3PO_4 \rightleftharpoons H_3O^+ + H_2PO_4^-$; $pK_1 = 2.15$

$H_2O + H_2PO_4^- \rightleftharpoons H_3O^+ + HPO_4^{2-}$; $pK_2 = 7.20$

Hence, pH of 0.01 M NaH_2PO_4 is:

(a) 9.35 (b) 4.675 (c) 2.675 (d) 7.350

225. Acetyl salicylic acid



called aspirin is a pain killer with $pK_a = 2$. If two tablets each of 0.09 g mass, containing aspirin are dissolved in 100 mL solution. Its pH will be:

(a) 0.5 (b) 1.0
(c) 0.0 (d) 2.0

226. If ionic product of water is $K_w = 10^{-16}$ at 4°C, then a solution with pH = 7.5 at 4°C will:

(a) turn blue litmus red (b) turn red litmus blue
(c) turn turmeric paper brown (d) be neutral to litmus

227. How do we differentiate between Fe^{3+} and Cr^{3+} in group III? **(AIEEE 2002)**

(a) By taking excess of NH_4OH
(b) By increasing NH_4^+ ion concentration
(c) By decreasing OH^- ion concentration
(d) Both (b) and (c)

228. Which has the highest pH? **[CBSE (PMT) 2002]**

(a) CH_3COOK (b) Na_2CO_3
(c) NH_4Cl (d) $NaNO_3$

229. Water is a: **(KCET 2002)**

(a) protophobic solvent (b) protophilic solvent
(c) amphiprotic solvent (d) aprotic solvent

230. 1 M NaCl and 1 M HCl are present in an aqueous solution. The solution is: **(AIEEE 2002)**
(a) not a buffer solution with pH < 7
(b) not a buffer solution with pH > 7
(c) a buffer solution with pH < 7
(d) a buffer solution with pH = 7

231. Solution of 0.1 M NH_4OH and 0.1 M NH_4Cl has pH 9.25. Then pK_b of NH_4OH is: **[CBSE (PMT) 2002]**
(a) 9.25 (b) 4.75
(c) 3.75 (d) 8.25

232. Solubility of an MX_2 type electrolyte is 0.5×10^{-4} mol/litre, then K_{sp} of electrolyte is: **[CBSE (PMT) 2002]**
(a) 5×10^{-12} (b) 25×10^{-10}
(c) 1×10^{-13} (d) 5×10^{-13}

233. The concentration of KI and KCl in a certain solution containing both is 0.001 M each. If 20 mL of this solution is added to 20 mL of a saturated solution of AgI in water. What will happen?
(K_{sp} AgCl $= 10^{-10}$; K_{sp} AgI $= 10^{-16}$). **[PET (MP) 2004]**
(a) AgI will be precipitated
(b) AgCl will be precipitated
(c) There will be no precipitate
(d) Both AgCl and AgI will be precipitated

234. Degree of dissociation of NH_4OH in water is 1.8×10^{-5}, then hydrolysis constant of NH_4OH is: **[CECE (Bihar) Pre. 2004]**
(a) 1.8×10^{-5} (b) 1.8×10^{-10}
(c) 5.55×10^{-5} (d) 5.55×10^{-10}

235. What is the pH of 0.01 M glycine solution? For glycine $K_{a_1} = 4.5 \times 10^{-3}$; $K_{a_2} = 1.7 \times 10^{-10}$ at 298 K: **(AIIMS 2004)**
(a) 3.02 (b) 6.94 (c) 7.06 (d) 10.02

236. The rapid change of pH near the stoichiometric point of an acid base titration is the basis of indicator detection. pH of the solution is related to the ratio of the concentrations of the conjugate acid HIn and base In^- forms of the indicator by the expression: **[CBSE (PMT) 2004]**
(a) $\log \frac{[In^-]}{[HIn]} = pK_{In} - pH$ (b) $\log \frac{[HIn]}{[In^-]} = pK_{In} - pH$
(c) $\log \frac{[HIn]}{[In^-]} = pH - pK_{In}$ (d) $\log \frac{[In^-]}{[HIn]} = pH - pK_{In}$

237. A weak acid HX has the dissociation constant 1×10^{-5} M. It forms a salt NaX on reaction with alkali. The degree of hydrolysis of 0.1 M solution of NaX is: **[IIT (S) 2004]**
(a) 0.0001% (b) 0.01% (c) 0.1% (d) 0.15%

238. The molar solubility (in mol litre^{-1}) of a sparingly soluble salt MX_4 is S. The corresponding solubility product K_{sp} is given by the relation: **(AIEEE 2004)**
(a) $S = (K_{sp}/128)^{1/4}$ (b) $S = (218\,K_{sp})^{1/4}$
(c) $S = (256\,K_{sp})^{1/5}$ (d) $S = (K_{sp}/256)^{1/5}$

239. The K_{sp} of $Mg(OH)_2$ is 1×10^{-12}. 0.01 M $Mg(OH)_2$ will precipitate at the limiting pH: **(DPMT 2005)**
(a) 3 (b) 9 (c) 5 (d) 8

[**Hint:** $[Mg^{2+}][OH^-]^2 = 10^{-12}$
$0.01 \times [OH^-]^2 = 10^{-12}$
$[OH^-] = 10^{-5}\,M$
$\therefore [H^+] = 10^{-9}\,M$ and $pH = -\log[10^{-9}] = 9$]

240. The correct expression for the solubility product of $Ca_3(PO_4)_2$ is: **[JEE (Orissa) 2005]**
(a) $108S^5$ (b) $27S^5$ (b) $16S^4$ (d) $81S^4$

241. The solubility product of a salt, having the general formula MX_2, in water is 4×10^{-12}. The concentration of M^{2+} ions in the aqueous solution of the salt is: **(AIEEE 2005)**
(a) $2 \times 10^{-6}\,M$ (b) $1 \times 10^{-4}\,M$
(c) $1.6 \times 10^{-4}\,M$ (d) $4 \times 10^{-10}\,M$

[**Hint:** It is ternary electrolyte.
$\therefore \quad K_{sp} = 4S^3$
$4 \times 10^{-12} = 4S^3$
$S = 10^{-4}\,M$
$\therefore \quad (M^{2+}) = 10^{-4}\,M$]

242. The ionization constant of ammonium hydroxide is 1.77×10^{-5} at 298 K. Hydrolysis constant of ammonium chloride is: **[CBSE (PMT) 2009]**
(a) 5.65×10^{-12} (b) 5.65×10^{-10}
(c) 6.50×10^{-12} (d) 5.65×10^{-13}

[**Hint:** $K_h = \frac{K_w}{K_b} = \frac{10^{-14}}{1.77 \times 10^{-5}}$
$= 5.65 \times 10^{-10}$]

243. The K_a values of formic acid and acetic acid are respectively 1.77×10^{-4} and 1.75×10^{-5}. The ratio of the acid strength of 0.1 M acid is: **[PMT (Kerala) 2005]**
(a) 10 (b) 3.178 (c) 0.3 (d) 0.1
(e) 100

244. Equal volumes of the following Ca^{2+} and F^- solutions are mixed. In which solution will the precipitation occur?

K_{sp} of $CaF_2 = 1.7 \times 10^{-10}$

1. $10^{-2}\,M\,Ca^{2+} + 10^{-5}\,M\,F^-$ 2. $10^{-3}\,M\,Ca^{2+} + 10^{-3}\,M\,F^-$
3. $10^{-4}\,M\,Ca^{2+} + 10^{-2}\,M\,F^-$ 4. $10^{-2}\,M\,Ca^{2+} + 10^{-3}\,M\,F^-$

Select the correct answer using the codes given below: **[PMT (Kerala) 2005]**
(a) in 4 only (b) in 1 and 2 (c) in 3 and 4 (d) in 2, 3 and 4
(e) in all of these

245. Given, pH of a solution A is 3 and it is mixed with another solution B having pH 2. If both are mixed, then the resultant pH of the solution will be: **[BHU (Pre.) 2005]**
(a) 3.2 (b) 1.9 (c) 3.4 (d) 3.5

246. When 10 mL of 0.1 M acetic acid ($pK_a = 5$) is titrated against 10 mL of 0.1 M ammonia solution ($pK_b = 5$), the equivalent point will occur at pH: **(AIIMS 2005)**
(a) 5 (b) 6 (c) 7 (d) 9

247. On adding 0.1 M solution each of Ag^+, Ba^{2+} and Ca^{2+} in an Na_2SO_4 solution, the species first precipitated is: **(DCE 2005)**
(K_{sp} $BaSO_4 = 10^{-11}$, K_{sp} $CaSO_4 = 10^{-6}$, K_{sp} $Ag_2SO_4 = 10^{-5}$)
(a) Ag_2SO_4 (b) $BaSO_4$
(c) $CaSO_4$ (d) all of these

248. When 0.1 mole of CH_3NH_2 (ionization constant, $K_b = 5 \times 10^{-4}$) is mixed with 0.08 mole HCl and the volume is made up to 1 litre, find the $[H^+]$ of resulting solution: **(IIT 2005)**

(a) 8×10^{-2} (b) 2×10^{-11}
(c) 1.23×10^{-4} (d) 8×10^{-11}

[**Hint:**
$$\begin{array}{cccc} CH_3NH_2 + & HCl & \longrightarrow & CH_3NH_3^+Cl^- \\ 0.1\text{ mol} & 0.08\text{ mol} & & 0 \\ 0.02\text{ mol} & 0 & & 0.08 \end{array}$$

$$pOH = pK_b + \log\frac{[Salt]}{[Base]}$$

$$= -\log 5 \times 10^{-4} + \log\frac{0.08}{0.02} = 3.903$$

$$pH = 10.0967$$

$$[H^+] = \text{antilog}[-10.0967] = 8 \times 10^{-11}]$$

249. At 25°C, the dissociation constant of a base BOH is 1×10^{-12}. The concentration of hydroxyl ions in 0.01 M aqueous solution of the base would be: **[CBSE-PMT (Pre.) 2005]**

(a) 10^{-5} mol L^{-1} (b) 10^{-6} mol L^{-1}
(c) 2×10^{-6} mol L^{-1} (d) 10^{-7} mol L^{-1}

[**Hint:** $[OH^-] = \sqrt{CK_b} = \sqrt{0.01 \times 10^{-12}} = 10^{-7}$ mol L^{-1}]

250. Which of the following solutions has pH equal to 10? **[UGET (Manipal) 2006]**

(a) 10^{-4} M KOH (b) 10^{-10} M KOH
(c) 10^{-10} M HCl (d) 10^{-4} M HCl

251. A weak monobasic acid is half neutralised by a strong base. If the pH of the solution is 5.4, its pK_a is: **[JEE (Orissa) 2006]**

(a) 6.8 (b) 2.7 (c) 5.4 (d) 10.8

[**Hint:** [Acid] = [Salt]

$$pH = pK_a + \log\frac{[Salt]}{[Acid]}$$

$$5.4 = pK_a + \log_{10} 1$$

$$\therefore\ pK_a = 5.4]$$

252. ZnS is not precipitated by passing H_2S in acidic medium but CuS precipitated. The reason for it is: **[JEE (Orissa) 2006]**

(a) K_{sp} CuS << K_{sp} ZnS (b) K_{sp} CuS >> K_{sp} ZnS
(c) K_{sp} CuS = K_{sp} ZnS (d) none of these

253. Solubility product of salt AB is 1×10^{-8} M^2 in a solution, in which the concentration of A^+ ions is 10^{-3} M. The salt will precipitate when the concentration of B^- ions is kept: **(KCET 2006)**

(a) between 10^{-8} M to 10^{-7} M (b) between 10^{-7} M to 10^{-8} M
(c) $> 10^{-5}$ M (d) $< 10^{-8}$ M

254. NaOH(*aq.*), HCl(*aq.*) and NaCl(*aq.*) have concentration of 10^{-3} M each. Their pH will be respectively: **[PMT (Uttarakhand) 2006]**

(a) 10, 6, 2 (b) 11, 3, 7
(c) 10, 3, 7 (d) 10, 4, 7

255. The weak acid, HA, has a K_a of 1.00×10^{-5}. If 0.1 mol of this acid is dissolved in one litre of water, the percentage of acid dissociated at equilibrium is closest to: **[CBSE (Med.) 2007]**

(a) 1% (b) 99.9%
(c) 0.1% (d) 99%

[**Hint:**
$$\begin{array}{lccc} & HA & \rightleftharpoons & H^+ & + & A^- \\ t=0 & C & & 0 & & 0 \\ t_{eq.} & C - C\alpha & & C\alpha & & C\alpha \end{array}$$

$$K_a = \frac{[H^+][A^-]}{[HA]} = \frac{C^2\alpha^2}{C - C\alpha}$$

$$= \frac{C\alpha^2}{1-\alpha} \approx C\alpha^2$$

$$\alpha = \sqrt{\frac{K_a}{C}} = \sqrt{\frac{10^{-5}}{0.1}} = 10^{-2}$$

% ionisation = $\alpha \times 100 = 1$]

256. At 25° C, the value of pK_b (K_b being the dissociation constant as a base) for NH_3 in aqueous solution is 4.7. What is the pH of 0.1 M aqueous solution of NH_4Cl with 0.01 M NH_3 (approximately)? **(SCRA 2007)**

(a) 8.3 (b) 9 (c) 9.5 (d) 10

[**Hint:** $pOH = pK_b + \log_{10}\frac{[NH_4Cl]}{[NH_4OH]}$

$$= 4.7 + \log\left[\frac{0.1}{0.01}\right] = 5.7$$

$$pH = 14 - 5.7 = 8.3]$$

257. The ionisation of strong electrolytes in acetic acid compared to that in water is: **[CET (J&K) 2007]**

(a) weak, low (b) strong, more
(c) medium, the same (d) no ionisation, 100%

258. By adding a little of acid or base, the change in pH of blood is not significant, because blood: **[PET (Raj.) 2006]**

(a) has iron as a part of molecule
(b) is a body fluid
(c) has serum protein which works as buffer
(d) is easily coagulated

259. 2.5 mL of 2/5 M weak monoacidic base ($K_b = 1 \times 10^{-12}$ at 25°C) is titrated with 2/15 M HCl in water at 25°C. The concentration of H^+ ion at equivalence point is: ($K_w = 1 \times 10^{-14}$ at 25°C) **(IIT 2008)**

(a) $3.7 \times 10^{-13} M$ (b) $3.2 \times 10^{-7} M$
(c) $3.2 \times 10^{-2} M$ (d) $2.7 \times 10^{-2} M$

[**Hint:** $1\ BOH + 1HCl \longrightarrow BCl + H_2O$

$$\frac{M_1V_1}{1}\text{ (Base)} = \frac{M_2V_2}{1}\text{ (Acid)}$$

$$\frac{2}{5} \times 2.5 = \frac{2}{15} \times V_2$$

$$V_2 = 7.5\text{ mL}$$

Total volume = 7.5 + 2.5 = 10 mL

Concentration of salt in the mixture :

$$M_1V_1\text{ (Base)} = M_2V_2\text{ (Salt)}$$

$$\frac{2}{5} \times 2.5 = M_2 \times 10$$

$$M_2 = 0.1$$

$$pH = \frac{1}{2}[pK_w - pK_b - \log C]$$

$$= \frac{1}{2}[14 - 12 - (-1)] = 1.5$$

$$[H^+] = \text{Antilog}(-1.5) = 0.032\ M]$$

260. Solubility product constants (K_{sp}) of salts of types MX, MX_2, M_3X at temperature T are 4×10^{-8}, 3.2×10^{-14} and 2.7×10^{-15} respectively. Solubility (mol dm^{-3}) of the salts at temperature T are in the order: **(IIT 2008)**

(a) $MX > MX_2 > M_3X$ (b) $M_3X > MX_2 > MX$

(c) $MX_2 > M_3X > MX$ (d) $MX > M_3X > MX_2$

[**Hint:**

Solubility (S_1) of $MX = \sqrt{K_{sp}} = \sqrt{4 \times 10^{-8}} = 2 \times 10^{-4} M$

Solubility (S_2) of

$$MX_2 = \left(\frac{K_{sp}}{4}\right)^{\frac{1}{3}} = \left(\frac{3.2 \times 10^{-14}}{4}\right)^{\frac{1}{3}} = 2 \times 10^{-5} M$$

Solubility (S_3) of

$$M_3X = \left(\frac{K_{sp}}{27}\right)^{\frac{1}{4}} = \left(\frac{2.7 \times 10^{-15}}{27}\right)^{\frac{1}{4}} = 10^{-4} M$$

$\therefore S_1 > S_3 > S_2$]

261. In aqueous solution, the ionization constants for carbonic acid are :

$$K_1 = 4.2 \times 10^{-7} \text{ and } K_2 = 4.8 \times 10^{-11}$$

Select the correct statement for a saturated 0.034 M solution of the carbonic acid : **(AIEEE 2010)**

(a) The concentrations of H^+ and HCO_3^- are approximately equal

(b) The concentration of H^+ is double that of CO_3^{2-}

(c) Concentration of CO_3^{2-} is 0.034 M

(d) The concentration of CO_3^{2-} is greater than that of HCO_3^-

Set-2: The Questions given below may have more than one correct answers

1. For dissociation constant (K) and ionic product (K_w) of water which is correct?

(a) $K > K_w$ (b) $K_w > K$

(c) $K_w = K$ (d) None of these

2. Which is an example of auto protolysis?

(a) $H_2O + H_2O \rightleftharpoons H_3O^+ + OH^-$

(b) $NH_3 + NH_3 \rightleftharpoons NH_4^+ + NH_2^-$

(c) $H_2SO_4 + H_2SO_4 \rightleftharpoons H_3SO_4^+ + HSO_4^-$

(d) All of the above

3. If concentrations of two acids are same, their relative strengths can be compared by:

(a) α_1/α_2 (b) K_1/K_2

(c) $[H^+]_1/[H^+]_2$ (d) $\sqrt{K_1/K_2}$

4. Three bases XOH, YOH and ZOH have pK_b values 2, 3 and 4 respectively; the strongest conjugate acid is:

(a) XOH_2^+ (b) YOH_2^+

(c) ZOH_2^+ (d) all are same

5. Aqueous solution of HNO_3, KOH, CH_3COOH and CH_3COONa of identical concentrations are provided. The pair(s) of solutions which form a buffer upon mixing is (are): **(IIT 2010)**

(a) HNO_3 and CH_3COOH

(b) KOH and CH_3COONa

(c) HNO_3 and CH_3COONa

(d) CH_3COOH and CH_3COONa

6. Four solutions of NH_4Cl are taken with concentrations 1 M, 0.1 M, 0.01 M and 0.001 M. Their degree of hydrolysis are h_1, h_2, h_3 and h_4. What is the graduation of degree of hydrolysis?

(a) $h_1 > h_2 > h_3 > h_4$ (b) $h_1 = h_2 = h_3 = h_4$

(c) $h_4 > h_3 > h_2 > h_1$ (d) None of these

7. Which has maximum solubility AB, AB_2, AB_3 and AB_4 if K_{sp} for all the salts are 10^{-10} ?

(a) AB (b) AB_2 (c) AB_3 (d) AB_4

8. Dissociation of an indicator can be considered as,

$$HIn \rightleftharpoons H^+ + In^-$$

Colours of HIn and In^- are different. Which statement is correct?

(a) Solution assumes colours of HIn when pH = P_{K-1}

(b) Solution assumes colours of In^- when pH = P_{K+1}

(c) Solution assumes colours of HIn^- when pH = P_{K+1}

(d) Solution assumes colours of In^- when pH = P_{K-1}

9. The % error in $[H^+]$ made by neglecting the ionisation of water in 10^{-6} M NaOH is:

(a) 1% (b) 2% (c) 3% (d) 4%

10. 50 mL $N/10$ NaOH solution is mixed with 50 mL $N/20$ HCl solution. The resulting solution will:

(a) turn phenolphthalein solution pink

(b) turn blue litmus red

(c) turn methyl orange red

(d) $[H^+] < [OH^-]$

11. An acid indicator HIn has $K_a = 3 \times 10^{-5}$, the acid form is red and basic form is blue. Which is correct?

(a) pH = 5 when indicator is 75% red

(b) pH = 4.05 when indicator is 75% red

(c) pH = 5 when indicator is 75% blue

(d) pH = 4.05 when indicator is 75% blue

12. Which of the following will function as buffer? **[IAS (Pre.) 1997]**

(a) NaCl + NaOH (b) Borax + boric acid

(c) $NaH_2PO_4 + NaHPO_4$ (d) $NH_4Cl + NH_4OH$

13. Choose the correct statement(s):

(a) pH of an acidic buffer increases if more salt is added.

(b) pH of a basic buffer decreases if more salt is added.

(c) In a saturated solution, ionic product is equal to its solubility product.

(d) The term solubility product is only for sparingly soluble salts.

14. In the following reaction,

$$\underset{(A)}{[Cu(H_2O)_3(OH)]^+} + \underset{(B)}{[Al(H_2O)_6]^{3+}} \longrightarrow \underset{(C)}{[Cu(H_2O)_4]^{2+}} + \underset{(D)}{[Al(H_2O)_5(OH)]^{2+}} :$$

(a) (A) is an acid and (B) is a base

(b) (A) is a base and (B) is an acid

(c) (*C*) is the conjugate acid of (*A*) and (*D*) is the conjugate base of (*B*)

(d) (*C*) is the conjugate base of (*A*) and (*D*) is the conjugate acid of (*B*)

15. Which among the following will not react with NaOH or which is not acid salt?

(a) NaH_2PO_2 (b) Na_2HPO_3 (c) Na_2HPO_2 (d) $NaHCO_3$

Direction: In the following three questions, more than one of the answers given may be correct. Select the correct answers and mark it according to the codes. [BHU (Med.) 2007]

Codes:

(a) 1, 2 and 3 are correct (b) 1 and 2 are correct

(c) 2 and 4 are correct (d) 1 and 3 are correct

16. If equal volumes of 0.1 *M* HBr and 0.1 *M* KOH are mixed, then which of the following is/are correct about the resulting solution?

(1) $[H_3O^+] = 1.0 \times 10^{-7}$ mol L^{-1}

(2) $[OH^-] = 1.0 \times 10^{-7}$ mol L^{-1}

(3) $[K^+] = 0.05$ mol L^{-1}

(4) $[Br^-] = 0.10$ mol L^{-1}

17. Which of the following solutions will be acidic?

(1) 0.1 *M* $FeSO_4$ (2) 0.1 *M* $(NH_4)_2SO_4$

(3) 0.1 *M* CH_3COONa (4) 0.1 *M* NH_4OH

18. In a buffer solution consisting NaH_2PO_4 and Na_2HPO_4: [BHU (Mains) 2010]

(1) NaH_2PO_4 is acid and Na_2HPO_4 is salt

(2) The pH of solution can be calculated using the relation :

$$pH = pK_2 + \log_{10}\frac{[HPO_4^{2-}]}{[H_2PO_4^-]}$$

(3) The Na_2HPO_4 is acid and NaH_2PO_4 is salt

(4) The pH can not be calculated

Assertion-Reason TYPE QUESTIONS

The questions given below consist of two statements each printed as **'Assertion' (A)** and **'Reason' (R).** While answering these questions you are required to choose any one of the following four responses:

(a) If both (A) and (R) are correct and (R) is the correct explanation for (A).
(b) If both (A) and (R) are correct but (R) is not the correct explanation for (A).
(c) If (A) is correct, but (R) is incorrect.
(d) If both (A) and (R) are incorrect.

1. (A) A very dilute acidic solution of Cd^{2+} and Ni^{2+} gives yellow precipitate of CdS on passing hydrogen sulphide.
(R) Solubility product of CdS is more than that of NiS.

2. (A) In the titration of Na_2CO_3 with HCl using methyl orange indicator, the volume of the acid required at the equivalence point is twice that of the acid required using phenolphthalein as indicator.
(R) Two moles of HCl are required for the complete neutralisation of one mole of Na_2CO_3. **(IIT 1991)**

3. (A) The pH of an aqueous solution of acetic acid remains unchanged on the addition of sodium acetate.
(R) The ionisation of acetic acid is suppressed by the addition of sodium acetate.

4. (A) In acidic medium, Zn^{2+} is not precipitated by S^{2-} ions.
(R) Common ion effect reduces the concentration of S^{2-} ions to the minimum level.

5. (A) In the acid-base titration involving a strong base and a weak acid, methyl orange can be used as an indicator.
(R) Methyl orange changes its colour in pH range 3 to 5.

6. (A) A mixture of sodium acetate and sodium propionate forms a buffer solution.
(R) A buffer solution reacts with small quantities of hydrogen or hydroxyl ions and keeps the pH almost same.

7. (A) When small amount of an acid or base is added to pure water its pH undergoes a change.
(R) Addition of an acid or a base increases the degree of ionisation of water.

8. (A) At 25°C, the pH of $10^{-8}\ M$ HCl is 8.
(R) pH of acidic solution is always below 7 at 25° C.

9. (A) The addition of silver ions to a mixture of aqueous sodium chloride and sodium bromide solution, will first precipitate AgBr rather than AgCl.
(R) The value of K_{sp} of AgCl $<$ K_{sp} of AgBr. **(AIIMS 2004)**

10. (A) Sb (III) is not precipitated as sulphide when in its alkaline solution H_2S is passed.
(R) Concentration of S^{2-} ions in alkaline medium is inadequate for precipitation. **(AIIMS 2004)**

11. (A) Sb_2S_3 is not soluble in yellow ammonium sulphide.
(R) The common ion effect due to S^{2-} ions reduces the solubility of Sb_2S_3. **(AIIMS 2006)**

12. (A) H_2SO_4 acts as a base in presence of $HClO_4$.
(R) Perchloric acid is stronger acid than H_2SO_4.

13. (A) pH of a neutral solution is always 7.
(R) pH of a solution does not depend upon temperature.

14. (A) pH of $10^{-8}\ M$ HCl is not equal to 8.
(R) HCl does not dissociate properly in very dilute solution.

15. (A) If a solution with pH = 2 is diluted to double the volume, the pH of the solution will fall to 1.
(R) pH is inversely proportional to the volume of the solution.

16. (A) If HCl gas is passed through saturated NaCl solution, solid NaCl starts separating out.
(R) HCl decreases the solubility product of NaCl.

17. (A) pH of a buffer changes with temperature.
(R) Ionic product of water (K_w) changes with temperature.

18. (A) $I_2 + I^- \longrightarrow I_3^-$
In above reaction, I_2 is Lewis base.
(R) Electron pair acceptor is Lewis base.

19. (A) Phenolphthalein is used as indicator during the titration of oxalic acid against sodium hydroxide.
(R) The pH range of phenolphthalein is from 8 to 9.6.

20. (A) If K_{sp} is less than K_{ip}, the precipitate is formed.
(R) Solubility product (K_{sp}) is the highest limit of ionic product of electrolyte solutions.

21. (A) H_3PO_3 is a dibasic acid.
(R) There are two hydrogen atoms directly attached to phosphorus. **(AIIMS 2007)**

22. (A) NaCl is precipitated when HCl gas is passed in a saturated solution of NaCl.
(R) HCl is a strong acid. **(AIIMS 2007)**

23. (A) On mixing 500 mL of $10^{-6}\ M$ Ca^{2+} ion and 500 mL of $10^{-6}\ MF^-$ ion, the precipitate of CaF_2 will be obtained. $K_{sp}(CaF_2) = 10^{-18}$.
(R) If K_{sp} is greater than ionic product, precipitate will be obtained. **(AIIMS 2007)**

24. (A) The aqueous solution of CH_3COONa is alkaline in nature.
(R) Acetate ion undergoes an ionic hydrolysis. **(EAMCET 2008)**

25. (A) An aqueous solution of ammonium acetate can act as a buffer.
(R) Acetic acid is a weak acid and NH_4OH is a weak base. **(EAMCET 2010)**

26. (A) $[Al(H_2O)_6]^{3+}$ is a stronger acid than $[Mg(H_2O)_6]^{2+}$.
(R) Size of $[Al(H_2O)_6]^{3+}$ smaller than $[Mg(H_2O)_6]^{2+}$ and possesses more effective nuclear charge. **(AIIMS 2010)**

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS *for* IIT ASPIRANTS

The following questions contain single correct option:

1. The pH value of 10^{-3} M aqueous solution of NaCl is:
(a) 7 (b) 3 (c) 11 (d) 14
[**Hint:** NaCl is the salt of strong acid HCl and strong base NaOH. Its aqueous solution will be neutral with pH equal to seven.]

2. The acidic buffer solution can be prepared by mixing solutions of:
(a) sodium acetate and acetic acid
(b) ammonium chloride and ammonium hydroxide
(c) sulphuric acid and sodium sulphate
~~(d) sodium chloride and sodium hydroxide~~

3. ~~Hydrolysis constants of two salts KA and KB of weak acids~~ HA and HB are 10^{-8} and 10^{-6}. If the dissociation constant of third acid HC is 10^{-2}. The order of acidic strengths of three acids will be:
(a) $HA > HB > HC$ (b) $HB > HA > HC$
(c) $HC > HA > HB$ (d) $HA = HB = HC$

[**Hint:** $K_a(HA) = \frac{K_w}{K_h} = \frac{10^{-14}}{10^{-8}} = 10^{-6}$

$K_a(HB) = \frac{K_w}{K_h} = \frac{10^{-14}}{10^{-6}} = 10^{-8}$

$K_a(HC) = 10^{-2}$

Greater the value of dissociation constant K_a, more is the acidic strength.]

4. Three sparingly soluble salts that have same solubility products are given below:
I. A_2X II. AX III. AX_3
Their solubilities in a saturated solution will be such that:
(a) III > II > I (b) III > I > II (c) II > III > I (d) II > I > III

[**Hint:** $S = \sqrt{K_{sp}}$ for AX; $S = \left[\frac{K_{sp}}{4}\right]^{1/3}$ for A_2X;

$S = \left[\frac{K_{sp}}{27}\right]^{1/4}$ for AX_3

$\therefore \quad S_{II} > S_I > S_{III}$]

5. Consider the three solutions of 1 M concentration.
1. Sodium acetate (CH_3COONa)
2. Acetic acid + Sodium acetate ($CH_3COOH + CH_3COONa$)
3. Acetic acid (CH_3COOH)

The pH of these solutions will lie in the following sequence:
(a) 3 < 2 < 1 (b) 2 < 1 < 3 (c) 1 < 2 < 3 (d) 3 < 1 < 2

[**Hint:** $\underset{\text{pH} < 7}{CH_3COOH \text{ (Acetic acid)}} < \underset{\text{Buffer}}{(CH_3COOH + CH_3COONa)} < \underset{\substack{\text{pH} > 7 \\ \text{Salt of weak acid} \\ \text{with strong base}}}{CH_3COONa}$]

6. Glycine NH_2CH_2COOH behaves:
(a) as a Bronsted acid
(b) as a Bronsted base
(c) both as an acid and a base
(d) neither as an acid nor as a base

7. Solubility of Hg_2Cl_2 in a solvent is S moles/litre. Its solubility product will be:
(a) $16S^2$ (b) $8S^2$ (c) $16S^4$ (d) $4S^3$
[**Hint:** $Hg_2Cl_2 \longrightarrow Hg_2^{2+} + 2Cl^-$]

8. Arrange the following acids in increasing order of their acid strength:
I. $HClO_4$ II. H_2SO_4 III. H_3PO_4
(a) III < II < I (b) I < II < III (c) II < III < I (d) III < I < II

9. Select the anion which is the strongest bronsted base:
(a) ClO_4^- (b) ClO_3^- (c) ClO_2^- (d) ClO^-

[**Hint:** $HClO_4 > HClO_3 > HClO_2 > HClO$
(Decreasing acidic character)

$ClO_4^- < ClO_3^- < ClO_2^- < ClO^-$
(Increasing basic strength)

(Conjugate base of strong acid is weak base)]

10. $M(OH)_x$ has a K_{sp} of 4×10^{-9} and its solubility is 10^{-3} M. The value of x is:
(a) 4 (b) 1 (c) 3 (d) 2

11. What is the maximum possible concentration of Ni^{2+} ions in a solution containing 0.15 M HCl and 0.10 M H_2S? [Given that, $K_{sp}(NiS) = 2 \times 10^{-21}$ and $[S^{2-}]_{H_2S} = 4 \times 10^{-21}$]:
(a) 0.65 M (b) 0.45 M (c) 0.10 M (d) 0.15 M

12. The pH of 10^{-10} M H_2SO_4 will be almost:
(a) 4 (b) 7 (c) 6 (d) 0

13. Solubility of calcium phosphate (molecular mass, M) in water is W g per 100 mL at 25°C. Its solubility product at 25°C will be approximately:
(a) $10^9\left(\frac{W}{M}\right)^5$ (b) $10^7\left(\frac{W}{M}\right)^5$ (c) $10^5\left(\frac{W}{M}\right)^5$ (d) $10^3\left(\frac{W}{M}\right)^5$

[**Hint:** $S = \frac{10W}{M}$ mol litre

K_{sp} of $Ca_3(PO_4)_2 = 108S^5$

$= 108\left(\frac{10W}{M}\right)^5$

$= 10^7\left(\frac{W}{M}\right)^5$ (approximately)]

14. When some amount of sodium acetate is further added to a mixture of acetic acid and sodium acetate, then pH of the solution:

(a) increases
(b) decreases
(c) remains same
(d) none of these can be predicted from given information

[**Hint:** $pH = pK_a + \log \frac{[\text{Salt}]}{[\text{Acid}]}$

When the concentration of salt is increased, the value of pH will increase.]

15. When strong base (NaOH) is added to the weak acid (acetic acid, CH_3COOH), then dissociation of acetic acid increases; this effect is known as:

(a) common ion effect (b) reverse ion effect
(c) saltation effect (d) solubility effect

[**Hint:** $CH_3COOH + NaOH \longrightarrow CH_3COONa + H_2O$

Ionization of acetic acid will increase with the progress of its neutralization. This effect is called reverse ion effect.]

16. In our body, carbon dioxide (CO_2) combines with water (H_2O) to form carbonic acid.

$$H_2O + CO_2 \longrightarrow H_2CO_3$$

Carbonic acid undergoes dissociation as,

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

During the physical and mental stress, the rate of respiration increases, which results in the decrease in concentration of CO_2 in the blood. What will be the effect on pH of human blood during the stress?

(a) Decreases (b) Remains same
(c) Increases (d) Cannot be predicted

17. The correct order of basic strength is: **(AIIMS 2007)**

(a) $H_2O < OH^- < CH_3OH < CH_3O^-$
(b) $CH_3OH < H_2O < CH_3O^- < OH^-$
(c) $H_2O < CH_3OH < OH^- < CH_3O^-$
(d) $OH^- < H_2O < CH_3O^- < CH_3OH$

18. Which of the following orders is expected to be correct?

(a) $pK_a(ClCH_2COOH) > pK_a(CH_3COOH) > pK_a(CH_3CH_2COOH)$
(b) $pK_a(ClCH_2COOH) < pK_a(CH_3COOH) < pK_a(CH_3CH_2COOH)$ /
(c) $pK_a(ClCH_2COOH) > pK_a(CH_3COOH) < pK_a(CH_3CH_2COOH)$
(d) $pK_a(ClCH_2COOH) < pK_a(CH_3COOH) > pK_a(CH_3CH_2COOH)$

19. The concentration of H_3^+O ions in pure water is 10^{-6} mol dm^{-3}. The corresponding concentration of OH^- ions will be:

(a) 10^{-14} mol dm^{-3} (b) 10^{-8} mol dm^{-3}
(c) 10^{-6} mol dm^{-3} (d) 10^{-7} mol dm^{-3}

[**Hint:** In water, $[H^+] = [OH^-] = 10^{-6}$ mol dm^{-3}]

20. What will be the pH of a solution formed by mixing 40 cm^3 of 0.1 *M* HCl with 10 cm^3 of 0.45 *M* NaOH?

(a) 10 (b) 8 (c) 5 (d) 12

[**Hint:** Number of moles of HCl $= \frac{MV}{1000} = \frac{0.1 \times 40}{1000} = 0.004$

Number of moles of NaOH $= \frac{MV}{1000} = \frac{0.45 \times 10}{1000} = 0.0045$

Remaining moles of NaOH after neutralization = 0.0005

Molarity of $OH^- = \frac{0.0005}{50} \times 1000 = 0.01M$

$pOH = 2 \quad \therefore \quad pH = 14 - 2 = 12$]

21. In the following reaction:

$$HCO_3^- + H_2O \rightleftharpoons CO_3^{2-} + H_3O^+$$

which two substances are Bronsted bases?

(a) CO_3^{2-} and H_3O^+ (b) HCO_3^- and H_3O^+
(c) HCO_3^- and CO_3^{2-} (d) CO_3^{2-} and H_2O

22. Which are strong acids?

I. $HClO_3$ II. H_2SeO_3 III. H_3AsO_4

(a) I only (b) III only
(c) I and III only (d) II and III only

23. $HCOOH \rightleftharpoons HCOO^- + H^+; \quad K_a = 1.7 \times 10^{-4}$

The ionization of formic acid is represented above. Calculate $[H^+]$ of a solution initially containing 0.1 *M* HCOOH and 0.05 *M* HCOONa:

(a) 8.5×10^{-5} *M* (b) 3.4×10^{-4} *M*
(c) 4.1×10^{-3} *M* (d) 1.8×10^{-2} *M*

24. Carbonic acid, H_2CO_3, is a diprotic acid for which $K_1 = 4.2 \times 10^{-7}$ and $K_2 = 4.7 \times 10^{-11}$. Which solution will produce a pH closest to 9?

(a) 0.1 *M* H_2CO_3
(b) 0.1 *M* Na_2CO_3
(c) 0.1 *M* $NaHCO_3$
(d) 0.1 *M* $NaHCO_3$ and 0.1 *M* Na_2CO_3

25. What is the conjugate acid of HPO_4^{2-}?

(a) H_3PO_4 (b) $H_2PO_4^-$ (c) H_3O^+ (d) PO_4^{3-}

26. What is the K_b of a weak base that produces one OH^- per molecule if a 0.05 *M* solution is 2.5% ionized?

(a) 7.8×10^{-8} (b) 1.6×10^{-6} (c) 3.2×10^{-5} (d) 1.2×10^{-3}

[**Hint:** $K_b = C\alpha^2$

$$= 0.05 \times \left(\frac{2.5}{100}\right)^2 = 3.1 \times 10^{-5}]$$

27. The amount of sodium hydrogen carbonate, $NaHCO_3$, in an antacid tablet is to be determined by dissolving the tablet in water and titrating the resulting solution with hydrochloric acid. Which indicator is the most appropriate for this titration?

Acid	K_a
H_2CO_3	2.5×10^{-4}
HCO_3^-	2.4×10^{-8}

(a) Methyl orange, $pK_{In} = 3.7$
(b) Bromothymol blue, $pK_{In} = 7.0$
(c) Phenolphthalein, $pK_{In} = 9.3$
(d) Alizarin yellow, $pK_{In} = 12.5$

28. If equal volumes of $BaCl_2$ and NaF solutions are mixed, which of these combinations will not give a precipitate?

Substance	K_{sp}
BaF_2	1.7×10^{-7}

(a) 0.004 *M* $BaCl_2$ and 0.02 *M* NaF
(b) 0.010 *M* $BaCl_2$ and 0.015 *M* NaF
(c) 0.015 *M* $BaCl_2$ and 0.010 *M* NaF
(d) 0.020 *M* $BaCl_2$ and 0.002 *M* NaF

[**Hint:** In the mixture of 0.02 M $BaCl_2$ and 0.002 M NaF, the ionic product is less than the solubility product, hence there will be no precipitation of BaF_2.]

29. HCN is a weak acid ($K_a = 6.2 \times 10^{-10}$). NH_4OH is a weak base ($K_b = 1.8 \times 10^{-5}$). A 1 M solution of NH_4CN would be:
(a) strongly acidic (b) weakly acidic
(c) neutral (d) weakly basic
[**Hint:** Since, $K_b > K_a$, hence the medium will be weakly basic.]

30. How many moles of HCOONa must be added to 1 L of 0.1 M HCOOH to prepare a buffer solution with a pH of 3.4?
Given: K_a for HCOOH $= 2 \times 10^{-4}$
(a) 0.01 (b) 0.05 (c) 0.1 (d) 0.2

31. Silver ions are added to the solution with:
$$[Br^-] = [Cl^-] = [CO_3^{2-}] = [AsO_4^{3-}] = 0.1\,M$$
Which compound will precipitate at the lowest $[Ag^+]$?
(a) AgBr ($K_{sp} = 5 \times 10^{-13}$)
(b) AgCl ($K_{sp} = 1.8 \times 10^{-10}$)
(c) Ag_2CO_3 ($K_{sp} = 8.1 \times 10^{-12}$)
(d) Ag_3AsO_4 ($K_{sp} = 10^{-22}$)
[**Hint:** In case of AgBr, the ionic product will exceed the solubility product before AgCl, Ag_2CO_3 and Ag_3AsO_4. Thus, AgBr will start precipitation before other salts.]

32. The equilibrium constant for this reaction is approximately 10^{-3}.
$$HPO_4^{2-}(aq.) + HCO_3^-(aq.) \rightleftharpoons H_2PO_4^-(aq.) + CO_3^{2-}(aq.)$$
Which is the strongest conjugate base in this reaction?
(a) $HPO_4^{2-}(aq.)$ (b) $HCO_3^-(aq.)$
(c) $H_2PO_4^-(aq.)$ (d) $CO_3^{2-}(aq.)$
[**Hint:** Conjugate base of weak acid is strong base.]

33. Which mixture forms a buffer when dissolved in 1 L of water?
(a) 0.2 mol NaOH + 0.2 mol HBr
(b) 0.2 mol NaCl + 0.3 mol HCl
(c) 0.4 mol HNO_2 + 0.2 mol NaOH
(d) 0.5 mol NH_3 + 0.5 mol HCl

34. The equilibrium constant for this reaction is 3.6×10^{-7}.
$$OCl^-(aq.) + H_2O(l) \rightleftharpoons HOCl(aq.) + OH^-(aq.)$$
What is K_a for HOCl?
(a) 2.8×10^{-8} (b) 3.6×10^{-7} (c) 6×10^{-4} (d) 2.8×10^{-6}

35. What is the concentration of H^+ in a solution that is prepared by mixing 50 mL of 0.5 M HCl and 200 mL of 0.25 M HCl?
(a) 0.30 M (b) 0.35 M (c) 0.40 M (d) 0.45 M

36. K_a for hydrofluoric acid is 6.9×10^{-4}. What is the equilibrium constant K for the following reaction?
$$F^-(aq.) + H_2O(l) \rightleftharpoons HF(aq.) + OH^-(aq.)$$
(a) 6.9×10^{-11} (b) 1.4×10^{-11} (c) 2.6×10^{-9} (d) 8.3×10^{-6}

37. A solution of 2 M formic acid (HCOOH) is 0.95% ionized. What is the K_a of formic acid?
(a) 1.9×10^{-2} (b) 1.8×10^{-4} (c) 9×10^{-5} (d) 4.5×10^{-5}
[**Hint:** $K_a = C\alpha^2 = 2 \times \left(\frac{0.95}{100}\right)^2$]

38. If 0.1 mol of salt is added to 1 L water, which of these salts is expected to produce the most acidic solution?
(a) $NaC_2H_3O_2$ (b) NH_4NO_3
(c) $CuSO_4$ (d) $AlCl_3$

39. A sample of hard water contains 0.005 mole of calcium chloride per litre. What is the minimum concentration of sodium sulphate which must be added for removing the Ca^{2+} ions from this water sample? K_{sp} of $CaSO_4 = 2.4 \times 10^{-5}$.
(a) 4.8×10^{-2} (b) 4.8×10^{-3}
(c) 2.4×10^{-2} (d) 2.4×10^{-3}

40. Match the List-I and List-II:

	List-I		List-II
(A)	The limits of pH values of buffer solution	(i)	5×10^{-12}
(B)	Concentration of $[H_3O^+]$ in 0.001 M $Ba(OH)_2$	(ii)	Equal
(C)	The buffer capacity of a solution is maximum when concentration of salt to that of acid is	(iii)	10^{-14}
(D)	Ionic product of water is	(iv)	$pK_a \pm 1$

Codes:	A	B	C	D
(a)	iv	ii	i	iii
(b)	iv	i	iii	ii
(c)	i	iv	ii	iii
(d)	iv	i	ii	iii

41. Match the List-I and List-II:

	List-I		List-II
(A)	Degree of ionization of weak electrolytes increases	(i)	Common ion effect
(B)	pH of water decreases on	(ii)	pH = 4
(C)	The solution has hydronium ion concentration of 0.0001 mol/litre	(iii)	Heating
(D)	The addition of NaOH to $Ca(OH)_2$ solution precipitates $Ca(OH)_2$	(iv)	On dilution

Codes:	A	B	C	D
(a)	iv	iii	i	ii
(b)	iii	iv	ii	i
(c)	iv	iii	ii	i
(d)	iv	ii	iii	i

42. Which of the following is not correct about the percentage ionization of BOH ?
(a) $\dfrac{K_w[H^+]}{K_b + K_w}$ (b) $100 \times \sqrt{\dfrac{K_b}{C}}$
(c) $\dfrac{100}{1 + 10^{(pK_b - pOH)}}$ (d) $\dfrac{K_b \times 100}{K_b + OH^-}$

[**Hint:** $BOH \rightleftharpoons B^+ + OH^-$
$$\begin{array}{llll} t_0 & C & 0 & 0 \\ t_{eq.} & C - C\alpha & C\alpha & C\alpha \end{array}$$
$$K_b = \frac{[B^+][OH^-]}{[BOH]} = \frac{C^2\alpha^2}{C(1-\alpha)}$$
$$\approx C\alpha^2 \qquad (\alpha <<< 1)$$

$$\alpha = \sqrt{\frac{K_b}{C}} \quad \% \text{ ionization} = 100 \times \sqrt{\frac{K_b}{C}} \qquad ...(1)$$

$$\alpha = \frac{[B^+]}{[B^+] + [BOH]} = \frac{1}{1 + \frac{[BOH]}{[B^+]}} = \frac{1}{1 + \frac{[OH^-]}{[K_b]}}$$

$$\alpha = \frac{K_b}{K_b + OH^-} \qquad ...(2)$$

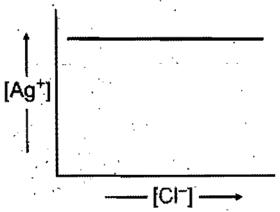
$$\text{Percentage ionization} = \frac{100\,K_b}{K_b + OH^-}$$

$$\alpha = \frac{1}{1 + \frac{[OH^-]}{K_b}} = \frac{1}{1 + \frac{10^{-\text{pOH}}}{10^{-\text{p}K_b}}}$$

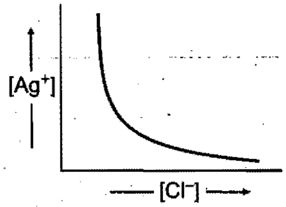
$$\alpha = \frac{1}{1 + 10^{(\text{p}K_b - \text{pOH})}}$$

$$\therefore \text{ Percentage ionization} = \frac{100}{1 + 10^{(\text{p}K_b - \text{pOH})}}]$$

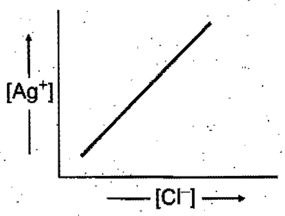
43. When NaCl is added gradually to the saturated solution of AgCl then which of the following plot is correct ?



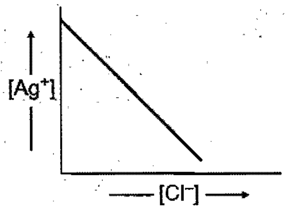
(a)



(b)



(c)



(d)

The following questions may have more than one correct options:

1. Which of the following statements is/are correct about the ionic product of water?
   (a) K (equilibrium constant of water) $< K_w$ (ionic product of water)
   (b) $\text{p}K > \text{p}K_w$
   (c) At 300 K, K_w of water becomes 10^{-12}
   (d) Ionic product of water at 25°C is 10^{-14}

2. Which among the following statements is/are correct?
   (a) $\text{pH} = -\log_{10} (H_3O^+)$
   (b) pH decreases with increase of temperature
   (c) pH cannot be zero, negative or more than 14
   (d) If a solution is diluted ten times, its pH increases by 1

3. Which among the following statements is/are correct?
   (a) pH of 10^{-8} M HCl is equal to 8
   (b) Conjugate base of $H_2PO_4^-$ is HPO_4^{2-}
   (c) pH of 0.1 M NaCl (aqueous solution) $= \frac{1}{2}\text{p}K_w$
   (d) Ionization of water increases with decrease in temperature

4. Let us consider the ionization of HCl in the aqueous solution of CH_3COOH.

   $$CH_3COOH + HCl \rightleftharpoons CH_3COOH_2^+ + Cl^-$$

   Select the correct statement(s) among the following:
   (a) Cl^- is the conjugate base of HCl
   (b) CH_3COOH is the conjugate base of $CH_3COOH_2^+$
   (c) $CH_3COOH_2^+$ is the conjugate base of CH_3COOH
   (d) Cl^- is the conjugate base of CH_3COOH

5. Which among the following species act both as an acid as well as a base?
   (a) SO_4^{2-} (b) HSO_4^-
   (c) PO_4^{3-} (d) NH_3

6. Which among the following salts will give basic solution on hydrolysis? **[PET (MP) 2008]**
   (a) NaH_2PO_4 (b) NH_4Cl
   (c) NaCl (d) K_2CO_3

7. Which among the following represent the conjugate acid/base pairs?
   (a) H_3O^+ / H_2O
   (b) H_2SO_4 / SO_4^{2-}
   (c) HCO_3^- / CO_3^{2-}
   (d) All are conjugate acid/base pairs

8. If you have saturated solution of CaF_2 then:
   (a) $[Ca^{2+}] = \sqrt{K_{sp}}$ (b) $[Ca^{2+}] = 2[F^-]$
   (c) $2[Ca^{2+}] = [F^-]$ (d) $[Ca^{2+}] = [K_{sp/4}]^{1/3}$

9. The relative strength of two weak bases at same concentration may be given as:
   (a) $\frac{K_{b_1}}{K_{b_2}}$ (b) $\frac{[OH^-]_1}{[OH^-]_2}$
   (c) $\frac{\alpha_1}{\alpha_2}$ (d) $\frac{\sqrt{K_{b_1}}}{\sqrt{K_{b_2}}}$

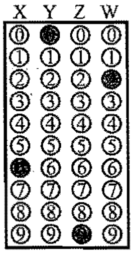
Integer Answer TYPE QUESTIONS

This section contains 13 questions. The answer to each of the questions is a single digit integer, ranging from 0 to 9. If the correct answers to question numbers X, Y, Z and W (say) are 6, 0, 9 and 2 respectively, then the correct darkening of bubbles will look like the given figure :



1. What will be the pH of 0.1 M CH_3COONH_4? Dissociation constants of CH_3COOH and NH_4OH are $K_a = 1.8 \times 10^{-5}$ and $K_b = 1.8 \times 10^{-5}$ respectively.

2. Ionic product of water is 1×10^{-12}. pH of water will be :

3. Calculate the pH at which an acid indicator HIn with concentration 0.1 M changes its colour. (K_a for HIn $= 1 \times 10^{-5}$)

4. Sum of basicity of H_3PO_4, H_3PO_3, H_3PO_2 is equal to :

5. A given weak acid ($0.01\,M$) has $pK_a = 6$. The pH of this solution is :

6. Solubility product of an electrolyte is $6912S^7$. How many ions will be obtained by the ionization of one molecule of electrolyte?

7. The solubility product of $Mg(OH)_2$ is 5×10^{-19} at 25°C. pH of saturated solution of $Mg(OH)_2$ will be :

8. pH of $10^{-x}\,M$ HCl is 6.9586. The value of x will be :

9. If the equilibrium constant of the reaction of weak acid HA with strong base is 10^9, then the pH of 0.1 M NaA solution will be :

10. Consider the titration of 50 mL of 0.1 M HBr with 0.1 M KOH. Calculate pH after 49 mL of the base has been added to the 50 mL of HBr.

11. The dissociation constant of a substituted benzoic acid at 25°C is 1×10^{-4}. The pH of a 0.01 M solution of its sodium salt is: **(IIT 2009)**

[**Hint :** pH of salt after hydrolysis may be calculated as,

$$\begin{aligned} pH &= \frac{1}{2}[pK_w + pK_a + \log C] \\ &= \frac{1}{2}[14 + (-\log 10^{-4}) + \log 0.01] \\ &= \frac{1}{2}[14 + 4 - 2] = 8 \end{aligned}$$

]

12. The total number of diprotic acids among the following is: H_3PO_4, H_2SO_4, H_3PO_3, H_2CO_3, $H_2S_2O_7$, H_2BO_3, H_3PO_2, H_2CrO_4, H_2SO_3 **(IIT 2010)**

[**Hint :** H_2SO_4, H_3PO_3, H_2CO_3, $H_2S_2O_7$, H_2CrO_4, H_2SO_3 are diprotic acid.]

13. Amongst the following, the total number of compounds whose aqueous solution turns red litmus paper blue is: KCN, K_2SO_4, $(NH_4)_2C_2O_4$, NaCl, $Zn(NO_3)_2$, $FeCl_3$, K_2CO_3, NH_4NO_3, LiCN **(IIT 2010)**

[**Hint :** Salts of weak acid and strong base will give basic solution on hydrolysis and will turn red litmus to blue KCN, K_2CO_3 and LiCN are such type of salts.]

LINKED COMPREHENSION TYPE QUESTIONS

• Passage 1

Higher the amount of acid or base used to produce a definite change of pH in a buffer solution, higher will be its buffer capacity. Buffer capacity of solution is maximum under the following conditions:

$$[Salt] = [Acid] \text{ (in acid buffer)}$$
$$[Salt] = [Base] \text{ (in base buffer)}$$

pH of a buffer solution lies in the range given below:

$$pH = pK_a \neq 1$$

In other words, any buffer solution can be used as buffer up to two pH units only, depending upon the value of pK_a or pK_b. A buffer is said to be efficient when $pH = pK_a$ or $pOH = pK_b$.

Answer the following questions:

1. Any buffer can be used as a buffer up to:
   (a) 10 pH units (b) 5 pH units (c) 2 pH units (d) 1 pH unit
2. Which among the following solutions will be the most efficient buffer?
   (a) 0.1 M CH_3COONa + 0.01 M CH_3COOH
   (b) 0.1 M NH_4Cl + 0.1 M NH_4OH
   (c) 0.001 M HCOOH + 0.002 M HCOONa
   (d) All of the above
3. The buffer capacity is equal to:
   (a) $\frac{\Delta n}{\Delta pH}$ (b) $\frac{pH}{\Delta n}$ (c) $\pm 1pK_a$ (d) none of these
4. A buffer of acetic acid ($pK_a \approx 4.8$) with sodium acetate will be, when CH_3COOH and CH_3COONa are present in equivalent amounts has pH limits equal to:
   (a) 0 to 4.8 (b) 3.8 to 5.8 (c) 4.3 to 5.3 (d) 4.8
5. Buffer capacity is maximum when:
   (a) one mole of NH_4Cl is added to two moles of NH_4OH
   (b) one mole of NH_4Cl is added to one mole of NH_4OH
   (c) one mole of NH_4Cl is added to one mole of NaOH
   (d) one mole of NaCl is added to one mole of NaOH
6. A buffer solution is prepared by mixing equal concentration of acid (ionisation constant K_a) and a salt. The pH of buffer is: **[JEE (Orissa) 2008]**
   (a) $pK_a + 7$ (b) $14 - pK_a$ (c) pK_a (d) $pK_a + 1$

• Passage 2

When a salt reacts with water to form acidic or basic solution, the process is called hydrolysis. The pH of salt solution can be calculated using the following relations:

$$pH = \frac{1}{2}[pK_w + pK_a + \log C]$$

(for salt of weak acid and strong base.)

$$pH = \frac{1}{2}[pK_w - pK_b - \log C]$$

(for salt of weak base and strong acid.)

$$pH = \frac{1}{2}[pK_w + pK_a - pK_b]$$

(for salt of weak acid and weak base.)

where, 'C' represents the concentration of salt.

When a weak acid or a weak base is not completely neutralized by strong base or strong acid respectively, then formation of buffer takes place. The pH of buffer solution can be calculated using the following relation:

$$pH = pK_a + \log\frac{[Salt]}{[Acid]};\ pOH = pK_b + \log\frac{[Salt]}{[Base]}$$

Answer the following questions using the following data:

$$pK_a = 4.7447, pK_b = 4.7447, pK_w = 14$$

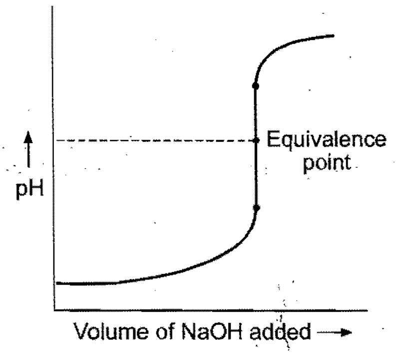
1. When 50 mL of 0.1 M NH_4OH is added to 50 mL of 0.05 M HCl solution, the pH is:
   (a) 1.6021 (b) 12.3979 (c) 4.7447 (d) 9.2553
2. 0.001 M NH_4Cl aqueous solution has pH:
   (a) 6.127 (b) 7.126 (c) 2.167 (d) 1.267
3. 50 mL 0.1 M NaOH is added to 50 mL of 0.1 M CH_3COOH solution, the pH will be:
   (a) 4.7447 (b) 9.2553 (c) 8.7218 (d) 1.6021
4. 1 mole CH_3COOH and 1 mole CH_3COONa are dissolved in water to form 1 litre aqueous solution. The pH of the resulting solution will be:
   (a) 9.2553 (b) 4.7447 (c) 14 (d) 7
5. When 50 mL of 0.1 M NaOH is added to 50 mL of 0.05 M CH_3COOH solution. The pH of the solution is:
   (a) 1.6021 (b) 12.3979 (c) 4.7447 (d) 8.7218

• Passage 3

An acid-base titration consists of the controlled addition of a dissolved base to a dissolved acid (or the reverse). Acid-base react rapidly to neutralize each other. At the equivalence point, enough titrant, the solution being added, has gone into make the chemical amounts of the acid and base exactly equal. The pH of a titration changes every time a drop of titrant is added, but the rate of this change varies enormously. A titration curve, graph of pH as a function of the volume of titrant, displays in detail how the pH changes over the course of an acid-base titration. Significantly, the pH changes most rapidly near the equivalence point. The exact shape of a titration curve depends on the K_a and K_b acid and base.

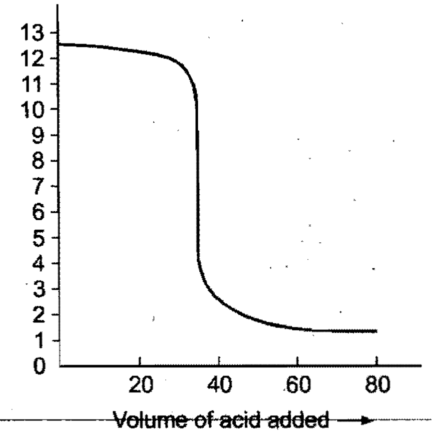
Answer the following questions:

1. The following figure represents titration curve of HCl against NaOH. The pH at equivalence point will be:



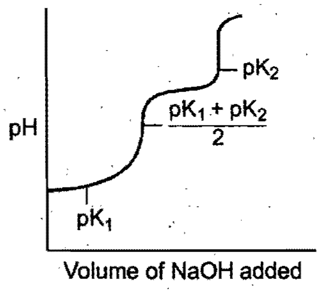
(a) 7 (b) 6 (c) 8 (d) 3

Examine the titration curve below:

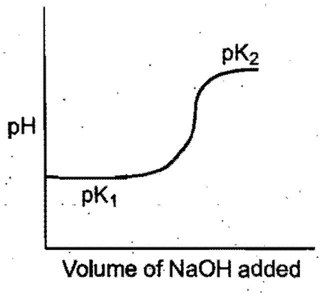


Answer the questions 2, 3 and 4 on the above curve.

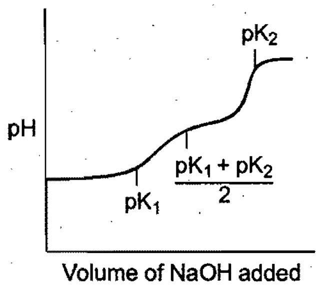
2. Which of the titrations could it represent?
   (a) HCl by KOH (b) RbOH by HBr
   (c) HCl by NaOH (d) NH_3 by HNO_3
3. The suitable indicator for this titration will be:
   (a) bromothymol blue (b) methyl orange
   (c) methyl red (d) all of these
4. The pH at equivalence point is:
   (a) 11 (b) 7 (c) 3 (d) 2
5. Which of the following curves indicates the titration of a weak diprotic acid by NaOH of equivalent strength?



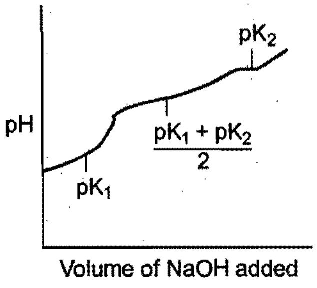
(a)



(b)



(c)



(d)

• Passage 4

Acid rain takes place due to combination of acidic oxides with water. In atmosphere, sulphur dioxide and nitrogen monoxide are oxidised to sulphur trioxide and nitrogen dioxide respectively, which react with water to give sulphuric and nitric acid. The resultant solution so called is acid rain. Sulphur dioxide dissolves in water to form diprotic acid in aqueous solution.

$$SO_2(g) + H_2O(l) \rightleftharpoons HSO_3^- + H^+; K_{a_1} = 10^{-2} M$$

$$HSO_3^- \rightleftharpoons SO_3^{2-} + H^+; \quad K_{a_2} = 10^{-7} M$$

and for equilibrium,

$$SO_2(aq.) + H_2O(l) \rightleftharpoons SO_3^{2-}(aq.) + 2H^+(aq.);$$

$$K_a = K_{a_1} \times K_{a_2} = 10^{-9} \text{ at } 300\,K \text{ at } 27°C$$

Answer the following questions:

1. Which of the following reagents will give white precipitate with the aqueous solution of sulphurous acid?
   (a) NaCl (b) KCl (c) $BaCl_2$ (d) HCl
2. The pH of 0.01 *M* aqueous solution of sodium sulphite will be:
   (a) 8.5 (b) 9 (c) 4.5 (d) 9.5
3. The dominant equilibrium in an aqueous solution of sodium hydrogen sulphite is:
   $$2HSO_3^-(aq.) \rightleftharpoons SO_2(aq.) + SO_3^{2-}(aq.) + H_2O(l)$$
   The equilibrium constant for the above reaction is:
   (a) 10^{-6} (b) 10^{-9} (c) 10^{-5} (d) 10^{-3}
4. Which among the following statements is correct?
   (a) CO_2 gas develops more acidity in rain-water than SO_2
   (b) H_2SO_3 is less acidic than H_2SO_4
   (c) HNO_3 is less acidic than HNO_2
   (d) $SO_2(g)$ is reduced in the atmosphere during thunderstorm

• Passage 5

The product of the concentrations of the ions of an electrolyte raised to power of their coefficients in the balanced chemical equation in the solution at any concentration. Its value is not constant and varies with change in concentration. Ionic product of the saturated solution is called solubility product K_{sp}.

(i) When $K_{ip} = K_{sp}$, the solution is just saturated and no precipitation takes place.

(ii) When $K_{ip} < K_{sp}$, the solution is unsaturated and precipitation will not take place.

(iii) When $K_{ip} > K_{sp}$, the solution is supersaturated and precipitation takes place.

Answer the following questions:

1. The solubility product, K_{sp}, of sparingly soluble salt *MX* at 25°C is 2.5×10^{-9}. The solubility of the salt in mol L^{-1} at this temperature is:
   (a) 1×10^{-14} (b) 5×10^{-8} (c) 1.25×10^{-9} (d) 5×10^{-5}
2. Which of the following is most soluble?
   (a) Bi_2S_3 ($K_{sp} = 1 \times 10^{-70}$) (b) MnS ($K_{sp} = 7 \times 10^{-16}$)
   (c) CuS ($K_{sp} = 8 \times 10^{-37}$) (d) Ag_2S ($K_{sp} = 6 \times 10^{-51}$)
3. The concentration of Ag^+ ions in a given saturated solution of AgCl at 25°C is 1.06×10^{-5} g ion per litre. The solubility product of AgCl is:
   (a) 0.353×10^{-10} (b) 0.530×10^{-10}
   (c) 1.12×10^{-10} (d) 2.12×10^{-10}
4. When equal volumes of the following solutions are mixed, precipitation of AgCl ($K_{sp} = 1.8 \times 10^{-10}$) will occur only with:

(a) $10^{-4}\ M\ Ag^+ + 10^{-4}\ M\ Cl^-$
(b) $10^{-5}\ M\ Ag^+ + 10^{-5}\ M\ Cl^-$
(c) $10^{-6}\ M\ Ag^+ + 10^{-6}\ M\ Cl^-$
(d) $10^{-10}\ M\ Ag^+ + 10^{-10}\ M\ Cl^-$

5. When HCl gas is passed through saturated NaCl solution, the ionic product of NaCl is exceeded because of:
(a) increase in Cl^- ion concentration
(b) increase in Na^+ ion concentration
(c) decrease in the NaCl concentration
(d) decrease in Cl^- ion concentration

6. If the solubility of $Li_3Na_3(AlF_6)_2$ is x mol L^{-1}, then its solubility product is equal to:
(a) $12x^3$ (b) $18x^3$ (c) x^8 (d) $2916x^8$

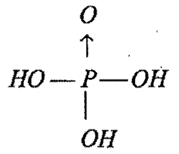
Passage 6

The dissociation of weak electrolyte (weak acid) is expressed in terms of Ostwald dilution law. Stronger is the acid, weaker is its conjugate base. The dissociation constants of an acid (K_a) *and its conjugate base* (K_b) *are related by the given relation:*

$$K_w = K_a \times K_b$$

At 25°C, K_w *(Ionic product of water)* = 10^{-14}.

Phosphoric acid is a weak acid. It is used in fertilizer, food, detergent and toothpaste. Structure of phosphoric acid is:



$$HO-\overset{\overset{O}{\uparrow}}{\underset{\underset{OH}{|}}{P}}-OH \quad (pK_{a_1} = 2.12,\ pK_{a_2} = 7.21,\ pK_{a_3} = 12.32)$$

Aqueous solution of phosphoric acid with a density of 1 g mL^{-1} *containing* 0.05% *by weight of phosphoric acid is used to impart tart taste to many soft drinks.*

Phosphate ion is an interfering radical in qualitative analysis. It should be removed for analysis beyond third group of qualitative analysis.

Answer the following questions:

1. The basicity of phosphoric acid is:
(a) 1 (b) 2 (c) 3 (d) 4

2. The state of hybridization of phosphorous in phosphoric acid is:
(a) sp (b) sp^2 (c) sp^3 (d) sp^3d

3. The removal of PO_4^{3-} in qualitative analysis of basic radicals is made by using a buffer solution of:
(a) HCO_3^- and CO_3^{2-} (b) CH_3COO^- and CH_3COOH
(c) NH_4^+ and NH_4OH (d) none of these

4. What is the molarity of phosphoric acid used in soft drinks?
(a) 5.1×10^{-3} (b) 1.5×10^{-3} (c) 3.1×10^{-3} (d) 2.1×10^{-3}

5. Which among the following relations is correct?
(a) $K_{a_1} < K_{a_2} < K_{a_3}$ (b) $K_{a_1} > K_{a_2} > K_{a_3}$
(c) $K_{a_1} = K_{a_2} = K_{a_3}$ (d) $K_{a_1} > K_{a_3} > K_{a_2}$

6. First ionization of phosphoric acid is:

$$H_3PO_4 \rightleftharpoons H_2PO_4^- + H^+$$
$$pK_{a_1} = 2.21$$

The dissociation constant of conjugate base of H_3PO_4 will be:
(a) 6.45×10^{-9} (b) 1.62×10^{-12}
(c) 3.48×10^{-11} (d) 4.62×10^{-2}

[Hint: $pK_{a_1} = 2.21$

$$K_{a_1} = \text{antilog}(-2.21) = 6.165 \times 10^{-3}$$

$$K_b \text{ (of conjugate base)} = \frac{K_w}{K_{a_1}} = \frac{10^{-14}}{6.165 \times 10^{-3}} = 1.62 \times 10^{-12}$$]

SELF ASSESSMENT

ASSIGNMENT NO. 10

SECTION-I

Straight Objective Type Questions

This section contains 7 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. When 50 mL of 0.1 M NaOH is mixed with 50 mL of 0.05 M CH_3COOH solution, pH becomes:
(a) 1.602 (b) 12.39
(c) 4.74 (d) 8.72

2. If the degree of dissociation of water at 90°C is 1.28×10^{-8} then the ionisation constant of water at 90°C is:
(a) $7.52 \times 10^{-12}\ M$ (b) $9.07 \times 10^{-15}\ M$
(c) $1.28 \times 10^{-14}\ M$ (d) $1.38 \times 10^{-14}\ M$

3. How much water from 5 litre of $10^{-3}\ M$ HCl should be evaporated to change its pH by 2 units?
(a) 1.5 litre (b) 0.5 litre (c) 2.54 litre (d) 4.95 litre

4. Which among the following cannot exist in an aqueous solution?
(a) NH_4^+ (b) NO_3^-
(c) NO_2^- (d) NH_2^-

5. The pH of an HCl solution is 2. Sufficient water is added to make the pH of new solutions. The hydrogen ion concentration is reduced:
(a) ten fold (b) seven fold
(c) thousand fold (d) hundred fold

6. Consider the following statements:
I. HNO_3 (strong acid) behaves as a base in HF.
II. H_2SO_4 dissociates to a small extent in glacial acetic acid.
III. CH_3COOH (a weak acid) behaves as strong acid in $NH_3(l)$. Select the correct alternate for these statements:
(a) I, II, and III (b) I and III
(c) II and III (d) I and II

7. The solubility of A_2X_5 is x mol dm^{-3}. Its solubility product is:
(a) $36x^6$ (b) $64 \times 10^4\ x^7$
(c) $126x^7$ (d) $1.25 \times 10^4\ x^7$

SECTION-II

Multiple Answers Type Objective Questions

8. During the titration of mixture of NaOH, Na_2CO_3 and an inert substance against hydrochloric acid:
(a) phenolphthalein is used to detect the end point when NaOH is completely neutralized and half of Na_2CO_3 is neutralized
(b) methyl orange is used to detect the final end point
(c) methyl orange is used to detect the first end point
(d) phenolphthalein is used to detect the final end point

9. Solubility product of the hydroxide $M(OH)_2$ is 4×10^{-12}. Select the correct statement(s) among the following:
(a) the pH of its saturated solution will be 10.3
(b) its solubility will decrease in a buffer medium of pH = 9
(c) its solubility will increase in a buffer medium of pH = 1
(d) its solubility is unaffected by pH of the medium

10. Which of the following salt solutions will be basic?
(a) NaCl (b) NaCN (c) K_2CO_3 (d) NH_4NO_3

11. Which of the following salts will not undergo hydrolysis?
(a) NaCl (b) KCl (c) NH_4Cl (d) CH_3COONa

12. Which of the following mixtures will be buffer?
(a) $CH_3COOH + CH_3COONH_4$
(b) HCl + NaCl
(c) Borax + boric acid
(d) $CH_3COOH + CH_3COONa$

SECTION-III

Assertion-Reason Type Questions

This section contains 5 questions. Each question contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; statement-2 is true; statement-2 is a correct explanation for statement-1.
(b) Statement-1 is true; statement-2 is true; statement-2 is not a correct explanation for statement-1.
(c) Statement-1 is true; statement-2 is false.
(d) Statement-1 is false; statement-2 is true.

13. **Statement-1:** Mixture of CH_3COOH and CH_3COONH_4 is not a buffer solution.

Because

Statement-2: Acid buffer contains the mixture of weak acid and its salt with strong base.

14. **Statement-1:** Addition of NH_4OH to an aqueous solution of $BaCl_2$ in the presence of excess NH_4Cl, precipitates $Ba(OH)_2$.

Because

Statement-2: $Ba(OH)_2$ is soluble in water.

15. **Statement-1:** pH of blood does not change inspite of taking acidic foods.

Because

Statement-2: Blood behaves as buffer solution.

16. **Statement-1:** Borax forms alkaline aqueous solution.

Because

Statement-2: Borax is the salt of a weak acid (H_3BO_3) and a strong base (NaOH).

17. **Statement-1:** When the aqueous solution of CH_3COONH_4 is diluted, then its degree of hydrolysis does not change.

Because

Statement-2: It is the salt of a weak acid and a weak base hence its degree of hydrolysis does not depend on the concentration.

SECTION-IV

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

If the correct matches are (a-p,s); (b-q,r); (c-p,q) and (d-s); then correct bubbled 4 × 4 matrix should be as given:

	p	q	r	s
a	●	ⓠ	ⓡ	●
b	ⓟ	●	●	ⓢ
c	●	●	ⓡ	ⓢ
d	ⓟ	ⓠ	ⓡ	●

18. Match the Column-I with Column-II:

Column-I (Salt solution in water)	**Column-II (Nature of hydrolysis)**
(a) NaCl	(p) Cationic hydrolysis
(b) CH_3COONa	(q) Anionic hydrolysis
(c) NH_4CN	(r) Both cationic and anionic hydrolysis
(d) NH_4Cl	(s) Does not undergo hydrolysis

19. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) H_3PO_2	(p) Dibasic
(b) H_3PO_4	(q) Monobasic
(c) H_3PO_3	(r) Tribasic
(d) H_3BO_3	(s) Aprotic

20. Match the Column-I with Column-II:

Column-I (Salt)	**Column-II (Degree of hydrolysis)**
(a) NH_4Cl	(p) No hydrolysis
(b) NaCl	(q) $h = \sqrt{\frac{K_h}{C}}$
(c) CH_3COONa	(r) $h = \sqrt{\frac{K_w}{CK_b}}$
(d) CH_3COONH_4	(s) $h = \sqrt{K_h}$

Answers

1. (b) **2.** (a) **3.** (a) **4.** (d) **5.** (c) **6.** (a) **7.** (d) **8.** (a, b)

9. (a, b, c) **10.** (b, c) **11.** (a, b) **12.** (c, d) **13.** (d) **14.** (d) **15.** (a) **16.** (a)

17. (a) **18.** (a-s) (b-q) (c-r) (d-p) **19.** (a-q) (b-r) (c-p) (d-q, s) **20.** (a-q, r) (b-p) (c-q) (d-s)

CHAPTER 11

OXIDATION AND REDUCTION

(Redox Reactions)

Several chemical reactions involve transfer of electrons from one chemical substance to another. These electron-transfer reactions are termed **oxidation-reduction** or **redox reactions.** Redox reactions play a vital role in our daily life. These reactions are accompanied by energy changes in the form of heat, light, electricity, etc. Generation of electricity in batteries, production of heat energy by burning chemical substances, extraction of metals such as sodium, aluminium, iron, etc., manufacture of a number of useful products such as caustic soda, potassium permanganate, etc.; electrodeposition or electroplating are common examples of redox reactions. Before we discuss the application of redox reactions in the production of electricity in different cells and the electrolysis phenomenon, it will be proper to study first the basic concepts of oxidation-reduction. The present chapter deals with the basic fundamentals of oxidation-reduction.

11.1 MOLECULAR AND IONIC EQUATIONS

Consider the reaction between solutions of ferric chloride and stannous chloride. When they are mixed, ferrous chloride and stannic chloride are formed. The chemical change can be represented by the following equation:

$$2FeCl_3 + SnCl_2 = 2FeCl_2 + SnCl_4$$

The reactants and products have been written in molecular forms; thus, the equation is termed as **molecular equation.** Since, the reactants and products involved in the chemical change are ionic compounds, these will be present in the form of ions in the solution. So, the above chemical change can be written in the following manner also:

$$2Fe^{3+} + 6Cl^- + Sn^{2+} + 2Cl^- \rightarrow 2Fe^{2+} + 4Cl^- + Sn^{4+} + 4Cl^-$$

or $$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$$

The ferric ions combine with stannous ions to form ferrous ions and stannic ions. This is an **ionic equation** for the above chemical change.

Ionic equations represent chemical changes in terms of ions which actually undergo reaction. The ions which do not undergo any electronic change during a chemical change are termed **spectator ions.** The spectator ions are not included in the final balanced equations.

The rules to be followed for writing ionic equations are:

(i) All soluble ionic compounds involved in a chemical change are expressed in ionic symbols and covalent substances are written in molecular form. H_2O, NH_3, NO_2, NO, SO_2, CO, CO_2, etc., are expressed in molecular form.

(ii) The ionic compound which is highly insoluble is expressed in molecular form.

(iii) The ions which are common and equal in number on both sides, *i.e.*, spectator ions, are cancelled.

(iv) Besides the atoms, the ionic charges must also be balanced on both the sides.

SOME SOLVED EXAMPLES

Example 1. *Write the following equation in ionic form.*

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$$

Solution: In this equation HCl and $MnCl_2$ are ionic in nature. Writing these compounds in ionic form,

$$MnO_2 + 4H^+ + 4Cl^- = Mn^{2+} + 2Cl^- + 2H_2O + Cl_2$$

$2Cl^-$ ions are common on both sides; so these are cancelled. The desired ionic equation reduces to,

$$MnO_2 + 4H^+ + 2Cl^- = Mn^{2+} + 2H_2O + Cl_2$$

Example 2. *Represent the following equation in ionic form.*

$$K_2Cr_2O_7 + 7H_2SO_4 + 6FeSO_4 = 3Fe_2(SO_4)_3 + Cr_2(SO_4)_3 + 7H_2O + K_2SO_4$$

Solution: In this equation except H_2O, all are ionic in nature. Representing these compounds in ionic forms,

$$2K^+ + Cr_2O_7^{2-} + 14H^+ + 7SO_4^{2-} + 6Fe^{2+} + 6SO_4^{2-} \longrightarrow$$

$$6Fe^{3+} + 9SO_4^{2-} + 2Cr^{3+} + 3SO_4^{2-} + 2K^+ + SO_4^{2-} + 7H_2O$$

$2K^+$ ions and $13SO_4^{2-}$ ions are common on both sides, so these are cancelled. The desired ionic equation reduces to,

$$Cr_2O_7^{2-} + 14H^+ + 6Fe^{2+} = 6Fe^{3+} + 2Cr^{3+} + 7H_2O$$

Total charges are equal on both sides; thus, the balanced ionic equation is the same as above.

Example 3. *Write the balanced ionic equation for the reaction of sodium bicarbonate with sulphuric acid.*

Solution: The molecular equation for the chemical change is:

$$NaHCO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O + CO_2$$

$NaHCO_3, H_2SO_4$ and Na_2SO_4 are ionic compounds; so these are written in ionic forms.

$$Na^+ + HCO_3^- + 2H^+ + SO_4^{2-} \longrightarrow 2Na^+ + SO_4^{2-} + H_2O + CO_2$$

Na^+ and SO_4^{2-} ions are spectator ions; hence these shall not appear in the final equation.

$$HCO_3^- + 2H^+ \longrightarrow H_2O + CO_2$$

To make equal charges on both sides, HCO_3^- should have a coefficient 2.

$$2HCO_3^- + 2H^+ \longrightarrow H_2O + CO_2$$

In order to balance the hydrogen and carbon on both sides, the molecules of H_2O and CO_2 should have a coefficient 2 respectively.

$$2HCO_3^- + 2H^+ = 2H_2O + 2CO_2$$

or $$HCO_3^- + H^+ = H_2O + CO_2$$

This is the balanced ionic equation.

Example 4. *Write the following ionic equation in the molecular form if the reactants are chlorides.*

$$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$$

Solution: For writing the reactants in molecular forms, the requisite number of chloride ions are added.

$$\underbrace{2Fe^{3+} + 6Cl^-} + \underbrace{Sn^{2+} + 2Cl^-}$$

or $$2FeCl_3 + SnCl_2$$

Similarly $8Cl^-$ ions are added on RHS to neutralise the charges.

$$\underbrace{2Fe^{2+} + 4Cl^-} + \underbrace{Sn^{4+} + 4Cl^-}$$

or $$2FeCl_2 + SnCl_4$$

Thus, the balanced molecular equation is

$$2FeCl_3 + SnCl_2 = 2FeCl_2 + SnCl_4$$

11.2 OXIDATION AND REDUCTION

Early Ideas of Oxidation and Reduction: The term oxidation was first used to describe chemical reactions in which oxygen was added to an element or a compound. The phenomenon of combustion was the earliest example of oxidation. Later on the term oxidation was extended to describe many more reactions which occurred without the use of even oxygen.

Oxidation is a process which involves:

(a) Addition of oxygen:

$2Mg + O_2^* = 2MgO$ (Oxidation of magnesium)

$S + O_2^* = SO_2$ (Oxidation of sulphur)

$2CO + O_2^* = 2CO_2$ (Oxidation of carbon monoxide)

$Na_2SO_3 + H_2O_2^* = Na_2SO_4 + H_2O$ (Oxidation of sodium sulphite)

(b) Removal of hydrogen:

$H_2S + Cl_2^* = 2HCl + S$ (Oxidation of hydrogen sulphide)

$4HI + O_2^* = 2H_2O + 2I_2$ (Oxidation of hydrogen iodide)

$4HCl + MnO_2^* = MnCl_2 + 2H_2O + Cl_2$ (Oxidation of hydrogen chloride)

(c) Addition of an electronegative element:

$Fe + S^* = FeS$ (Oxidation of iron)

$SnCl_2 + Cl_2^* = SnCl_4$ (Oxidation of stannous chloride)

$2Fe + 3F_2^* = 2FeF_3$ (Oxidation of iron)

(d) Removal of an electropositive element:

$2KI + H_2O_2^* = 2KOH + I_2$ (Oxidation of potassium iodide)

$2K_2MnO_4 + Cl_2^* = 2KCl + 2KMnO_4$ (Oxidation of potassium manganate)

$2KI + Cl_2^* = 2KCl + I_2$ (Oxidation of potassium iodide)

A substance which brings oxidation is known as **oxidising agent.** The substances marked with asterisk sign (*) in above equations are oxidising agents.

Reduction is just the reverse of oxidation.

Reduction is a process which involves:

(a) Removal of oxygen:

$CuO + C^* = Cu + CO$ (Reduction of cupric oxide)

$\underset{\text{Steam}}{H_2O} + \underset{\text{Coke}}{C^*} = \underbrace{CO + H_2}_{\text{Water gas}}$ (Reduction of water)

$Fe_3O_4 + 4H_2^* = 3Fe + 4H_2O$ (Reduction of magnetic oxide)

(b) Addition of hydrogen:

$Cl_2 + H_2^* = 2HCl$ (Reduction of chlorine)

$S + H_2^* = H_2S$ (Reduction of sulphur)

$C_2H_4 + H_2^* = C_2H_6$ (Reduction of ethene)

(c) Removal of an electronegative element:

$2HgCl_2 + SnCl_2^* = Hg_2Cl_2 + SnCl_4$ (Reduction of mercuric chloride)

$2FeCl_3 + H_2^* = 2FeCl_2 + 2HCl$ (Reduction of ferric chloride)

$2FeCl_3 + H_2S^* = 2FeCl_2 + 2HCl + S$

(Reduction of ferric chloride)

(d) Addition of an electropositive element:

$HgCl_2 + Hg^* = Hg_2Cl_2$ (Reduction of mercuric chloride)

$CuCl_2 + Cu^* = Cu_2Cl_2$ (Reduction of cupric chloride)

The substance which brings reduction is known as **reducing agent.** The substances marked with asterisk sign (*) in the above equations are reducing agents.

A substance, which undergoes oxidation, acts as a reducing agent while a substance, which undergoes reduction, acts as an oxidising agent.

Mg, S, Cu, Na_2SO_3, H_2S, HI, H_2, C, KI are reducing agents, while O_2, Cl_2, F_2, H_2O_2, MnO_2, $FeCl_3$, $CuCl_2$, Fe_3O_4, CuO, etc., are oxidising agents in the above examples.

All oxidation and reduction reactions are complimentary of one another and occur simultaneously, one cannot take place without the other. No single oxidation and no single reduction process is known. The simultaneous oxidation and reduction reactions are generally termed as redox reactions.

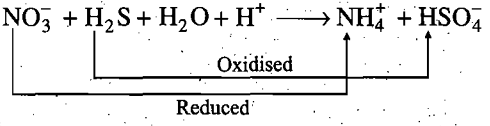
e.g., $2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$

$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$

In above example iron undergoes reduction from +3 to +2 and tin undergoes oxidation from +2 to +4.

Redox reactions are divided into two main types:

(i) Intermolecular redox: In such redox reactions, one molecule of reactant is oxidised whereas molecule of other reactant is reduced.



e.g., $NO_3^- + H_2S + H_2O + H^+ \longrightarrow NH_4^+ + HSO_4^-$

(ii) Intramolecular redox: One atom of a molecule is oxidised and other atom of same molecule is reduced then it is intramolecular redox reaction.

e.g., $2Mn_2O_7 \longrightarrow 4MnO_2 + 3O_2$

11.3 MODERN CONCEPT OF OXIDATION AND REDUCTION

According to the modern concept, loss of electrons is oxidation whereas gain of electrons is reduction.

Examples of oxidation reactions are:

$$Na \longrightarrow Na^+ + e$$

$$Zn \longrightarrow Zn^{2+} + 2e$$

$$Fe^{2+} \longrightarrow Fe^{3+} + e$$

$$Sn^{2+} \longrightarrow Sn^{4+} + 2e$$

$$H_2O_2 \longrightarrow O_2 + 2H^+ + 2e$$

$$2S_2O_3^{2-} \longrightarrow S_4O_6^{2-} + 2e$$

$$[Fe(CN)_6]^{4-} \longrightarrow [Fe(CN)_6]^{3-} + e$$

$$MnO_4^{2-} \longrightarrow MnO_4^- + e$$

Examples of reduction reactions are:

$$Cl_2 + 2e \longrightarrow 2Cl^-$$

$$S + 2e \longrightarrow S^{2-}$$

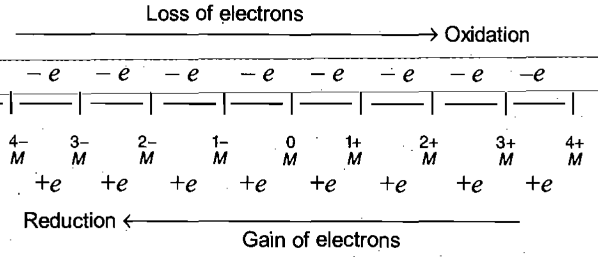
$$Cu^{2+} + 2e \longrightarrow Cu$$

$$MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O$$

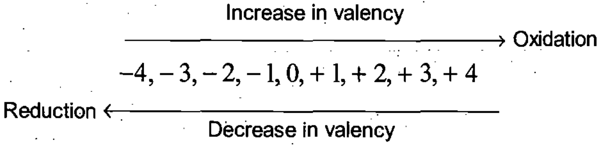
$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O$$

$$H_2O_2 + 2H^+ + 2e \longrightarrow 2H_2O$$

Oxidation and reduction can be represented in a general way as shown below :



In a redox process the valency of the involved species changes. The valency of a reducing agent increases while the valency of an oxidising agent decreases in a redox reaction. The valency of a free element is taken as zero.



When there is no change in valency it means there is no oxidation or reduction, *e.g.*, in

$$\left.\begin{array}{r} BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl \\ BaSO_4 \longrightarrow Ba^{2+} + SO_4^{2-} \end{array}\right\} \text{(No change in valency)}$$

Conclusions

(i) Oxidation is a process in which one or more electrons are lost or valency of the element increases.

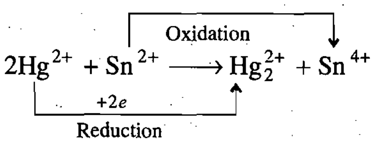
(ii) Reduction is a process in which one or more electrons are gained or valency of the element decreases.

(iii) Oxidising agent is a material which can gain one or more electrons, *i.e.*, valency decreases.

(iv) Reducing agent is a material which can lose one or more electrons, *i.e.*, valency increases.

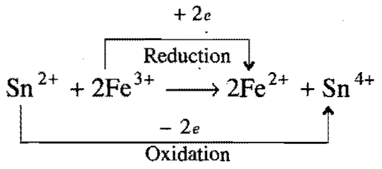
(v) Redox reaction involves two half reactions, one involving loss of electron or electrons (oxidation) and the other involving gain of electron or electrons (reduction).

Examples:

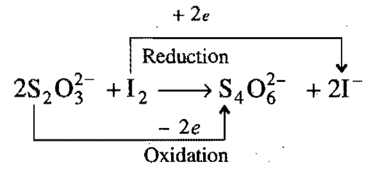


1. $2Hg^{2+} + Sn^{2+} \longrightarrow Hg_2^{2+} + Sn^{4+}$

2.



3.



11.4 ION-ELECTRON METHOD FOR BALANCING REDOX REACTIONS

The method for balancing redox reactions by ion electron method was developed by **Jette** and **LaMev** in 1927. It involves the following steps:

(i) Write down the redox reaction in ionic form.

(ii) Split the redox reaction into two half reactions, one for oxidation and the other for reduction.

(iii) Balance each half reaction for the number of atoms of each element. For this purpose:

(a) Balance the atoms other than H and O for each half reaction using simple multiples.

(b) Add water molecules to the side deficient in oxygen and H^+ to the side deficient in hydrogen. This is done in acidic or neutral solutions.

(c) In alkaline solution, for each excess of oxygen, add one water molecule to the same side and two OH^- ions to the other side. If hydrogen is still unbalanced, add one OH^- ion for each excess hydrogen on the same side and one water molecule to the other side.

(iv) Add electrons to the side deficient in electrons as to equalise the charge on both sides.

(v) Multiply one or both the half reactions by a suitable number so that the number of electrons become equal in both the equations.

(vi) Add the two balanced half reactions and cancel any term common to both sides.

The following solved problems illustrate the various steps of ion electron method:

Example 5. *Balance the following equations by ion electron method.*

(a) $FeCl_3 + H_2S \longrightarrow FeCl_2 + HCl + S$

(b) $Cu + HNO_3 \longrightarrow Cu(NO_3)_2 + NO + H_2O$

(c) $KI + Cl_2 \longrightarrow KCl + I_2$

(d) $MnO_2 + HCl \longrightarrow MnCl_2 + H_2O + Cl_2$

(e) $H_2S + HNO_3 \longrightarrow H_2SO_4 + NO_2 + H_2O$

Solution: (a) $FeCl_3 + H_2S \longrightarrow FeCl_2 + HCl + S$

Ionic equation, $Fe^{3+} + H_2S \longrightarrow Fe^{2+} + H^+ + S$

1st step. Splitting the redox reaction into two half reactions,

$$\underset{\text{(Oxidation half reaction)}}{H_2S \longrightarrow 2H^+ + S} \qquad \underset{\text{(Reduction half reaction)}}{Fe^{3+} \longrightarrow Fe^{2+}}$$

2nd step. Adding electrons to the side deficient in electrons,

$$H_2S \longrightarrow 2H^+ + S + 2e$$

$$Fe^{3+} + e \longrightarrow Fe^{2+}$$

3rd step. Balancing electrons in both the half reactions,

$$H_2S \longrightarrow 2H^+ + S + 2e$$

$$2Fe^{3+} + 2e \longrightarrow 2Fe^{2+}$$

4th step. Adding both the half reactions,

$$H_2S + 2Fe^{3+} \longrightarrow 2H^+ + S + 2Fe^{2+}$$

Converting it into molecular form,

$$H_2S + 2Fe^{3+} + 6Cl^- \longrightarrow 2H^+ + 2Cl^- + S + 2Fe^{2+} + 4Cl^-$$

or $\quad H_2S + 2FeCl_3 \longrightarrow 2HCl + S + 2FeCl_2$

(b) $Cu + HNO_3 \longrightarrow Cu(NO_3)_2 + NO + H_2O$

Ionic equation,

$$Cu + H^+ + NO_3^- \longrightarrow Cu^{2+} + NO + H_2O$$

1st step. Splitting into two half reactions,

$$\underset{\text{(Oxidation half reaction)}}{Cu \longrightarrow Cu^{2+}} \;; \quad \underset{\text{(Reduction half reaction)}}{NO_3^- + H^+ \rightarrow NO + H_2O}$$

2nd step. Adding H^+ ions to the side deficient in hydrogen,

$$Cu \longrightarrow Cu^{2+}; \quad NO_3^- + 4H^+ \longrightarrow NO + 2H_2O$$

3rd step. Adding electrons to the side deficient in electrons,

$$Cu \longrightarrow Cu^{2+} + 2e; \; NO_3^- + 4H^+ + 3e \longrightarrow NO + 2H_2O$$

4th step. Balancing electrons in both half reactions,

$$3Cu \longrightarrow 3Cu^{2+} + 6e; \; 2NO_3^- + 8H^+ + 6e \longrightarrow 2NO + 4H_2O$$

5th step. Adding both the half reactions,

$$3Cu + 2NO_3^- + 8H^+ \longrightarrow 3Cu^{2+} + 2NO + 4H_2O$$

Converting it into molecular form,

$$3Cu + 2NO_3^- + 8H^+ + 6NO_3^- \longrightarrow 3Cu^{2+} + 6NO_3^- + 2NO + 4H_2O$$

or $\quad 3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$

(c) $\quad KI + Cl_2 \longrightarrow KCl + I_2$

Ionic equation, $I^- + Cl_2 \longrightarrow Cl^- + I_2$

Splitting into two half reactions,

$$\underset{\text{(Oxidation)}}{I^- \longrightarrow I_2}\;; \qquad \underset{\text{(Reduction)}}{Cl_2 \longrightarrow Cl^-}$$

Making number of atoms equal,

$$2I^- \longrightarrow I_2\;; \qquad Cl_2 \longrightarrow 2Cl^-$$

Adding electrons to the sides deficient in electrons,

$$2I^- \longrightarrow I_2 + 2e; \quad Cl_2 + 2e \longrightarrow 2Cl^-.$$

Adding both the half reactions,

$$2I^- + Cl_2 \longrightarrow I_2 + 2Cl^-$$

Converting it into molecular form,

$$2K^+ + 2I^- + Cl_2 \longrightarrow I_2 + 2Cl^- + 2K^+$$

or $$2KI + Cl_2 \longrightarrow I_2 + 2KCl$$

(d) $MnO_2 + HCl \longrightarrow MnCl_2 + H_2O + Cl_2$

Ionic equation,

$$MnO_2 + H^+ + Cl^- \longrightarrow Mn^{2+} + H_2O + Cl_2$$

1st step. Splitting into two half reactions,

$$\underset{\text{(Oxidation half reaction)}}{Cl^- \longrightarrow Cl_2} \quad ; \quad \underset{\text{(Reduction half reaction)}}{MnO_2 + H^+ \longrightarrow Mn^{2+} + H_2O}$$

2nd step. Adding H^+ ions to the side deficient in hydrogen,

$$Cl^- \longrightarrow Cl_2 \quad ; \quad MnO_2 + 4H^+ \longrightarrow Mn^{2+} + 2H_2O$$

3rd step. Making atoms equal on both sides,

$$2Cl^- \longrightarrow Cl_2 \, ; \quad MnO_2 + 4H^+ \longrightarrow Mn^{2+} + 2H_2O$$

4th step. Adding electrons to the side deficient in electrons,

$$2Cl^- \longrightarrow Cl_2 + 2e$$

$$MnO_2 + 4H^+ + 2e \longrightarrow Mn^{2+} + 2H_2O$$

5th step. Adding both the half reactions,

$$2Cl^- + MnO_2 + 4H^+ \longrightarrow Cl_2 + Mn^{2+} + 2H_2O$$

Converting it into molecular form,

$$MnO_2 + 2Cl^- + 4H^+ + 2Cl^- \rightarrow Cl_2 + Mn^{2+} + 2Cl^- + 2H_2O$$

or $$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$$

(e) $H_2S + HNO_3 \longrightarrow H_2SO_4 + NO_2 + H_2O$

Ionic equation,

$$H_2S + NO_3^- \longrightarrow NO_2 + H_2O$$

1st step. Splitting into two half reactions,

$$\underset{\text{(Oxidation half reaction)}}{H_2S \longrightarrow SO_4^{2-}} \quad ; \quad \underset{\text{(Reduction half reaction)}}{NO_3^- \longrightarrow NO_2 + H_2O}$$

2nd step. Add water to the side deficient in oxygen,

$$H_2S + 4H_2O \longrightarrow SO_4^{2-} + 10H^+$$

3rd step. Add H^+ ions to the side deficient in hydrogen,

$$NO_3^- + 2H^+ \longrightarrow NO_2 + H_2O$$

4th step. Add electrons to the side deficient in electrons,

$$H_2S + 4H_2O \longrightarrow SO_4^{2-} + 10H^+ + 8e$$

$$NO_3^- + 2H^+ + e \longrightarrow NO_2 + H_2O$$

5th step. Balancing electrons in both the half reactions,

$$H_2S + 4H_2O \longrightarrow SO_4^{2-} + 10H^+ + 8e$$

$$[NO_3^- + 2H^+ + e \longrightarrow NO_2 + H_2O] \times 8$$

6th step. Adding both the half reactions,

$$H_2S + 4H_2O + 8NO_3^- + 6H^+ \longrightarrow SO_4^{2-} + 8NO_2 + 8H_2O$$

or $$H_2S + 8NO_3^- + 6H^+ \longrightarrow SO_4^{2-} + 8NO_2 + 4H_2O$$

Converting it into molecular form,

$$H_2S + 8HNO_3 \longrightarrow H_2SO_4 + 8NO_2 + 4H_2O$$

Example 6. *Balance the following equations by ion electron method:*

(a) $MnO_4^- + Fe^{2+} + H^+ \longrightarrow Mn^{2+} + Fe^{3+} + H_2O$

(b) $MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O$

(c) $Cr_2O_7^{2-} + I^- + H^+ \longrightarrow Cr^{3+} + I_2 + H_2O$

(d) $Cr_2O_7^{2-} + SO_2 + H^+ \longrightarrow Cr^{3+} + HSO_4^- + H_2O$

(e) $I_2 + OH^- \longrightarrow IO_3^- + I^- + H_2O$

(f) $Cl_2 + IO_3^- + OH^- \longrightarrow IO_4^- + Cl^- + H_2O$

Solution:

(a) $MnO_4^- + Fe^{2+} + H^+ \longrightarrow Mn^{2+} + Fe^{3+} + H_2O$

1st step. Splitting into two half reactions,

$$\underset{\text{(Reduction half reaction)}}{MnO_4^- + H^+ \longrightarrow Mn^{2+} + H_2O} \, ; \quad \underset{\text{(Oxidation half reaction)}}{Fe^{2+} \longrightarrow Fe^{3+}}$$

2nd step. Adding hydrogen ions to the side deficient in hydrogen,

$$MnO_4^- + 8H^+ \longrightarrow Mn^{2+} + 4H_2O$$

3rd step. Adding electrons to the sides deficient in electrons,

$$MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O$$

$$Fe^{2+} \longrightarrow Fe^{3+} + e$$

4th step. Balancing electrons in both half reactions,

$$MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O$$

$$5Fe^{2+} \longrightarrow 5Fe^{3+} + 5e$$

5th step. Adding both the half reactions,

$$MnO_4^- + 8H^+ + 5Fe^{2+} \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

(b) $MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O$

Splitting into two half reactions,

$$MnO_4^- + H^+ \longrightarrow Mn^{2+} + H_2O; \quad C_2O_4^{2-} \longrightarrow 2CO_2$$

Balanced as in Question (a),

$$MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O$$

$$C_2O_4^{2-} \longrightarrow 2CO_2 + 2e$$

Balancing electrons in both half reactions,

$$2[MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O];$$

$$5[C_2O_4^{2-} \longrightarrow 2CO_2 + 2e]$$

Adding both the half reactions,

$$2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

(c) $Cr_2O_7^{2-} + I^- + H^+ \longrightarrow Cr^{3+} + I_2 + H_2O$

1st step. Splitting into two half reactions,

$$\underset{\text{(Reduction half reaction)}}{Cr_2O_7^{2-} + H^+ \longrightarrow Cr^{3+} + H_2O} \qquad \underset{\text{(Oxidation half reaction)}}{I^- \longrightarrow I_2}$$

2nd step. Adding hydrogen ions to the side deficient in hydrogen,

$$Cr_2O_7^{2-} + 14H^+ \longrightarrow Cr^{3+} + 7H_2O$$

3rd step. Making atoms equal on both sides,

$$Cr_2O_7^{2-} + 14H^+ \longrightarrow 2Cr^{3+} + 7H_2O \;;\; 2I^- \longrightarrow I_2$$

4th step. Adding electrons to the sides deficient in electrons,

$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O$$

$$2I^- \longrightarrow I_2 + 2e$$

5th step. Balancing electrons,

$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O$$

$$3[2I^- \longrightarrow I_2 + 2e]$$

6th step. Adding both the half reactions,

$$Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$$

(d) $Cr_2O_7^{2-} + SO_2 + H^+ \longrightarrow Cr^{3+} + HSO_4^- + H_2O$

1st step. Splitting into two half reactions,

$$\underset{\text{(Reduction half reaction)}}{Cr_2O_7^{2-} + H^+ \longrightarrow Cr^{3+} + H_2O;} \qquad \underset{\text{(Oxidation half reaction)}}{SO_2 \longrightarrow HSO_4^-}$$

2nd step. Adding H^+ ions to side deficient in hydrogen,

$$Cr_2O_7^{2-} + 14H^+ \longrightarrow Cr^{3+} + 7H_2O$$

3rd step. Adding water to the side deficient in oxygen,

$$SO_2 + 2H_2O \longrightarrow HSO_4^- + 3H^+$$

4th step. Making atoms equal on both sides,

$$Cr_2O_7^{2-} + 14H^+ \longrightarrow 2Cr^{3+} + 7H_2O$$

5th step. Adding electrons to the sides deficient in electrons,

$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O;$$

$$SO_2 + 2H_2O \longrightarrow HSO_4^- + 3H^+ + 2e$$

6th step. Balancing electrons in both the half reactions,

$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O$$

$$[SO_2 + 2H_2O \longrightarrow HSO_4^- + 3H^+ + 2e] \times 3$$

7th step. Adding both the half reactions,

$$Cr_2O_7^{2-} + 5H^+ + 3SO_2 \longrightarrow 2Cr^{3+} + 3HSO_4^- + H_2O$$

(e) $I_2 + OH^- \longrightarrow IO_3^- + I^- + H_2O$

1st step. Splitting into two half reactions,

$$\underset{\text{(Oxidation half reaction)}}{I_2 + OH^- \longrightarrow IO_3^- + H_2O;} \qquad \underset{\text{(Reduction half reaction)}}{I_2 \longrightarrow I^-}$$

2nd step. Adding OH^- ions,

$$I_2 + 12OH^- \longrightarrow 2IO_3^- + 6H_2O$$

3rd step. Adding electrons to the sides deficient in electrons,

$$I_2 + 12OH^- \longrightarrow 2IO_3^- + 6H_2O + 10e;\; I_2 + 2e \longrightarrow 2I^-$$

4th step. Balancing electrons in both the half reactions,

$$I_2 + 12OH^- \longrightarrow 2IO_3^- + 6H_2O + 10e$$

$$5[I_2 + 2e^- \longrightarrow 2I^-]$$

5th step. Adding both the half reactions,

$$6I_2 + 12OH^- \longrightarrow 2IO_3^- + 10I^- + 6H_2O$$

Dividing by 2,

$$3I_2 + 6OH^- \longrightarrow IO_3^- + 5I^- + 3H_2O$$

(f) $Cl_2 + IO_3^- + OH^- \longrightarrow IO_4^- + Cl^- + H_2O$

1st step. Splitting into two half reactions,

$$\underset{\text{(Oxidation half reaction)}}{IO_3^- + OH^- \longrightarrow IO_4^- + H_2O\;;} \qquad \underset{\text{(Reduction half reaction)}}{Cl_2 \longrightarrow Cl^-}$$

2nd step. Adding QH^- ions,

$$IO_3^- + 2OH^- \longrightarrow IO_4^- + H_2O$$

3rd step. Adding electrons to the sides deficient in electrons,

$$IO_3^- + 2OH^- \longrightarrow IO_4^- + H_2O + 2e$$

$$Cl_2 + 2e \longrightarrow 2Cl^-$$

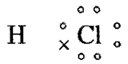
4th step. Adding both the half reactions,

$$IO_3^- + 2OH^- + Cl_2 \longrightarrow IO_4^- + 2Cl^- + H_2O$$

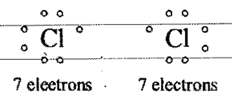
11.5 OXIDATION NUMBER (Oxidation State)

It is defined as **the charge (real or imaginary) which an atom appears to have when it is in combination.** In the case of electrovalent compounds, the oxidation number of an element or radical is the same as the charge on the ion. This is the real charge and is developed by the loss and gain of electron or electrons. For example, in the electrovalent compound, sodium chloride (NaCl), the charge on sodium and chlorine is +1 and −1, respectively. The charges have been developed by the transfer of one electron from Na-atom to Cl-atom. Thus, in NaCl (Na^+Cl^-), the oxidation number of sodium is +1 and that of chlorine is −1.

The oxidation numbers of atoms in covalent compounds can be derived by assigning the electrons of each bond to the more electronegative atom of the bonded atoms. For a molecule of HCl both the electrons of the covalent bond are assigned to the chlorine atom since it is more electronegative than hydrogen.



Thus, chlorine atom has one more electron than the neutral chlorine atom which brings one unit negative charge on chlorine. The oxidation number of chlorine in this compound is –1. The hydrogen atom has lost the only electron possessed by it, thus acquiring one unit positive charge. The oxidation number of hydrogen is, therefore, +1 in this compound. In the case of covalent bond between two identical atoms, *i.e.*, electronegativity difference is zero, the bonding electrons are shared equally between the bonded atoms, *i.e.*, no charge is developed on any of the atoms. Thus, the oxidation numbers of both chlorine atoms are zero in the molecule of chlorine.



[In neutral chlorine atom, 7 electrons are present in the valency shell]

Counting of electrons in this fashion is not convenient in many molecules and therefore the following operational rules are followed which are helpful and convenient in determining the oxidation numbers:

(i) The oxidation number (Ox.no.) of an atom in free elements is zero, no matter how complicated the molecule is, hydrogen in H_2, sulphur in S_8, phosphorus in P_4, oxygen in O_2 or O_3, all have zero value of oxidation numbers.

(ii) The fluorine, which is the most electronegative element, has oxidation number –1 in all of its compounds.

(iii) Oxidation number of oxygen is –2 in all compounds except in peroxides, superoxides and oxygen fluorides. In peroxides (O_2^{2-}), oxygen has oxidation number –1; in superoxides (O_2^-), oxygen has oxidation number $-1/2$; and in OF_2, the oxygen has an oxidation number +2.

(iv) The oxidation number of hydrogen is +1 in all of its compounds except in metallic hydrides like NaH, BaH_2, etc. Hydrogen is in –1 oxidation state in these hydrides.

(v) The oxidation number of an ion is equal to the electrical charge present on it.

(vi) The oxidation number of IA elements (Li, Na, K, Rb, Cs and Fr) is +1 and the oxidation number of IIA elements (Be, Mg, Ca, Sr, Ba and Ra) is +2.

(vii) For complex ions, the algebraic sum of oxidation numbers of all the atoms is equal to the net charge on the ion.

(viii) In the case of neutral molecules, the algebraic sum of the oxidation numbers of all the atoms present in the molecule is zero.

The following solved examples illustrate the application of the above rules for finding out the oxidation number of an element in particular species:

Example 7. *What is the oxidation number of Mn in $KMnO_4$ and of S in $Na_2S_2O_3$?*

Solution: Let the Ox.no. of Mn in $KMnO_4$ be x.

We know that, Ox. no. of K = +1
Ox. no. of O = – 2

$$\begin{aligned} \text{So,}\quad & \text{Ox. no. K} + \text{Ox. no. Mn} + 4(\text{Ox. no. O}) = 0 \\ \text{or}\quad & +1 + x + 4(-2) = 0 \\ \text{or}\quad & +1 + x - 8 = 0 \\ \text{or}\quad & x = +8 - 1 = +7 \end{aligned}$$

Hence, Ox.no. of Mn in $KMnO_4$ is +7.

Similarly, for S in $Na_2S_2O_3$,

$$2(\text{Ox. no. Na}) + 2(\text{Ox. no. S}) + 3(\text{Ox. no. O}) = 0$$
$$2 \times (+1) + 2x + 3(-2) = 0$$
$$x = +2$$

Hence, Ox.no. of S in $Na_2S_2O_3$ = + 2.

Example 8. *What is the oxidation number of Cr in $K_2Cr_2O_7$?* (Ranchi 1996)

Solution: Let the Ox.no. of Cr in $K_2Cr_2O_7$ be x.

We know that, Ox.no. of K = + 1
Ox. no. of O = – 2

$$\begin{aligned} \text{So,}\quad & 2(\text{Ox. no. K}) + 2(\text{Ox. no. Cr}) + 7(\text{Ox. no. O}) = 0 \\ & 2(+1) + 2(x) + 7(-2) = 0 \\ \text{or}\quad & +2 + 2x - 14 = 0 \\ \text{or}\quad & 2x = +14 - 2 = +12 \\ \text{or}\quad & x = +\frac{12}{2} = +6 \end{aligned}$$

Hence, oxidation number of Cr in $K_2Cr_2O_7$ is +6.

Example 9. *What is the oxidation number of Fe in $K_4Fe(CN)_6$?*

Solution: Let the oxidation number of Fe be x.

We know that, Ox.no. of K = +1
Ox. no. of $(CN)^-$ = –1

$$\begin{aligned} \text{So,}\quad & 4(\text{Ox. no. K}) + \text{Ox. no. Fe} + 6(\text{Ox. no. CN}^-) = 0 \\ & 4(+1) + x + 6(-1) = 0 \\ \text{or}\quad & +4 + x - 6 = 0 \\ \text{or}\quad & x = +6 - 4 = +2 \end{aligned}$$

The oxidation number of iron in $K_4Fe(CN)_6$ is +2.

Example 10. *Find the oxidation number of*

(a) S in SO_4^{2-} ion *(b) S in HSO_3^- ion*

(c) Pt in $(PtCl_6)^{2-}$ ion *(d) Mn in $(MnO_4)^-$ ion*

Solution: (a) Let the oxidation number of S be x.

We know that, Ox.no. of O = – 2

$$\begin{aligned} \text{So,}\quad & \text{Ox. no. S} + 4(\text{Ox. no. O}) = -2 \\ \text{or}\quad & x + 4(-2) = -2 \\ \text{or}\quad & x - 8 = -2 \\ \text{or}\quad & x = +8 - 2 = +6 \end{aligned}$$

The oxidation number of S in SO_4^{2-} ion is +6.

(b) Let the oxidation number of S be x in HSO_3^- ion.

We know that, Ox.no. of H = + 1
Ox.no. of O = – 2

$$
\begin{aligned}
\text{So,}\quad & \text{Ox. no. H} + \text{Ox. no. S} + 3(\text{Ox. no. O}) = -1\\
& +1 + x + 3(-2) = -1\\
\text{or}\quad & +1 + x - 6 = -1\\
\text{or}\quad & x - 5 = -1\\
\text{or}\quad & x = +5 - 1 = +4
\end{aligned}
$$

The oxidation number of S in HSO_3^- ion is + 4.

(c) Let oxidation number of Pt be x.

We know that Ox.no. of Cl = − 1.

$$
\begin{aligned}
\text{So,}\quad & \text{Ox. no. Pt} + 6(\text{Ox. no. Cl}) = -2\\
& x + 6(-1) = -2\\
\text{or}\quad & x - 6 = -2\\
\text{or}\quad & x = +6 - 2 = +4
\end{aligned}
$$

The oxidation number of Pt in $[Pt(Cl)_6]^{2-}$ ion is + 4.

(d) Let oxidation number of Mn be x.

We know that, Ox.no. of O = − 2.

$$
\begin{aligned}
\text{So,}\quad & \text{Ox. no. Mn} + 4(\text{Ox. no. O}) = -1\\
& x + 4(-2) = -1\\
\text{or}\quad & x - 8 = -1\\
\text{or}\quad & x = +8 - 1 = +7
\end{aligned}
$$

The oxidation number of Mn in $[MnO_4]^-$ ion is +7.

Example 11. *Which compound amongst the following has the highest oxidation number for Mn?*

$KMnO_4$, K_2MnO_4, MnO_2 and Mn_2O_3.

Solution:

		Ox.no. of Mn
$KMnO_4$	$+1 + x - 8 = 0$ $x = +7$	$+7$
K_2MnO_4	$+2 + x - 8 = 0$ $x = +6$	$+6$
MnO_2	$x - 4 = 0$ $x = +4$	$+4$
Mn_2O_3	$2x - 6 = 0$ $x = +3$	$+3$

Thus, the highest oxidation number for Mn is in $KMnO_4$.

Sometimes, oxidation numbers have such values which at first sight appear strange. For example, the oxidation number of carbon in cane sugar ($C_{12}H_{22}O_{11}$), glucose ($C_6H_{12}O_6$), dichloromethane, etc., is zero.

Cane sugar ($C_{12}H_{22}O_{11}$)	Glucose ($C_6H_{12}O_6$)
$12 \times x + 22 \times 1 + 11(-2) = 0$	$6 \times x + 12 \times 1 + 6(-2) = 0$
$12x + 22 - 22 = 0$	$6x + 12 - 12 = 0$
So, $x = 0$	So, $x = 0$

Dichloromethane (CH_2Cl_2)

$$
\begin{aligned}
& x + 2 \times 1 + 2(-1) = 0\\
& x + 2 - 2 = 0\\
& \text{So, } x = 0
\end{aligned}
$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. Oxidation state of S in SO_4^{2-}: [BCECE (Medical) 2005]

(a) +6 (b) +3
(c) +2 (d) −2

[**Ans.** (a)]

[**Hint:** Let oxidation state of S is x.

$$\therefore \quad x + 4(-2) = -2$$
$$x = +6]$$

2. Arrange the following in the increasing order of oxidation state of Mn: (JCECE 2004)

(i) Mn^{2+} (ii) MnO_2 (iii) $KMnO_4$ (iv) K_2MnO_4

(a) (i) > (ii) > (iii) > (iv) (b) (i) < (ii) < (iv) < (iii)
(c) (ii) < (iii) < (i) < (iv) (d) (iii) < (i) < (iv) < (ii)

[**Ans.** (b)]

[**Hint:** $\underset{(+2)}{Mn^{2+}} < \underset{(+4)}{MnO_2} < \underset{(+6)}{K_2MnO_4} < \underset{(+7)}{KMnO_4}$]

3. Which of the following has least oxidation state of Fe? (JCECE 2004)

(a) $K_3[Fe(OH)_6]$
(b) $K_2[FeO_4]$
(c) $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$
(d) $[Fe(CN)_6]^{3-}$

[**Ans.** (c)]

[**Hint:** In mohr salt $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$, oxidation state of iron is +2 which is least.

$K_3[Fe(OH)_6]$	$+3 + x - 6 = 0$	$x = +3$
$K_2[FeO_4]$	$+2 + x - 8 = 0$	$x = +6$
$FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$	**+2 state** in $FeSO_4$ ($x - 2 = 0$)	
$Fe(CN)_6^{3-}$	$x - 6 = -3$	$x = +3]$

4. Oxidation state of carbon in HCOOH will be:

(a) +1 (b) +2 (c) − 4 (d) 0

[**Ans.** (b)]

[**Hint:** Let the oxidation state of carbon be x.

$$2 + x - 4 = 0$$
$$x = 2]$$

5. Oxidation states of chlorine in $HClO_4$ and $HClO_3$ are:

(a) +4, +3 (b) +7, +5 (c) +3, +4 (d) +5, +7

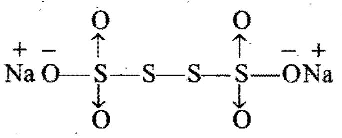
[**Ans.** (b)]

[**Hint:** $HClO_4$: $+1 + x - 8 = 0$, $x = +7$

$HClO_3$: $+1 + x - 6 = 0$, $x = +5$]

11.6 SPECIAL EXAMPLES OF OXIDATION STATE DETERMINATION

1. Oxidation state of sulphur in $Na_2S_4O_6$: It is only average oxidation number of sulphur. Let us see the structure of $Na_2S_4O_6$.



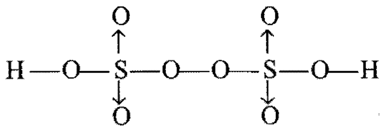
From the structure, it is clear that the sulphur atoms acting as donor atoms have +5 oxidation number (each). On the other hand, the sulphur atom involved in pure covalent bond formation has zero oxidation number.

2. Oxidation number of sulphur in $(CH_3)_2SO$ (dimethyl sulphoxide): Here, oxidation number $O = -2$; oxidation number of each CH_3 group is +1.

$\therefore$ $$+2 + x - 2 = 0 \text{ or } x = 0$$

Thus, sulphur lies in zero oxidation state.

3. Oxidation number of sulphur in perdisulphuric acid $H_2S_2O_8$: It may be done only when the structure is drawn.



$$\mathrm{H-O-\overset{\overset{O}{\uparrow}}{\underset{\underset{O}{\downarrow}}{S}}-O-O-\overset{\overset{O}{\uparrow}}{\underset{\underset{O}{\downarrow}}{S}}-O-H}$$

Oxidation number of S = x; oxidation number of H = +1; oxidation number of oxygen in peroxo linkage = −1; oxidation number of other six oxygen atoms = −2 each.

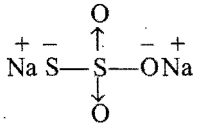
$\therefore$ $$+2 + (-12) + 2x - 2 = 0$$

$\therefore$ $$x = +6 \qquad \text{(oxidation number of sulphur)}$$

4. Oxidation number of sulphur in hypo, $Na_2S_2O_3$: Let the average oxidation number of sulphur be 'x'.

$\therefore$ $$+2 + 2x - 6 = 0 \quad \therefore \quad x = +2$$

Structure of hypo may be drawn as—



$$\mathrm{\overset{+}{Na}\,\overset{-}{S}-\overset{\overset{O}{\uparrow}}{\underset{\underset{O}{\downarrow}}{S}}-\overset{-}{O}\overset{+}{Na}}$$

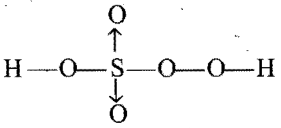
Here, the two sulphur atoms have different oxidation states:

(i) Oxidation number of donor sulphur atom is +5. It gives up four electrons in coordination and one electron in covalent bond formation with oxygen.

(ii) Sulphur, bonded with Na, lies in −1 state since one electron of Na lies towards the sulphur. Electrons of S—S bond are equally shared between two sulphur atoms.

Thus +5 and −1 are two oxidation states of the two sulphur atoms.

5. Oxidation number of sulphur in peroxo monosulphuric acid (H_2SO_5): Let us draw its structure.



$$\mathrm{H-O-\overset{\overset{O}{\uparrow}}{\underset{\underset{O}{\downarrow}}{S}}-O-O-H}$$

Here, we have to consider Ox.no. of H = + 1

Ox.no. of oxygen in peroxo linkage = − 1

Ox. no. of rest of oxygen = − 2

$\therefore$ $$+2 + x - 6 - 2 = 0 \text{ or } x = +6$$

Thus, sulphur in H_2SO_5 lies in + 6 oxidation state.

6. Fe in its oxides, FeO, Fe_2O_3 and Fe_3O_4:

In FeO $\longrightarrow x - 2 = 0, x = +2$

In $Fe_2O_3 \longrightarrow 2x - 6 = 0, x = +3$

In $Fe_3O_4 \longrightarrow 3x - 8 = 0, x = +8/3$ (fractional)

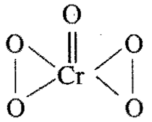
Here, in Fe_3O_4, oxidation number is the average of those in FeO and Fe_2O_3.

$$FeO + Fe_2O_3 = Fe_3O_4$$

Average oxidation number of Fe in

$$Fe_3O_4 = \frac{+2 + 2(+3)}{3} = +\frac{8}{3}$$

7. Oxidation state of chromium in CrO_5: CrO_5 has butterfly structure having two peroxo bonds



Peroxo oxygen has (−1) oxidation state.

Let oxidation state of chromium be 'x'.

$$x + 4(-1) + (-2) = 0$$

$$x = +6$$

8. Oxidation state of chlorine in bleaching powder: Bleaching powder has two chlorine atoms having different oxidation states.

$$Ca^{2+} \quad \underset{\substack{\text{(hypochloride ion)}\\ \text{Chlorine in}\\ +1 \text{ state}}}{(OCl)^-} \quad \underset{\substack{\text{(chloride ion)}\\ \text{Chlorine in}\\ -1 \text{ state}}}{Cl^-}$$

9. Fractional values of oxidation numbers are possible as in $Na_2S_4O_6$, Fe_3O_4, N_3H, etc.

$Na_2S_4O_6$	Fe_3O_4
$2 \times 1 + 4x + 6(-2) = 0$	$3 \times x + 4(-2) = 0$
$2 + 4x - 12 = 0$	$3x - 8 = 0$
$4x = +10$	$3x = 8$
$x = +\frac{10}{4} = +2.5$	$x = +\frac{8}{3}$ or $+2\frac{2}{3}$
Oxidation number of S is + 2.5	Oxidation number of iron is $+2\frac{2}{3}$

N_3H

$$3x + 1 = 0$$

$$3x = -1$$

$$x = -1/3$$

Oxidation number of nitrogen is −1/3

10. Oxidation state of carbon and nitrogen in HCN and HNC: We should take into consideration the following fundamental aspects of bonding while counting the oxidation state of covalently bonded molecules:

(a) Single covalent bond contributes one unit for oxidation number.

(b) Negative oxidation number is assigned to more electronegative atom and positive oxidation number to less electronegative atom.

(c) Coordinate bond is represented by an arrow from donor atom to acceptor atom.

$$\underset{\text{Donor}}{A} \longrightarrow \underset{\text{Acceptor}}{B}$$

If donor atom is less electronegative and acceptor is more, then + 2 state is given to donor and −2 state is given to acceptor.

But it should be noted that if the donor is more electronegative than the acceptor, then contribution of coordinate bond for both atoms regarding oxidation state is neglected, *e.g.,*

(i) $$H—C\equiv N$$

$$+1+a-3=0$$

$$a=+2$$

Carbon is in +2 state and nitrogen is in − 3 state. Each bond contributes −1 state to more electronegative atom.

(ii) $$H—N\equiv C$$

Oxidation state of H = + 1

Oxidation state of nitrogen = (−1) + (−2) + (0) = − 3

Covalent bond with hydrogen contributes (−1) and covalent bond with carbon contributes (−2) and there is zero contribution of coordinate bond. Let the oxidation state of carbon be '*x*'.

$$+1-3+x=0;\ x=+2$$

11. $Fe_{0.94}O$ (Oxidation state of iron is to be determined):

$$0.94x-2=0$$

$$x=2/0.94=200/94$$

12. $NH_2—NH_2$ (Oxidation state of nitrogen is to be determined):

$$2x+4=0$$

$$x=-2$$

13. KI_3 (Oxidation state of iodine is to be determined):

$$+1+3x=0$$

$$x=-1/3$$

KI_3 is mixture of $\overset{+1}{K}\,\overset{-1}{I}$ and $\overset{0}{I_2}$. Thus, two iodine atoms lie in zero state and one lies in −1 state.

14. $Na_2[Fe(CN)_5NO]$: In iron complex NO lies in NO^+ state; thus oxidation state of 'Fe' may be determined as:

$$+2+x-5+1=0$$

$$x=+2$$

15. $[Fe(NO)(H_2O)_5]SO_4$:

$$x+1+5(0)-2=0$$

$$x=+1$$

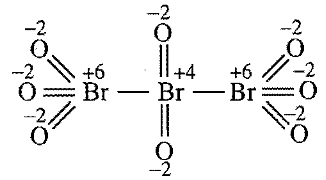
16. NOCl or $Cl—N=O$:

Oxidation state of chlorine = − 1

Oxidation state of oxygen = − 2

Thus, Oxidation state of nitrogen

17. Br_3O_8 (Tribromo octa-oxide):



$$\text{Average oxidation state}=\frac{(+6)+(4)+(+6)}{3}=\frac{16}{3}$$

18. C_3O_2 (Carbon sub-oxide):

$$\overset{-2}{O}=\overset{+2}{C}=\overset{0}{C}=\overset{+2}{C}=\overset{-2}{O}$$

$$\text{Average oxidation state}=\frac{+4}{3}.$$

11.7 OXIDATION NUMBERS (States) IN DIFFERENT TYPES OF ELEMENTS

Zero group elements have zero oxidation number (state) as they do not show chemical activity while other elements have at least two oxidation states: zero when they exist in free state and positive or negative when they exist in compounds. Many elements show different oxidation states in different compounds. In the case of representative elements, the highest positive oxidation number (state) of an element is the same as its group number while the highest negative oxidation state is equal to (8 − group number) with negative sign with a few exceptions.

(i) Alkali metals (IA) show uniformly +1 oxidation state, as they have ns^1 configuration and have only a tendency to lose this electron.

(ii) Alkaline earth metals (IIA) show a common oxidation state of +2 as they have ns^2 configuration.

(iii) Elements of group IIIA have ns^2np^1 outer shell configuration, suggesting +1 and +3 oxidation states corresponding to use of *np* or *ns np* electrons.

(iv) Elements of group IVA have ns^2np^2 outer shell configuration. They show oxidation states +4 (maximum) and − 4 (minimum). However, Sn and Pb show either +2 or +4 oxidation states being metallic in nature.

(v) VB elements have outer shell configuration ns^2np^3. They show oxidation states between +5 and −3.

(vi) The elements of VIA (with the exception of oxygen) show maximum oxidation state +6 and minimum oxidation state −2.

(vii) The elements of VIIA (with the exception of fluorine) show maximum +7 and minimum −1 oxidation state.

(viii) Transition metals exhibit a large number of oxidation states due to involvement of $(n-1)d$ electrons besides *ns* electrons.

The most common oxidation states of the representative elements are shown in the following table:

Group	Outer shell configuration	Common oxidation numbers (states) except zero in free state
IA	ns^1	+ 1
IIA	ns^2	+ 2
IIIA	ns^2np^1	+ 3, + 1
IVA	ns^2np^2	+ 4, + 3, + 2, + 1, − 1, − 2, − 3, − 4
VA	ns^2np^3	+ 5, + 3, + 1, − 1, − 3
VIA	ns^2np^4	+ 6, + 4, + 2, − 2
VIIA	ns^2np^5	+ 7, + 5, + 3, + 1, − 1

11.8 VALENCY AND OXIDATION NUMBER

Valency of an element means the power or capacity of the element to combine with other elements. The valency of an element is numerically equal to the number of hydrogen atoms or chlorine atoms or twice the number of oxygen atoms that combine with one atom of that element. It is also equal to the number of electrons lost or accepted or shared by the atom of an element. In every case valency of an element is a pure number and has no plus or minus sign associated with it, while oxidation number (state) is an arbitrary number which can have positive, negative, zero or even fractional value. For example, in the following compounds of carbon, the oxidation number varies from – 4 to + 4 but valency of carbon is 4 in all the compounds:

Compound	CH_4	CH_3Cl	CH_2Cl_2	$CHCl_3$	CCl_4
Ox.no. of carbon	– 4	–2	0	+2	+4

Thus, valency and oxidation number concepts are different. In some cases (mainly in the case of electrovalent compounds), valency and oxidation number are the same but in other cases they may have different values. Points of difference between the two have been tabulated below:

Valency	Oxidation number
1. It is the combining capacity of the element. No plus or minus sign is attached to it.	Ox.no. is the charge (real or imaginary) present on the atom of the element when it is in combination. It may have plus or minus sign.
2. Valency of an element is usually fixed.	Ox.no. of an element may have different values. It depends on the nature of the compound in which it is present.
3. Valency is always a whole number.	Ox.no. of the element may be a whole number or fractional.
4. Valency of the element is never zero except of noble gases.	Ox.no. of the element may be zero.

Term	Oxidation number
Oxidation	Increases
Reduction	Decreases
Oxidising agent	Decreases
Reducing agent	Increases

Example 12. *In the following reactions, identify the species oxidised, the species reduced, the oxidising agent and the reducing agent:*

(a) $4HCl + MnO_2 = MnCl_2 + 2H_2O + Cl_2$

(b) $SnCl_2 + 2FeCl_3 = SnCl_4 + 2FeCl_2$

(c) $2H^+ + Mg = Mg^{2+} + H_2$

(d) $H_2SO_4 + 2H_2S = 3S + 3H_2O$

Solution: (a) $MnO_2 + 4HCl = MnCl_2 + Cl_2 + 2H_2O$

Writing the oxidation numbers on various atoms,

$$\overset{+4\ -2}{MnO_2} + 4\overset{+1\ -1}{HCl} = \overset{+2\ -1}{MnCl_2} + \overset{0}{Cl_2} + 2\overset{+1\ -2}{H_2O}$$

Ox.no. of Mn changes from +4 to +2, *i.e.*, decrease in oxidation number. MnO_2 is thus reduced. It acts as an oxidising agent. Ox.no. of Cl changes from –1 to 0, *i.e.*, increase in oxidation number. HCl is thus oxidised. It acts as a reducing agent.

(b) $SnCl_2 + 2FeCl_3 = SnCl_4 + 2FeCl_2$

Writing the oxidation numbers on various atoms,

$$\overset{+2\ -1}{SnCl_2} + 2\overset{+3\ -1}{FeCl_3} = \overset{+4\ -1}{SnCl_4} + 2\overset{+2\ -1}{FeCl_2}$$

Ox.no. of Sn changes from +2 to +4, *i.e.*, increase in oxidation number. $SnCl_2$ is thus oxidised or it acts as a reducing agent.

Ox.no. of Fe changes from +3 to +2, *i.e.*, decrease in oxidation number. $FeCl_3$ is thus reduced or it acts as an oxidising agent.

(c) $Mg + 2H^+ \longrightarrow Mg^{2+} + H_2$

Writing oxidation numbers of various atoms,

Decrease

$$\overset{0}{Mg} + 2\overset{+1}{H^+} \longrightarrow \overset{(+2)}{Mg^{2+}} + \overset{0}{H_2}$$

Increase

Mg is oxidised, *i.e.*, it acts as a reducing agent. H^+ is reduced, *i.e.*, it acts as an oxidising agent.

(d) $H_2SO_3 + 2H_2S = 3S + 3H_2O$

Writing oxidation numbers on various atoms,

Increase

$$\overset{+1\ +4-2}{H_2SO_3} + 2\overset{+1\ -2}{H_2S} \longrightarrow 3\overset{0}{S} + 3\overset{+1\ -2}{H_2O}$$

Decrease

H_2SO_3 is reduced, *i.e.*, it acts as oxidising agent. H_2S is Oxidised, *i.e.*, it acts as reducing agent.

Example 13. *Which one of the following reactions is a redox reaction?*

(a) $CuSO_4 + 4NH_3 \longrightarrow [Cu(NH_3)_4]SO_4$

(b) $Na_2SO_4 + BaCl_2 \longrightarrow BaSO_4 + 2NaCl$

(c) $SO_2 + H_2O \longrightarrow H_2SO_3$

(d) $2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2$

Solution: The reaction in which change in oxidation numbers of some of the atoms takes place is termed as a redox reaction.

(a) $\overset{+2+6-2}{CuSO_4} + 4\overset{-3+1}{NH_3} \longrightarrow [\overset{+2\ -3-1}{Cu(NH_3)_4}]\overset{+6-2}{SO_4}$

No change in oxidation number of any of the atoms.

(b) $\overset{+1\ +6\ -2}{Na_2SO_4} + \overset{+2\ -1}{BaCl_2} \longrightarrow \overset{+2\ +6-2}{BaSO_4} + 2\overset{+1\ -1}{NaCl}$

No change in oxidation number of any one of the atoms.

(c) $\overset{+4-2}{SO_2} + \overset{+1\ -2}{H_2O} \longrightarrow \overset{+1\ +4-2}{H_2SO_3}$

No change in oxidation number of any one of the atoms.

(d) $2\overset{+2+6-2}{CuSO_4} + 4\overset{+1-1}{KI} \longrightarrow \overset{+1\ -1}{Cu_2I_2} + 2\overset{+1\ +6-2}{K_2SO_4} + \overset{0}{I_2}$

Oxidation number of Cu decreases from +2 to +1 and oxidation number of iodine increases from −1 to 0.

Thus, out of the above four reactions, the reaction (d) is a redox reaction.

Example 14. *Explain why HNO_3 acts only as oxidising agent while HNO_2 can act both as a reducing agent and an oxidising agent?*

Solution: Nitrogen can have oxidation numbers from −3 to +5. The oxidation number of nitrogen in HNO_3 is +5. Thus, increase in oxidation number beyond +5 cannot occur. Hence, HNO_3 cannot act as reducing agent. The oxidation number of nitrogen in HNO_3 can only decrease; thus it acts as an oxidising agent. In HNO_2, the oxidation number of nitrogen is +3. Thus, it can increase or decrease within the range −3 to +5. Hence, it can act as an oxidising as well as a reducing agent.

11.9 BALANCING OXIDATION-REDUCTION REACTIONS BY OXIDATION NUMBER METHOD

In a balanced redox reaction, total increase in oxidation number must be equal to the total decrease in oxidation number. This equivalence provides the basis for balancing redox reactions. This method is applicable to both molecular and ionic equations. The general procedure involves the following steps:

(i) Write the skeleton equation (if not given, frame it) representing the chemical change.

(ii) Assign oxidation numbers to the atoms in the equation and find out which atoms are undergoing oxidation and reduction. Write separate equations for the atoms undergoing oxidation and reduction.

(iii) Find the change in oxidation number in each equation. Make the change equal in both the equations by multiplying with suitable integers. Add both the equations.

(iv) Complete the balancing by inspection. First balance those substances which have undergone change in oxidation number and then other atoms except hydrogen and oxygen. Finally balance hydrogen and oxygen by putting H_2O molecules wherever needed.

The final balanced equation should be checked to ensure that there are as many atoms of each element on the right as there are on the left.

(v) In ionic equations the net charges on both sides of the equation must be exactly the same. Use H^+ ion/ions in acidic reactions and OH^- ion/ions in basic reactions to balance the charge and number of hydrogen and oxygen atoms.

The following examples illustrate the above rules:

Example 15. *Balance the following equation by oxidation number method:*

$$Cu + HNO_3 \longrightarrow Cu(NO_3)_2 + NO_2 + H_2O$$

Solution: Writing the oxidation numbers of all the atoms.

$$\overset{0}{Cu} + \overset{+1}{H}\overset{+5}{N}\overset{-2}{O_3} \longrightarrow \overset{+2}{Cu}(\overset{+5}{N}\overset{-2}{O_3})_2 + \overset{+4}{N}\overset{-2}{O_2} + \overset{+1}{H_2}\overset{-2}{O}$$

Change in Ox.no. has occurred in copper and nitrogen.

$$\overset{0}{Cu} \longrightarrow \overset{+2}{Cu}(NO_3)_2 \quad \text{... (i)}$$

$$H\overset{+5}{N}O_3 \longrightarrow \overset{+4}{N}O_2 \quad \text{... (ii)}$$

Increase in Ox.no. of copper = 2 units per molecule Cu

Decrease in Ox.no. of nitrogen = 1 unit per molecule HNO_3

To make increase and decrease equal, eq. (ii) is multiplied by 2.

$$Cu + 2HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + H_2O$$

Balancing nitrate ions, hydrogen and oxygen, the following equation is obtained:

$$Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$$

This is the balanced equation.

SOME SOLVED EXAMPLES

Example 16. *Balance the following equation by oxidation number method:*

$$K_2Cr_2O_7 + FeSO_4 + H_2SO_4 = Cr_2(SO_4)_3 + Fe_2(SO_4)_3 + K_2SO_4 + H_2O$$

Solution: Writing oxidation numbers of all the atoms.

$$\overset{+2}{K_2}\overset{+6}{Cr_2}\overset{-2}{O_7} + \overset{+2}{Fe}\overset{+6}{S}\overset{-2}{O_4} + \overset{+1}{H_2}\overset{+6}{S}\overset{-2}{O_4} = \overset{+3}{Cr_2}(\overset{+6}{S}\overset{-2}{O_4})_3 + \overset{+3}{Fe_2}(\overset{+6}{S}\overset{-2}{O_4})_3 + \overset{+1}{K_2}\overset{+6}{S}\overset{-2}{O_4} + \overset{+1}{H_2}\overset{-2}{O}$$

Change in Ox.no. has occurred in chromium and iron.

$$K_2\overset{+6}{Cr_2}O_7 \longrightarrow \overset{+3}{Cr_2}(SO_4)_3 \quad \text{... (i)}$$

$$\overset{+2}{Fe}SO_4 \longrightarrow \overset{+3}{Fe_2}(SO_4)_3 \quad \text{... (ii)}$$

Decrease in Ox.no. of Cr per molecule

$$= (2 \times 6 - 2 \times 3) = 6 \text{ units}$$

Increase in Ox.no. of Fe per molecule = 1 unit

Hence, eq. (ii) should be multiplied by 6,

$$K_2Cr_2O_7 + 6FeSO_4 \longrightarrow Cr_2(SO_4)_3 + 3Fe_2(SO_4)_3$$

To balance sulphate ions and potassium ions, 7 molecules of H_2SO_4 are needed.

$$K_2Cr_2O_7 + 6FeSO_4 + 7H_2SO_4 = Cr_2(SO_4)_3 + 3Fe_2(SO_4)_3 + K_2SO_4$$

To balance hydrogen and oxygen, $7H_2O$ should be added on RHS. Hence, balanced equation is,

$$K_2Cr_2O_7 + 6FeSO_4 + 7H_2SO_4 = Cr_2(SO_4)_3 + 3Fe_2(SO_4)_3 + K_2SO_4 + 7H_2O$$

Example 17. *Balance the following equation by oxidation number method:*

$$K_2Cr_2O_7 + HCl \longrightarrow KCl + CrCl_3 + H_2O + Cl_2$$

Solution: Writing the oxidation numbers of all the atoms.

$$\overset{+1}{K_2}\overset{+6}{Cr_2}\overset{-2}{O_7} + \overset{+1}{H}\overset{-1}{Cl} \longrightarrow \overset{+1}{K}\overset{-1}{Cl} + \overset{+3}{Cr}\overset{-1}{Cl_3} + \overset{+1}{H_2}\overset{-2}{O} + \overset{0}{Cl_2}$$

The Ox.no. of Cr has decreased while that of chlorine has increased.

$$K_2\overset{+6}{Cr_2}O_7 \longrightarrow 2\overset{+3}{Cr}Cl_3 \quad \text{... (i)}$$

$$H\overset{-1}{Cl} \longrightarrow \overset{0}{Cl} \quad \text{... (ii)}$$

Decrease in Ox.no. of Cr = 6 units per molecule $K_2Cr_2O_7$

Increase in Ox.no. of Cl = 1 unit per molecule HCl

Eq. (ii) is multiplied by 6.

$$K_2Cr_2O_7 + 6HCl \longrightarrow 2CrCl_3 + 3Cl_2$$

To balance chlorine and potassium, 14 molecules of HCl are required.

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2CrCl_3 + 3Cl_2 + 2KCl$$

To balance hydrogen and oxygen, $7H_2O$ are added to RHS. Hence, the balanced equation is,

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 3Cl_2 + 7H_2O$$

Example 18. *Balance the following equation by oxidation number method:*

$$NaIO_3 + NaHSO_3 \longrightarrow Na_2SO_4 + NaHSO_4 + I_2 + H_2O$$

Solution: Writing oxidation numbers of all the atoms.

$$\overset{+1}{Na}\,\overset{+5}{I}\,\overset{-2}{O_3} + \overset{+1}{Na}\overset{+1}{H}\,\overset{+4}{S}\,\overset{-2}{O_3} \longrightarrow \overset{+1}{Na_2}\overset{+6}{S}\overset{-2}{O_4} + \overset{+1}{Na}\overset{+1}{H}\overset{+6}{S}\overset{-2}{O_4} + \overset{0}{I_2} + \overset{+1}{H_2}\overset{-2}{O}$$

The oxidation no. of I has decreased while that of S has increased.

$$\overset{+5}{NaIO_3} \longrightarrow \overset{0}{I} \qquad \text{... (i)}$$

$$\overset{+4}{NaHSO_3} \longrightarrow \overset{+6}{NaHSO_4} \qquad \text{... (ii)}$$

Decrease in Ox.no. of I = 5 units per molecule $NaIO_3$

Increase in Ox.no. of S = 2 units per molecule $NaHSO_3$

Eq. (i) is multiplied by 2 and eq. (ii) is multiplied by 5 as to make decrease and increase equal.

$$2NaIO_3 + 5NaHSO_3 \longrightarrow I_2 + 3NaHSO_4 + 2Na_2SO_4$$

To balance hydrogen and oxygen, one H_2O molecule should be added on RHS. Hence, the balanced equation is

$$2NaIO_3 + 5NaHSO_3 \rightarrow I_2 + 3NaHSO_4 + 2Na_2SO_4 + H_2O$$

Example 19. *Balance the following equation by oxidation number method:*

$$I_2 + NaOH \longrightarrow NaIO_3 + NaI + H_2O$$

Solution: Writing oxidation numbers of all the atoms,

$$\overset{0}{I_2} + \overset{+1}{Na}\overset{-2}{O}\overset{+1}{H} \longrightarrow \overset{+1}{Na}\overset{+5}{I}\overset{-2}{O_3} + \overset{+1}{Na}\overset{-1}{I} + \overset{+1}{H_2}\overset{-2}{O}$$

The Ox.no. of iodine has increased as well as decreased.

$$\overset{0}{I} \longrightarrow \overset{+5}{NaIO_3} \qquad \text{... (i)}$$

$$\overset{0}{I} \longrightarrow \overset{-1}{NaI} \qquad \text{... (ii)}$$

Increase in Ox.no. of I = 5 units per I atom

Decrease in Ox.no. of I = 1 unit per I atom

Eq. (ii) should be multiplied by 5 as to make increase and decrease equal.

$$3I_2 \longrightarrow NaIO_3 + 5NaI$$

To balance Na, 6 molecules of NaOH should be added on LHS.

$$3I_2 + 6NaOH \longrightarrow NaIO_3 + 5NaI$$

To balance hydrogen and oxygen, $3H_2O$ should be added on RHS. Hence, the balanced equation is

$$3I_2 + 6NaOH \longrightarrow NaIO_3 + 5NaI + 3H_2O$$

Example 20. *Balance the following equation by oxidation number method:*

$$PbS + H_2O_2 \longrightarrow PbSO_4 + H_2O$$

Solution: Writing oxidation numbers of all the atoms,

$$\overset{+2}{Pb}\,\overset{-2}{S} + \overset{+1}{H_2}\overset{-1}{O_2} \longrightarrow \overset{+2}{Pb}\overset{+6}{S}\overset{-2}{O_4} + \overset{+1}{H_2}\overset{-2}{O}$$

The oxidation number of S has increased and O has decreased.

$$\overset{-2}{PbS} \longrightarrow \overset{+6}{PbSO_4} \qquad \text{... (i)}$$

$$\overset{-1}{H_2O_2} \longrightarrow \overset{-2}{H_2O} \qquad \text{... (ii)}$$

Increase in Ox.no. of S = 8 units per PbS molecule

Decrease in Ox.no. of O = 1 unit per $\frac{1}{2}$ H_2O_2 molecule

= 2 units per H_2O_2 molecule

Multiplying eq. (ii) by 4 as to make increase and decrease equal.

$$PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$$

This is the balanced equation.

Example 21. *Balance the following equation by oxidation number method:*

$$Zn + HNO_3 \longrightarrow Zn(NO_3)_2 + NH_4NO_3 + H_2O$$

Solution: Writing oxidation numbers of all the atoms,

$$\overset{0}{Zn} + \overset{+1}{H}\overset{+5}{N}\overset{-2}{O_3} \longrightarrow \overset{+2}{Zn}(\overset{+5}{N}\overset{-2}{O_3})_2 + \overset{-3}{N}\overset{+1}{H_4}\overset{+5}{N}\overset{-2}{O_3} + \overset{+1}{H_2}\overset{-2}{O}$$

The oxidation numbers of Zn and N have changed.

$$\overset{0}{Zn} \longrightarrow \overset{+2}{Zn(NO_3)_2} \qquad \text{... (i)}$$

$$\overset{+5}{HNO_3} \longrightarrow \overset{-3}{NH_4NO_3} \qquad \text{... (ii)}$$

Increase in Ox.no. of Zn = 2 units per Zn atom

Decrease in Ox.no. of N = 8 units per HNO_3 molecule

Eq. (i) should be multiplied by 4

$$4Zn + HNO_3 \longrightarrow 4Zn(NO_3)_2 + NH_4NO_3$$

To balance nitrogen, 9 molecules of HNO_3 should be added on LHS.

To balance hydrogen and oxygen, $3H_2O$ molecules should be added on RHS. Hence, the balanced equation is

$$4Zn + 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + NH_4NO_3 + 3H_2O$$

Example 22. *Balance the following equation by oxidation number method:*

$$HgS + HCl + HNO_3 \longrightarrow H_2HgCl_4 + NO + S + H_2O$$

Solution: Writing the oxidation numbers of the atoms.

$$\overset{+2}{Hg}\overset{-2}{S} + \overset{+1}{H}\overset{-1}{Cl} + \overset{+1}{H}\overset{+5}{N}\overset{-2}{O_3} \longrightarrow \overset{+1}{H_2}\overset{+2}{Hg}\overset{-1}{Cl_4} + \overset{+2}{N}\overset{-2}{O} + \overset{0}{S} + \overset{+1}{H_2}\overset{-2}{O}$$

The oxidation numbers of S and N have changed.

$$\overset{-2}{HgS} \longrightarrow \overset{0}{S} \qquad \text{... (i)}$$

$$\overset{+5}{HNO_3} \longrightarrow \overset{+2}{NO} \qquad \text{... (ii)}$$

Increase in Ox.no. of S = 2 units per HgS molecule

Decrease in Ox. no. of N = 3 units per HNO_3 molecule

Multiplying eq. (i) by 3 and eq. (ii) by 2 as to make increase and decrease equal

$$3HgS + 2HNO_3 \longrightarrow 3S + 2NO$$

Balancing Hg and chlorine,

$$3HgS + 2HNO_3 + 12HCl \longrightarrow 3H_2HgCl_4 + 3S + 2NO$$

To balance hydrogen and oxygen, $4H_2O$ molecules are added on RHS. Hence, the balanced equation is

$$3HgS + 2HNO_3 + 12HCl \rightarrow 3H_2HgCl_4 + 3S + 2NO + 4H_2O$$

Example 23. *Balance the following equation by oxidation number method:*

$$Cl_2 + IO_3^- + OH^- \longrightarrow IO_4^- + Cl^- + H_2O$$

Solution: Writing oxidation numbers of all atoms,

$$\overset{0}{Cl_2} + \overset{+5\,-2}{IO_3^-} + \overset{-2\,+1}{OH^-} \longrightarrow \overset{+7\,-2}{IO_4^-} + \overset{-1}{Cl^-} + \overset{+1\,-2}{H_2O}$$

Oxidation numbers of Cl and I have changed.

$$\overset{0}{Cl_2} \longrightarrow 2\overset{-1}{Cl^-} \qquad \text{... (i)}$$

$$\overset{+5}{IO_3^-} \longrightarrow \overset{+7}{IO_4^-} \qquad \text{... (ii)}$$

Decrease in Ox.no. of Cl = 2 units per Cl_2 molecule

Increase in Ox. no. of I = 2 units per IO_3^- molecule

$$Cl_2 + IO_3^- \longrightarrow IO_4^- + 2Cl^-$$

To balance oxygen $2OH^-$ ions be added on LHS and one H_2O molecule on RHS. Hence, the balanced equation is

$$Cl_2 + IO_3^- + 2OH^- \longrightarrow IO_4^- + 2Cl^- + H_2O$$

Example 24. *Balance the following equation by oxidation number method:*

$$Al + KMnO_4 + H_2SO_4 \longrightarrow Al_2(SO_4)_3 + K_2SO_4 + MnSO_4 + H_2O$$

Solution: Writing oxidation numbers of all atoms,

$$\overset{0}{Al} + \overset{+1\,+7\,-2}{KMnO_4} + \overset{+1\,+6\,-2}{H_2SO_4} \longrightarrow \overset{+3\,+6\,-2}{Al_2(SO_4)_3} + \overset{+1\,+6\,-2}{K_2SO_4} + \overset{+2\,+6\,-2}{MnSO_4} + \overset{+1\,-2}{H_2O}$$

The oxidation numbers of Al and Mn have changed

$$\overset{0}{Al} \longrightarrow \overset{+3}{Al_2(SO_4)_3} \qquad \text{... (i)}$$

$$K\overset{+7}{Mn}O_4 \longrightarrow \overset{+2}{Mn}SO_4 \qquad \text{... (ii)}$$

Increase in Ox.no. of Al = 3 units per Al atom

= 6 units per $Al_2(SO_4)_3$ molecule

Decrease in Ox. no. of Mn = 5 units per $KMnO_4$ molecule

Multiply eq. (i) by 10 and eq. (ii) by 6 as to make increase and decrease equal

$$10Al + 6KMnO_4 \longrightarrow 5Al_2(SO_4)_3 + 6MnSO_4 + 3K_2SO_4$$

To balance SO_4^{2-} ions, $24H_2SO_4$ molecules be added on LHS.

$$10Al + 6KMnO_4 + 24H_2SO_4 \longrightarrow 5Al_2(SO_4)_3 + 6MnSO_4 + 3K_2SO_4$$

To balance hydrogen and oxygen, 24 H_2O molecules be added on RHS. Hence, the balanced equation is

$$10Al + 6KMnO_4 + 24H_2SO_4 \longrightarrow 5Al_2(SO_4)_3 + 6MnSO_4 + 3K_2SO_4 + 24H_2O$$

11.10 DISPROPORTIONATION AND OXIDATION-REDUCTION

One and the same substance may act simultaneously as an oxidising agent and as a reducing agent with the result that a part of it gets oxidised to a higher state and rest of it is reduced to lower state of oxidation. Such a reaction, in which a substance undergoes simultaneous oxidation and reduction is called disproportionation and the substance is said to **disproportionate.**

The following are some of the examples of disproportionation:

Increase

$$\text{(a)}\quad H_2\overset{-1}{O_2} + H_2\overset{-1}{O_2} \longrightarrow H_2\overset{-2}{O} + \overset{0}{O_2}$$

Decrease

Decrease

$$\text{(b)}\quad 4K\overset{+5}{Cl}O_3 \longrightarrow 3K\overset{+7}{Cl}O_4 + K\overset{-1}{Cl}$$

Increase

Decrease

$$\text{(c)}\quad 4\overset{0}{P} + 3NaOH + 3H_2O \longrightarrow 3NaH_2\overset{+1}{P}O_2 + \overset{-3}{P}H_3$$

Increase

Decrease

$$\text{(d)}\quad 3\overset{0}{Cl_2} + \underset{\text{(conc.)}}{6NaOH} \xrightarrow{\text{Hot}} 5Na\overset{-1}{Cl} + Na\overset{+5}{Cl}O_3 + 3H_2O$$

Increase

(e) Oxidation state of chlorine lies between –1 to +7; thus out of ClO^-, ClO_2^-, ClO_3^-, ClO_4^-; ClO_4^- does not undergo disproportionation because in this oxidation state of chlorine is highest, *i.e.*, +7. Disproportionation of the other oxoanions are:

$$3\overset{+1}{Cl}O^- \longrightarrow 2\overset{-1}{Cl} + \overset{+5}{Cl}O_3^-$$

$$6\overset{+3}{Cl}O_2^- \longrightarrow 4\overset{+5}{Cl}O_3^- + 2\overset{-1}{Cl^-}$$

$$4\overset{+5}{Cl}O_3^- \longrightarrow \overset{-1}{Cl^-} + 3\overset{+7}{Cl}O_4^-$$

Equivalent mass of substance undergoing disproportionation can be calculated by n-factor method:

$$\text{Equivalent mass} = \frac{\text{Molecular mass}}{n\text{-factor}}$$

$$n\text{-factor} = \frac{n_1 \times n_2}{n_1 + n_2}$$

Example :

$n = 2$ (loss of two electron)

$$3\overset{+1}{H_3PO_2} \longrightarrow \overset{-3}{PH_3} + 2\overset{+3}{H_3PO_3}$$

$n = 4$ (gain of four electrons)

$$n\text{-factor} = \frac{4 \times 2}{4 + 2} = \frac{4}{3}$$

$$\text{Equivalent mass of } H_3PO_2 = \frac{\text{Molecular mass}}{n\text{-factor}}$$

$$= \frac{m}{4/3} = \frac{3m}{4}$$

11.11 AUTOXIDATION

Turpentine and numerous other unsaturated compounds, phosphorus and certain metals like Zn and Pb can absorb oxygen from the air in presence of water. The water is oxidised to hydrogen peroxide. This phenomenon of formation of H_2O_2 by the oxidation of H_2O is known as **autoxidation.** The substance such as turpentine or phosphorus or lead which can activate the oxygen is called **activator.** The activator is supposed to first combine with oxygen to form an addition compound, which acts as an **autoxidator** and reacts with water or some other acceptor so as to oxidise the latter. For example:

$$\underset{\text{(Activator)}}{Pb} + O_2 \longrightarrow \underset{\text{(Autoxidator)}}{PbO_2}$$

$$PbO_2 + \underset{\text{(Acceptor)}}{H_2O} \longrightarrow PbO + H_2O_2$$

The turpentine or other unsaturated compounds which act as activators are supposed to take-up oxygen molecule at the double bond position to form unstable peroxide called moloxide, which then gives up the oxygen to water molecule or any other acceptor.

$$RCH{=}CHR + O_2 \longrightarrow \underset{\displaystyle O\!-\!O}{RHC\!-\!CHR}$$

$$\underset{\displaystyle O\!-\!O}{RHC\!-\!CHR} + 2H_2O \longrightarrow RCH{=}CHR + 2H_2O_2$$

$$2KI + H_2O_2 \longrightarrow 2KOH + I_2$$

The evolution of iodine from KI solution in presence of turpentine can be confirmed with starch solution which turns blue.

With this concept, the phenomenon of induced oxidation can also be explained. Na_2SO_3 solution is oxidised by air but Na_3AsO_3 solution is not oxidised by air. If mixture of both is taken, it is observed that both are oxidised. This is induced oxidation.

$$Na_2SO_3 + O_2 \longrightarrow \underset{\text{Moloxide}}{Na_2SO_5}$$

$$Na_2SO_5 + Na_3AsO_3 \longrightarrow Na_3AsO_4 + Na_2SO_4$$

$$\overline{Na_2SO_3 + Na_3AsO_3 + O_2 \longrightarrow Na_2SO_4 + Na_3AsO_4}$$

11.12 FORMAL CHARGE

In polyatomic molecule or ion the net charge is possessed by the ion or molecule as a whole and not by particular atom. For certain purpose formal charge (F.C.) is assigned to each atom.

Formal charge (F.C.) on an atom in a Lewis structure = Total number of valence electrons in the free atom (*V*) − Total number of non-bonding (lone pair) electrons (*N*) $-\frac{1}{2}\times$ Total number of bonding (shared electrons) (*B*)

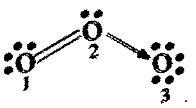
The formal charge of atom in a polyatomic ion/molecule is defined as:

$$F.C. = V - N - \frac{1}{2}B$$

The formal charge is the difference between the number of valence electrons in an isolated (i.e., free) atom and the number of electrons assigned to that atom, in its dot structure.

Let us calculate formal charge on each atom of ozone:

Formal charge at oxygen number 1



$$V = 6, N = 4, B = 4$$

$$F.C. = V - N - \frac{1}{2}B$$

$$= 6 - 4 - \frac{1}{2} \times 4 = 0$$

Formal charge at oxygen number 2

$$V = 6, N = 2, B = 6$$

$$F.C. = V - N - \frac{1}{2}B$$

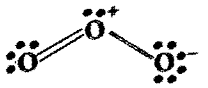
$$= 6 - 2 - \frac{1}{2} \times 6 = 1$$

Formal charge at oxygen number 3

$$V = 6, N = 6, B = 2$$

$$F.C. = 6 - 6 - \frac{1}{2} \times 2 = -1$$

On the basis of formal charge, the structure of ozone may be drawn as,



we must note that formal charges do not indicate real charge separation within the molecule.

Formal charges help in the selection of the lowest energy structure from a number of possible Lewis structures for a compound. The lowest energy structure means the structure with the smallest formal charges on each atom of the compound. Formal charge is based on the concept that electron pairs are shared equally by neighbouring atoms.

Note: (1) A Lewis dot structure for a molecule is preferable when all formal charges are zero.

(2) In a dot structure adjacent formal charges should be zero or of opposite sign.

(3) Among the several Lewis dot structure for same species, the structure with negative formal charges on more electronegative atom is preferred.

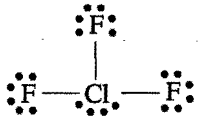
Let us consider thiocyanate:

	Formal charges			Total
	N	C	S	
~~Structure I $(:\ddot{N}=C=\ddot{S}:)^-$~~	~~–1~~	~~0~~	~~0~~	~~–1~~
Structure II $(:\ddot{C}=N=\ddot{S}:)^-$	+1	–2	0	–1
Structure III $(:\ddot{C}=S=\ddot{N}:)^-$	–1	–2	+2	–1

Structure III will be correct structure because each atom has non-zero formal charge in the lowest energy state.

Some illustrations of formal charge calculation:

1.



Formal charge at chlorine:

$$V = 7, N = 4, B = 6$$

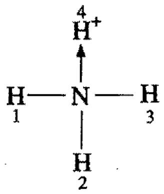
$$\text{F.C.} = 7 - 4 - \frac{1}{2} \times 6 = 0$$

Formal charge at fluorine:

$$V = 7, N = 6, B = 2$$

$$\text{F.C.} = 7 - 6 - \frac{1}{2} \times 2 = 0$$

2.



Formal charge at nitrogen:

$$V = 5, N = 0, B = 8$$

$$\text{F.C.} = 5 - 0 - \frac{1}{2} \times 8 = +1$$

Formal charge at hydrogens 1,2,3:

$$V = 1, N = 0, B = 2$$

$$\text{F.C.} = V - N - \frac{1}{2} \times B$$

$$= 1 - 0 - \frac{1}{2} \times 2 = 0$$

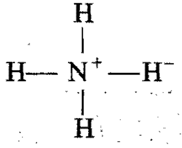
Formal charge at hydrogen number 4:

$$V = 0, N = 0, B = 2$$

$$\text{F.C.} = V - N - \frac{1}{2} \times B$$

$$= 0 - 0 - \frac{1}{2} \times 2 = -1$$

The, structure according to formal charge:



11.13 STOCK NOTATION

~~In the compounds of metals, the oxidation number is represented by the Roman numeral, placed in parenthesis, after the symbol of~~ the metal in the molecular formula. For example:

(i) Cu_2O (Cuprous oxide, oxidation state of copper = +1); its stock notation will be Cu_2(I)O.

(ii) CuO (Cupric oxide, oxidation state of copper = +2); its stock notation will be Cu(II)O.

The stock notation is not used in case of compounds formed by non-metals.

Stock Notation of Some Compounds

Formula of compound	Chemical name of compound	Oxidation state of metal	Stock notation
$HAuCl_4$	Chloroauric acid	Au (+3)	HAu (III) Cl_4
Tl_2O	Thallous oxide	Tl (+1)	Tl_2 (I) O
FeO	Ferrous oxide	Fe (+2)	Fe (II) O
Fe_2O_3	Ferric oxide	Fe (+3)	Fe_2 (III) O_3
Cr_2O_3	Chromic oxide	Cr (+3)	Cr_2 (III) O_3
CuI	Cuprous iodide	Cu (+1)	Cu (I) I
MnO	Mangnese oxide	Mn (+2)	Mn (II) O
MnO_2	Mangnese dioxide	Mn (+4)	Mn (IV) O_2
$K_2Cr_2O_7$	Potassium dichromate	Cr (+6)	Kr Cr_2 (VI) O_7
$KMnO_4$	Potassium permanganate	Mn (+7)	K Mn (VII) O_4
V_2O_5	Vanadium pentoxide	V (+5)	V_2 (V) O_5
$FeSO_4$	Ferrous sulphate	Fe (+2)	Fe_2 (II) SO_4
$Fe_2(SO_4)_3$	Ferric sulphate	Fe (+3)	Fe_2 (III) $(SO_4)_3$
$CuCl_2$	Cupric chloride	Cu (+2)	Cu (II) Cl_2

11.14 STOICHIOMETRY OF REDOX REACTIONS IN SOLUTIONS

Calculations based on chemical equations are known as stoichiometry. A chemical equation is the symbolic representation of a chemical change. It gives the following informations used in solving the numerical problems based on a chemical equation:

(i) It gives the number of moles of the reactants and the products involved in the reaction.

(ii) It gives relative masses of the reactants and products.

(iii) It gives volume of the gaseous reactants and products.

Problems based on chemical equations have also been dealt in Chapter-1. In this section, we will deal with redox reactions only. In the stoichiometry of redox reactions, the chemical equations must be balanced.

Example 25. *Balance the following chemical equation:*

$$H_2O_2 + O_3 \longrightarrow H_2O + O_2$$

Indicating the changes in oxidation numbers of oxygen, find the equivalent weight of H_2O_2 for this reaction. (West Bengal 2005)

Solution: $$\overset{-1}{H_2O_2} + \overset{0}{O_3} \xrightarrow[\text{Oxidised}]{} \overset{-2}{H_2O} + \overset{0}{O_2}$$

Balanced equation will be:

$$H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$$

Equivalent mass of $H_2O_2 = \frac{34}{2} = 17$

SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. Molecular and ionic equations: When the reactants and products involved in a chemical change are written in molecular forms in the chemical equation, it is termed as molecular equation. The chemical changes when represented in terms of ions which actually undergo reaction are called ionic equations. The ions which do not undergo any change and equal in number in both reactants and products are termed spectator ions and are not included in the final balanced equations.

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3 \quad \text{(Molecular equation)}$$

$$Ag^+ + Cl^- \longrightarrow AgCl \quad \text{(Ionic equation)}$$

[NO_3^- and Na^+ ions are spectator ions.]

2. Oxidation and reduction: Oxidation is a process which involves either of the following:

(i) addition of oxygen,
(ii) removal of hydrogen,
(iii) addition of an electronegative element or group,
(iv) removal of an electropositive element or group,
(v) increase in the valency of an electropositive element,
(vi) loss of one or more electrons by an atom or an ion or a molecule.

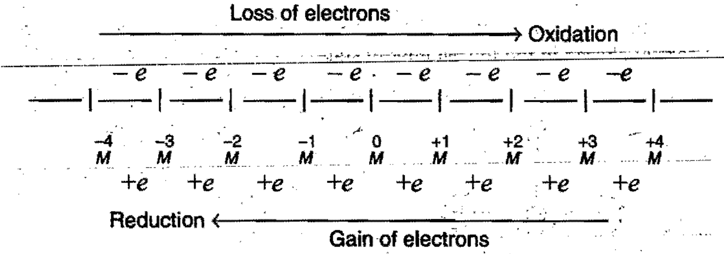
Reduction is just reverse of oxidation. It is a process which involves either of the following:

(i) removal of oxygen,
(ii) addition of hydrogen,
(iii) removal of an electronegative element or group,
(iv) addition of an electropositive element or group,
(v) decrease in the valency of electropositive element,
(vi) gain of one or more electrons by an atom or an ion or a molecule.

A substance which undergoes oxidation or gets oxidised acts as a **reducing agent** while a substance which undergoes reduction or gets reduced acts as an **oxidising agent.**

All oxidation-reduction reactions are complimentary of one another and occur simultaneously. Oxidation-reduction reaction is termed **redox reaction.** The word "redox" includes **red + ox; red** means reduction and **ox** means oxidation. In redox reaction one substance undergoes oxidation and the other substance undergoes reduction, *i.e.*, the reaction between a reducing agent and an oxidising agent is termed as redox reaction.

Any material which is capable of accepting electron or electrons acts as an oxidising agent and the material which loses electron or electrons acts as reducing agents.



3. Ion electron method for balancing redox reaction: The following steps are followed:

(i) Ionic equation of redox reaction is first written.
(ii) The ionic reaction is split into two half reactions, one for oxidation and the other for reduction.
(iii) Each half reaction is balanced for the number of atoms of each element. For this purpose: (a) First of all atoms other than H and O for each half reaction are balanced using simple multiples. (b) In acidic and neutral mediums, H ions are added to the side deficient in hydrogen and water molecules to the side deficient in oxygen. (c) In alkaline medium, for each excess of oxygen atom, one water molecule is added to the same side and two OH^- ions to the other side. If hydrogen is still unbalanced, one OH^- ion is added for each excess of hydrogen on the same side and one water molecule to the other side.
(iv) Electrons are added to the side deficient in electrons as to equalise the charges on both sides of the half reactions.
(v) Electrons are made equal in both the half reactions by multiplying one or both the half reactions by a suitable number.
(vi) Both the balanced half reactions are added and any term common to both sides is cancelled.

4. Oxidation number or oxidation state: It is defined as the charge (real or imaginary) which an atom appears to have when it is in combination. In the case of electrovalent compounds, the oxidation number of an element or radical is the same as the charge on the ion. The following rules are followed in ascertaining the oxidation number in any type of compounds:

- (i) The oxidation number of an atom in free elements is zero no matter how complicated the molecule is.
- (ii) The oxidation number of fluorine is always –1.
- (iii) The oxidation number of oxygen is –2 in all compounds except in peroxides, super oxides and oxygen fluorides.
- (iv) The oxidation number of hydrogen is +1 in all of its compounds except in metallic hydrides. In metallic hydrides, oxidation number of hydrogen is –1.
- (v) The oxidation number of an ion is equal to the electrical charge present on it.
- (vi) The oxidation number of alkali metals is +1 and that of alkaline earth metals is +2.
- (vii) For complex ions, the algebraic sum of oxidation no. of all the atoms is equal to the net charge on the ion.
- (viii) In the case of neutral molecules, the algebraic sum of the oxidation numbers of all the atoms present in the molecules is zero.

Oxidation numbers are quite arbitrary. The values may be positive, negative, zero and even fractional. Many elements show different oxidation numbers in different compounds. In the case of representative elements, the highest oxidation number of an element is the same as its group number while highest negative oxidation number is equal to (8-group number) with negative sign with a few exceptions.

IA elements	+1	VA elements	–3 to +5
IIA elements	+2	VIA elements	–2 to +6
IIIA elements	+3, +1	VIIA elements	–1 to +7
IVA elements	–4 to +4		

The valency and oxidation number concepts are different. In some cases (electrovalent compounds), valency and oxidation number are the same but in other cases they have different values. Valency of an element is usually fixed while oxidation number may have different values.

5. Oxidation and reduction in terms of change in oxidation numbers: Oxidation and reduction are defined on the basis of change in oxidation number.

Oxidation is a process in which an atom undergoes algebraic increase in oxidation number and reduction is a process in which an atom undergoes algebraic decrease in oxidation number. In an oxidising agent, there is always decrease in oxidation number and in reducing agent, there is always increase in oxidation number.

6. Balancing oxidation-reduction reactions by oxidation number method:

- **(i)** The skeleton equation of the chemical change is written.
- **(ii)** Oxidation numbers are assigned to atoms in the equation. The atoms in which change in oxidation number has taken place are selected and two half reactions involving oxidation and reduction are selected.
- **(iii)** Change in oxidation numbers in both the equations is made equal by multiplying with suitable integers and then both the equations are added.
- **(iv)** First of all, those substances are balanced which have undergone change in oxidation number and then other atoms except hydrogen and oxygen. Finally hydrogen and oxygen are balanced.

In ionic equations, the net charges on both sides are made equal. H^+ ions in acidic reactions and OH^- ions in basic reactions are used to balance the charge and number of hydrogen and oxygen atoms.

7. Autoxidation: Certain materials such as turpentine, olefinic compounds, phosphorus, metals like zinc and lead, etc., can absorb oxygen from the air in presence of water and the water is converted to hydrogen peroxide. This phenomenon of formation of H_2O_2 by oxidation of H_2O is known as **autoxidation.** The material which absorbs oxygen and activates it, is called the **activator.** The addition compound of activator and oxygen is termed **autoxidator.** This reacts with water or some other acceptor so as to oxidise the latter.

8. Disproportionation: One and the same substance may act simultaneously as an oxidising agent and as a reducing agent with the result that a part of it gets oxidised and rest of it is reduced. This nature of the change is termed **disproportionation.**

Questions

1. Matrix-Match Type Questions

[A] Match the Column-I with Column-II:

Column-I (Compound)	**Column-II (Oxidation state)**
(a) CrO_5	(p) +6
(b) H_2SO_4	(q) +1
(c) $CaOCl_2$	(r) −1
(d) $(CH_3)_2SO$	(s) 0

[B] Match the Column-I with Column-II:

Column-I (Redox process)	**Column-II (*n*-factor for underlined species)**
~~(a) $\underline{As_2S_3} \rightarrow AsO_3^- + SO_4^{2-}$~~	~~(p) 28~~
(b) $\underline{I_2} \rightarrow I^- + IO_3^-$	(q) 4/3
(c) $\underline{H_3PO_2} \rightarrow PH_3 + 2H_3PO_3$	(r) 1
(d) $\underline{H_3PO_2} + NaOH \rightarrow NaH_2PO_2 + H_2O$	(s) 5/3

[C] Match the Column-I with Column-II:

Column-I (Compound)	**Column-II (Oxidation state of nitrogen)**
(a) Mg_3N_2	(p) −1
(b) NO	(q) +2
(c) $(N_2H_5)_2SO_4$	(r) −2
(d) NH_2OH	(s) −3

[D] Match the Column-I with Column-II:

Column-I (Compound)	**Column-II (Oxidation state of)**
(a) CrO_5	(p) Oxygen is −2
(b) $Na_2S_2O_3$	(q) Oxygen is −1
(c) H_2SO_5	(r) Sulphur is +6
(d) $H_2S_2O_7$	(s) Sulphur is +2

[E] Match the Column-I with Column-II:

Column-I	**Column-II**
(a) $(NH_4)_2Cr_2O_7 \rightarrow N_2 + Cr_2O_3 + 4H_2O$	(p) Intermolecular redox reaction
(b) $PbO_2 + H_2O \rightarrow PbO + H_2O_2$	(q) Disproportionation
(c) $Cr_2O_3 + 2Al \rightarrow Al_2O_3 + 2Cr$	(r) Intramolecular redox reaction
(d) $Cl_2 + 2OH^- \rightarrow ClO^- + Cl^- + H_2O$	(s) Metal displacement

2. Indicate which of the substance/ion in the following reactions is an oxidising agent and which is a reducing agent?
   (i) $2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$
   (ii) $2Mg + SO_2 \longrightarrow 2MgO + S$
   (iii) $2SO_2 + O_2 \longrightarrow 2SO_3$
   (iv) $Ca + Cl_2 \longrightarrow CaCl_2$
   (v) $Sn^{2+} + 2Hg^{2+} \longrightarrow Hg_2^{2+} + Sn^{4+}$
   (vi) $2Cu^{2+} + 4I^- \longrightarrow 2CuI + I_2$
   (vii) $2I^- + H_2O_2 \longrightarrow 2OH^- + I_2$
   (viii) $SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$
   (ix) $SO_2 + 2HNO_3 \longrightarrow H_2SO_4 + 2NO_2$
   (x) $SO_2 + Cl_2 + 2H_2O \longrightarrow 2HCl + H_2SO_4$

3. Which substance/ion is oxidised and which substance/ion is reduced in the following reactions?
   (i) $PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$
   (ii) $H_2S + 2FeCl_3 \longrightarrow 2FeCl_2 + 2HCl + S$
   ~~(iii) $MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$~~
   ~~(iv) $SnCl_2 + 2FeCl_3 \longrightarrow SnCl_4 + 2FeCl_2$~~
   (v) $2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 8H_2O + 10CO_2$
   (vi) $3N_2H_4 + 2BrO_3^- \longrightarrow 3N_2 + 2Br^- + 6H_2O$
   (vii) $Cl_2 + SO_3^{2-} + H_2O \longrightarrow 2Cl^- + SO_4^{2-} + 2H^+$
   (viii) $2I^- + Cl_2 \longrightarrow 2Cl^- + I_2$

4. Arrange the following in the order of:
   (a) increasing oxidation number of iodine:
   I_2, HI, HIO_4, ICl
   (b) increasing oxidation number of chlorine:
   Cl_2O_7, Cl_2O, HCl, ClF_3, Cl_2
   (c) increasing oxidation number of nitrogen:
   NH_3, N_3H, N_2O, NO, N_2O_5

5. Find the oxidation number of :
   (i) I in KIO_3
   (ii) P in NaH_2PO_4
   (iii) P in $P_2O_7^{4-}$
   (iv) Fe in $[Fe(CN)_6]^{4-}$
   (v) Ni in $[Ni(CN)_6]^{4-}$
   (vi) S in $H_2S_2O_8$
   (vii) N in NO_3^-
   (viii) S in S_2Cl_2
   (ix) P in $Mg_2P_2O_7$
   (x) Cr in $K_2Cr_2O_7$ (Ranchi 1996)
   (xi) Mn in MnO_4^-
   (xii) Pt in $[PtCl_6]^{2-}$
   (xiii) P in PH_4^+
   (xiv) C in $C_{12}H_{22}O_{11}$
   (xv) Fe in $Na_2[Fe(CN)_5NO]$
   (xvi) Cr in $(NH_4)_2Cr_2O_7$
   (xvii) V in $Rb_4Na[HV_{10}O_{28}]$
   (xviii) Xe in $BaXeO_6$
   (xix) Cl in $Ca(ClO_2)_2$
   (xx) Ni in $Ni(CO)_4$

6. (a) Which compound among the following has the lowest oxidation number of Mn?
$KMnO_4$, K_2MnO_4, MnO_2 and Mn_2O_3
(b) Which compound among the following has the highest oxidation number of P?
PH_3, H_3PO_2, PCl_3, H_3PO_4
(c) Which compound among the following has the zero oxidation state of carbon?
CH_4, CH_3Cl, CH_2Cl_2, $CHCl_3$, CCl_4
(d) Which compound among the following has the lowest oxidation number of chlorine?
$HClO_4$, $HOCl$, ClF_3, $HClO_3$, HCl

Short Answer Type

7. Balance the following equations by ion electron method:

(i) $MnO_4^- + Fe^{2+} \longrightarrow Mn^{2+} + Fe^{3+} + H_2O$ (acidic medium)

(ii) $MnO_4^- + SnO_2^{2-} + H_2O \longrightarrow MnO_2 + SnO_3^{2-} + OH^-$ (alkaline medium)

(iii) $Cu + NO_3^- + 8H^+ \longrightarrow Cu(NO_3)_2 + NO + H_2O$ (acidic medium)

(iv) $Cl_2 + IO_3^- + OH^- \longrightarrow IO_4^- + Cl^- + H_2O$ (alkaline medium)

(v) $I_2 + NaOH \longrightarrow NaIO_3 + NaI + H_2O$ (alkaline medium)

(vi) $Zn + NO_3^- + OH^- \longrightarrow ZnO_2^{2-} + NH_3 + H_2O$ (alkaline medium)

(vii) $Cr(OH)_3 + ClO^- + OH^- \longrightarrow CrO_4^{2-} + Cl^- + H_2O$

[**Hint:** Half reactions

$$[Cr(OH)_3 + 5OH^- \longrightarrow CrO_4^{2-} + 4H_2O + 3e] \times 2$$
$$[ClO^- + H_2O + 2e \longrightarrow Cl^- + 2OH^-] \times 3$$
$$2Cr(OH)_3 + 4OH^- + 3ClO^- \longrightarrow 2CrO_4^{2-} + 3Cl^- + 5H_2O\ ]$$

(viii) $As_2S_3 + NO_3^- + H^+ + H_2O \longrightarrow H_3AsO_4 + NO + S$

[**Hint:** Half reactions

$$[As_2S_3 + 8H_2O \longrightarrow 2H_3AsO_4 + 3S + 10H^+ + 10e] \times 3$$
$$[NO_3^- + 4H^+ + 3e \longrightarrow NO + 2H_2O] \times 10$$
$$3As_2S_3 + 4H_2O + 10NO_3^- + 10H^+ \longrightarrow 6H_3AsO_4 + 9S + 10NO\ ]$$

(ix) $Zn + H^+ + NO_3^- \longrightarrow Zn^{2+} + NH_4^+ + H_2O$

(x) $P_4 + OH^- + H_2O \longrightarrow H_2PO_2^- + PH_3$

[**Hint:** Half reactions

$$[P_4 + 8OH^- \longrightarrow 4H_2PO_2^- + 4e] \times 3$$
$$P_4 + 12H_2O + 12e \longrightarrow 4PH_3 + 12OH^-$$
$$4P_4 + 12OH^- + 12H_2O \longrightarrow 12H_2PO_2^- + 4PH_3$$
$$\text{or} \quad P_4 + 3OH^- + 3H_2O \longrightarrow 3H_2PO_2^- + PH_3\ ]$$

(xi) $HgS + Cl^- + H^+ + NO_3^- \longrightarrow HgCl_4^{2-} + S + NO + H_2O$

[**Hint:** Half reactions

$$[HgS + 4Cl^- \longrightarrow HgCl_4^{2-} + S + 2e] \times 3$$
$$[NO_3^- + 4H^+ + 3e \longrightarrow NO + 2H_2O] \times 2$$
$$3HgS + 12Cl^- + 2NO_3^- + 8H^+ \longrightarrow 3HgCl_4^{2-} + 3S + 2NO + 4H_2O\ ]$$

(xii) $Co^{2+} + NO_2^- + H^+ \longrightarrow Co^{3+} + NO + H_2O$

(xiii) $CrI_3 + H_2O_2 + OH^- \longrightarrow CrO_4^{2-} + IO_4^- + H_2O$

[**Hint:** Half reactions

$$[CrI_3 + 32OH^- \longrightarrow CrO_4^{2-} + 3IO_4^- + 16H_2O + 27e] \times 2$$
$$[H_2O_2 + 2e \longrightarrow 2OH^-] \times 27$$
$$2CrI_3 + 27H_2O_2 + 10OH^- \longrightarrow 2CrO_4^{2-} + 6IO_4^{2-} + 32H_2O\ ]$$

(xiv) $MnO_4^- + H^+ + H_2O_2 \longrightarrow Mn^{2+} + H_2O + O_2$

[**Hint:** Half reactions

$$[MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O] \times 2$$
$$[H_2O_2 \longrightarrow 2H^+ + O_2 + 2e] \times 5$$
$$2MnO_4^- + 6H^+ + 5H_2O_2 \longrightarrow 2Mn^{2+} + 8H_2O + 5O_2\ ]$$

(xv) $C_2H_5OH + I_2 + OH^- \longrightarrow CHI_3 + HCO_2^- + I^- + H_2O$

[**Hint:** Half reactions

$$[C_2H_5OH + \tfrac{3}{2}I_2 + 6OH^- \longrightarrow CHI_3 + HCO_2^- + 5H_2O + 5e] \times 2$$
$$[I_2 + 2e \longrightarrow 2I^-] \times 5$$
$$2C_2H_5OH + 8I_2 + 12OH^- \longrightarrow 2CHI_3 + 2HCO_2^- + 10I^- + 10H_2O$$
$$\text{or} \quad C_2H_5OH + 4I_2 + 6OH^- \longrightarrow CHI_3 + HCO_2^- + 5I^- + 5H_2O\ ]$$

(xvi) $Cr_2O_7^{2-} + H^+ + C_2O_4^{2-} \longrightarrow Cr^{3+} + CO_2 + H_2O$

(xvii) $Ag^+ + AsH_3 + H_2O \longrightarrow H_3AsO_3 + H^+ + Ag$

(xviii) $MnO_2 + OH^- + O_2 \longrightarrow MnO_4^{2-} + H_2O$

[**Hint:** Half reactions

$$[MnO_2 + 4OH^- \longrightarrow MnO_4^{2-} + 2H_2O + 2e] \times 2$$
$$O_2 + 2H_2O + 4e \longrightarrow 4OH^-$$
$$2MnO_2 + 4OH^- + O_2 \longrightarrow 2MnO_4^{2-} + 2H_2O\ ]$$

8. Balance the following equations by oxidation number method.

(i) $CO + Fe_3O_4 \longrightarrow FeO + CO_2$

(ii) $H_2O_2 + ClO_2 + OH^- \longrightarrow Cl^- + O_2 + H_2O$

(iii) $Cr_2O_7^{2-} + I^- + H^+ \longrightarrow Cr^{3+} + I_2 + H_2O$

(iv) $Cr_2O_7^{2-} + HNO_2 + H^+ \longrightarrow Cr^{3+} + NO_3^- + H_2O$

(v) $KI + H_2SO_4 \longrightarrow K_2SO_4 + I_2 + SO_2 + H_2O$

(vi) $HgS + HCl + HNO_3 \longrightarrow H_2HgI_4 + NO + S + H_2O$

(vii) $[Fe(CN)_6]^{3-} + N_2H_4 + OH^- \rightarrow [Fe(CN)_6]^{4-} + N_2 + H_2O$

[**Hint:** Two half reactions

$$\overset{+3}{[Fe(CN)_6]^{3-}} \longrightarrow \overset{+2}{[Fe(CN)_6]^{4-}}$$

(change in Ox.no. per Fe atom = −1)

$$\overset{-2}{N_2H_4} \longrightarrow \overset{0}{N_2}$$

(change in Ox.no. per N atom = +2)

Total increase = $2 \times (+2) = +4$

$$4[Fe(CN)_6]^{3-} + N_2H_4 \longrightarrow 4[Fe(CN)_6]^{4-} + N_2$$
$$[4Fe(CN)_6]^{3-} + N_2H_4 + 4OH^- \longrightarrow 4[Fe(CN)_6]^{4-} + N_2 + 4H_2O]$$

(viii) $MnO_4^{2-} + H^+ \longrightarrow MnO_2 + MnO_4^- + H_2O$ (IIT 1994)

[**Hint:**

$$\overset{VI}{MnO_4^{2-}} \longrightarrow \overset{IV}{MnO_2}$$
$$[\overset{VI}{MnO_4^{2-}} \longrightarrow \overset{VII}{MnO_4^-}] \times 2$$
$$3MnO_4^{2-} + 4H^+ \longrightarrow 2MnO_4^- + MnO_2 + 2H_2O]$$

(ix) $HNO_3 + Cu_2O \longrightarrow Cu(NO_3)_2 + NO + H_2O$

(x) $AuCl_4^- + Sn^{2+} + H^+ \longrightarrow Sn^{4+} + AuCl + HCl$

(xi) $S + OH^- \longrightarrow S^{2-} + S_2O_3^{2-}$

[**Hint:** $\overset{0}{S} \longrightarrow S^{2-}$ (decrease of 2)

$2\overset{0}{S} \longrightarrow S_2O_3^{2-}$ (increase of 2 per S atom)]

(xii) $NaClO_3 + KI + HCl \longrightarrow NaCl + KCl + I_2 + H_2O$

(xiii) $PbCrO_4 + H_2SO_4 + FeSO_4 \longrightarrow Fe_2(SO_4)_3 + PbSO_4 + Cr_2(SO_4)_3 + H_2O$

(xiv) $As + HNO_3 \longrightarrow H_3AsO_4 + NO_2 + H_2O$

(xv) $Fe_2(SO_4)_3 + H_2SO_3 + H_2O \longrightarrow FeSO_4 + H_2SO_4$

(xvi) $C_6H_{12}O_6 + H_2SO_4 \longrightarrow CO_2 + SO_2 + H_2O$

9. Balance the following equations:

(i) $Ca_3(PO_4)_2 + SiO_2 + C \longrightarrow CaSiO_3 + P_4 + CO$

(ii) $P_2H_4 \longrightarrow PH_3 + P_4H_2$

[**Hint:** $3 \times [P_2H_4 + 2H^+ + 2e \longrightarrow 2PH_3]$

$2P_2H_4 \longrightarrow P_4H_2 + 6H^+ + 6e$

$5P_2H_4 \longrightarrow 6PH_3 + P_4H_2$]

(iii) $Na_2HAsO_3 + KBrO_3 + HCl \longrightarrow NaCl + KBr + H_3AsO_4$

[**Hint:** $[HAsO_3^{2-} + H_2O \longrightarrow H_3AsO_4 + 2e] \times 3$

$BrO_3^- + 6H^+ + 6e \longrightarrow Br^- + 3H_2O$

$3HAsO_3^{2-} + BrO_3^- + 6H^+ + 3H_2O \longrightarrow 3H_3AsO_4 + Br^- + 3H_2O$

or $3Na_2HAsO_3 + KBrO_3 + 6HCl \longrightarrow 3H_3AsO_4 + KBr + 6NaCl$]

(iv) $FeS_2 + O_2 \longrightarrow Fe_2O_3 + SO_2$

[**Hint:** Both iron and sulphur in FeS_2 undergo a change in oxidation state.

Increase

$\overset{+2-1}{FeS_2} \longrightarrow \overset{+3}{Fe} + 2\overset{+4}{SO_2}$ Total increase = 10 + 1 = 11

Increase 5 × 2 = 10

$O_2^0 \longrightarrow 2O^{2-}$ Total decrease = 2 × 2 = 4]

(v) $As_2S_5 + HNO_3 \longrightarrow H_3AsO_4 + H_2SO_4 + NO_2 + H_2O$

Increase 5 × 8 = 40

[**Hint:** $As_2\overset{-2}{S_5} + H\overset{+5}{N}O_3 \longrightarrow H_2\overset{+6}{S}O_4 + \overset{+4}{N}O_2$]

Decrease 1 × 1 = 1

(vi) $MnO + PbO_2 + HNO_3 \longrightarrow HMnO_4 + Pb(NO_3)_2 + H_2O$

(vii) $P + NaOH + H_2O \longrightarrow NaH_2PO_2 + PH_3$

Increase 1 × 1 = 1

[**Hint:** $\overset{0}{P} \longrightarrow NaH_2\overset{+1}{P}O_2 + \overset{-3}{P}H_3$]

Decrease 1 × 3 = 3

(viii) $KClO_3 + H_2SO_4 \longrightarrow KHSO_4 + O_2 + ClO_2 + H_2O$

[**Hint:** $[ClO_3^- + 2H^+ + e \longrightarrow ClO_2 + H_2O] \times 2$

$2ClO_3^- \longrightarrow 2ClO_2 + O_2 + 2e$

$4ClO_3^- + 4H^+ \longrightarrow 4ClO_2 + O_2 + 2H_2O$

or $4KClO_3 + 4H_2SO_4 \longrightarrow 4KHSO_4 + 4ClO_2 + O_2 + 2H_2O$]

(ix) $Ag + KCN + O_2 + H_2O \longrightarrow KAg(CN)_2 + KOH$

[**Hint:** $[Ag + 2CN^- \longrightarrow [Ag(CN)_2]^- + e] \times 4$

$O_2 + 2H_2O + 4e \longrightarrow 4OH^-$]

(x) $Ca(OCl)_2 + KI + HCl \longrightarrow CaCl_2 + I_2 + KCl + H_2O$

[**Hint:** $OCl^- + 2H^+ + 2e \longrightarrow Cl^- + H_2O$

$2I^- \longrightarrow I_2 + 2e$

$OCl^- + 2H^+ + 2I^- \longrightarrow Cl^- + I_2 + H_2O$

or $2OCl^- + 4H^+ \longrightarrow 2Cl^- + 2I_2 + 2H_2O$]

---

10. Calculate the oxidation state of underlined:

(a) $Ba_2\underline{Xe}O_2$ (b) $\underline{Ba}Cl_2$ (c) $\underline{C_{12}}H_{22}O_{11}$ (d) $\underline{I}F_7$

(e) $Na_2[\underline{Fe}(CN)_5NO]$ (f) $\underline{Ru}O_4$ (g) $K_2\underline{Ta}F_7$ (h) $Na_2\underline{Mo}O_4$

(i) $\underline{U_2}O_7^{4-}$ (j) C in diamond.

11. Give the oxidation state of underlined:

(a) $\underline{Fe}_3O_4$ (b) $CaO\underline{Cl_2}$ (c) $\underline{N}H_4\underline{N}O_3$

(d) $\underline{N}H_4\underline{N}O_2$ (e) $K\underline{O_2}$ (f) $H_2\underline{S}O_5$

(g) $(CH_3)_2\underline{S}O$ (h) $H_2\underline{S_2}O_8$ (i) $Na_2\underline{S_2}O_3$

(j) $Na_2\underline{S_4}O_6$ (k) $\underline{Cr}O_5$ (l) $\underline{Co}SeO_4$

12. Balance the following equations by ion electron method:

(a) $Zn + BrO_4^- + OH^- + H_2O \longrightarrow [Zn(OH)_4]^{2-} + Br^-$

(b) $MnO_4^{2-} + H_2O \longrightarrow MnO_4^- + OH^- + MnO_2$

(c) $Fe(CN)_6^{4-} + H^+ + MnO_4^- \longrightarrow Fe^{3+} + CO_2 + NO_3^- + Mn^{2+}$

(d) $Cu_3P + Cr_2O_7^{2-} \longrightarrow Cu^{2+} + H_3PO_4 + Cr^{3+}$ (acid medium)

(e) $Hg_2(CN)_2 + Ce^{4+} \longrightarrow CO_3^{2-} + NO_3^- + Hg(OH)_2 + Ce^{3+}$ (basic medium)

(f) $K_3Fe(CN)_6 + Cr_2O_3 + KOH \longrightarrow K_4Fe(CN)_6 + K_2CrO_4 + H_2O$ (basic medium)

(g) $Na_2HAsO_3 + KBrO_3 + HCl \longrightarrow NaCl + KBr + H_3AsO_4$

13. Calculate the oxidation state of vanadium in the following complex compound: $Rb_4Na[HV_{10}O_{28}]$

14. **(a)** Arrange the following compounds in increasing order of oxidation number of manganese:

$MnCl_2, MnO_2, KMnO_4, K_2MnO_4$

(b) Indicate valency and oxidation states of carbon in the following compounds:

$CH_4, CH_3Cl, CH_2Cl_2, CHCl_3, CCl_4$

15. Complete and balance the following compounds:

(a) Acidic solution of Fe^{2+} ion gives a brown ring when it comes in contact with NO_3^- ion. Complete the following reactions of this process:

$[Fe(H_2O)_6]^{2+} + NO_3^- + H^+ \longrightarrow ..... + [Fe(H_2O)_6]^{3+} + H_2O$

$[Fe(H_2O)_6]^{2+} ..... \longrightarrow ..... + H_2O$

(b) $Ca_5(PO_4)_3F + H_2SO_4 + H_2O \xrightarrow{Heat} ..... + 5CaS \cdot 2H_2O + ...$

(c) $Sn + 2KOH + 4H_2O \longrightarrow ..... + ...$ (IIT 1994)

(d) $AlBr_3 + K_2Cr_2O_7 + H_3PO_4 \longrightarrow K_3PO_4 + AlPO_4 + ... + ...$

(e) $K_2Cr_2O_7 + HCl \longrightarrow KCl + ... + ... + H_2O$ (IIT 1992)

(f) $Ag^+ + AsH_3 \longrightarrow H_3AsO_3 + H^+ + ...$

16. Arrange following ions in increasing order of oxidation number of sulphur: $S_4O_6^{2-}, HS^-, HSO_4^-, S_2O_8^{2-}, S_2O_3^{2-}, SO_3^{2-}$

17. Determine equivalent weight of underlined species:

(a) $\underline{NH_4NO_3} \longrightarrow N_2O + 3H_2O$

(b) $\underline{3MnO_2} + 6KOH + KClO_3 \longrightarrow 3K_2MnO_4 + KCl + 3H_2O$

(c) $2HS^- + \underline{4HSO_3^-} \longrightarrow 3S_2O_3^{2-} + 3H_2O$

(d) $3Cl_2 + 6NaOH \longrightarrow 5NaCl + \underline{NaClO_3} + 3H_2O$

(e) $\underline{K_2Cr_2O_7} + 7H_2SO_4 + 6FeSO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 3Fe_2(SO_4)_3 + 7H_2O$

18. Which of the following structures is accurate on the basis of formal charge?

(a) $H-C\equiv N:$; (b) $H-N\equiv C:$

[**Hint:** (a) $H-C\equiv N:$

$$\text{F.C.} = V - N - \frac{1}{2}B$$

F.C. at 'H' $= 1 - 0 - \frac{1}{2} \times 2 = 0$

F.C. at 'C' $= 4 - 0 - \frac{1}{2} \times 8 = 0$

F.C. at 'N' $= 5 - 2 - \frac{1}{2} \times 6 = 0$

(b) $H-N\equiv C:$

F.C. at 'H' $= 1 - 0 - \frac{1}{2} \times 2 = 0$

F.C. at 'N' $= 5 - 0 - \frac{1}{2} \times 8 = +1$

F.C. at 'C' $= 4 - 2 - \frac{1}{2} \times 6 = -1$

Structure (a) having zero formal charges at each atom will be accurate.]

19. On the basis of formal charge select the most plausible structure:

(a) H_2NOH or H_2ONH (b) SCN^- or CNS^- or CSN^-

(c) $[:\overset{\bullet\bullet}{N}=N=\overset{\bullet\bullet}{N}:]^-$ or $[:\underset{\bullet\bullet}{\overset{\bullet\bullet}{N}}-N\equiv N:]^-$

(d) NOCl or ONCl

Answers

1. [A] (a — p); (b — p); (c — q, r); (d — s)

[B] (a — p); (b — s); (c — q); (d — r)

[C] (a — s); (b — q); (c — s); (d — p)

[D] (a — p, q); (b — p, s); (c — p, q, r); (d — p, r)

[E] (a — r); (b — p); (c — p, s); (d — q)

2.

	Oxidising agent	Reducing agent
(i)	$FeCl_3$	$SnCl_2$
(ii)	SO_2	Mg
(iii)	O_2	SO_2
(iv)	Cl_2	Ca
(v)	Hg^{2+}	Sn^{2+}
(vi)	Cu^{2+}	I^-
(vii)	H_2O_2	I^-
(viii)	SO_2	H_2S
(ix)	HNO_3	SO_2
(x)	Cl_2	SO_2

3.

	Oxidised	Reduced
(i)	PbS	H_2O_2
(ii)	H_2S	$FeCl_3$
(iii)	HCl	MnO_2
(iv)	$SnCl_2$	$FeCl_3$
(v)	$C_2O_4^{2-}$	MnO_4^-
(vi)	N_2H_4	BrO_3^-
(vii)	SO_3^{2-}	Cl_2
(viii)	I^-	Cl_2

4. (a) $HI(-1), I_2(0), ICl(+1), HIO_4(+7)$

(b) $HCl(-1), Cl_2(0), Cl_2O(+1), ClF_3(+3), Cl_2O_7\ (+7)$

(c) $NH_3(-3), N_3H(-1/3), N_2O(+1), NO(+2), N_2O_5(+5)$.

5. (i) + 5 (ii) + 5 (iii) + 5 (iv) + 2 (v) + 2 (vi) + 6 (one peroxo linkage is present) (vii) + 5 (viii) + 1 (ix) + 5 (x) + 6 (xi) + 7 (xii) + 4 (xiii) −3 (xiv) 0 (zero)(xv) + 3 (xvi) + 6 (xvii) + 5 (xviii) + 8 (xix) +3 (xx) 0 (zero).

6. (a) Mn_2O_3 (b) H_3PO_4 (c) CH_2Cl_2 (d) HCl.

7. (i) $MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$

(ii) $2MnO_4^- + 3SnO_2^{2+} + H_2O \longrightarrow 2MnO_2 + 3SnO_3^{2-} + 2OH^-$

(iii) $3Cu + 2NO_3^- + 8H^+ \longrightarrow 3Cu^{2+} + 2NO + 4H_2O$

(iv) $Cl_2 + IO_3^- + 2OH^- \longrightarrow IO_4^- + 2Cl^- + H_2O$

(v) $3I_2 + 6NaOH \longrightarrow NaIO_3 + 5NaI + 3H_2O$

(vi) $4Zn + NO_3^- + 7OH^- \longrightarrow 4ZnO_2^{2-} + NH_3 + 2H_2O$

(ix) $4Zn + NO_3^- + 10H^+ \longrightarrow 4Zn^{2+} + NH_4^+ + 3H_2O$

(xii) $CO^{2+} + NO_2^- + 2H^+ \longrightarrow CO^{3+} + NO + H_2O$

(xvi) $Cr_2O_7^{2-} + 14H^+ + 3C_2O_4^{2-} \longrightarrow 2Cr^{3+} + 7H_2O + 6CO_2$

(xvii) $AsH_3 + 3H_2O + 6Ag^+ \longrightarrow H_3AsO_3 + 6H^+ + 6Ag$

8. (i) $CO + Fe_3O_4 \longrightarrow 3FeO + CO_2$

(ii) $5H_2O_2 + 2ClO_2 + 2OH^- \longrightarrow 2Cl^- + 5O_2 + 6H_2O$

(iii) $Cr_2O_7^{2-} + 6I^- + 14H^+ \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$

(iv) $Cr_2O_7^{2-} + 3HNO_2 + 5H^+ \longrightarrow 2Cr^{3+} + 3NO_3^- + 4H_2O$

(v) $2KI + 2H_2SO_4 \longrightarrow K_2SO_4 + I_2 + SO_2 + 2H_2O$

(vi) $3HgS + 12HCl + 2HNO_3 \longrightarrow 3H_2HgCl_4 + 2NO + 3S + 4H_2O$

(ix) $3Cu_2O + 14HNO_3 \longrightarrow 6Cu(NO_3)_2 + 2NO + 7H_2O$

(x) $AuCl_4^- + Sn^{2+} + 3H^+ \longrightarrow AuCl + Sn^{4+} + 3HCl$

(xi) $4S + 6OH^- \longrightarrow 2S^{2-} + S_2O_3^{2-} + 3H_2O$

(xii) $NaClO_3 + 6KI + 6HCl \longrightarrow NaCl + 6KCl + 3I_2 + 3H_2O$

(xiii) $2PbCrO_4 + 6FeSO_4 + 8H_2SO_4 \longrightarrow 2PbSO_4 + Cr_2(SO_4)_3 + 3Fe_2(SO_4)_3 + 8H_2O$

(xiv) $As + 5HNO_3 \longrightarrow H_3AsO_4 + 5NO_2 + H_2O$

(xv) $Fe_2(SO_4)_3 + H_2SO_3 + H_2O \longrightarrow 2FeSO_4 + 2H_2SO_4$

(xvi) $C_6H_{12}O_6 + 12H_2SO_4 \longrightarrow 6CO_2 + 12SO_2 + 18H_2O$

9. (i) $2Ca_3(PO_4)_2 + 6SiO_2 + 10C \longrightarrow 6CaSiO_3 + P_4 + 10CO$

(iv) $4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2$

(v) $As_2S_5 + 40HNO_3 \longrightarrow 5H_2SO_4 + 2H_3AsO_4 + 40NO_2 + 12H_2O$

(vi) $2MnO + 5PbO_2 + 10HNO_3 \longrightarrow 2HMnO_4 + 5Pb(NO_3)_2 + 4H_2O$

(vii) $4P + 3NaOH + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3$

(ix) $4Ag + 8KCN + O_2 + 2H_2O \longrightarrow 4KAg(CN)_2 + 4KOH$

(x) $Ca(OCl)_2 + 4KI + 4HCl \longrightarrow CaCl_2 + 4KCl + 2I_2 + 2H_2O$

10. (a) 0 (b) +2 (c) 0 (d) +7 (e) 3 (f) +8 (g) +5 (h) +2 (i) +5 (j) 0

OBJECTIVE QUESTIONS

Set–1 : Questions with single correct answer

1. Oxidation is defined as:
(a) loss of electrons (b) gain of electrons
(c) gain of protons (d) loss of protons

2. A reducing agent is a substance which can:
(a) accept electrons (b) donate electrons
(c) accept protons (d) donate protons

3. A redox reaction is:
(a) proton transfer reaction (b) ion combination reaction
(c) a reaction in solution (d) electron transfer reaction

4. Which of the following is not a redox reaction?
(a) Burning of candle (b) Rusting of iron
(c) Dissolving a salt in water (d) Dissolving Zn in dil. H_2SO_4

5. The reaction, $H_2S + H_2O_2 = S + 2H_2O$ manifests:
(a) oxidising action of H_2O_2 (b) reducing nature of H_2O_2
(c) acidic nature of H_2O_2 (d) alkaline nature of H_2O_2

6. The oxidation number of Fe in $K_4Fe(CN)_6$ is: (CBSE 1993; KCET 2008)
(a) + 6 (b) + 4 (c) + 3 (d) + 2

7. In $Ni(CO)_4$, the oxidation state of Ni is:
(a) 4 (b) zero (c) 2 (d) 8

8. Pick the group which does not contain a neutral oxide : (ISAT 2010)
(a) $NO_2, P_4O_{10}, Al_2O_3, NO$ (b) MgO, N_2O_5, SO_3, N_2O
(c) CO_2, SO_3, CaO, XeO_3 (d) $CO, SiO_2, SnO_2, Na_2O_3$

9. Magnesium reacts with acids producing hydrogen and corresponding magnesium salts. In such reactions Mg undergoes:
(a) reduction
(b) oxidation
(c) neither oxidation nor reduction
(d) simple dissolution

10. When P reacts with caustic soda, the products are PH_3 and NaH_2PO_2. The reaction is an example of:
(a) oxidation
(b) reduction
(c) both oxidation and reduction
(d) neutralisation

11. Which of the following reactions is not a redox reaction ? [PET (Raj.) 2008]
(a) $Ag^+ + Cl^- \longrightarrow AgCl$
(b) $Zn(s) + Cu^{2+}(aq.) \longrightarrow Zn^{2+}(aq.) + Cu(s)$
(c) $2Mg(s) + O_2(g) \longrightarrow 2MgO$
(d) $FeO + C \longrightarrow Fe + CO$

12. Which of the following is not a redox change?
(a) $2H_2S + SO_2 = 2H_2O + 3S$
(b) $2BaO + O_2 = 2BaO_2$
(c) $BaO_2 + H_2SO_4 = BaSO_4 + H_2O_2$
(d) $2KClO_3 = 2KCl + 3O_2$

13. The conversion of $K_2Cr_2O_7$ into $Cr_2(SO_4)_3$ is a process of:
(a) oxidation (b) reduction
(c) decomposition (d) substitution

14. In the reaction, $2Na_2S_2O_3 + I_2 = Na_2S_4O_6 + 2NaI$, I_2 acts as:
(a) reducing agent
(b) oxidising agent
(c) oxidising as well as reducing agent
(d) none of the above

15. The most common oxidation state of oxygen is –2. This is best explained as due to:
(a) 2 electrons in the outermost shell
(b) 4 electrons in the outermost shell
(c) 6 electrons in the outermost shell
(d) 8 electrons in the outermost shell

16. Select the compound in which chlorine shows oxidation state + 7:
(a) $HClO_4$ (b) $HClO_3$ (c) $HClO_2$ (d) HClO

17. Which one of the following is a reducing agent?
(a) Ozone (b) Chlorine (c) $FeCl_3$ (d) Na_2SO_3

18. The oxidation number of nitrogen in NH_2OH is:
(a) zero (b) +1 (c) –1 (d) –2

19. HBr and HI reduce sulphuric acid. HCl can reduce $KMnO_4$ and HF can reduce:
(a) H_2SO_4 (b) $KMnO_4$
(c) $K_2Cr_2O_7$ (d) none of these

20. One mole of N_2H_4 loses 10 moles of electrons to form a new compound *Y*. Assuming that all nitrogen appear in the new compound, what is the oxidation state of nitrogen? (There is no change in the oxidation state of hydrogen.)
(a) –1 (b) –3 (c) +3 (d) +5

21. The brown ring complex compound is formulated as $[Fe(H_2O)_5(NO)]SO_4$. The oxidation state of iron is: (CET Karnataka 2009)
(a) +1 (b) +2 (c) +3 (d) zero

22. A solution of sodium metal in liquid ammonia is strongly reducing due to the presence of :
(a) sodium atoms (b) sodium hydroxide
(c) sodium amide (d) solvated electrons

23. In which of the following compounds, iron has an oxidation state of +3? (DPMT 2009)

(a) $Fe(NO_3)_2$
(b) FeC_2O_4
(c) $[Fe(H_2O)_6]Cl_3$
(d) $(NH_4)_2SO_4 \cdot FeSO_4 \cdot 6H_2O$

24. When $KMnO_4$ is reduced with oxalic acid in acidic solution, the oxidation number of Mn changes from:
(a) 7 to 2 (b) 7 to 4 (c) 7 to 6 (d) 6 to 2

25. In which of the following reactions the underlined substance is oxidised?
(a) $3Mg + \underline{N_2} + Mg_3N_2$ (b) $2KI + \underline{Br_2} = 2KBr + I_2$
(c) $\underline{CuO} + \overline{H_2} = Cu + H_2O$ (d) $\underline{CO} + \overline{Cl_2} = COCl_2$

26. Of the following elements, which one has the same oxidation state in all of its compounds?
(a) Hydrogen (b) Fluorine (c) Carbon (d) Oxygen

27. When tin(IV) chloride is treated with excess of conc. hydrochloric acid, the complex ion $(SnCl_6)^{2-}$ is formed. The oxidation state of tin in this complex ion is:
(a) +4 (b) zero (c) −2 (d) −4

28. In the following reaction,

$$3Br_2 + 6CO_3^{2-} + 3H_2O = 5Br^- + BrO_3^- + 6HCO_3^-$$

[PMT (MP) 1997]
(a) bromine is oxidised, carbonate is reduced
(b) bromine is reduced, carbonate is oxidised
(c) bromine is neither reduced nor oxidised
(d) bromine is reduced as well as oxidised

29. If an element is in its lowest oxidation state, under proper conditions, it can act as:
(a) a reducing agent
(b) an oxidising agent
(c) oxidising as well as reducing agent
(d) neither oxidising nor reducing agent

30. The oxidation state of phosphorus varies from:
(a) −1 to +1 (b) −3 to +3
(c) −3 to +5 (d) −5 to +1

31. In which of the following reactions no change in valency occurs?
(a) $SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$
(b) $2Na + O_2 \longrightarrow Na_2O_2$
(c) $Cl_2 + 2NaOH \longrightarrow NaClO + NaCl + H_2O$
(d) $AgNO_3 + KCl \longrightarrow AgCl + KNO_3$

32. When SO_2 is passed through an acidified solution of $K_2Cr_2O_7$, then chromium sulphate is formed. Change in oxidation state of Cr is from: (KCET 2008)
(a) +4 to +2 (b) +6 to +3
(c) +7 to +2 (d) +5 to +3

33. In a reaction,
$2Ag + 2H_2SO_4 \longrightarrow Ag_2SO_4 + H_2O + SO_2$, H_2SO_4 acts as:
(a) reducing agent (b) oxidising agent
(c) dehydrate (d) none of these

34. Oxidation number of iodine varies from:
(a) −1 to +1 (b) −1 to +7 (c) +3 to +5 (d) −1 to +5

35. Oxidation number of fluorine in F_2O is:
(a) +1 (b) +2 (c) −1 (d) −2

36. In the compounds $KMnO_4$ and $K_2Cr_2O_7$, the highest oxidation state is of the element:
(a) potassium (b) chromium (c) oxygen (d) manganese

37. In a reaction, the oxidation number of an element becomes zero from −1. It is a case of:
(a) oxidation
(b) reduction
(c) neither oxidation nor reduction
(d) both oxidation and reduction

38. $Cl_2 + H_2S \longrightarrow 2HCl + S$,
In the above reaction, oxidation state of chlorine changes from : [PET (Raj.) 2008]
(a) zero to −1 (b) 1 to zero
(c) zero to 1 (d) remains unchanged

39. During electrolysis the reaction at anode is:
(a) oxidation (b) reduction
(c) decomposition (d) none of these

40. Which of the following is a mild oxidising agent?
(a) Ag_2O (b) $KMnO_4$ (c) $K_2Cr_2O_7$ (d) Cl_2

41. The common oxidation state of alkali metals in the combined state is:
(a) +1 (b) +2 (c) −1 (d) −2

42. Carbon is in highest oxidation state in:
(a) CH_3Cl (b) CCl_4 (c) $CHCl_3$ (d) CH_2Cl_2

43. The oxidation number and covalency of sulphur in S_8 is:
(a) +2, 0 (b) 0, 2 (c) 0, 8 (d) 6, 2

44. Addition of iron or zinc to copper sulphate causes precipitation of copper owing to the:
(a) reduction of Cu^{2+} (b) oxidation of Cu^{2+}
(c) hydrolysis of $CuSO_4$ (d) ionisation of $CuSO_4$

45. In a reaction,

$$H_2O\,(steam) + C\,(glowing) = CO + H_2$$

(a) H_2O is the reducing agent
(b) H_2O is the oxidising agent
(c) carbon is the oxidising agent
(d) oxidation-reduction does not occur

46. The oxidation numbers of C in CH_4, CH_3Cl, CH_2Cl_2, $CHCl_3$ and CCl_4 are respectively:
(a) + 4, + 2, 0, −2, −4 (b) + 2, + 4, 0, −4, −2
(c) −4, −2, 0, + 2, + 4 (d) −2, −4, 0, + 4, + 2

47. Which of the following statements is correct?
(a) Oxidation of a substance is followed by reduction of another
(b) Reduction of a substance is followed by oxidation of another
(c) Oxidation and reduction are complementary reactions
(d) It is not necessary that both oxidation and reduction should take place in the same reaction

48. Reduction never involves:
(a) gain of electrons
(b) decrease in oxidation number
(c) loss of electrons
(d) decrease in valency of electropositive component

49. In which of the following reactions has the underlined substance been reduced?
(a) <u>Carbon monoxide</u> + copper oxide ⟶ carbon dioxide + copper
(b) <u>Copper oxide</u> + hydrochloric acid ⟶ copper chloride + water

(c) $\underline{\text{Hydrogen}}$ + iron oxide ⟶ iron + water

(d) $\underline{\text{Steam}}$ + iron ⟶ iron oxide + hydrogen

50. In which of the following reactions, the underlined element has decreased its oxidation number during the reaction?

(a) $\underline{Fe} + CuSO_4 \longrightarrow Cu + FeSO_4$

(b) $\underline{H_2} + Cl_2 \longrightarrow 2HCl$

(c) $\underline{C} + H_2O \longrightarrow CO + H_2$

(d) $\underline{MnO_2} + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$

51. If three electrons are lost by a metal ion, M^{3+}, its final oxidation number would be:

(a) zero (b) + 6

(c) + 2 (d) + 4

52. Select the compound in which chlorine is assigned the oxidation number +5:

~~(a) $HClO_4$ (b) $HClO_2$ (c) $HClO_3$ (d) HCl~~

53. ~~In the alumino thermic process, aluminium acts as:~~

(a) an oxidising agent (b) a flux

(c) a reducing agent (d) a solder

54. The strongest reducing agent is:

(a) K (b) Ca (c) Al (d) Zn

55. In the reaction; $Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$; Zn undergoes:

(a) oxidation (b) reduction

(c) simple dissolution (d) double decomposition

56. Phosphorus has the oxidation state of +3 in:

(a) ortho phosphoric acid (b) phosphorus acid

(c) meta phosphoric acid (d) pyrophosphoric acid

57. Oxidation number of P in PO_4^{3-}, of S in SO_4^{2-} and that of Cr in $Cr_2O_7^{2-}$ are respectively: [CBSE (PMT) 2009]

(a) −3, +6 and +6 (b) +5, +6 and +6

(c) +3, +6 and +5 (d) +5, +3 and +6

58. The conversion of PbO into $Pb(NO_3)_2$ involves:

(a) oxidation

(b) reduction

(c) neither oxidation nor reduction

(d) both oxidation and reduction

59. The highest state of Mn is shown in:

(a) K_2MnO_4 (b) $KMnO_4$ (c) MnO_2 (d) Mn_2O_3

60. In which one of the following changes, there is transfer of five electrons?

(a) $MnO_4^- \longrightarrow Mn^{2+}$ (b) $CrO_4^{2-} \longrightarrow Cr^{3+}$

(c) $MnO_4^- \longrightarrow MnO_2$ (d) $Cr_2O_7^{2-} \longrightarrow 2Cr^{3+}$

61. The oxidation number of phosphorus in $Ba(H_2PO_2)_2$ is: (IIT 1990)

(a) + 3 (b) + 2 (c) + 1 (d) −1

62. The oxidation state of the most electronegative element in the products of the reaction between BaO_2 and H_2SO_4 are: (IIT 1991)

(a) 0 and −1 (b) −1 and −2

(c) −2 and 0 (d) −2 and + 1

63. In the reaction, $4Fe + 3O_2 \longrightarrow 4Fe^{3+} + 6O^{2-}$ which of the following statements is incorrect? (MLNR 1991)

(a) It is a redox reaction

(b) Metallic iron is a reducing agent

(c) Fe^{3+} is an oxidising agent

(d) Metallic iron is reduced to Fe^{2+}

64. Which of the following halide ions is easiest to oxidise?

(a) F^- (b) Cl^- (c) Br^- (d) I^-

65. In the reaction of sodium thiosulphate with I_2 in aqueous medium the equivalent weight of sodium thiosulphate is equal to: [JEE (WB) 2010]

(a) molar mass of sodium thiosulphate

(b) the average molar masses of $Na_2S_2O_3$ and I_2

(c) half the molar mass of sodium thiosulphate

(d) twice of molar mass of sodium thiosulphate

66. The oxidation number of chlorine in HOCl is:

(a) −1 (b) zero (c) + 1 (d) + 2

67. ~~In the reaction, $Cl_2 + OH^- \longrightarrow Cl^- + ClO_4^- + H_2O$, chlorine~~ is:

(a) oxidised

(b) reduced

(c) oxidised as well as reduced

(d) neither oxidised nor reduced

68. The oxidation number of arsenic atom in H_3AsO_4 is:

(a) −1 (b) −3 (c) + 3 (d) + 5

69. In which of the following reactions, hydrogen is acting as an oxidising agent?

(a) With iodine to give hydrogen iodide

(b) With lithium to give lithium hydride

(c) With nitrogen to give ammonia

(d) With sulphur to give hydrogen sulphide

70. In acid medium, the reaction, $MnO_4^- \longrightarrow Mn^{2+}$ is:

(a) oxidation by 3 electrons (b) reduction by 3 electrons

(c) oxidation by 5 electrons (d) reduction by 5 electrons

71. For the redox reaction,

$$MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O$$

the correct coefficients of the reactants for the balanced equation are: (IIT 1992)

	MnO_4^-	$C_2O_4^{2-}$	H^+
(a)	2	5	16
(b)	16	5	2
(c)	5	16	2
(d)	2	16	5

72. The oxidation number of Pt in $[Pt(C_2H_4)Cl_3]^-$ is: (MLNR 1993)

(a) + 1 (b) + 2 (c) + 3 (d) + 4

73. Oxidation number of P in $Mg_2P_2O_7$ is:

(a) + 3 (b) + 2 (c) + 5 (d) −3

74. The oxidation number of phosphorus in PO_4^{3-}, P_4O_{10} and $P_2O_7^{4-}$ is: (CPMT 1992)

(a) + 5 (b) + 3 (c) −3 (d) + 2

75. The oxidation state of Cr in $K_2Cr_2O_7$ is: [CEE (Bihar) 1992; AFMC 1993]

(a) + 7 (b) + 6 (c) + 3 (d) + 2

76. Bromine reacts with hot aqueous alkali to give bromide and

bromate. What is the change that is brought about in oxidation state of bromine to bromate?
(a) –1 to + 5 (b) 0 to + 5
(c) –1 to + 7 (d) None of these

77. Which one of the following leads to redox reaction?
(a) $AgNO_3 + HCl$ (b) $KOH + HCl$
(c) $KI + Cl_2$ (d) $NH_3 + HCl$

78. Oxidation number of 'S' in $Na_2S_4O_6$ is: (CBSE 1993)
(a) + 0.5 (b) 2.5 (c) + 4 (d) + 6

79. Which one of the following is not a redox reaction? (AIIMS 1993)
(a) $CaCO_3 \longrightarrow CaO + CO_2$
(b) $2H_2 + O_2 \longrightarrow 2H_2O$
(c) $Na + H_2O \longrightarrow NaOH + \frac{1}{2}H_2$
(d) $MnCl_3 \longrightarrow MnCl_2 + \frac{1}{2}Cl_2$

80. The oxidation number of nitrogen in NO_3^- is:
(a) –1 (b) + 2 (c) + 3 (d) + 5

81. Oxygen has an oxidation state of + 2 in:
(a) H_2O_2 (b) OF_2 (c) SO_2 (d) H_2O

82. When iron is rusted, it is:
(a) oxidised (b) reduced
(c) evaporated (d) decomposed

83. An element, which never has a positive oxidation state in any of its compounds, is:
(a) boron (b) oxygen
(c) chlorine (d) fluorine

84. Starch iodide paper is used to test for the presence of:
(a) iodine (b) iodide ion
(c) oxidising agent (d) reducing agent

85. Which of the acid possesses oxidising, reducing and complex forming properties?
(a) HNO_3 (b) H_2SO_4 (c) HCl (d) HNO_2

86. Which substance is serving as a reducing agent in the following reaction?
$14H^+ + Cr_2O_7^{2-} + 3Ni \longrightarrow 2Cr^{3+} + 7H_2O + 3Ni^{2+}$ (CBSE 1994)
(a) H_2O (b) Ni (c) H^+ (d) $Cr_2O_7^{2-}$

87. The oxidation state of iodine in $H_4IO_6^-$ is:
(a) + 7 (b) –1 (c) + 5 (d) +1

88. Oxidation number of N in NH_4NO_3 is: [PMT (Raj.) 1993]
(a) –3 (b) + 5 (c) –3 and +5 (d) +3 and –5

89. The element, which shows minimum oxidation number in its compounds, is: [PET (Raj.) 1992]
(a) Fe (b) Mn (c) Ca (d) K

90. In which of the following compounds, the oxidation number of iodine is fractional? [PET (Raj.) 1992]
(a) IF_7 (b) I_3^- (c) IF_5 (d) IF_3

91. The missing term in the following equation is:

$$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + \ldots$$

(a) Sn^{4+} (b) Sn^{3+} (c) Sn^{2+} (d) Sn^+

92. A compound contains atoms A, B and C. The oxidation number of A is + 2, of B is + 5 and of C is –2. The possible formula of the compound is:
(a) ABC_2 (b) $B_2(AC_3)_2$
(c) $A_3(BC_4)_2$ (d) $A_3(B_4C)_2$

93. The correct set of oxidation numbers of nitrogen in ammonium nitrate is: [PET (Raj.) 2007]
(a) – 3, + 3 (b) – 1, + 1 (c) + 1, – 1 (d) – 3, + 5

94. In which of the following pairs, the oxidation states of sulphur and chromium are same? [PET (Raj.) 2007]
(a) SO_3^{2-}, CrO_4^{2-} (b) SO_3, CrO_4^{2-}
(c) SO_2, CrO_4^{2-} (d) SO_2, $Cr_2O_7^{2-}$

95. For the redox reaction, $HgCl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4$, the correct coefficients of reactants for the balanced equation are:
(a) 1, 1 (b) 1, 2
(c) 2, 2 (d) 2, 1

96. The value of n in the following equation is:

$$Cr_2O_7^{2-} + 14H^+ + nFe^{2+} \longrightarrow 2Cr^{3+} + nFe^{3+} + 7H_2O$$

[PET (MP) 2008]
(a) 2 (b) 3 (c) 7 (d) 6

97. In the reaction, $8Al + 3Fe_3O_4 \longrightarrow 4Al_2O_3 + 9Fe$, the number of electrons transferred from reductant to oxidant is:
(a) 8 (b) 4 (c) 16 (d) 24

[**Hint:** $8Al \longrightarrow 8Al^{3+} + 24e$
$9Fe^{8/3+} + 24e \longrightarrow 9Fe$]

98. Which of the following examples does not represent disproportionation?
(a) $MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$
(b) $2H_2O_2 \longrightarrow 2H_2O + O_2$
(c) $4KClO_3 \longrightarrow 3KClO_4 + KCl$
(d) $3Cl_2 + 6NaOH \longrightarrow 5NaCl + NaClO_3 + 3H_2O$

99. Why is the following reaction is not possible?

$$Cr_2O_7^{2-} + Fe^{3+} + H^+ \longrightarrow \ldots + \ldots + \ldots$$

(a) Both $Cr_2O_7^{2-}$ and Fe^{3+} are reducing agents
(b) Both $Cr_2O_7^{2-}$ and Fe^{3+} are oxidising agents
(c) $Cr_2O_7^{2-}$ is a strong oxidising agent while Fe^{3+} is a weak oxidising agent
(d) The solution is acidic in nature

100. Which one of the following statements is not correct?
(a) Oxidation number of S in $(NH_4)_2S_2O_8$ is + 6
(b) Oxidation number of Os in OsO_4 is + 8
(c) Oxidation number of S in H_2SO_5 is + 8
(d) Oxidation number of O in KO_2 is $-\frac{1}{2}$

101. The oxide which cannot act as a reducing agent, is: (CBSE 1995)
(a) SO_2 (b) NO_2
(c) CO_2 (d) ClO_2

102. Coordination number and oxidation number of Cr in $K_3Cr(C_2O_4)_3$ are respectively: (CBSE 1995)
(a) 4 and + 2 (b) 6 and + 3 (c) 3 and –3 (d) 3 and 0

103. In the following reaction,

$$4P + 3KOH + 3H_2O \longrightarrow 3KH_2PO_2 + PH_3$$

(a) P is oxidised only
(b) P is reduced only
(c) P is oxidised as well as reduced
(d) none of the above

104. Which reaction does not involve either oxidation nor reduction?
(a) $VO^{2+} \longrightarrow V_2O_3$ (b) $Na \longrightarrow Na^+$
(c) $CrO_4^{2-} \longrightarrow Cr_2O_7^{2-}$ (d) $Zn^{2+} \longrightarrow Zn$

105. In which of the following processes is nitrogen oxidised?
(a) $NH_4^+ \longrightarrow N_2$ (b) $NO_3^- \longrightarrow NO$
(c) $NO_2 \longrightarrow NO_2^-$ (d) $NO_3 \longrightarrow NH_4^+$

106. It is found that V forms a double salt isomorphous with Mohr's salt. The oxidation number of V in this compound is:
(a) + 3 (b) + 2 (c) + 4 (d) − 4

107. How many moles of electrons are involved in the reduction of one mole of MnO_4^- ion in alkaline medium to MnO_3^- ?
(a) 2 (b) 1 (c) 3 (d) 4

108. One mole of N_2H_4 loses 10 moles of electrons to form a new compound *Y*. Assuming that all nitrogen appears in the new compound, what is the oxidation number of nitrogen in *Y* (there is no change in the oxidation state of hydrogen)?
(a) −3 (b) + 3 (c) + 5 (d) + 1

109. Oxidation number of C in HNC is:
(a) + 2 (b) −3 (c) + 3 (d) zero

110. Oxidation number of Fe in $Fe_{0.94}O$ is:
(a) 200 (b) 200/94 (c) 94/200 (d) none of these

111. Oxidation number of Fe in $Na_2[Fe(CN)_5NO]$ is:
(a) + 2 (b) + 1 (c) + 3 (d) −2

112. Oxidation number of Cl in $CaOCl_2$ is:
(a) −1 and + 1 (b) + 2
(c) −2 (d) none of these

113. Equivalent weight of FeC_2O_4 in the change,
$FeC_2O_4 \longrightarrow Fe^{3+} + 2CO_2$ is:
(a) $M/3$ (b) $M/6$ (c) $M/2$ (d) $M/1$

114. Oxidation state of Fe in Fe_3O_8 is: (CBSE 1999)
(a) 3/2 (b) 4/5 (c) 5/4 (d) 8/3

115. In which of the following compounds transition metal has zero oxidation state? (CBSE 1999)
(a) CrO_5 (b) Fe_3O_4 (c) $FeSO_4$ (d) $Fe(CO)_5$

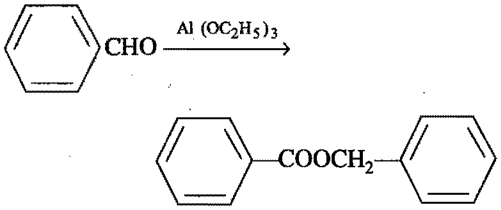
116. The oxidation number of sulphur in S_8, S_2F_2 and H_2S respectively are: (IIT 1999)
(a) 0, +1 and −2 (b) +2, +1 and −2
(c) 0, +1 and +2 (d) −2, +1 and −2

117. The reaction, $3ClO^-(aq.) \rightarrow ClO_3^-(aq.) + 2Cl^-(aq.)$ is an example of: [IIT (S) 2000]
(a) oxidation reaction
(b) reduction reaction
(c) disproportionation reaction
(d) decomposition reaction

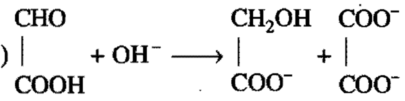
118. The oxidation state of 'S' in $H_2S_2O_8$ is: [PET (MP) 2002; RPMT 2007]
(a) +2 (b) +4 (c) +6 (d) +7

119. Which is not a disproportionation reaction?

(a) 2



(b)



$$\begin{array}{c}CHO\\|\\COOH\end{array} + OH^- \longrightarrow \begin{array}{c}CH_2OH\\|\\COO^-\end{array} + \begin{array}{c}COO^-\\|\\COO^-\end{array}$$

(c) $NaH + H_2O \longrightarrow NaOH + H_2$
(d) All of the above

120. Which of the following is a disproportionation reaction?
(a) $Cu_2O + 2H^+ \longrightarrow Cu + Cu^{2+} + H_2O$
(b) $2CrO_4^2 + 2H^+ \longrightarrow Cr_2O_7^{2-} + H_2O$
(c) $CaCO_3 + 2H^+ \longrightarrow Ca^{2+} + H_2O + CO_2$
(d) $Cr_2O_7^{2-} + 2OH^- \longrightarrow 2CrO_4^{2-} + H_2O$

121. When $KMnO_4$ acts as an oxidising agent and ultimately forms MnO_4^{2-}, MnO_2, Mn_2O_3 and Mn^{2+}, then the number of electrons transferred in each case respectively is: (AIEEE 2002)
(a) 4, 3, 1, 5 (b) 1, 5, 3, 7
(c) 1, 3, 4, 5 (d) 3, 5, 7, 1

122. Which of the following is a redox reaction: (AIEEE 2002)
(a) $NaCl + KNO_3 \longrightarrow NaNO_3 + KCl$
(b) $CaC_2O_4 + 2HCl \longrightarrow CaCl_2 + H_2C_2O_4$
(c) $Mg(OH)_2 + 2NH_4Cl \longrightarrow MgCl_2 + 2NH_4OH$
(d) $Zn + 2AgCN \longrightarrow 2Ag + Zn(CN)_2$

123. For the decolourisation of 1 mole of $KMnO_4$, the no. of moles of H_2O_2 required is: (AIIMS 2004)
(a) $\frac{1}{2}$ (b) $\frac{3}{2}$ (c) $\frac{5}{2}$ (d) $\frac{7}{2}$

124. In H_2O_2, the oxidation state of oxygen is: (CPMT 2000)
(a) −2 (b) −1 (c) 0 (d) − 4

125. The reaction of $KMnO_4$ and HCl results in:
(a) oxidation of Mn in $KMnO_4$ and production of Cl_2
(b) reduction of Mn in $KMnO_4$ and production of H_2
(c) oxidation of Mn in $KMnO_4$ and production of H_2
(d) reduction of Mn in $KMnO_4$ and production of Cl_2

126. Consider the following reaction,

$$5H_2O_2 + xClO_2 + 2OH^- \longrightarrow x\,Cl^- + y\,O_2 + 6H_2O$$

The reaction is balanced if:
(a) $x = 5, y = 2$ (b) $x = 2, y = 5$
(c) $x = 4, y = 10$ (d) $x = 5, y = 5$

127. In the chemical reaction,

$$Ag_2O + H_2O + 2e^- \longrightarrow 2Ag + 2OH^-$$

(a) water is oxidised (b) electrons are reduced
(c) silver is oxidised (d) silver is reduced
(e) hydrogen is reduced

128. The reaction, $2H_2O(l) \rightarrow 4H^+(aq.) + O_2(g) + 4e^-$ is:
(a) a redox reaction
(b) a hydrolysis reaction
(c) a solvolysis reaction
(d) an oscillatory reaction
(e) an acid catalyst reaction

129. Which of the following molecules can act as an oxidising agent as well as a reducing agent?
(a) H_2S (b) SO_3 (c) H_2O_2 (d) F_2
(e) H_2SO_4

130. Which of the following is not a reducing agent?
(a) SO_2 (b) H_2O_2 (c) CO_2 (d) NO_2

131. Equivalent mass of oxidising agent in the reaction,

$$SO_2 + 2H_2S \longrightarrow 3S + 2H_2O \quad \text{is:}$$

(a) 32 (b) 64 (c) 16 (d) 8

132. A, B and C are three elements forming part of a compound in oxidation states of +2, +5 and –2 respectively. What could be the compound?
(a) $A_2(BC)_2$ (b) $A_2(BC_4)_3$ (c) $A_3(BC_4)_2$ (d) ABC

133. Among the following, identify the species with an atom in +6 oxidation state:
(a) MnO_4^- (b) $Cr(CN)_6^{3-}$ (c) NiF_6^{2-} (d) CrO_2Cl_2

134. On reduction of $KMnO_4$ by oxalic acid in acidic medium, the oxidation number of Mn changes. What is the magnitude of this change?
(a) 7 to 2 (b) 6 to 2 (c) 5 to 2 (d) 7 to 4

135. The oxidation number of iron in Fe_3O_4 is:
(a) +2 (b) +3 (c) 8/3 (d) 2/3

136. Number of moles of $K_2Cr_2O_7$ reduced by one mole of Sn^{2+} ions is:
(a) 1/3 (b) 3 (c) 1/6 (d) 6

137. In standardization of $Na_2S_2O_3$ using $K_2Cr_2O_7$ by iodometry the equivalent weight of $K_2Cr_2O_7$ is:
(a) molecular weight /2
(b) molecular weight /6
(c) molecular weight /3
(d) same as molecular weight

138. In the balanced chemical reaction,

$$IO_3^- + aI^- + bH^+ \longrightarrow cH_2O + dI_2$$

a, b, c and d respectively correspond to: (AIIMS 2005; AMU 2009)
(a) 5, 6, 3, 3 (b) 5, 3, 6, 3 (c) 3, 5, 3, 6 (d) 5, 6, 5, 5
[Hint: The balanced equation will be:

$$IO_3^- + 5I^- + 6H^+ \longrightarrow 3I_2 + 3H_2O]$$

139. In alkaline medium ClO_2 oxidises to H_2O_2 and O_2 and itself gets reduced to Cl^-. How many moles of H_2O_2 are oxidised by 1 mole of ClO_2? (PET 2005)
(a) 1 (b) 1.5 (c) 2.5 (d) 3.5
(e) 5
[Hint: The balanced chemical equation is:

$$2ClO_2 + 5H_2O_2 + 2OH^- \longrightarrow 2Cl^- + 5O_2 + 6H_2O$$

$$2 \text{ mol } ClO_2 \equiv 5 \text{ mol } H_2O_2$$

$$\therefore \quad 1 \text{ mol } ClO_2 \equiv 2.5 \text{ mol } H_2O_2]$$

140. Oxidation number of xenon in $XeOF_2$ is: [CET (J&K) 2005]
(a) zero (b) 2
(c) 4 (d) 3

141. The oxidation number of cobalt in $K[Co(CO)_4]$ is:
(a) +1 (b) +3 (c) –1 (d) –3

142. The oxidation state of iodine in IPO_4 is: [JEE (Orissa) 2005]
(a) +1 (b) +3
(c) +5 (d) +7
[Hint: Let oxidation state of iodine be x
$x - 3 = 0, \ x = +3,$
$\because PO_4^{3-}$ has combined oxidation number –3.]

143. The oxidation state of Cr in $[Cr(NH_3)_4Cl_2]^+$ is:
(a) +3 (b) +2
(c) +1 (d) 0

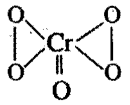
144. Nitrogen forms a variety of compounds in all oxidation states ranging from: [PMT (Himachal) 2006]
(a) –3 to +5 (b) –3 to +3
(c) –3 to +4 (d) –3 to +6

145. In alkaline medium, H_2O_2 reacts with Fe^{3+} and Mn^{2+} separately to give: [JEE (Orissa) 2006]
(a) Fe^{4+} and Mn^{4+} (b) Fe^{2+} and Mn^{2+}
(c) Fe^{2+} and Mn^{4+} (d) Fe^{4+} and Mn^{2+}

[Hint: $$2K_3[\overset{3+}{Fe}(CN)_6] + 2KOH + 2H_2O_2 \longrightarrow 2K_4[\overset{2+}{Fe}(CN)_6] + 2H_2O + O_2$$

$$\overset{2+}{Mn}SO_4 + H_2O_2 \longrightarrow \overset{4+}{Mn}O_2 + H_2SO_4]$$

146. CrO_5 has structure as shown,



The oxidation number of chromium in the above compound is: [PMT (Kerala) 2006; JEE (Orissa) 2008]
(a) +4 (b) +5 (c) +6 (d) +10 (e) 0

147. Which of the following chemical reactions depicts the oxidising behaviour of H_2SO_4? (AIEEE 2006)
(a) $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$
(b) $Ca(OH)_2 + H_2SO_4 \longrightarrow CaSO_4 + 2H_2O$
(c) $NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$
(d) $2PCl_5 + H_2SO_4 \longrightarrow 2POCl_3 + 2HCl + SO_2Cl_2$

148. The oxidation numbers of the sulphur atoms in peroxymonosulphuric acid (H_2SO_5) and peroxydisulphuric acid ($H_2S_2O_8$) are respectively : [JEE (J & K) 2009]
(a) + 8 and + 7 (b) + 3 and + 3
(c) + 6 and + 6 (d) + 4 and + 6

149. When phosphorus reacts with caustic soda, the products are PH_3 and NaH_2PO_2. This reaction is an example of: [BHU (Mains) 2007]
(a) oxidation (b) reduction
(c) disproportionation (d) none of these

150. When hydrogen peroxide is added to acidified potassium dichromate, a blue colour is produced due to formation of: [PET (Kerala) 2007]
(a) CrO_3 (b) Cr_2O_3 (c) CrO_5 (d) CrO_4^{2-}
(e) $Cr_2O_7^{2-}$

[**Hint:** $K_2Cr_2O_7 + H_2SO_4 \longrightarrow K_2SO_4 + H_2Cr_2O_7$

$[H_2O_2 \longrightarrow H_2O + (O)]4$

$H_2Cr_2O_7 + 4(O) \longrightarrow 2CrO_5 + H_2O$

$\overline{K_2Cr_2O_7 + H_2SO_4 + 4H_2O_2 \longrightarrow 2CrO_5 + K_2SO_4 + 5H_2O}$]

151. Number of moles of MnO_4^- required to oxidise one mole of ferrous oxalate completely in acid medium will be :
(a) 7.5 moles (b) 0.2 moles (c) 0.6 moles (d) 0.4 moles [CBSE-PMT (Pre) 2008]

[**Hint:** $2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + 10CO_2$

Number of moles of MnO_4^- required to oxidise one mole of oxalate $= \frac{2}{5} = 0.4$]

152. Oxidation number of iodine in IO_3^-, IO_4^-, KI and I_2 respectively are : [PMT (Kerala) 2008]
(a) −1, −1, 0, +1 (b) +3, +5, +7, 0
(c) +5, +7, −1, 0 (d) −1, −5, −1, 0
(e) −2, −5, −1, 0

153. In the redox reaction :

$$x\,KMnO_4 + y\,NH_3 \rightarrow KNO_3 + MnO_2 + KOH + H_2O$$

(DPMT 2009)

(a) $x = 4, y = 6$ (b) $x = 3, y = 8$
(c) $x = 8, y = 6$ (d) $x = 8, y = 3$

[**Hint :** Balanced equation is :

$$8KMnO_4 + 3NH_3 \longrightarrow 8MnO_2 + 3KNO_3 + 5KOH + 2H_2O\,]$$

154. The reaction :

$3ClO^- \longrightarrow ClO_3^- + 2Cl^-$ is an example of : (SCRA 2009)

(a) oxidation reaction
(b) reduction reaction
(c) disproportionation reaction
(d) decomposition reaction

155. Which of the following species will not exhibit disproportionation reaction? [AMU (Engg.) 2009]
(a) ClO^- (b) ClO_2^-
(c) ClO_3^- (d) ClO_4^-

156. Which of the following shows nitrogen with its increasing order of oxidation number ? [PMT (Kerala) 2010]
(a) $NO < N_2O < NO_2 < NO_3^- < NH_4^+$
(b) $NH_4^+ < N_2O < NO_2 < NO_3^- < NO$
(c) $NH_4^+ < N_2O < NO < NO_2 < NO_3^-$
(d) $NH_4^+ < NO < N_2O < NO_2 < NO_3^-$

157. Oxidation states of P in $H_4P_2O_5, H_4P_2O_6, H_4P_2O_7$ are respectively : (AIPMT 2010)
(a) +3, +5, +4 (b) +5, +3, +4
(c) +5, +4, +3 (d) +3, +4, +5

Assertion-Reason TYPE QUESTIONS

Set–1

The questions given below consist of an '**Assertion**' **(A)** and '**Reason**' **(R)**. Use the following keys to choose the appropriate answer:

(a) If both (A) and (R) are correct, and (R) is the correct explanation of (A).
(b) If both (A) and (R) are correct, but (R) is not the correct explanation of (A).
(c) If (A) is correct, but (R) is incorrect.
(d) If (A) is incorrect, but (R) is correct.

1. (A) In aqueous solution, SO_2 reacts with H_2S liberating sulphur.
   (R) SO_2 is an effective reducing agent.
2. (A) Fluorine acts as a stronger reducing agent than oxygen.
   (R) Fluorine is more electronegative.
3. (A) $PbCl_2$ is more stable than $PbCl_4$.
   (R) $PbCl_4$ is a powerful oxidising agent.
4. (A) Among halogens fluorine is the.
   (R) Fluorine is the most electronegative element.
5. (A) In the reaction between potassium permanganate and potassium iodide, potassium permanganate act as oxidising agent.
   (R) Oxidation state of manganese changes from +2 to +7 during the reaction.

Set–2

The questions given below consist of two statements each as '**Assertion**' **(A)** and '**Reason**' **(R)**. While answering these questions you are required to choose any one of the following four:

(a) If both (A) and (R) are true, and (R) is the correct explanation of (A).
(b) If both (A) and (R) are true, but (R) is not the correct explanation of (A).
(c) If (A) is true, but (R) is false.
(d) If (A) and (R) are both false.

1. (A) Identification of cathode and anode is done with the help of thermometer.
   (R) Higher is the value of reduction potential, greater would be its reducing power. (AIIMS 1999)
2. (A) Zinc reacts with H_2SO_4 to give H_2 gas but copper does not.
   (R) Zinc has higher reduction potential than copper.
3. (A) Absolute electrode potential can be easily measured by using vacuum tube voltmeter.
   (R) Oxidation or reduction cannot take place alone.
4. (A) Sulphur dioxide and chlorine are both bleaching agents.
   (R) Both are reducing agents. (AIIMS 1994)
5. (A) Hydrogen peroxide acts only as oxidising agent.
   ($H_2O_2 \longrightarrow H_2O + O$)
   (R) All peroxides behave as the oxidising agent only.

6. (A) $HClO_4$ is stronger acid than $HClO_3$.
   (R) Oxidation state of Cl in $HClO_4$ is +VII and in $HClO_3$; it is +V.
7. (A) Oxidation number of Ni in $Ni(CO)_4$ is taken zero.
   (R) The oxidation number of CO has been taken to be zero.
8. (A) Oxidation state of 'H' is +1 in CuH_2 and is −1 in CaH_2.
   (R) Ca is stronger electropositive than hydrogen.
9. (A) Iodine shows oxidation state of +1 and +3 in the compounds ICl and ICl_3 respectively.
   (R) Iodine coming below the halogens F, Cl and Br in the halogen group of elements in the periodic table shows a higher degree of electropositive nature. (SCRA 2007)

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS *for* IIT ASPIRANTS

1. Oxidation states of carbon atoms in diamond and graphite are:
(a) +2, +4 (b) +4, +2 (c) – 4, 4 (d) zero, zero

2. Oxidation state(s) of chlorine in $CaOCl_2$ (bleaching powder) is/are:
(a) +1 and –1 (b) +1 only
(c) –1 only (d) none of these

3. Oxidation number of sulphur in S_8, S_2F_2 and H_2S are:
(a) +2, 0, +2 (b) 0, +1, –2 (c) –2, 0, +2 (d) 0, +1, +2

4. The reaction, $H_2S + H_2O_2 \longrightarrow 2H_2O + S$, shows:
(a) acidic nature of H_2O_2 (b) reducing nature of H_2O_2
(c) oxidising action of H_2O_2 (d) alkaline nature of H_2O_2

5. For the redox reaction,
$$MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O,$$
the correct coefficients of the reactants for the balanced reaction are:

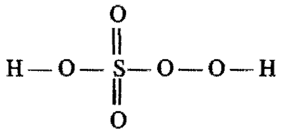
	MnO_4^-	$C_2O_4^{2-}$	H^+
(a)	2	5	16
(b)	16	3	12
(c)	15	16	12
(d)	2	16	5

6. Number of moles of $K_2Cr_2O_7$ that can be reduced by 1 mole of Sn^{2+} ions is:
(a) $\frac{1}{3}$ (b) $\frac{3}{2}$ (c) $\frac{5}{6}$ (d) $\frac{6}{5}$
[**Hint:** Balanced equation is:
$$Cr_2O_7^{2-} + 14H^+ + 3Sn^{2+} \longrightarrow 2Cr^{3+} + 7H_2O + 3Sn^{4+}$$
1 mole of $Sn^{2+} \equiv \frac{1}{3}$ mole of $Cr_2O_7^{2-}$]

7. The reaction, $3ClO^-(aq.) \longrightarrow ClO_3^-(aq.) + 2Cl^-(aq.)$, is an example of:
(a) reduction reaction
(b) oxidation reaction
(c) disproportionation reaction
(d) spallation reaction

8. The oxidation states of sulphur in Caro's and Marshall's acid are:
(a) +6, +6 (b) +4, +6 (c) +6, –6 (d) +6, +4
[**Hint:**

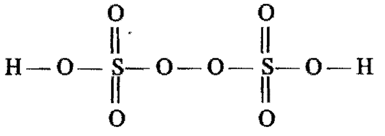
H_2SO_5 **Caro's Acid**



$$H-O-\overset{\overset{\displaystyle O}{\|}}{\underset{\underset{\displaystyle O}{\|}}{S}}-O-O-H$$

(+6) State

$H_2S_2O_8$ **Marshall's Acid**



$$H-O-\overset{\overset{\displaystyle O}{\|}}{\underset{\underset{\displaystyle O}{\|}}{S}}-O-O-\overset{\overset{\displaystyle O}{\|}}{\underset{\underset{\displaystyle O}{\|}}{S}}-O-H$$

(+6) State

Both these acids have peroxy link.]

9. Which among the following compounds have +6 state with the metal atoms?
(a) $[Fe(CN)_6]^{4-}$ (b) $[Fe(CN)_6]^{3-}$
(c) $[Cr(CN)_6]^{3-}$ (d) CrO_2Cl_2

10. The oxidation number of nitrogen atoms in NH_4NO_3 are:
(a) +3, +3 (b) +3, –3 (c) –3, +5 (d) –5, +3
[**Hint:** $NH_4NO_3 \rightleftharpoons NH_4^+ + NO_3^-$
NH_4^+ $x + 4 = +1$
$x = -3$
NO_3^- $x - 6 = -1$
$x = +5$]

11. In the chemical reaction,
$$K_2Cr_2O_7 + xH_2SO_4 + ySO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + zH_2O$$
the values of x, y and z respectively are:
(a) $x = 1, y = 3, z = 1$ (b) $x = 4, y = 1, z = 4$
(c) $x = 3, y = 2, z = 1$ (d) $x = 2, y = 2, z = 2$

12. In which of the following pairs both members contain peroxy linkage?
(a) $H_2S_2O_8, H_4P_2O_6$ (b) $H_2SO_5, H_4P_2O_7$
(c) $H_2TiO_4, H_4P_2O_8$ (d) S_3O_9, P_4O_7

13. Which of the following agents is the most oxidising?
(a) O_3 (b) $KMnO_4$ (c) H_2O_2 (d) $K_2Cr_2O_7$

14. When methane is burnt in oxygen to produce CO_2 and H_2O, the oxidation number changes by:
(a) –8 (b) zero (c) +8 (d) +4
[**Hint:** $\overset{-4}{C}H_4 + 2O_2 \longrightarrow \overset{+4-4}{C}O_2 + 2H_2O$
Oxidation number change $= +4 - (-4) = +8$]

15. Which of the following has been arranged in order of increasing oxidation number of nitrogen?
(a) $NH_3 < N_2O_5 < NO < N_2$
(b) $NO_2^+ < NO_3^- < NO_2^- < N_3^-$
(c) $NH_4^+ < N_2H_4 < NH_2OH < N_2O$
(d) $NO_2 < NaN_3 < NH_4^+ < N_2O$

16. In the ethylene molecule the two carbon atoms have the oxidation numbers:
(a) –1, –1 (b) –2, –2 (c) –1, –2 (d) +2, –2

17. In which of the following coordination compounds do the transition metals have an oxidation number of +6?
(a) $[Cr(H_2O)_4Cl_2]Cl \cdot 2H_2O$ (b) $[Fe(CO)_5]$
(c) $[(H_2O)_5Cr-O-Cr(H_2O)_5]^{4+}$
(d) $K_2[Cr(CN)_2O_2(O_2)NH_3]$

18. In the redox reaction:
$$xMnO + yPbO_2 + zHNO_3 \longrightarrow HMnO_4 + Pb(NO_3)_2 + H_2O$$
(a) $x = 2, y = 5, z = 10$ (b) $x = 2, y = 7, z = 8$
(c) $x = 2, y = 5, z = 8$ (d) $x = 2, y = 5, z = 5$

19. In the redox reaction:

$x\text{KMnO}_4 + y\text{NH}_3 \longrightarrow \text{KNO}_3 + \text{MnO}_2 + \text{KOH} + \text{H}_2\text{O}$

(a) $x = 4, y = 6$ (b) $x = 8, y = 3$
(c) $x = 8, y = 6$ (d) $x = 3, y = 8$

20. In the ionic equation:

$x\text{CH}_3\text{CH}_2\text{OH} + y\text{I}_2 + z\text{OH}^- \longrightarrow \text{CHI}_3 + \text{HCO}_2^- + \text{I}^- + \text{H}_2\text{O}$

(a) $x = 1, y = 4, z = 6$ (b) $x = 1, y = 6, z = 4$
(c) $x = 1, y = 8, z = 12$ (d) $x = 1, y = 8, z = 8$

21. The oxidation number of Cr is +6 in:

(a) FeCr_2O_4 (b) KCrO_3Cl (c) CrO_5 (d) $[\text{Cr(OH)}_4]^-$

22. The oxidation number of carbon is zero in:

(a) HCHO (b) CH_2Cl_2 (c) $\text{C}_6\text{H}_{12}\text{O}_6$ (d) $\text{C}_{12}\text{H}_{22}\text{O}_{11}$

23. Which of the following have been arranged in order of decreasing oxidation number of sulphur?

(a) $\text{H}_2\text{S}_2\text{O}_7 > \text{Na}_2\text{S}_4\text{O}_6 > \text{Na}_2\text{S}_2\text{O}_3 > \text{S}_8$
(b) $\text{SO}^{2+} > \text{SO}_4^{2-} > \text{SO}_3^{2-} > \text{HSO}_4^-$
(c) $\text{H}_2\text{SO}_5 > \text{H}_2\text{SO}_3 > \text{SCl}_2 > \text{H}_2\text{S}$
(d) $\text{H}_2\text{SO}_4 > \text{SO}_2 > \text{H}_2\text{S} > \text{H}_2\text{S}_2\text{O}_8$

24. Oxidation number of carboxylic carbon atom in CH_3COOH is:

(a) +2 (b) +4 (c) +1 (d) +3

25. Which among the following are autoredox reactions?

(a) $\text{P}_4 + \text{OH}^- \longrightarrow \text{H}_2\text{PO}_4^- + \text{PH}_3$
(b) $\text{S}_2\text{O}_3^{2-} \longrightarrow \text{SO}_4^{2-} + \text{S}$
(c) $\text{H}_2\text{O}_2 \longrightarrow \text{H}_2\text{O} + \text{O}_2$
(d) $\text{AgCl} + \text{NH}_3 \longrightarrow [\text{Ag(NH}_3)_2]\text{Cl}$

26. Oxidation state of nitrogen is incorrectly given for: **[PMT (Pb.) 2006]**

Compound	Oxidation state
(a) $[\text{Co(NH}_3)_5\text{Cl}]\text{Cl}_2$	−3
(b) NH_2OH	−1
(c) $(\text{N}_2\text{H}_5)_2\text{SO}_4$	+2
(d) Mg_3N_2	−3

27. Oxidation number of C in HNC is:

(a) +2 (b) −3
(c) +3 (d) zero

[**Hint:** HNC
$+1 - 3 + x = 0$
$x = +2$]

28. Which of the following groups of molecules act both as oxidising agent as well as reducing agent?

(a) $\text{KMnO}_4, \text{O}_3, \text{SO}_3$ (b) $\text{HClO}_4, \text{HNO}_2, \text{H}_2\text{O}_2$
(c) $\text{HNO}_2, \text{SO}_2, \text{H}_2\text{O}_2$ (d) $\text{HNO}_3, \text{SO}_2, \text{H}_2\text{SO}_4$

29. Match the List-I with List-II and select the correct answer from the given Codes:

List-I (Compound)	List-II (Oxidation state of nitrogen)
A. N_2O_5	(i) −2
B. NaN_3	(ii) +5
C. NO	(iii) −1/3
D. N_2H_4	(iv) +2

Codes:	A	B	C	D
(a)	(ii)	(iii)	(iv)	(i)
(b)	(i)	(ii)	(iii)	(iv)
(c)	(iv)	(i)	(ii)	(iii)
(d)	(iii)	(i)	(iv)	(ii)

30. The oxidation state of molybdenum in its oxo complex species $[\text{Mo}_2\text{O}_4(\text{C}_2\text{H}_4)_2(\text{H}_2\text{O}_2)]^{2-}$ is:

(a) 2 (b) 3 (c) 4 (d) 5

31. KMnO_4 is a strong oxidising agent in acid medium. To provide acid medium, H_2SO_4 is used instead of HCl. This is because: **[PMT (Kerala) 2007]**

(a) H_2SO_4 is a stronger acid than HCl
(b) HCl is oxidised by KMnO_4 to Cl_2
(c) H_2SO_4 is a dibasic acid
(d) rate is faster in the presence of H_2SO_4
(e) only H_2SO_4 is completely ionized

32. Which of the following oxides cannot work as a reducing agent? **[PET (Raj.) 2006]**

(a) CO_2 (b) NO_2 (c) SO_2 (d) ClO_2

33. The coordination number and oxidation state of Cr in $\text{K}_3[\text{Cr(C}_2\text{O}_4)_3]$ are respectively: **[PET (Raj.) 2006]**

(a) 3 and +3 (b) 2 and 0
(c) 6 and +3 (d) 4 and +2

34. The reaction, $\text{P}_4 + 3\text{NaOH} + 3\text{H}_2\text{O} \longrightarrow 3\text{NaH}_2\text{PO}_2 + \text{PH}_3$ is an example of : **[JEE (Orissa) 2008]**

(a) disproportionation reaction
(b) neutralisation reaction
(c) double decomposition reaction
(d) pyrolytic reaction

35. Balance the following equation and choose the correct value of sum of coefficients of the products :

$\text{CS}_2 + \text{Cl}_2 \longrightarrow \text{CCl}_4 + \text{S}_2\text{Cl}_2$

(a) 5 (b) 3 (c) 6 (d) 2

36. 6×10^{-3} mole $\text{K}_2\text{Cr}_2\text{O}_7$ reacts completely with 9×10^{-3} mole X^{n+} to give $X\text{O}_3^-$ and Cr^{3+}. The value of 'n' is :

(a) 1 (b) 2 (c) 3 (d) 5

37. Hydrazine reacts with KIO_3 in presence of HCl as;

$\text{N}_2\text{H}_4 + \text{IO}_3^- + 2\text{H}^+ + \text{Cl}^- \longrightarrow \text{ICl} + \text{N}_2 + 3\text{H}_2\text{O}$

The equivalent masses of N_2H_4 and KIO_3 respectively are :

(a) 8, 87 (b) 8, 35.6 (c) 16, 53.5 (d) 8, 53.5

Answers

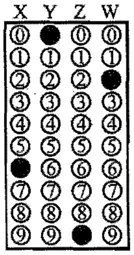
Integer Answer TYPE QUESTIONS

This section contains 9 questions. The answer to each of the questions is a single digit integer, ranging from 0 to 9. If the correct answers to question numbers X, Y, Z and W (say) are 6, 0, 9 and 2 respectively, then the correct darkening of bubbles will look like the given figure :



1. The oxidation number of Mn in the product of alkaline oxidative fusion of MnO_2 is: **(IIT 2009)**

   [**Hint :** $4KOH + 2MnO_2 + O_2 \longrightarrow 2\overset{+2}{K_2}\overset{+6}{Mn}\overset{-8}{O_4} + 2H_2O$]

2. How many peroxy links are there in CrO_5?

   [**Hint :** Structure of CrO_5 is :

   There are two peroxy links in this molecule.]

3. How many moles of electrons are involved in the conversion of 1 mol $Cr_2O_7^{2-}$ into Cr^{3+} ion?

   $$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$

4. In the following reaction, hydrazine is oxidised to N_2

   $$N_2H_4 + OH^- \longrightarrow N_2 + H_2O + e^-$$

   The equivalent mass of N_2H_4 (hydrazine) is:

5. Nitrobenzene ($C_6H_5NO_2$) can be reduced to aniline ($C_6H_5NH_2$) by electrolytic reduction; the equivalent mass of nitrobenzene will be equal to $\left(\frac{\text{molecular mass}}{n}\right)$. The value of n is:

   [**Hint :** $\underset{\text{Nitrobenzene}}{C_6H_5NO_2} + 6[H] \longrightarrow \underset{\text{Aniline}}{C_6H_5NH_2} + 2H_2O$]

6. How many sulphur atoms in $Na_2S_4O_6$ have zero oxidation state?

7. 6×10^{-3} mole $K_2Cr_2O_7$ reacts completely with 9×10^{-3} mole x^{n+} to give XO_3^- and Cr^{3+}. The value of n is:

8. The sum of oxidation number of nitrogen in NH_4NO_3 is :

9. The value of n in the molecular formula $Be_nAl_2Si_6O_{18}$ is: **(IIT 2010)**

   [**Hint :** $Si_6O_{18}^{-12}$ is a cyclic silicate. The value of n will be '3' to balance the charge $Be_nAl_2Si_6O_{18}$

   $$2n + 6 - 12 = 0$$
   $$n = 3$$]

LINKED COMPREHENSION TYPE QUESTIONS

Passage 1

Valency and oxidation number are different for an element. Valency of carbon is generally 4, however, the oxidation state may be $-4, -2, 0, +2, -1$, etc. In the compounds containing carbon, hydrogen and oxygen, the oxidation number of carbon can be calculated as:

$$\text{Oxidation number of carbon} = \frac{2n_O - n_H}{n_C}$$

where, n_H, n_O and n_C are number of respective atoms.

Answer the following questions:

1. Which of the following compounds have zero oxidation state at carbon?
   (a) $C_6H_{12}O_6$ (b) HCOOH (c) HCHO (d) CH_4
2. Which of the following oxides of carbon has fractional oxidation state?
   (a) Carbon monoxide (b) Carbon dioxide
   (c) Carbon suboxide (d) All of these
3. Which of the following compounds of carbon has highest oxidation state?
   (a) CH_4 (b) CH_3OH (c) CH_2O (d) HCOOH
4. Oxidation state of carbon in diamond is:
   (a) zero (b) +1 (c) −1 (d) +2
5. In which of the following compounds, the valency of carbon is two?
   (a) Carbenes (b) Allenes (c) Alkenes (d) Ketenes

Passage 2

Oxidation and reduction process involves the transaction of electrons. Loss of electrons is oxidation and the gain of electrons is reduction. It is thus obvious that in a redox reaction, the oxidant is reduced by accepting the electrons and the reductant is oxidised by losing electrons. The reactions in which a species disproportionates into two oxidation states (lower and higher) are called disproportionation reactions. In electrochemical cells, redox reaction is involved, i.e., oxidation takes place at anode and reduction at cathode.

Answer the following questions:

1. The reaction,
   $$Cl_2 \longrightarrow Cl^- + ClO_3^-$$
   is:
   (a) oxidation
   (b) reduction
   (c) disproportionation
   (d) neither oxidation nor reduction
2. Select the correct statement:
   (a) oxidation takes place at anode in electrochemical cell
   (b) reduction takes place at cathode in electrolytic cell
   (c) oxidation takes place at cathode in electrolytic cell
   (d) all are correct
3. In the reaction:
   $$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$$
   (a) I_2 is a reducing agent (b) I_2 is an oxidising agent
   (c) $S_2O_3^{2-}$ is a reducing agent (d) $S_2O_3^{2-}$ is an oxidising agent
4. Determine the change in oxidation number of sulphur in H_2S and SO_2 respectively in the following reaction:
   $$2H_2S + SO_2 \longrightarrow 2H_2O + 3S$$
   (a) 0, +2 (b) +2, −4 (c) −2, +2 (d) +4, 0
5. Which of the following reactions is/are correctly indicated?

   Oxidant **Reductant**

   (a) $HNO_3 + Cu \longrightarrow Cu^{2+} + NO_2$
   (b) $2Zn + O_2 \longrightarrow ZnO$
   (c) $Cl_2 + 2Br^- \longrightarrow 2Cl^- + Br_2$
   (d) $4Cl_2 + CH_4 \longrightarrow CCl_4 + 4HCl$

Passage 3

Redox reactions are of three types:

(*i*) *Intermolecular redox reactions,*
(*ii*) *Intramolecular redox reactions,*
(*iii*) *Auto redox reactions*
OR
Disproportionation reactions.

Redox reactions are divided into two main types:

(*i*) *Chemical redox reactions,*
(*ii*) *Electrochemical redox reactions which either produce or consume electricity.*

Oxidation and reduction process takes place in a reaction simultaneously.

Answer the following questions:

1. Which of the following is a redox reaction?
   (a) $NaCl + KNO_3 \longrightarrow NaNO_3 + KCl$
   (b) $CaC_2O_4 + 2HCl \longrightarrow CaCl_2 + H_2C_2O_4$
   (c) $Mg(OH)_2 + 2NH_4Cl \longrightarrow MgCl_2 + 2NH_4OH$
   (d) $Zn + 2AgCN \longrightarrow 2Ag + Zn(CN)_2$
2. Select the intramolecular redox reaction(s) among the following:
   (a) $2KClO_3 \longrightarrow 2KCl + 3O_2$
   (b) $(NH_4)_2Cr_2O_7 \longrightarrow N_2 + Cr_2O_3 + 4H_2O$
   (c) $Cl_2 \longrightarrow Cl^- + ClO_3^-$
   (d) $NH_4NO_2 \longrightarrow N_2 + 2H_2O$
3. In which of the following reactions, H_2O_2 acts as reducing agent?
   (a) $Cl_2 + H_2O_2 \longrightarrow 2HCl + O_2$
   (b) $H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$
   (c) $HCHO + H_2O_2 \longrightarrow HCOOH + H_2O$
   (d) $PbO_2 + H_2O_2 \longrightarrow PbO + H_2O + O_2$
4. Which among the following acts as oxidising as well as reducing agent?
   (a) HNO_2 (b) HNO_3 (c) H_2SO_4 (d) $KMnO_4$
5. The value of x in the following reaction,
   $$MnO_4^- + 8H^+ + xe \longrightarrow Mn^{2+} + 4H_2O \text{ is:}$$
   (a) 5 (b) 10 (c) 2 (d) 3

[illegible]

Passage 1.	1. (a, c)	2. (c)	3. (d)	4. (a)	5. (a)
Passage 2.	1. (c)	2. (a, b)	3. (b, c)	4. (b)	5. (a, c, d)
Passage 3.	1. (d)	2. (a, b, d)	3. (a, b, d)	4. (a)	5. (a)

SELF ASSESSMENT

ASSIGNMENT NO. 11

SECTION-I

Straight Objective Type Questions

This section contains 8 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. In the reaction:

$$S_2O_8^{2-} + 2I^- \longrightarrow 2SO_4^{2-} + I_2 \quad \textbf{[PET (MP) 2007]}$$

(a) oxidation of iodide into iodine takes place
(b) reduction of iodine into iodide takes place
(c) both oxidation and reduction of iodine takes place
(d) none of the above

2. The oxidation state of chromium in chromium trioxide is: **[CET (J&K) 2007]**

(a) + 3 (b) + 4 (c) + 5 (d) + 6

3. For the reaction between $KMnO_4$ and H_2O_2, the number of electrons transferred per mol of H_2O_2 is:

(a) one (b) two
(c) three (d) four

4. In the ionic equation,

$$BiO_3^- + 6H^+ + xe^- \longrightarrow Bi^{3+} + 3H_2O$$

the value of x is:

(a) 6 (b) 2
(c) 4 (d) 3

5. In $[Cr(O_2)(NH_3)_4H_2O]Cl_2$, oxidation number of Cr is + 3, then oxygen will be in the form:

(a) dioxo (b) peroxo
(c) superoxo (d) oxo

6. In the reaction, $CrO_5 + SnCl_2 \longrightarrow CrO_4^{2-} + SnCl_4$, the element undergoing oxidation and reduction respectively are:

(a) Cr, Sn (b) Sn, Cr
(c) Sn, O (d) Cl, C

7. Equivalent mass of $KMnO_4$ in acidic, basic and neutral are in the ratio of:

(a) 3 : 5 : 15 (b) 5 : 3 : 1
(c) 5 : 1 : 3 (d) 3 : 15 : 5

8. A compound of Xe and F is found to have 53.5% Xe. What is the oxidation number of Xe in this compound?

(a) – 4 (b) 0
(c) + 4 (d) + 6

SECTION-II

Multiple Answers Type Objective Questions

9. Peroxide ions are present in:

(a) H_2O_2 (b) BaO_2
(c) OF_2 (d) $H_2S_2O_8$

10. The metals undergoing disproportionation are:

(a) Sn (b) Na (c) Cu (d) Ca

11. The non-metals undergoing disproportionation are:

(a) P_4 (b) Cl_2 (c) I_2 (d) F

12. Which of the following can act as oxidising as well as reducing agent?

(a) O_3 (b) HNO_3 (c) SO_2 (d) H_2O_2

13. When Cl_2 reacts with aqueous NaOH in cold condition then oxidation number of chlorine changes from 0 to:

(a) – 1 (b) + 1 (c) – 2 (d) + 2

14. Select those species that can function both as oxidising and also as reducing agent: **[BHU (Mains) 2010]**

(a) KI (b) KI_3 (c) I_2 (d) H_2O_2

15. The species that contain peroxide ions are: **[BHU (Mains) 2010]**

(a) PbO_2 (b) H_2O_2 (c) SrO_2 (d) BaO_2

SECTION-III

Assertion-Reason Type Questions

This section contains 4 questions. Each question contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; statement-2 is true; statement-2 is a correct explanation for statement-1.
(b) Statement-1 is true; statement-2 is true; statement-2 is not a correct explanation for statement-1.
(c) Statement-1 is true; statement-2 is false.
(d) Statement-1 is false; statement-2 is true.

16. **Statement-1:** Spectator ions are the species that are present in the solution but do not take part in the reaction.

Because

Statement-2: The phenomena of formation of H_2O_2 by the oxidation of H_2O is known as auto-oxidation.
[**Hint:** $Zn + 2H^+ + 2Cl^- \longrightarrow Zn^{2+} + 2Cl^- + H_2$. Here, Cl^- ion is spectator ion.]

17. Statement-1: Oxidation number of carbon in HCN is + 2.

Because

Statement-2: Carbon always shows an oxidation state of + 4.

18. Statement-1: Bromide ion acts as a reducing agent in the reaction,

$$2MnO_4^- + Br^- + H_2O \longrightarrow 2MnO_2 + BrO_3^- + 2OH^-.$$

Because

Statement-2: Oxidation number of bromine increases from – 1 to + 5.

19. Statement-1: Oxidation number of carbon in HCHO is zero.

Because

Statement-2: HCHO is a covalent organic compound.

SECTION-IV

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

	p	q	r	s
a	●	ⓠ	ⓡ	●
b	ⓟ	●	●	ⓢ
c	●	●	ⓡ	ⓢ
d	ⓟ	ⓠ	ⓡ	●

If the correct matches are (a-p,s); (b-q,r); (c-p,q) and (d-s); then correct bubbled 4 × 4 matrix should be as follows:

20. Match the Column-I with Column-II:

Column-I (Chemical species)	**Column-II (Oxidation number of sulphur)**
(a) S	(p) + 6
(b) H_2S	(q) + 1
(c) S_2Cl_2	(r) 0
(d) $H_2S_2O_8$	(s) – 2

21. Match the Column-I with Column-II:

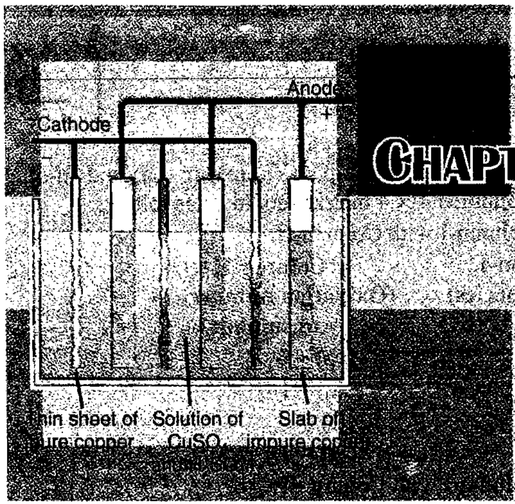
Column-I (Compound)	**Column-II (Oxidation state of sulphur)**
(a) Sulphurus acid (H_2SO_3)	(p) + 5
(b) Peroxy mono sulphuric acid (H_2SO_5)	(q) + 3
(c) Dithionic acid ($H_2S_2O_6$)	(r) + 6
(d) Dithionous acid ($H_2S_2O_4$)	(s) + 4

22. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) $O_2^- \longrightarrow O_2 + O_2^{2-}$	(p) Redox reaction
(b) $CrO_4^{2-} + H^+ \longrightarrow$	(q) One of the products has trigonal planar structure
(c) $MnO_4^- + NO_2^- + H^+ \longrightarrow$	(r) dimeric bridged tetrahedral metal ion
(d) $NO_3^- + H_2SO_4 + Fe^{2+} \rightarrow$	(s) disproportionation

Answers

1. (a) **2.** (d) **3.** (c) **4.** (b) **5.** (c) **6.** (c) **7.** (d) **8.** (d)
9. (a, b, d) **10.** (a, c) **11.** (a, b, c) **12.** (c, d) **13.** (a, b) **14.** (b, c, d) **15.** (b, c, d) **16.** (b)
17. (c) **18.** (a) **19.** (b) **20.** (a-r) (b-s) (c-q) (d-p) **21.** (a-s) (b-r) (c-p) (d-q)
22. (a-p,s) (b-r) (c-p,q) (d-p)



CHAPTER 12

ELECTROCHEMISTRY

SECTION I : ELECTROLYTES AND ELECTROLYSIS

12.1 INTRODUCTION

Electrochemistry deals with the interactions of electrical energy with chemical species. It is broadly divided into two categories, namely (i) production of chemical change by electrical energy (phenomenon of electrolysis) and (ii) conversion of chemical energy into electrical energy, *i.e.*, generation of electricity by spontaneous redox reactions. In this chapter both of these aspects will be described. All electrochemical reactions involve transfer of electrons and are, therefore, oxidation-reduction (redox) reactions.

Substances which allow the passage of electric current through them are called **electrical conductors** or simply conductors. Those which do not allow the flow of electric current through them are termed **insulators.** Electrical conductors are of two types:

(i) Metallic or electronic conductors: Conductors which transfer electric current by transfer of electrons, without transfer of any matter, are known as **metallic or electronic conductors.** Metals such as copper, silver, aluminium, etc., non-metals like carbon (graphite—an allotropic form of carbon) and various alloys belong to this class. These materials contain electrons which are relatively free to move. The passage of current through these materials has no observable effect other than a rise in their temperature.

(ii) Electrolytic conductors: Conductors like aqueous solutions of acids, bases and salts in which the flow of electric current is accompanied by chemical decomposition are known as **electrolytic conductors.** The substances whose aqueous solutions allow the passage of electric current and are chemically decomposed, are termed **electrolytes.**

The substances whose aqueous solutions do not conduct electric current are called **non-electrolytes.** Solutions of cane sugar, glycerine, alcohol, etc., are examples of non-electrolytes.

In order to pass the current through an electrolytic conductor (aqueous solution or fused electrolyte), two rods or plates (metallic conductors) are always needed which are connected with the terminals of a battery. These rods or plates are known as **electrodes.** The electrode through which the current enters the electrolytic solution is called the **anode** (positive electrode) while the electrode through which the current leaves the electrolytic solution is known as **cathode** (negative electrode). The electrolytic solution conducts electricity not by virtue of flow of electrons as in metallic conductors but as a result of movement of charged particles called **ions** towards the respective oppositely charged electrodes. The ions which carry positive charge and move towards cathode are termed **cations** while ions carrying negative charge which move towards anode are called **anions.** When these ions reach the boundary between a metallic and an electrolytic conductor, electrons are being either attached to or removed from the ions. Removal of electrons is termed **oxidation** (de-electronation) which occurs at anode while addition of electrons is called **reduction** (electronation) that takes place at cathode. Hence, flow of electrons through the outer circuit from anode to cathode across the boundary is accompanied by oxidation and reduction.

Distinction between metallic and electrolytic conduction

Metallic conduction	Electrolytic conduction
1. Electric current flows by movement of electrons.	Electric current flows by movement of ions.
2. No chemical change occurs.	Ions are oxidised or reduced at the electrodes.
3. It does not involve the transfer of any matter.	It involves transfer of matter in the form of ions.
4. Ohm's law is followed.	Ohm's law is followed.
5. Resistance increases with increase of temperature.	Resistance decreases with increase of temperature.
6. Faraday's law is not followed.	Faraday's law is followed.

The process of chemical decomposition of an electrolyte by passage of electric current through its solution is called electrolysis.

Or

Chemical change (oxidation and reduction) occurring at electrodes when electric current is passed through electrolytic solution is called electrolysis.

Molecules of an electrolyte when dissolved in water split up into ions, *i.e.*, into cations and anions. On passing current, these ions move towards oppositely charged electrodes. On reaching the electrodes the ions lose their charge either by accepting electrons or losing electrons and thereby deposited at the respective electrodes or undergo a secondary change. For example, when electric current is passed through a solution of hydrochloric acid, the H^+ ions move towards cathode and Cl^- ions move towards anode.

$$HCl \rightleftharpoons H^+ + Cl^-$$

Cathode	Anode
$H^+ + e^- \longrightarrow H$	$Cl^- \longrightarrow Cl + e^-$
$2H \longrightarrow H_2$	$2Cl \longrightarrow Cl_2$
(Reduction)	(Oxidation)

The decomposition of HCl into H_2 and Cl_2 as a result of passage of current is termed electrolysis of HCl. It is, thus, a process in which electric current brings the chemical change.

The device in which electrolysis (chemical reaction involving oxidation and reduction) is carried out by using electricity or in which conversion of electrical energy into chemical change is done is known as **electrolytic cell.** An electrolytic cell consists of a vessel for the electrolytic solution or fused electrolyte and two metallic electrodes immersed in the reaction material which are connected to a source of electric current. The metallic electrodes which do not react with ions or final products are called **inert electrodes.** Inert electrodes are usually used in an electrolytic cell.

12.2 PREFERENTIAL DISCHARGE THEORY

If an electrolytic solution consists of more than two ions and the electrolysis is done, it is observed that all the ions are not discharged at the electrodes simultaneously but certain ions are liberated at the electrodes in preference to others. This is explained by **preferential discharge theory.** It states that if more than one type of ions are attracted towards a particular electrode, then the one discharged is the ion which requires least energy. The potential at which the ion is discharged or deposited on the appropriate electrode is termed the discharge or deposition potential. The values of discharge potential are different for different ions. For example, the discharge potential of H^+ ions is lower than Na^+ ions when platinum or most of the other metals* are used as cathodes. Similarly, discharge potential of Cl^- ions is lower than that of OH^- ions. This can be explained by some examples given below:

(i) Electrolysis of sodium chloride solution

The solution of sodium chloride besides Na^+ and Cl^- ions possesses H^+ and OH^- ions due to ionisation of water. However, the number is small as water is a weak electrolyte. When potential difference is established across the two electrodes, Na^+ and H^+ ions move towards cathode and Cl^- and OH^- ions move towards anode. At cathode H^+ ions are discharged in preference to Na^+ ions as the discharge potential of H^+ ions is lower than Na^+ ions. Similarly at anode, Cl^- ions are discharged in preference to OH^- ions.

$$NaCl \rightleftharpoons Na^+ + Cl^-$$
$$H_2O \rightleftharpoons H^+ + OH^-$$

At cathode	At anode
$H^+ + e^- \longrightarrow H$	$Cl^- \longrightarrow Cl + e^-$
$2H \longrightarrow H_2$	$2Cl \longrightarrow Cl_2$

Thus, Na^+ and OH^- ions remain in solution and the solution when evaporated yields crystals of sodium hydroxide.

(ii) Electrolysis of copper sulphate solution using platinum electrodes

$$CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}$$
$$H_2O \rightleftharpoons H^+ + OH^-$$

At cathode	At anode
$Cu^{2+} + 2e^- \longrightarrow Cu$	$2OH^- \longrightarrow H_2O + O + 2e^-$
	$O + O \longrightarrow O_2$

Copper is discharged at cathode as Cu^{2+} ions have lower discharge potential than H^+ ions. OH^- ions are discharged at anode as these have lower discharge potential than SO_4^{2-} ions. Thus, copper is deposited at cathode and oxygen gas is evolved at anode.

(iii) Electrolysis of sodium sulphate solution using inert electrodes

$$Na_2SO_4 \rightleftharpoons 2Na^+ + SO_4^{2-}$$
$$H_2O \rightleftharpoons H^+ + OH^-$$

At cathode	At anode
$H^+ + e^- \longrightarrow H$	$2OH^- \longrightarrow H_2O + O + 2e^-$
$2H \longrightarrow H_2$	$O + O \longrightarrow O_2$

Hydrogen is discharged at cathode as H^+ ions have lower discharge potential than Na^+ ions. OH^- ions are discharged at anode as these have lower discharge potential than SO_4^{2-} ions. Thus, hydrogen is evolved at cathode and oxygen is evolved at anode, *i.e.*, the net reaction describes the electrolysis of water. The ions of Na_2SO_4 conduct the current through the solution and take no part in the overall chemical reaction.

---

*When Hg is used as a cathode, Na^+ ions have lower discharge potential than H^+ ions.

The decreasing order of discharge potential or the increasing order of deposition of some of the ions is given below:

For cations: $K^+, Na^+, Ca^{2+}, Mg^{2+}, Al^{3+}, Zn^{2+}, H^+, Cu^{2+}, Hg^{2+}, Ag^+$

For anions: $SO_4^{2-}, NO_3^-, OH^-, Cl^-, Br^-, I^-$

(iv) Electrolysis of copper sulphate solution using copper electrodes

$$CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}$$

At cathode, copper is deposited.

$$Cu^{2+} + 2e^- \longrightarrow Cu$$

At anode, the copper of the electrode is oxidised to Cu^{2+} ions or SO_4^{2-} ions dissolve equivalent amount of copper of the anode.

$$Cu \longrightarrow Cu^{2+} + 2e^-$$

or $$Cu + SO_4^{2-} \longrightarrow CuSO_4 + 2e^-$$

Thus, during electrolysis, copper is transferred from anode to cathode.

(v) Electrolysis of silver nitrate solution using silver electrodes

$$AgNO_3 \rightleftharpoons Ag^+ + NO_3^-$$

At cathode, silver is deposited.

$$Ag^+ + e^- \longrightarrow Ag$$

At anode, the silver of the electrode is oxidised to Ag^+ ions which go into the solution or NO_3^- ions dissolve equivalent amount of silver of the electrode.

$$Ag \longrightarrow Ag^+ + e^-$$

$$Ag + NO_3^- \longrightarrow AgNO_3 + e^-$$

Table 12.1 Some More Examples of Electrolysis

Electrolyte	Electrode	Cathodic reaction	Anodic reaction
Aqueous acidified $CuCl_2$ solution	Pt	$Cu^{2+} + 2e^- \longrightarrow Cu$	$2Cl^- \longrightarrow Cl_2 + 2e^-$
Molten $PbBr_2$	Pt	$Pb^{2+} + 2e^- \longrightarrow Pb$	$2Br^- \longrightarrow Br_2 + 2e^-$
Sodium chloride solution	Hg	$2Na^+ + 2e^- \longrightarrow 2Na$	$2Cl^- \longrightarrow Cl_2 + 2e^-$
Silver nitrate solution	Pt	$Ag^+ + e^- \longrightarrow Ag$	$2OH^- \longrightarrow \frac{1}{2}O_2 + H_2O + 2e^-$
Sodium nitrate solution	Pt	$2H^+ + 2e^- \longrightarrow H_2$	$2OH^- \longrightarrow \frac{1}{2}O_2 + H_2O + 2e^-$

12.3 FARADAY'S LAWS OF ELECTROLYSIS

The relationship between the quantity of electric charge passed through an electrolyte and the amount of the substance deposited at the electrodes was presented by Faraday in 1834, in the form of laws of electrolysis.

(i) Faraday's first law

When an electric current is passed through an electrolyte, the amount of substance deposited is proportional to the quantity of electric charge passed through the electrolyte.

If W be the mass of the substance deposited by passing Q coulomb of charge, then according to the law, we have the relation:

$$W \propto Q$$

A coulomb is the quantity of charge when a current of one ampere is passed for one second. Thus, amount of charge in coulombs,

$$Q = \text{current in amperes} \times \text{time in seconds}$$
$$= I \times t$$

So, $$W \propto I \times t$$

or $$W = Z \times I \times t$$

where, Z is a constant, known as **electrochemical equivalent,** and is characteristic of the substance deposited.

When a current of one ampere is passed for one second, *i.e.*, one coulomb $(Q = 1)$, then

$$W = Z$$

Thus, **electrochemical equivalent** can be defined as the **mass of the substance deposited by one coulomb of charge or by one ampere of current passed for one second.** For example, when a charge of one coulomb is passed through silver nitrate solution, the amount of silver deposited is 0.001118 g. This is the value of electrochemical equivalent of silver.

(ii) Faraday's second law

When the same quantity of charge is passed through different electrolytes, then the masses of different substances deposited at the respective electrodes will be in the ratio of their equivalent masses.

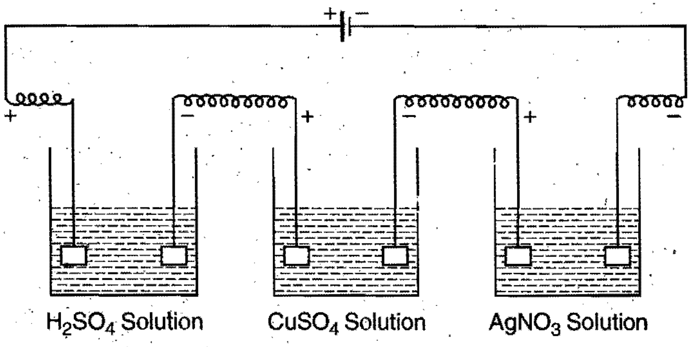


Fig. 12.1 Voltameters arranged in series

The law can be illustrated by passing same quantity of electric current through three voltameters containing solutions of H_2SO_4, $CuSO_4$ and $AgNO_3$ respectively as shown in Fig. 12.1. In the first voltameter, hydrogen and oxygen will be liberated; in the second, copper will be deposited and in the third, silver will be deposited.

$$\frac{\text{Mass of hydrogen}}{\text{Mass of copper}} = \frac{\text{Equivalent mass of hydrogen}}{\text{Equivalent mass of copper}}$$

or $$\frac{\text{Mass of copper}}{\text{Mass of silver}} = \frac{\text{Equivalent mass of copper}}{\text{Equivalent mass of silver}}$$

or $$\frac{\text{Mass of silver}}{\text{Mass of hydrogen}} = \frac{\text{Equivalent mass of silver}}{\text{Equivalent mass of hydrogen}}$$

It is observed that by passing one coulomb of electric charge,

Hydrogen evolved = 0.00001036 g,

Copper deposited = 0.0003292 g,

and Silver deposited = 0.001118 g

These masses are in the ratio of their equivalent masses. From these masses, the amount of electric charge required to deposit one equivalent of hydrogen or copper or silver can be calculated.

$$\text{For hydrogen} = \frac{1}{0.00001036} \approx 96500 \text{ coulomb}$$

$$\text{For copper} = \frac{31.78}{0.0003292} \approx 96500 \text{ coulomb}$$

$$\text{For silver} = \frac{107.88}{0.001118} \approx 96500 \text{ coulomb}$$

This follows that 96500 coulomb of electric charge will deposit one g-equivalent of any substance. 96500 coulomb is termed as one **Faraday** and is denoted by F.

Again according to first law,

$$W = Z \times Q$$

When, $Q = 96500$ coulomb, W becomes gram equivalent mass (E).

Thus, $$E = Z \times 96500$$

or $$Z = \frac{E}{96500}$$

$$\frac{Z_1}{Z_2} = \frac{E_1}{E_2}$$

Fundamental unit of charge: As one g-equivalent of an ion is liberated by 96500 coulomb, it follows that charge carried by one g-equivalent of an ion is 96500 coulomb. If the valency of an ion is 'n', then one mole of these ions will carry a charge of nF coulomb. One g-mole of an ion contains 6.02×10^{23} ions. Then,

$$\text{The charge carried by an ion} = \frac{nF}{6.02 \times 10^{23}} \text{ coulomb}$$

For $n = 1$,

$$\text{The fundamental unit of charge} = \frac{F}{6.02 \times 10^{23}}$$

i.e., $$\frac{96500}{6.02 \times 10^{23}} \approx 1.6 \times 10^{-19} \text{ coulomb}$$

or $$1 \text{ coulomb} {}^{*}= 6.24 \times 10^{18} \text{ electrons}$$

The rate of flowing of electric charge through a conductor is called the electric current.

$$\text{Electric current} = \frac{\text{Electric charge}}{\text{Time}}$$

$$1 \text{ ampere} = \frac{1 \text{ coulomb}}{1 \text{ second}}$$

Volt is a unit of electrical potential difference. It is defined as potential energy per unit charge.

$$1 \text{ volt} = \frac{1 \text{ joule}}{1 \text{ coulomb}} = \frac{1 \text{ newton} \times 1 \text{ metre}}{1 \text{ ampere} \times 1 \text{ second}}$$

$$\begin{aligned} \text{Electrical energy} &= \text{Potential difference} \times \text{Quantity of charge} \\ &= V \times Q \\ &= V \times I \times t \qquad (I = \text{ampere}; t = \text{second}) \\ &= \text{watt-second} \end{aligned}$$

Faraday's Law for Gaseous Electrolytic Product

We know that, $$W = ZQ$$
$$= ZIt$$
$$W = \frac{ItE}{96500} \qquad \text{... (i)}$$

where, $$Z = E/96500$$

Equation (i) is used to calculate the mass of solid substance dissolved or deposited at an electrode.

For the gases, we use

$$V = \frac{ItV_e}{96500} \qquad \text{....(ii)}$$

***Coulomb:** It is the unit of electric charge. It is the amount of charge that moves past any given point in a circuit when a current of 1 ampere is supplied for one second.

1 coulomb = 1 ampere-second

It is also defined as the amount of charge which is required to deposit by electrolysis 0.001118 g of silver from a solution of silver nitrate.

An electron has 1.6×10^{-19} coulomb of negative charge. Hence, one coulomb of charge is carried by 6.24×10^{18} electrons. 1 mole of electrons carry a charge of 96500 coulomb. This quantity of charge is called **Faraday.**

Charge carried by 1 mole of electrons

$$\begin{aligned} &= (6.023 \times 10^{23})(1.6 \times 10^{-19}) \\ &= 96368 \text{ coulomb} \\ &\approx 96500 \text{ coulomb} \end{aligned}$$

where, V = Volume of gas evolved at STP at an electrode

V_e = Equivalent volume

= Volume of gas evolved at an electrode at STP by 1 faraday charge

Illustration

O_2: $M = 32$, $E = 8$

$$\begin{aligned} 32 \text{ g } O_2 &\equiv 22.4 \text{ L at STP} \\ 8 \text{ g } O_2 &\equiv 5.6 \text{ L at STP} \end{aligned} \qquad \begin{bmatrix} M = \text{Molecular mass} \\ E = \text{Equivalent mass} \end{bmatrix}$$

Thus, V_e of $O_2 = 5.6$ L

H_2: $M = 2$, $E = 1$

$$\begin{aligned} 2 \text{ g } H_2 &\equiv 22.4 \text{ L at STP} \\ 1 \text{ g } H_2 &\equiv 11.2 \text{ L at STP} \end{aligned}$$

Thus, V_e of $H_2 = 11.2$ L

Cl_2: $M = 71$, $E = 35.5$

$$\begin{aligned} 71 \text{ g } Cl_2 &\equiv 22.4 \text{ L at STP} \\ 35.5 \text{ g } Cl_2 &\equiv 11.2 \text{ L at STP} \end{aligned}$$

Thus, V_e of $Cl_2 = 11.2$ L

12.4 APPLICATIONS OF ELECTROLYSIS

The phenomenon of electrolysis has wide applications. The important ones are:

(1) Determination of equivalent masses of elements: According to second law of electrolysis when the same quantity of electric current is passed through solutions of salts of two different metals taken in two different cells, the amounts of the metals deposited on the cathodes of the two cells are proportional to their equivalent masses of the respective metals. If the amounts of the metals deposited on the cathodes be W_A and W_B respectively, then

$$\frac{W_A}{W_B} = \frac{\text{Equivalent mass of } A}{\text{Equivalent mass of } B}$$

Knowing the equivalent mass of one metal, the equivalent mass of the other metal can be calculated from the above relationship. The equivalent masses of those non-metals which are evolved at anodes can also be determined by this method.

(2) Electrometallurgy: The metals like sodium, potassium, magnesium, calcium, aluminium, etc., are obtained by electrolysis of fused electrolytes.

Fused electrolyte	Metal isolated
$NaCl + CaCl_2 + KF$	Na
$CaCl_2 + CaF_2$	Ca
Al_2O_3 + cryolite	Al
$MgCl_2$ (35%) + NaCl (50%) + $CaCl_2$ (15%)	Mg
NaOH	Na
$KCl + CaCl_2$	K

(3) Manufacture of non-metals: Non-metals like hydrogen, fluorine, chlorine are obtained by electrolysis.

(4) Electro-refining of metals: The metals like copper, silver, gold, aluminium, tin, etc., are refined by electrolysis.

(5) Manufacture of compounds: Compounds like NaOH, KOH, Na_2CO_3, $KClO_3$, white lead, $KMnO_4$, etc., are manufactured by electrolysis.

(6) Electroplating: The process of coating an inferior metal with a superior metal by electrolysis is known as **electroplating.**

The aims of electroplating are:

(i) To prevent the inferior metal from corrosion.

(ii) To make it more attractive in appearance.

The object to be electroplated is made the cathode and block of the metal to be deposited is made the anode in an electrolytic bath containing a solution of a salt of the anodic metal. On passing electric current in the cell, the metal of the anode dissolves out and is deposited on the cathode-article in the form of a thin film. The following are the requirements for fine coating:

(i) The surface of the article should be free from greasy matter and its oxide layer. The surface is cleaned with chromic acid or detergents.

(ii) The surface of the article should be rough so that the metal deposited sticks permanently.

(iii) The concentration of the electrolyte should be so adjusted as to get smooth coating.

(iv) Current density must be the same throughout.

For electroplating	Anode	Cathode	Electrolyte
With copper	Cu	Object	$CuSO_4$ + dilute H_2SO_4
With silver	Ag	Object	$KAg(CN)_2$
With nickel	Ni	Object	Nickel ammonium sulphate
With gold	Au	Object	$KAu(CN)_2$
With zinc	Zn	Iron objects	$ZnSO_4$
With tin	Sn	Iron objects	$SnSO_4$

Thickness of Coated Layer

Let the dimensions of metal sheet to be coated be $(a \text{ cm} \times b \text{ cm})$.

Thickness of coated layer = c cm

Volume of coated layer = $(a \times b \times c)$ cm^3

Mass of the deposited substance = volume × density

$$= (a \times b \times c) \times d \text{ g}$$

$$\therefore \quad (a \times b \times c) \times d = \frac{I \times t \times E}{96500}$$

Using above relation we may calculate the thickness of coated layer.

Note: Sometimes radius of atom of deposited metal is given instead of density, *e.g.*,

Radius of silver atom $= 10^{-8}$ cm

Atomic mass of Ag $= 108$

Mass of single silver atom $= \dfrac{108}{6.023 \times 10^{23}}$ g

Volume of single atom $= \dfrac{4}{3} \times \pi R^3$

$$= \frac{4}{3} \times 3.14 \times (10^{-8})^3 \text{ cm}^3$$

$$\text{Density of Ag} = \frac{\text{Mass of single atom}}{\text{Volume of single atom}}$$

$$= \frac{108 / 6.023 \times 10^{23}}{\frac{4}{3} \times 3.14 \times (10^{-8})^3} = 42.82 \text{ g / cm}^3$$

Current Efficiency

Sometimes the ammeter shows false current due to mechanical fault. In this case,

$$\% \text{ current efficiency} = \frac{\text{Actual current}}{\text{Ammeter current}} \times 100$$

[**Note :** The conditions for the operating electrolytic cell are: $\Delta G > 0$ and $E < 0$]

SOME SOLVED EXAMPLES

Example 1. *Find the charge in coulomb on* 1 *g-ion of* N^{3-}.

Solution: Charge on one ion of N^{3-}

$$= 3 \times 1.6 \times 10^{-19} \text{ coulomb}$$

$$\text{one g-ion} = 6.02 \times 10^{23} \text{ ions}$$

Thus, charge on one g-ion of N^{3-}

$$= 3 \times 1.6 \times 10^{-19} \times 6.02 \times 10^{23}$$

$$= 2.89 \times 10^5 \text{ coulomb}$$

Example 2. *How much charge is required to reduce* (a) 1 *mole of* Al^{3+} *to Al and* (b) 1 *mole of* MnO_4^- *to* Mn^{2+}*?*

Solution: (a) The reduction reaction is:

$$\underset{1\text{ mole}}{Al^{3+}} + \underset{3\text{ mole}}{3e^-} \longrightarrow Al$$

Thus, 3 mole of electrons are needed to reduce 1 mole of Al^{3+}.

$$Q = 3 \times F$$

$$= 3 \times 96500 = 289500 \text{ coulomb}$$

(b) The reduction reaction is:

$$\underset{1\text{ mole}}{MnO_4^-} + 8H^+ + \underset{5\text{ mole}}{5e^-} \longrightarrow Mn^{2+} + 4H_2O$$

$$Q = 5 \times F$$

$$= 5 \times 96500 = 482500 \text{ coulomb}$$

Example 3. *How much electric charge is required to oxidise* (a) 1 *mole of* H_2O *to* O_2 *and* (b) 1 *mole of FeO to* Fe_2O_3*?*

Solution: (a) The oxidation reaction is:

$$\underset{1\text{ mole}}{H_2O} \longrightarrow \frac{1}{2} O_2 + 2H^+ + \underset{2\text{ mole}}{2e^-}$$

$$Q = 2 \times F$$

$$= 2 \times 96500 = 193000 \text{ coulomb}$$

(b) The oxidation reaction is:

$$FeO + \frac{1}{2} H_2O \longrightarrow \frac{1}{2} Fe_2O_3 + H^+ + e^-$$

$$Q = F = 96500 \text{ coulomb}$$

Example 4. *Exactly* 0.4 *faraday electric charge is passed through three electrolytic cells in series, first containing* $AgNO_3$, *second* $CuSO_4$ *and third* $FeCl_3$ *solution. How many grams of each metal will be deposited assuming only cathodic reaction in each cell?*

Solution: The cathodic reactions in the cells are respectively,

$$\underset{\substack{1\text{ mole}\\108\text{ g}}}{Ag^+} + \underset{\substack{1\text{ mole}\\1\text{ F}}}{e^-} \longrightarrow Ag$$

$$\underset{\substack{1\text{ mole}\\63.5\text{ g}}}{Cu^{2+}} + \underset{\substack{2\text{ mole}\\2\text{ F}}}{2e^-} \longrightarrow Cu$$

and

$$\underset{\substack{1\text{ mole}\\56\text{ g}}}{Fe^{3+}} + \underset{\substack{3\text{ mole}\\3\text{ F}}}{3e^-} \longrightarrow Fe$$

Hence, $\text{Ag deposited} = 108 \times 0.4 = 43.2 \text{ g}$

$$\text{Cu deposited} = \frac{63.5}{2} \times 0.4 = 12.7 \text{ g}$$

and $\text{Fe deposited} = \frac{56}{3} \times 0.4 = 7.47 \text{ g}$

Example 5. *An electric current of* 100 *ampere is passed through a molten liquid of sodium chloride for* 5 *hours. Calculate the volume of chlorine gas liberated at the electrode at NTP.*

Solution: The reaction taking place at anode is:

$$\underset{71.0\text{ g}}{2Cl^-} \longrightarrow \underset{\substack{71.0\text{ g}\\1\text{ mole}}}{Cl_2} + \underset{2 \times 96500\text{ coulomb}}{2e^-}$$

$$Q = I \times t = 100 \times 5 \times 60 \times 60 \text{ coulomb}$$

The amount of chlorine liberated by passing $100 \times 5 \times 60 \times 60$ coulomb of electric charge

$$= \frac{1}{2 \times 96500} \times 100 \times 5 \times 60 \times 60 = 9.3264 \text{ mole}$$

Volume of Cl_2 liberated at NTP $= 9.3264 \times 22.4 = 208.91$ L

Example 6. *A* 100 *watt,* 110 *volt incandescent lamp is connected in series with an electrolytic cell containing cadmium sulphate solution. What mass of cadmium will be deposited by the current flowing for* 10 *hours?*

Solution: We know that,

$$\text{Watt} = \text{ampere} \times \text{volt}$$

$$100 = \text{ampere} \times 110$$

$$\text{Ampere} = \frac{100}{110}$$

$$\text{Quantity of charge} = \text{ampere} \times \text{second}$$

$$= \frac{100}{110} \times 10 \times 60 \times 60 \text{ coulomb}$$

The cathodic reaction is:

$$\underset{112.4\text{ g}}{Cd^{2+}} + \underset{2 \times 96500\text{ C}}{2e^-} \longrightarrow Cd$$

Mass of cadmium deposited by passing $\frac{100}{110}\times 10\times 60\times 60$ coulomb charge

$$= \frac{112.4}{2\times 96500}\times\frac{100}{110}\times 10\times 60\times 60 = 19.0598 \text{ g}$$

Example 7. *In an electrolysis experiment, a current was passed for 5 hours through two cells connected in series. The first cell contains a solution of gold salt and the second cell contains copper sulphate solution. 9.85 g of gold was deposited in the first cell. If the oxidation number of gold is +3, find the amount of copper deposited on the cathode in the second cell. Also calculate the magnitude of the current in ampere.*

Solution: We know that,

$$\frac{\text{Mass of Au deposited}}{\text{Mass of Cu deposited}} = \frac{\text{Eq. mass of Au}}{\text{Eq. mass of Cu}}$$

$$\text{Eq. mass of Au} = \frac{197}{3}\ ;\ \text{Eq. mass of Cu} = \frac{63.5}{2}$$

Mass of copper deposited

$$= 9.85\times\frac{63.5}{2}\times\frac{3}{197}\text{ g} = 4.7625 \text{ g}$$

Let Z be the electrochemical equivalent of Cu.

$$E = Z\times 96500$$

or $$Z = \frac{E}{96500} = \frac{63.5}{2\times 96500}$$

Applying $$W = Z\times I\times t$$

$$t = 5 \text{ hour} = 5\times 3600 \text{ second}$$

$$4.7625 = \frac{63.5}{2\times 96500}\times I\times 5\times 3600$$

or $$I = \frac{4.7625\times 2\times 96500}{63.5\times 5\times 3600} = 0.804 \text{ ampere}$$

Example 8. *How long has a current of 3 ampere to be applied through a solution of silver nitrate to coat a metal surface of 80 cm^2 with 0.005 mm thick layer? Density of silver is 10.5 g/cm^3.*

Solution: Mass of silver to be deposited

= volume × density

= Area × thickness × density

Given: Area $= 80 \text{ cm}^2$, thickness $= 0.0005$ cm and density $= 10.5 \text{ g/cm}^3$

Mass of silver to be deposited = $80\times 0.0005\times 10.5$

= 0.42 g

Applying to silver $$E = Z\times 96500$$

$$Z = \frac{108}{96500}\text{ g}$$

Let the current be passed for t seconds.

We know that, $$W = Z\times I\times t$$

So, $$0.42 = \frac{108}{96500}\times 3\times t$$

or $$t = \frac{0.42\times 96500}{108\times 3} = 125.09 \text{ second}$$

Example 9. *What current strength in ampere will be required to liberate 10 g of chlorine from sodium chloride solution in one hour?*

Solution: Applying $E = Z\times 96500$ (E for chlorine = 35.5),

$$35.5 = Z\times 96500$$

or $$Z = \frac{35.5}{96500}\text{ g}$$

Now, applying the formula

$$W = Z\times I\times t$$

where, $W = 10$ g, $Z = \frac{35.5}{96500}$, $t = 60\times 60 = 3600$ second

$$I = \frac{10\times 96500}{35.5\times 3600} = 7.55 \text{ ampere}$$

Example 10. 0.2964 *g of copper was deposited on passage of a current of* 0.5 *ampere for* 30 *minutes through a solution of copper sulphate. Calculate the atomic mass of copper.* (1 *faraday* = 96500 *coulomb*)

Solution: Quantity of charge passed

$$= 0.5\times 30\times 60 = 900 \text{ coulomb}$$

900 coulomb deposit copper = 0.2964 g

$$96500 \text{ coulomb deposit copper} = \frac{0.2964}{900}\times 96500 = 31.78 \text{ g}$$

Thus, 31.78 is the equivalent mass of copper.

At. mass = Eq. mass × Valency

= 31.78 × 2 = 63.56

Example 11. 19 *g of molten* $SnCl_2$ *is electrolysed for some time using inert electrodes until* 0.119 *g of Sn is deposited at the cathode. No substance is lost during electrolysis. Find the ratio of the masses of* $SnCl_2 : SnCl_4$ *after electrolysis.*

Solution: The chemical reaction occurring during electrolysis is:

$$\underset{2\times 190\text{ g}}{2SnCl_2} \longrightarrow \underset{261\text{ g}}{SnCl_4} + \underset{119\text{ g}}{Sn}$$

119 g of Sn is deposited by the decomposition of 380 g of $SnCl_2$.

So, 0.119 g of Sn is deposited by the decomposition of

$$\frac{380}{119}\times 0.119 = 0.380 \text{ g of } SnCl_2$$

Remaining amount of $SnCl_2 = (19 - 0.380) = 18.62$ g

380 g of $SnCl_2$ produce = 261 g of $SnCl_4$

So, 0.380 g of $SnCl_2$ produce $= \frac{261}{380} \times 0.380 = 0.261$ g of $SnCl_4$

Thus, the ratio $SnCl_2 : SnCl_4 = \frac{18.62}{0.261}$, *i.e.*, 71.34 : 1

Example 12. *A current of 2.68 ampere is passed for one hour through an aqueous solution of copper sulphate using copper electrodes. Calculate the change in mass of cathode and that of the anode. (At. mass of copper = 63.5)*

Solution: The electrode reactions are:

$$\underset{1\text{ mole}}{Cu^{2+}} + \underset{2 \times 96500\text{ C}}{2e^-} \longrightarrow Cu \text{ (Cathode)}$$

$$Cu \longrightarrow Cu^{2+} + 2e^- \text{ (Anode)}$$

Thus, cathode increases in mass as copper is deposited on it and the anode decreases in mass as copper from it dissolves.

Charge passed through cell = 2.68 × 60 × 60 coulomb

$$\text{Copper deposited or dissolved} = \frac{63.5}{2 \times 96500} \times 2.68 \times 60 \times 60$$
$$= 3.174 \text{ g}$$

Increase in mass of cathode = Decrease in mass of anode
$$= 3.174 \text{ g}$$

Example 13. *An ammeter and a copper voltameter are connected in series through which a constant current flows. The ammeter shows 0.52 ampere. If 0.635 g of copper is deposited in one hour, what is the percentage error of the ammeter? (At. mass of copper = 63.5)*

Solution: The electrode reaction is:

$$\underset{1\text{ mole}}{Cu^{2+}} + \underset{2 \times 96500\text{ C}}{2e^-} \longrightarrow Cu$$

63.5 g of copper deposited by passing charge
$$= 2 \times 96500 \text{ coulomb}$$

0.635 g of copper deposited by passing charge
$$= \frac{2 \times 96500}{63.5} \times 0.653 \text{ coulomb}$$
$$= 2 \times 965 \text{ coulomb}$$
$$= 1930 \text{ coulomb}$$

We know that,

$$Q = I \times t$$
$$1930 = I \times 60 \times 60$$
$$I = \frac{1930}{3600} = 0.536 \text{ ampere}$$

$$\therefore \quad \text{Percentage error} = \frac{(0.536 - 0.52)}{0.536} \times 100 = 2.985$$

Example 14. *A current of 3.7 ampere is passed for 6 hours between platinum electrodes in 0.5 litre of a 2 M solution of $Ni(NO_3)_2$. What will be the molarity of the solution at the end of electrolysis? What will be the molarity of the solution if nickel electrodes are used? (1F = 96500 coulomb; Ni = 58.7)*

Solution: The electrode reaction is:

$$\underset{1\text{ mole}}{Ni^{2+}} + \underset{2 \times 96500\text{ C}}{2e^-} \longrightarrow Ni$$

Quantity of electric charge passed
$$= 3.7 \times 6 \times 60 \times 60 \text{ coulomb} = 79920 \text{ coulomb}$$

Number of moles of $Ni(NO_3)_2$ decomposed or nickel deposited
$$= \frac{1}{2 \times 96500} \times 79920 = 0.4140$$

Number of moles of $Ni(NO_3)_2$ present before electrolysis
$$= 0.5 \times 2 = 1.0$$

Number of moles of $Ni(NO_3)_2$ present after electrolysis
$$= (1.0 - 0.4140) = 0.586$$

Since, 0.586 moles are present in 0.5 litre,
$$\text{Molarity of the solution} = 2 \times 0.586 = 1.72\, M$$

When nickel electrodes are used, anodic nickel will dissolve and get deposited at the cathode. The molarity of the solution will, thus, remain unaffected.

Example 15. *An acidic solution of Cu^{2+} salt containing 0.4 g of Cu^{2+} is electrolysed until all the copper is deposited. The electrolysis is continued for seven more minutes with volume of solution kept at 100 mL and the current at 1.2 amp. Calculate the gases evolved at NTP during the entire electrolysis.*

Solution: 0.4 g of $Cu^{2+} = \frac{0.4}{31.75} = 0.0126$ g - equivalent

At the same time, the oxygen deposited at anode
$$= 0.0126 \text{ g - equivalent}$$
$$= \frac{8}{32} \times 0.0126 = 0.00315 \text{ g-mole}$$

After the complete deposition of copper, the electrolysis will discharge hydrogen at cathode and oxygen at anode.

The amount of charge passed = 1.2 × 7 × 60 = 504 coulomb

$$\text{So, Oxygen liberated} = \frac{1}{96500} \times 504 = 0.00523 \text{ g - equivalent}$$
$$= \frac{8}{32} \times 0.00523 = 0.001307 \text{ g - mole}$$

Hydrogen liberated = 0.00523 g - equivalent
$$= \frac{1}{2} \times 0.00523 = 0.00261 \text{ g - mole}$$

Total gases evolved = (0.00315 + 0.001307 + 0.00261) g - mole
$$= 0.007067 \text{ g - mole}$$

Volume of gases evolved at NTP
$$= 22400 \times 0.007067 \text{ mL}$$
$$= 158.3 \text{ mL}$$

Example 16. *A current of 1.70 ampere is passed through 300 mL of 0.160 M solution of zinc sulphate for 230 seconds with a current efficiency of 90 per cent. Find out the molarity of Zn^{2+} ions after the deposition of zinc. Assume the volume of the solution to remain constant during electrolysis.* **(IIT 1991)**

Solution: Amount of charge passed = 1.70 × 230 coulomb

$$\text{Amount of actual charge passed} = \frac{90}{100} \times 1.70 \times 230$$
$$= 351.9 \text{ coulomb}$$

No. of moles of Zn deposited by passing 351.9 coulomb of charge

$$= \frac{1}{2 \times 96500} \times 351.9 = 0.000182$$

Molarity of Zn^{2+} ions after deposition of zinc

$$= \left[0.160 - \frac{0.000182 \times 1000}{300}\right] M$$
$$= 0.154\, M$$

Example 17. *Calculate the electricity that would be required to reduce* 12.3 *g of nitrobenzene to aniline, if the current efficiency for the process is* 50 *per cent. If the potential drop across the cell is* 3.0 *volt, how much energy will be consumed?* [AIPMT (Mains) 2008]

Solution: The reduction reaction is:

$$\underset{\substack{123\text{ g}\\1\text{ mole}}}{C_6H_5NO_2} + \underset{\substack{6\text{ g}\\3\text{ mole}}}{3H_2} \longrightarrow C_6H_5NH_2 + 2H_2O$$

Hydrogen required for reduction of $\frac{12.3}{123}$ or 0.1 mole of nitrobenzene $= 0.1 \times 3 = 0.3$ mole

Amount of charge required for liberation of 0.3 mole of hydrogen $= 2 \times 96500 \times 0.3 = 57900$ coulomb

Actual amount of charge required as efficiency is 50%

$$= 2 \times 57900 = 115800 \text{ coulomb}$$

$$\text{Energy consumed} = 115800 \times 3.0 = 347400 \text{ J}$$
$$= 347.4 \text{ kJ}$$

Example 18. *An aqueous solution of sodium chloride on electrolysis gives* $H_2(g)$, $Cl_2(g)$ *and NaOH according to the reaction:*

$$2Cl^-(aq.) + 2H_2O \longrightarrow 2OH^-(aq.) + H_2(g) + Cl_2(g)$$

A direct current of 25 *ampere with a current efficiency* 62% *is passed through* 20 *L of NaCl solution* (20% *by mass*). *Write down the reactions taking place at the anode and cathode. How long will it take to produce* 1 *kg of* Cl_2? *What will be the molarity of the solution with respect to hydroxide ion? Assume no loss due to evaporation.* (IIT 1992)

Solution: Reactions at anode and cathode are:

$$2Cl^- \longrightarrow Cl_2 + 2e^- \quad \text{(at anode)}$$
$$2H_2O + 2e^- \longrightarrow H_2 + 2OH^- \quad \text{(at cathode)}$$

$$1 \text{ kg of } Cl_2 = \frac{1000}{71.0} = 14.08 \text{ mole}$$

Charge to produce one mole of $Cl_2 = 2 \times 96500$ coulomb

Charge to produce 14.08 mole of $Cl_2 = 2 \times 96500 \times 14.08$ coulomb

$$\text{Effective current} = \frac{62}{100} \times 25.0 = 15.5 \text{ ampere}$$

$$\text{Time} = \frac{\text{Charge}}{\text{Current}} = \frac{2 \times 96500 \times 14.08}{15.5}$$
$$= 175318.7 \text{ second} = 48.699 \text{ hour}$$

$$OH^- \text{ ions produced} = 2 \times \text{moles of } Cl_2$$
$$= 2 \times 14.08 = 28.16 \text{ mole}$$

$$\text{Molarity} = \frac{\text{Mole}}{\text{Volume}} = \frac{28.16}{20} = 1.408\, M$$

Example 19. *Chromium metal can be plated out from an acidic solution containing* CrO_3 *according to the following reaction:*

$$CrO_3 + 6H^+ + 6e^- \longrightarrow Cr + 3H_2O$$

Calculate the mass of chromium plated out by 24000 *coulomb. How long will it take to plate out* 1.5 *g of chromium using* 12.5 *ampere current?* (IIT 1993)

Solution: $CrO_3 + 6H^+ + \underset{6 \times 96500\text{ C}}{6e^-} \longrightarrow \underset{\substack{1\text{ mole}\\52\text{ g}}}{Cr} + 3H_2O$

Mass of chromium plated out by 24000 coulomb charge

$$= \frac{52}{6 \times 96500} \times 24000 = 2.155 \text{ g}$$

Charge required for plating out 1.5 g of chromium

$$= \frac{6 \times 96500}{52} \times 1.5 = 16701.92 \text{ coulomb}$$

$$\text{Time} = \frac{\text{Charge}}{\text{Current}} = \frac{16701.92}{12.5} = 1336.15 \text{ second}$$
$$= 22.27 \text{ minute}$$

Example 20. *After electrolysis of a sodium chloride solution with inert electrodes for a certain period of time,* 600 *mL of the solution was left which was found to be* 1 *N in NaOH. During the same period* 31.75 *g of copper was deposited in the copper voltameter in series with the electrolytic cell. Calculate the percentage theoretical yield of NaOH obtained.*

Solution: Equivalent mass of NaOH = 40

$$\text{Amount of NaOH formed} = \frac{40}{1000} \times 600 = 24 \text{ g}$$

31.75 g of Cu = 1 g-equivalent of Cu.

During the same period, 1 g-equivalent of NaOH should have been formed.

$$1 \text{ g-equivalent of NaOH} = 40 \text{ g}$$
$$\% \text{ yield} = \frac{24}{40} \times 100 = 60$$

Example 21. *Peroxy disulphuric acid* ($H_2S_2O_8$) *can be prepared by electrolytic oxidation of* H_2SO_4 *as:*

$$2H_2SO_4 \longrightarrow H_2S_2O_8 + 2H^+ + 2e^-$$

Oxygen and hydrogen are by products. In such an electrolysis 9.72 *litre of* H_2 *and* 2.35 *litre of* O_2 *were generated at NTP. What is the mass of peroxy disulphuric acid formed?*

Solution:

Anodic reaction: $2H_2SO_4 \longrightarrow H_2S_2O_8 + 2H^+ + 2e^-$

$$2H_2O \longrightarrow 4H^+ + O_2 + 2e^-$$

Cathodic reaction: $2H_2O + 2e^- \longrightarrow 2OH^- + H_2$

Total equivalent of $H_2S_2O_8$ + equivalent of oxygen

$$= \text{Equivalent of } H_2$$

$$9.72 \text{ litre } H_2 = \frac{9.72}{11.2} = 0.868 \text{ equivalent}$$

$$2.35 \text{ litre } O_2 = \frac{2.35}{5.6} = 0.42 \text{ equivalent}$$

$$\text{Equivalent of } H_2S_2O_8 = (0.868 - 0.420) = 0.448$$

$$\text{Mass of } H_2S_2O_8 = 0.448 \times \frac{194}{2} = 43.456 \text{ g}$$

Example 22. *Cadmium amalgam is prepared by electrolysis of a solution of $CdCl_2$ using a mercury cathode. Find how long a current of 5 ampere should be passed in order to prepare 12% Cd-Hg amalgam on a cathode of 2 g mercury. At. mass of Cd = 112.40.*

Solution: 2 g Hg require Cd to prepare 12% amalgam

$$= \frac{12}{88} \times 2 = 0.273 \text{ g}$$

$$\underset{\substack{1 \text{ mole} \\ 112.40 \text{ g}}}{Cd^{2+}} + \underset{2 \times 96500 \text{ C}}{2e^-} \longrightarrow Cd$$

Charge required to deposit 0.273 g of Cd

$$= \frac{2 \times 96500}{112.40} \times 0.273 \text{ coulomb}$$

$$\text{Charge} = \text{ampere} \times \text{second}$$

$$\text{Second} = \frac{2 \times 96500 \times 0.273}{112.40 \times 5} = 93.75$$

Example 23. *Assume that impure copper contains iron, gold and silver as impurities. After passing a current of 140 ampere for 482.5 second, the mass of anode decreased by 22.260 g and the cathode increased in mass by 22.011 g. Estimate the percentage of iron and copper originally present.*

Solution: The increase at the cathode is due to copper only. Hence, there is 22.011 g of copper and rest impurities of iron, gold and silver.

$$\text{Mass of impurities} = (22.260 - 22.011) = 0.249 \text{ g}$$

At anode, only copper and iron are oxidised; the gold and silver collect below anode in the form of anodic mud.

$$\underset{\text{(Copper and iron)}}{M} \longrightarrow M^{2+} + 2e^-$$

$$\text{No. of moles of metal oxidised} = \frac{140 \times 482.5}{2 \times 96500} = 0.35$$

$$\text{No. of moles of copper} = \frac{22.011}{63.5} = 0.3466$$

$$\text{No. of moles of iron} = (0.35 - 0.3466) = 0.0034$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. Amount of energy used in the passage of 1 amp current for 100 sec under a potential of 115 V is:
(a) 20 kJ (b) 11.5 kJ (c) 115 kJ (d) 0.115 kJ
[Ans. (b)]
[Hint: $Q = I \times t = 1 \times 100 = 100$ C
$$\text{Energy} = \text{charge} \times \text{potential} = 100 \times 115 = 11500 \text{ J} = 11.5 \text{ kJ}]$$

2. One litre of 1 M $CuSO_4$ solution is electrolysed. After passing $2F$ charge, the molarity of $CuSO_4$ will be:
(a) $M/2$ (b) $M/4$ (c) M (d) zero
[Ans. (d)]
[Hint: $2F$ charge will deposit 2 equivalent or 1 mole of copper
$$Cu^{2+} + 2e^- \longrightarrow Cu$$
Thus, all the copper from $CuSO_4$ solution will be deposited and molarity of remaining $CuSO_4$ solution will be zero.]

3. The time required to coat a metal surface of 80 cm^2 with 5×10^{-3} cm thick layer of silver (density 1.05 g/cm^3) by passing a current of 3 amp through silver nitrate solution is:
(a) 115 sec (b) 125 sec (c) 135 sec (d) 145 sec
[Ans. (b)]
[Hint:
Mass of silver in coated layer = volume × density
$$= (80 \times 5 \times 10^{-3}) \times 1.05 \text{ g} = 0.42 \text{ g}$$
$$\because \quad W = \frac{ItE}{96500}$$
$$\therefore \quad t = \frac{W \times 96500}{I \times E} = \frac{0.42 \times 96500}{3 \times 108} = 125.09 \text{ sec}]$$

4. 4.5 g of aluminium (At. mass = 27 amu) is deposited at cathode from Al^{3+} solution by a certain quantity of electric charge. The volume of hydrogen produced at STP from H^+ ions in solution by the same quantity of electric charge will be: **[CBSE (PMT) 2005]**
(a) 44.8 L (b) 22.4 L (c) 11.2 L (d) 5.6 L
[Ans. (d)]
[Hint: Number of equivalents of aluminium deposited
$$= \frac{4.5}{9} = 0.5$$
∴ Number of equivalents of H_2 will also be 0.5.
Volume of H_2 gas at STP = Number of equivalents × Equivalent volume
$$= 0.5 \times 11.2 = 5.6 \text{ L}]$$

5. Cost of electricity for the production of x L H_2 at NTP at cathode is Rs x; then cost of production of x L O_2 at NTP at anode will be : (assume 1 mole of electrons as one unit of electricity)
(a) $2x$ (b) $4x$ (c) $16x$ (d) $32x$
[Ans. (a)]
[Hint: $\dfrac{\text{Volume of } H_2}{\text{Volume of } O_2} = \dfrac{\text{Equivalent volume of } H_2}{\text{Equivalent volume of } O_2}$

$$\frac{x}{\text{Volume of } O_2} = \frac{11.2}{5.6} = 2$$

$$\text{Volume of } O_2 = \frac{x}{2}$$

Thus, $\frac{x}{2}$ L O_2 requires Rs x for its production,

i.e., x L O_2 will require Rs $2x$ for the production.]

6. What current is to be passed for 0.25 sec for deposition of certain weight of metal which is equal to its electrochemical equivalent? **[AMU (Medical) 2006]**

(a) 4 A (b) 100 A (c) 200 A (d) 2 A

[**Ans.** (a)]

[**Hint:**
$$W = ZIt$$
$$\frac{W}{Z} = It$$
$$1 = It = I \times 0.25$$
$$I = 4 \text{ amp.}]$$

7. If the aqueous solutions of the following salts are electrolysed for 1 hour with 10 ampere current, which solution will deposit the maximum mass of the metal at cathode? The atomic weights are: Fe = 56, Zn = 65, Ag = 108, Hf = 178 and W = 184. **[PMT (Kerala) 2006]**

(a) $ZnSO_4$ (b) $FeCl_3$ (c) $HfCl_4$ (d) WCl_6

(e) $AgNO_3$

[**Ans.** (e)]

[**Hint:** Greater is the equivalent mass of the metal more will be the amount deposited at cathode.

Compound	**Equivalent mass of metals**
$ZnSO_4$	$65/2 = 32.5$
$FeCl_3$	$56/3 = 18.66$
$HfCl_4$	$178/4 = 44.5$
WCl_6	$184/6 = 30.66$
$AgNO_3$	$108/1 = 108$

∴ Maximum amount of silver will be deposited at cathode.]

8. When a quantity of electricity is passed through $CuSO_4$ solution, 0.16 g of copper gets deposited. If the same quantity of electricity is passed through acidulated water, then the volume of H_2 liberated at STP will be: (given atomic weight of Cu = 64) **(KCET 2006)**

(a) 4 cm^3 (b) 56 cm^3 (c) 604 cm^3 (d) 8 cm^3

[**Ans.** (b)]

[**Hint:** Number of equivalents of copper deposited $= \frac{0.16}{32} = 0.005$

Volume of H_2 gas at STP $= 11.2 \times 0.005$

$= 0.056 \text{ litre} = 56 \text{ cm}^3$]

9. Number of faraday's required to generate one gram atom of magnesium from molten $MgCl_2$ is: **[PMT (MP) 2007]**

(a) 1 (b) 2 (c) 3 (d) 4

[**Ans.** (b)]

[**Hint:** $Mg^{2+} + 2e^- \longrightarrow Mg$

1 mole of Mg atom requires 2 mole of electrons, *i.e.*, 2 faraday of charge.]

10. A direct current deposits 54 g of silver (Atomic mass = 108) during electrolysis. How much aluminium (Atomic mass = 27) would be deposited from aluminium chloride solution by the same amount of electricity? **[PMT (Kerala) 2008]**

(a) 4.5 g (b) 5.4g (c) 54g (d) 2.7g

(e) 27g

[**Ans.** (a)]

[**Hint:** Equivalent mass of silver = 108

Equivalent mass of aluminium in $(AlCl_3) = \frac{27}{3} = 9$

$$\frac{W_{Ag}}{W_{Al}} = \frac{E_{Ag}}{E_{Al}}$$
$$\frac{54}{W_{Al}} = \frac{108}{9}$$
$$W_{Al} = 4.5 \text{ g}]$$

SECTION II : CONDUCTANCE AND CONDUCTORS

12.5 ARRHENIUS THEORY OF ELECTROLYTIC DISSOCIATION

In order to explain the properties of electrolytic solutions, Arrhenius put forth, in 1884, a comprehensive theory which is known as theory of **electrolytic dissociation** or **ionic theory.** The main points of the theory are:

(i) An electrolyte, when dissolved in water, breaks up into two types of charged particles, one carrying a positive charge and the other a negative charge. These charged particles are called ions. Positively charged ions are termed cations and negatively charged as anions.

$$AB \longrightarrow A^+ + B^-$$

$$NaCl \longrightarrow Na^+ + Cl^-$$

$$\underset{\text{Electrolyte}}{K_2SO_4} \longrightarrow \underbrace{2K^+ + SO_4^{2-}}_{\text{Ions}}$$

In its modern form, the theory assumes that solid electrolytes are composed of ions which are held together by electrostatic forces of attraction. When an electrolyte is dissolved in a solvent, these forces are weakened and the electrolyte undergoes dissociation into ions. The ions are solvated.

$$A^+B^- \longrightarrow A^+ + B^-$$

or
$$A^+B^- + aq. \longrightarrow A^+(aq.) + B^-(aq.)$$

(ii) The process of splitting of the molecules into ions of an electrolyte is called **ionisation.** The fraction of the total number of molecules present in solution as ions is known as **degree of ionisation** or **degree of dissociation.** It is denoted by 'α'

$$\alpha = \frac{\text{Number of molecules dissociated into ions}}{\text{Total number of molecules}}$$

It has been observed that all electrolytes do not ionise to the same extent. Some are almost completely ionised while others are feebly ionised. The degree of ionisation depends on a number of factors (see 12.6).

(iii) Ions present in solution constantly re-unite to form neutral molecules and, thus, there is a state of dynamic equilibrium between the ionised and non-ionised molecules, *i.e.*,

$$AB \rightleftharpoons A^+ + B^-$$

Applying the law of mass action to above equilibrium

$$\frac{[A^+][B^-]}{[AB]} = K$$

K is known as ionisation constant. The electrolytes having high value of K are termed **strong electrolytes** and those having low value of K as **weak electrolytes.**

(iv) When an electric current is passed through the electrolytic solution, the positive ions (cations) move towards cathode and the negative ions (anions) move towards anode and get discharged, *i.e.*, electrolysis occurs.

The ions are discharged always in equivalent amounts, no matter what their relative speeds are.

(v) The electrolytic solution is always neutral in nature as the total charge on one set of ions is always equal to the total charge on the other set of ions. However, it is not necessary that the number of two sets of ions must be equal always.

$AB \rightleftharpoons A^+ + B^-$ (Both ions are equal)

$NaCl \rightleftharpoons Na^+ + Cl^-$ (Both ions are equal)

$AB_2 \rightleftharpoons A^{2+} + 2B^-$ (Anions are double that of cations)

$BaCl_2 \rightleftharpoons Ba^{2+} + 2Cl^-$ (Anions are double that of cations)

$A_2B \rightleftharpoons 2A^+ + B^{2-}$ (Cations are double that of anions)

$Na_2SO_4 \rightleftharpoons 2Na^+ + SO_4^{2-}$ (Cations are double that of anions)

(vi) The properties of electrolytes in solution are the properties of ions present in solution. For example, acidic solution always contains H^+ ions while basic solution contains OH^- ions and characteristic properties of solutions are those of H^+ ions and OH^- ions respectively.

(vii) The ions act like molecules towards depressing the freezing point, elevating the boiling point, lowering the vapour pressure and establishing the osmotic pressure.

(viii) The conductivity of the electrolytic solution depends on the nature and number of ions as the current is carried through solution by the movement of ions.

Evidences in Favour of Ionic Theory

A large number of experimental observations are available which support Arrhenius theory. A few of them are given below:

(i) Ions present in solid electrolytes: X-ray diffraction studies have shown that electrolytes are composed of ions. For example, a crystal of NaCl does not contain NaCl units but Na^+ and Cl^- ions. Each Na^+ ion is surrounded by six Cl^- ions and each Cl^- ion in turn is surrounded by six Na^+ ions. The whole system is composed of equal number of Na^+ and Cl^- ions. The ionic compounds behave as good conductors in fused state. It can only be possible if ions are already present in ionic solids.

(ii) Ohm's law applicability: The electrolytic solutions like metallic conductors obey Ohm's law, *i.e.*, the strength of the current flowing through a conductor is directly proportional to potential difference (E) applied across the conductor and is inversely proportional to the resistance of the conductor. Mathematically,

$$I = E/R$$

This can only be possible if ions are already present in the solution and no part of the current is used in splitting up the molecules into ions. The current has only directive effect on the ions.

(iii) Ionic reactions: Evidence for the existence of ions in aqueous solutions of electrolytes is furnished by well known reactions in inorganic chemistry. A white precipitate of silver chloride is obtained whenever Ag^+ ions come in contact with chloride ions.

$$Ag^+ + NO_3^- + Na^+ + Cl^- \longrightarrow \underset{\text{ppt.}}{AgCl} + Na^+ + NO_3^-$$

But no precipitation occurs when $AgNO_3$ solution is added to CCl_4, $CHCl_3$ or C_2H_5Cl as these substances being non-electrolytes do not furnish Cl^- ions in solution.

An acid which gives all tests of H^+ ions in aqueous solution, does not give the same tests when dissolved in any organic solvent because no ionisation of the acid occurs in the organic solvent to furnish H^+ ions.

(iv) Heat of neutralization: When one gram-equivalent of a strong acid is neutralized by one gram-equivalent of a strong base, the heat evolved is always the same, *i.e.*, 13.7 kcal. This can be explained on the basis of Arrhenius theory that an acid furnished H^+ ions and base OH^- ions when dissolved in water and the process of neutralisation involves the common reaction.

$$H^+ + OH^- \rightleftharpoons H_2O + 13.7\,\text{kcal}$$

Thus, heat of neutralisation is actually the heat of formation of H_2O from H^+ and OH^- ions.

(v) Abnormal colligative properties: The abnormal behaviour towards colligative properties as observed in the case of electrolytes can be explained on the basis of ionic theory. When an electrolyte is dissolved in water, the number of particles in the solution is always more than the number of molecules actually dissolved due to ionisation. The van't Hoff factor,

$$i = \frac{\text{Observed colligative property}}{\text{Calculated colligative property}}$$

is always more than one, *i.e.*, $i = 1 + (n-1)\alpha$ where, 'n' is the number of ions produced by the ionisation of one molecule of the electrolyte and 'α' is the degree of ionisation.

(vi) Colour of solutions: The colour of the electrolytes in solution, if any, is due to their ions. The $CuSO_4$ is blue in solution due to the presence of Cu^{2+} ions. Potassium permanganate ($KMnO_4$) is purple in solution due to the presence of MnO_4^- ions.

(vii) Explanation of some other phenomena: Ionic theory provides satisfactory explanations regarding various phenomena such as electrolysis, conductivity, salt hydrolysis, solubility product, etc.

Limitations of Arrhenius Theory

(i) Ostwald's dilution law which is based on Arrhenius theory is not applicable to strong electrolytes.

(ii) Strong electrolytes conduct electricity in fused state, *i. e.*, in absence of water. This is in contradiction of Arrhenius theory according to which the presence of solvent is a must for ionisation.

(iii) Arrhenius theory assumes independent existence of ions but fails to account for the factors which influence the mobility of the ions.

12.6 FACTORS PERTAINING TO DEGREE OF IONISATION

The degree of ionisation of an electrolyte in solution depends upon the following factors:

(i) Nature of solute: When the ionisable parts of a molecule of a substance are held more by covalent bonding than by electrovalent bonding, less ions are furnished in solution. Such substances are termed weak electrolytes. H_2S, HCN, NH_4OH, CH_3COOH are examples of this class. NaCl, $Ba(NO_3)_2$, KOH, etc., are strong electrolytes, in which the transfer of electrons seems to be more or less complete, furnish ions immediately when dissolved. Strong electrolytes are almost completely ionised in solution.

(ii) Nature of solvent: The main function of the solvent is to weaken the electrostatic forces of attraction between the two ions and separate them. The force of attraction holding the ions together in any medium is expressed as:

$$F = \frac{1}{K}\frac{q_1 q_2}{r^2}$$

where, K is the dielectric constant of medium.

Any solvent which has high value of dielectric constant has the capacity of separating ions. Water is considered to be the best solvent as it has the highest dielectric constant. The dielectric constants of some of the solvents are given below at 25°C.

Water	Methyl alcohol	Ethyl alcohol	Acetone
81	35	27	21

(iii) Dilution: The extent of ionisation of an electrolyte is inversely proportional to the concentration of its solution. Thus, degree of ionisation increases with the increase of dilution of the solution, *i. e.*, decreasing the concentration of the solution.

(iv) Temperature: The degree of ionisation increases with the increase of temperature. This is due to the fact that at higher temperature molecular speed is increased which overcomes the forces of attraction between the ions.

12.7 ELECTROLYTIC CONDUCTANCE

The conductance is the property of the conductor (metallic as well as electrolytic) which facilitates the flow of electricity through it. It is equal to the reciprocal of resistance, *i. e.*,

$$\text{Conductance} = \frac{1}{\text{Resistance}} = \frac{1}{R} \quad \text{... (i)}$$

It is expressed in the unit called reciprocal ohm (ohm^{-1} or mho) or siemens.

Specific Conductance or Conductivity

The resistance of any conductor varies directly as its length (l) and inversely as its cross-sectional area (a), *i. e.*,

$$R \propto \frac{l}{a} \text{ or } R = \rho\frac{l}{a} \quad \text{... (ii)}$$

where, ρ is called the specific resistance.

If $l = 1$ cm and $a = 1\text{ cm}^2$, then

$$R = \rho \quad \text{... (iii)}$$

The specific resistance is, thus, defined as the resistance of one centimetre cube of a conductor.

The reciprocal of specific resistance is termed the **specific conductance** or it is the conductance of one centimetre cube of a conductor.

It is denoted by the symbol κ. Thus,

$$\kappa = \frac{1}{\rho}, \quad \kappa = \text{kappa—The specific conductance} \quad \text{... (iv)}$$

Specific conductance is also called conductivity.

From eq. (ii), we have

$$\rho = \frac{a}{l}\cdot R \text{ or } \frac{1}{\rho} = \frac{l}{a}\cdot\frac{1}{R}$$

$$\kappa = \frac{l}{a}\times C \qquad \left(\frac{l}{a} = \text{cell constant}\right)$$

or Specific conductance = conductance × cell constant

In the case of electrolytic solutions, the specific conductance is defined as the conductance of a solution of definite dilution enclosed in a cell having two electrodes of unit area separated by one centimetre apart as shown in Fig. 12.2.

The unit of specific conductance is $\text{ohm}^{-1}\text{ cm}^{-1}$.

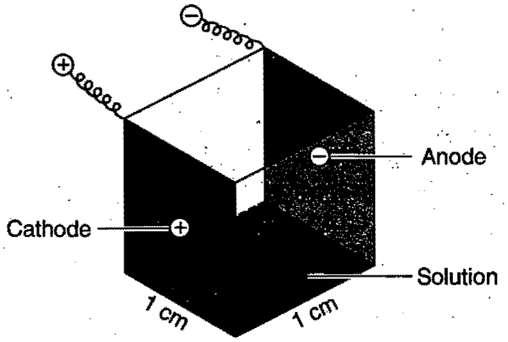

Fig. 12.2 Representation of specific conductance

Equivalent Conductance

One of the factors on which the conductance of an electrolytic solution depends, is the concentration of the solution. In order to obtain comparable results for different electrolytes, it is necessary to take equivalent conductances.

Equivalent conductance is defined as the conductance of all the ions produced by **one gram-equivalent** of an electrolyte in a given solution. It is denoted by Λ.

To understand the meaning of equivalent conductance, imagine a rectangular trough with two opposite sides made of metallic conductor (acting as electrodes) exactly 1 cm apart, If 1 cm^3 (1 mL)

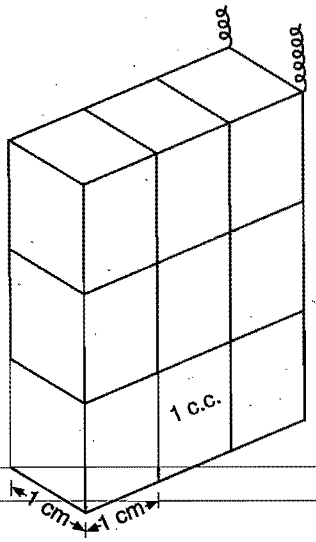

Fig. 12.3

solution containing 1 gram-equivalent of an electrolyte is placed in this container and conductance is measured.

According to definitions,

Conductance = Specific conductance (κ)

= Equivalent conductance (Λ)

If the solution is diluted to say ($9\,\text{cm}^3$) (9 mL), the conductance of the solution will be the same but specific conductance becomes 1/9 th as it contains nine cubes. The conductance is also equal to the equivalent conductance because the solution still has 1 g-equivalent of the electrolyte. This is shown in Fig. 12.3. Thus,

Equivalent conductance $(\Lambda) = 9 \times \kappa$

In general,

$$\Lambda = \kappa \times V \qquad \text{... (v)}$$

where, V is the volume in mL containing 1 g-equivalent of the electrolyte.

In case, if the concentration of the solution is c g-equivalent per litre, then the volume containing 1 g-equivalent of the electrolyte will be $1000/c$.

So, equivalent conductance,

$$\Lambda = \kappa \times \frac{1000}{c} \qquad \text{... (vi)}$$

$$\Lambda = \kappa \times \frac{1000}{N}$$

where, N = normality

The unit of equivalent conductance is $\text{ohm}^{-1}\ \text{cm}^2\ \text{eq}^{-1}$.

Molar Conductance

The molar conductance is defined as the conductance of all the ions produced by ionisation of **1 g-mole** of an electrolyte when present in V mL of solution. It is denoted by μ.

$$\text{Molar conductance } \mu = \kappa \times V \qquad \text{... (vii)}$$

where, V is the volume in mL containing 1 g-mole of the electrolyte. If c is the concentration of the solution in g-mole per litre, then

$$\mu = \kappa \times \frac{1000}{c}$$

Its unit is $\text{ohm}^{-1}\ \text{cm}^2\ \text{mol}^{-1}$.

$$\text{Equivalent conductance} = \frac{\text{Molar conductance}}{n}$$

where,
$$n = \frac{\text{Molecular mass}}{\text{Equivalent mass}}$$

Measurement of Conductance

It is now known to us that when the solution of an electrolyte is taken between two parallel electrodes of cross-sectional area 'a' and 'l' cm apart, then the specific conductance, κ, should be:

$$\kappa = \frac{l}{a} \cdot \frac{1}{R}$$

Thus, knowing the values of R, l and a, the specific conductance can be measured. The resistance of the solution between two parallel electrodes is determined by using Wheatstone bridge method. The diagram of the apparatus is shown in Fig. 12.4. AB is a uniform wire and X is a sliding contact which moves over it. C is the conductivity cell containing the solution of the electrolyte and S represents the source of alternating current. R is the resistance box and T is a headphone to detect the flow of current. A suitable resistance is taken out from the resistance box and the sliding contact X is moved on the wire to search a point of minimum sound in the headphone. At this point, the bridge is balanced.

$$\frac{\text{Resistance of solution}}{\text{Resistance from resistance box}} = \frac{\text{Resistance } XB}{\text{Resistance } XA} = \frac{\text{Length } XB}{\text{Length } XA}$$

Thus, resistance of solution can be determined. Reciprocal of this resistance gives the conductance of solution.

Direct current (DC) cannot be used because it produces two complications.

(i) Change in the concentration of the solution occurs due to electrolysis which will change the resistance.

(ii) Polarisation at the electrodes sets in which also changes the resistance.

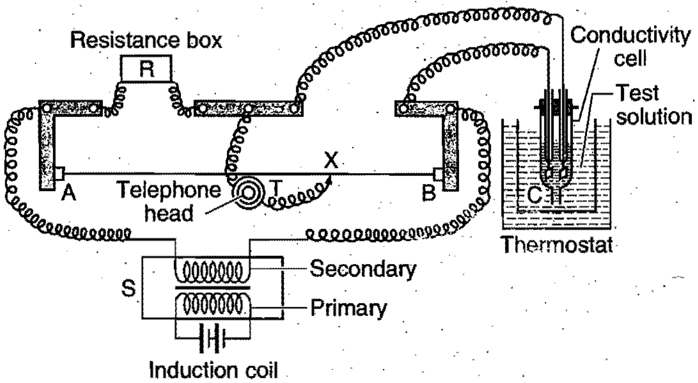

Fig. 12.4 Determination of conductivity

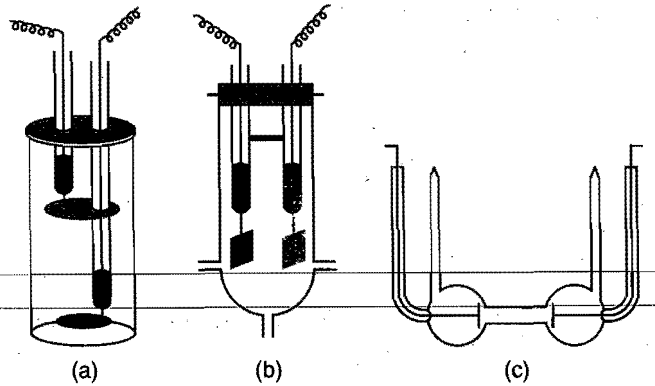
Thus, an alternating current (AC) is used to overcome the above complications.

The solution whose conductance is to be measured is taken in a special type of cell known as conductivity cell. Various types of cells are shown in Fig. 12.5. The electrodes consist of platinum discs coated with finely divided platinum black and welded to platinum wires fused in two glass tubes. The glass tubes contain mercury and are firmly fixed in the cover of cells. Contact with the platinum is made by dipping the copper wires of the circuit in the mercury contained in the tubes. As the conductivity changes with temperature, the cell is usually placed in a constant temperature bath during the experiment. Cells with long paths are used for concentrated solutions and cells with short paths and large electrodes are used for dilute solutions.



(a) (b) (c)

Fig. 12.5 Conductance cells

Cell Constant

Since, the electrodes are not exactly 1 unit apart and may not possess a surface area of 1 square unit, the measured resistance does not give the specific conductance of the solution. Actual measurements of l and a being inconvenient, an indirect method is employed to determine the value of $\frac{l}{a}$ which is a constant quantity for a particular cell and is known as cell constant. We know that,

$$\frac{\text{Specific conductance}}{\text{Conductance}} = \frac{l}{a} = \text{Cell constant}$$

The resistance of cell, *i.e.*, conductance is measured when filled with a standard solution (say $N/10\,\text{KCl}$ solution) at a given temperature. The standard values of specific conductance of KCl solutions of various concentrations at different temperatures are known. Thus, the cell constant is calculated by using the above equation. The same cell constant applies to a measurement with any other solution.

The determination of specific conductance of an electrolytic solution, thus, consists of two steps:

Step I: Determination of cell constant by using a standard KCl solution of known concentration in the conductivity cell.

Step II: Determination of resistance of the given solution using the same cell. The reciprocal of this gives the value of conductance.

Multiplication of conductance and cell constant gives the value of specific conductance of the solution.

In order to determine equivalent conductance or molar conductance, the concentration of the experimental solution should be known. In conductance measurements, the solutions are always prepared in **conductivity water** which has no conductance due to dissolved impurities. It is prepared by distilling a number of times the distilled water to which a little $KMnO_4$ and KOH have been added in a hard glass distillation assembly. Such water has very low conductance of the order of 4.3×10^{-8} ohm^{-1}. For ordinary purposes, double distilled water may be used.

Effect of Dilution on Equivalent Conductance

The value of equivalent conductance increases with dilution. This is due to the fact that degree of ionisation increases with dilution thereby increasing the total number of ions in solution. Solution which contains large number of ions compared to another solution of the same concentration at the same temperature has more conductance and is said to be **stronger electrolyte.** The one which has relatively small number of ions is called a **weak electrolyte.** The number of ions from an electrolyte depends on the degree of dissociation. The curve (Fig. 12.6) shows the variation of the equivalent conductance of some electrolytes with dilution. It shows that electrolytes behave in two ways on dilution:

(i) Electrolytes like KCl have high value of conductance even at low concentration and there is no rapid increase in their equivalent conductance on dilution. Such electrolytes are termed **strong electrolytes.** In the case of strong electrolytes, there is a tendency for equivalent conductance to approach a limiting value when the concentration approaches zero. When the whole of the electrolyte has ionised, further addition of the water does not bring any change in the value of equivalent conductance. This stage is called infinite dilution. The equivalent conductance has a limiting value at infinite dilution and is represented by Λ_∞.

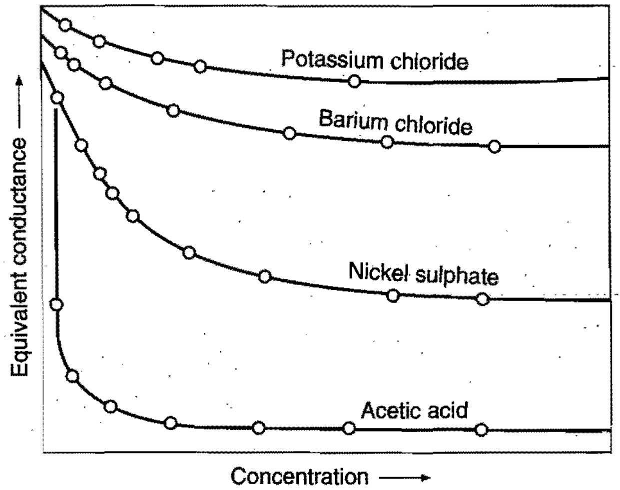


Fig. 12.6 Conductance curve

(ii) Electrolytes like acetic acid have a low value at high concentration and there is a rapid increase in the value of equivalent conductance with dilution. Such electrolytes are termed **weak electrolytes.** There is no indication that a limiting value of equivalent conductance can be attained even when the concentration approaches zero. Thus, graphically, Λ_∞ of weak electrolytes cannot be obtained.

It is thus concluded that equivalent conductance of electrolytes whether strong or weak increases with dilution and reaches to a maximum or limiting value which is termed Λ_∞ (equivalent conductance at infinite dilution). Λ_∞ in the case of strong electrolytes can be obtained by extrapolation of the graph of equivalent conductance to zero concentration but in the case of weak electrolytes it cannot be obtained accurately. An indirect method for obtaining Λ_∞ for weak electrolytes has been given by Kohlrausch.

12.8 KOHLRAUSCH'S LAW

"At infinite dilution, when dissociation is complete, each ion makes a definite contribution towards equivalent conductance of the electrolyte irrespective of the nature of the ion with which it is associated and the value of equivalent conductance at infinite dilution for any electrolyte is the sum of contribution of its constituent ions", *i.e.*, anions and cations. Thus,

$$\Lambda_\infty = \lambda_a + \lambda_c$$

The λ_c and λ_a are called the ionic conductances of cation and anion at infinite dilution respectively. The ionic conductances are proportional to their ionic mobilities. Thus, at infinite dilution,

$$\lambda_c = ku_c$$

and $$\lambda_a = ku_a$$

where, u_c and u_a are ionic mobilities of cation and anion respectively at infinite dilution. The value of k is equal to 96500 C, *i.e.*, one Faraday.

Thus, assuming that increase in equivalent conductance with dilution is due to increase in the degree of dissociation of the electrolyte, it is evident that the electrolyte achieves the degree of dissociation as unity when it is completely ionised at infinite dilution. Therefore, at any other dilution, the equivalent conductance is proportional to the degree of dissociation. Thus,

Degree of dissociation

$$\alpha = \frac{\Lambda}{\Lambda_\infty} = \frac{\text{Equivalent conductance at a given concentration}}{\text{Equivalent conductance at infinite dilution}}$$

Calculation of absolute ionic mobilities: It has been experimentally found that ionic conductance is directly proportional to ionic mobilities.

$$\lambda_+ \propto u_+$$

$$\lambda_- \propto u_-$$

where, u_+ and u_- are ionic mobilities of cations and anions.

$$\lambda_+ = Fu_+ \quad \text{where, } F = \text{Faraday}$$

$$\lambda_- = Fu_- \qquad = 96500 \text{ coulomb}$$

$$\text{Ionic mobility} = \frac{\text{Ionic velocity}}{\text{Potential gradient}}$$

$$= \frac{\text{Ionic velocity (cm/sec)}}{\text{Potential difference (volt)/electrode separation}}$$

Relation between Equivalent and Molar Conductance at Infinite Dilution

$$\Lambda^\infty = \frac{1}{z^+}\lambda_+^\infty + \frac{1}{z^-}\lambda_-^\infty \quad \text{... (i)}$$

where, z^+ and z^- are corresponding charges on the ions,

e.g., $$\Lambda_{BaCl_2}^\infty = \frac{1}{2}\lambda_{Ba^{2+}}^\infty + \frac{1}{1}\lambda_{Cl^-}^\infty \quad \text{... (ii)}$$

$$\Lambda_{AlCl_3}^\infty = \frac{1}{3}\lambda_{Al^{3+}}^\infty + \frac{1}{1}\lambda_{Cl^-}^\infty \quad \text{... (iii)}$$

$$\Lambda_{Al_2(SO_4)_3}^\infty = \frac{1}{3}\lambda_{Al^{3+}}^\infty + \frac{1}{2}\lambda_{SO_4^{2-}}^\infty \quad \text{... (iv)}$$

Molar Conductance at Infinite Dilution

$$\Lambda_m^\infty \text{ or } \mu^\infty = \text{Molar conductance at infinite dilution}$$

$$= m\lambda_+^\infty + n\lambda_-^\infty$$

where, m and n are number of ions formed.

$$\mu_{Al_2(SO_4)_3}^\infty = 2\lambda_{Al^{3+}}^\infty + 3\lambda_{SO_4^{2-}}^\infty = 6\Lambda_{Al_2(SO_4)_3}^\infty$$

$$\mu_{BaCl_2} = \lambda_{Ba^{2+}}^\infty + 2\lambda_{Cl^-}^\infty = 2\Lambda_{BaCl_2}^\infty$$

12.9 THEORY OF WEAK ELECTROLYTES

(i) Weak electrolytes are not completely ionized when dissolved in a polar medium like water. There exists equilibrium between ions and unionised molecules.

$$AB \rightleftharpoons A^+ + B^-$$

(ii) Concept of chemical equilibrium and law of mass action can be applied to ionic equilibrium also.

$$\begin{array}{lccc} & AB & \rightleftharpoons & A^+ \quad + \quad B^- \\ t=0 & C & & 0 \qquad 0 \\ t_{\text{eq.}} & C - C\alpha & & C\alpha \quad C\alpha \end{array}$$

$$K = \frac{[A^+][B^-]}{[AB]} = \frac{C\alpha \times C\alpha}{C(1-\alpha)}$$

$$K = \frac{C\alpha^2}{1-\alpha} \quad \text{... (i)}$$

For weak electrolytes, $\alpha << 1$

$$\therefore \quad (1-\alpha) \approx 1$$

Thus, equation (i) can be written as:

$$K = C\alpha^2$$

$$\alpha = \sqrt{\frac{K}{C}} \quad \text{... (ii)}$$

From eq. (ii), it is clear that on dilution concentration decreases, as a result of which degree of ionisation 'α' increases. At high degree of ionisation both equivalent and molar conductance increase.

(iii) Degree of ionisation can be calculated as:

$$\alpha = \frac{\Lambda_e^C}{\Lambda_e^\infty} = \frac{\Lambda_m^C}{\Lambda_m^\infty} \quad \text{... (iii)}$$

Λ_e^C, Λ_m^C = Equivalent and molar conductance at concentration 'C'

$\Lambda_e^\infty, \Lambda_m^\infty$ = Equivalent and molar conductance at infinite dilution.

Substituting the values of 'α' from eq. (iii) in eq. (i), we get

$$K = \frac{C \times \left(\frac{\Lambda_e^C}{\Lambda_e^\infty}\right)^2}{1 - \frac{\Lambda_e^C}{\Lambda_e^\infty}} = \frac{C(\Lambda_e^C)^2}{\Lambda_e^\infty(\Lambda_e^\infty - \Lambda_e^C)} \quad \text{... (iv)}$$

Similarly,

$$K = \frac{C(\Lambda_m^C)^2}{\Lambda_m^\infty(\Lambda_m^\infty - \Lambda_m^C)} \quad \ldots \text{(v)}$$

Equations (iv) and (v) are called **Ostwald equations.**

Example 24. *1.0 N solution of a salt surrounding two platinum electrodes 2.1 cm apart and 4.2 sq cm in area was found to offer a resistance of 50 ohm. Calculate the equivalent conductivity of the solution.*

Solution: Given, $l = 2.1$ cm, $a = 4.2$ sq cm, $R = 50$ ohm

Specific conductance, $\kappa = \frac{l}{a} \cdot \frac{1}{R}$

or $\kappa = \frac{2.1}{4.2} \times \frac{1}{50} = 0.01 \text{ ohm}^{-1} \text{ cm}^{-1}$

Equivalent conductivity $= \kappa \times V$

V = the volume containing 1 g-equivalent = 1000 mL

So, Equivalent conductivity $= 0.01 \times 1000$

$= 10 \text{ ohm}^{-1} \text{ cm}^2 \text{ eq}^{-1}$

Example 25. *Specific conductance of a decinormal solution of KCl is 0.0112 ohm^{-1} cm^{-1}. The resistance of a cell containing the solution was found to be 56. What is the cell constant?*

Solution: We know that,

Sp. conductance = Cell constant × Conductance

or Cell constant $= \frac{\text{Sp. conductance}}{\text{Conductance}}$

= Sp. conductance × Resistance

$= 0.0112 \times 56 = 0.6272 \text{ cm}^{-1}$

Example 26. *The specific conductivity of 0.02 M KCl solution at 25° C is 2.768×10^{-3} ohm^{-1} cm^{-1}. The resistance of this solution at 25° C when measured with a particular cell was 250.2 ohm. The resistance of 0.01 M $CuSO_4$ solution at 25° C measured with the same cell was 8331 ohm. Calculate the molar conductivity of the copper sulphate solution.*

Solution: Cell constant $= \frac{\text{Sp. cond. of KCl}}{\text{Conductance of KCl}}$

$= \frac{2.768 \times 10^{-3}}{1/250.2}$

$= 2.768 \times 10^{-3} \times 250.2$

For 0.01 M $CuSO_4$ solution

Sp. conductivity = Cell constant × Conductance

$= 2.768 \times 10^{-3} \times 250.2 \times \frac{1}{8331}$

Molar conductance = Sp. cond. $\times \frac{1000}{C}$

$$= \frac{2.768 \times 10^{-3} \times 250.2}{8331} \times \frac{1000}{1/100} = 8.312 \text{ ohm}^{-1} \text{ cm}^2 \text{ mol}^{-1}$$

Example 27. *The equivalent conductances of sodium chloride, hydrochloric acid and sodium acetate at infinite dilution are 126.45, 426.16 and 91.0 ohm^{-1} cm^2 eq^{-1}, respectively, at 25° C. Calculate the equivalent conductance of acetic acid at infinite dilution.*

Solution: According to Kohlrausch's law,

$$\Lambda_{\infty CH_3COONa} = \lambda_{CH_3COO^-} + \lambda_{Na^+} = 91.0 \quad \ldots \text{(i)}$$

$$\Lambda_{\infty HCl} = \lambda_{H^+} + \lambda_{Cl^-} = 426.16 \quad \ldots \text{(ii)}$$

$$\Lambda_{\infty NaCl} = \lambda_{Na^+} + \lambda_{Cl^-} = 126.45 \quad \ldots \text{(iii)}$$

Adding eqs. (i) and (ii) and subtracting eq. (iii),

$$\lambda_{CH_3COO^-} + \lambda_{Na^+} + \lambda_{H^+} + \lambda_{Cl^-} - \lambda_{Na^+} - \lambda_{Cl^-} = 91.0 + 426.16 - 126.45$$

$$\lambda_{CH_3COO^-} + \lambda_{H^+} = \Lambda_{\infty CH_3COOH} = 390.7 \text{ ohm}^{-1} \text{ cm}^2 \text{ eq}^{-1}$$

Example 28. *The equivalent conductivity of N/10 solution of acetic acid at 25° C is 14.3 ohm^{-1} cm^2 eq^{-1}. Calculate the degree of dissociation of CH_3COOH if $\Lambda_{\infty CH_3COOH}$ is 390.71.*

Solution:

$$\Lambda_{\infty CH_3COOH} = 390.71 \text{ ohm}^{-1} \text{ cm}^2 \text{ eq}^{-1}$$

$$\Lambda_{CH_3COOH} = 14.3 \text{ ohm}^{-1} \text{ cm}^2 \text{ eq}^{-1}$$

Degree of dissociation, $\alpha = \frac{\Lambda_v}{\Lambda_\infty} = \frac{14.3}{390.71}$

$= 0.0366$, *i.e.*, 3.66% dissociated

Example 29. *A decinormal solution of NaCl has specific conductivity equal to 0.0092. If ionic conductances of Na^+ and Cl^- ions at the same temperature are 43.0 and 65.0 ohm^{-1} respectively, calculate the degree of dissociation of NaCl solution.*

Solution: Equivalent conductance of N/10 NaCl solution

Λ_v = Sp. conductivity × dilution

$= 0.0092 \times 10{,}000 = 92 \text{ ohm}^{-1}$

$\Lambda_\infty = \lambda_{Na^+} + \lambda_{Cl^-}$

$= 43.0 + 65.0 = 108 \text{ ohm}^{-1}$

Degree of dissociation, $\alpha = \frac{\Lambda_v}{\Lambda_\infty} = \frac{92}{108} = 0.85$

Example 30. *At 18° C, the conductivities at infinite dilution of NH_4Cl, NaOH and NaCl are 129.8, 217.4 and 108.9 mho respectively. If the equivalent conductivity of N/100 solution of NH_4OH is 9.93 mho, calculate the degree of dissociation of NH_4OH at this dilution.*

Solution: $\Lambda_{\infty NH_4Cl} = \lambda_{NH_4^+} + \lambda_{Cl^-} = 129.8 \quad \ldots \text{(i)}$

$$\Lambda_{\infty NaOH} = \lambda_{Na^+} + \lambda_{OH^-} = 217.4 \quad \ldots \text{(ii)}$$

$$\Lambda_{\infty NaCl} = \lambda_{Na^+} + \lambda_{Cl^-} = 108.9 \quad \ldots \text{(iii)}$$

Adding eqs. (i) and (ii) and subtracting eq. (iii),

$$\lambda_{NH_4^+} + \lambda_{Cl^-} + \lambda_{Na^+} + \lambda_{OH^-} - \lambda_{Na^+} - \lambda_{Cl^-} =$$

$$\lambda_{NH_4^+} + \lambda_{OH^-} = 129.8 + 217.4 - 108.9$$

$$\Lambda_{\infty NH_4OH} = 238.3 \text{ mho}$$

$$\text{Degree of dissociation, } \alpha = \frac{\Lambda_v}{\Lambda_\infty} = \frac{9.93}{238.3} = 0.04167$$

or 4.17 % dissociated.

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

11. If the equivalent conductance of 1 M benzoic acid is 12.8 ohm^{-1} cm^2 eq^{-1} and if the conductance of benzoate ion and H^+ ions are 42 and 288.42 ohm^{-1} cm^2 eq^{-1} respectively, its degree of dissociation is: **(DPMT 2005)**

(a) 39% (b) 3.9%

(c) 0.35% (d) 0.039%

[Ans. (b)]

[Hint: $\alpha = \frac{\Lambda_m}{\Lambda_m^\circ} = \frac{12.8}{(42 + 288.42)} = 0.0387$

Percentage dissociation $= 0.0387 \times 100 \approx 3.9\%$]

12. Equivalent conductances of NaCl, HCl and CH_3COONa at infinite dilution are 126.45, 426.16 and 91 ohm^{-1} cm^2 eq^{-1} respectively. The equivalent conductance of CH_3COOH at infinite dilution would be:

(a) 101.38 ohm^{-1} cm^2 eq^{-1} (b) 253.62 ohm^{-1} cm^2 eq^{-1}

(c) 390.71 ohm^{-1} cm^2 eq^{-1} (d) 678.90 ohm^{-1} cm^2 eq^{-1}

[Ans. (c)]

[Hint: $\Lambda^\circ_{CH_3COOH} = \Lambda^\circ_{CH_3COONa} + \Lambda^\circ_{HCl} - \Lambda^\circ_{NaCl}$

$= 91 + 426.16 - 126.45$

$= 390.71$ ohm^{-1} cm^2 eq^{-1}]

13. The specific conductance of saturated solution of AgCl is found to be 1.86×10^{-6} ohm^{-1} cm^{-1} and that of water is 6×10^{-8} ohm^{-1} cm^{-1}. The solubility of AgCl is ....

Given, $\Lambda^\circ_{AgCl} = 137.2$ ohm^{-1} cm^2 eq^{-1}

(a) $1.7 \times 10^{-3}\, M$ (b) $1.3 \times 10^{-5}\, M$

(c) $1.3 \times 10^{-4}\, M$ (d) $1.3 \times 10^{-6}\, M$

[Ans. (b)]

[Hint: $\kappa_{AgCl} = \kappa_{AgCl\,(Solution)} - \kappa_{H_2O}$

$= 1.86 \times 10^{-6} - 6 \times 10^{-8} = 1.8 \times 10^{-6}$ ohm^{-1} cm^{-1}

$$\Lambda^\circ_{AgCl} = \kappa \times \frac{1000}{S}$$

$$\therefore \quad S = \frac{\kappa \times 1000}{\Lambda^\circ_{AgCl}} = \frac{1.8 \times 10^{-6} \times 1000}{137.2} = 1.31 \times 10^{-5}\, M]$$

14. The specific conductivity of $N/10$ KCl solution at 20°C is 0.0212 ohm^{-1} cm^{-1} and the resistance of the cell containing this solution at 20°C is 55 ohm. The cell constant is:

(a) 4.616 cm^{-1} (b) 1.166 cm^{-1}

(c) 2.173 cm^{-1} (d) 3.324 cm^{-1}

[Ans. (b)]

[Hint: $\kappa = C \times \frac{l}{A}$

$\frac{l}{A} = \kappa \times \frac{1}{C} = \kappa \times R = 0.0212 \times 55 = 1.166$ cm^{-1}]

15. The resistance of 1 N solution of CH_3COOH is 250 ohm; when measured in a cell of cell constant 1.15 cm^{-1}. The equivalent conductance will be:

(a) 4.6 ohm^{-1} cm^2 eq^{-1} (b) 9.2 ohm^{-1} cm^2 eq^{-1}

(c) 18.4 ohm^{-1} cm^2 eq^{-1} (d) 0.023 ohm^{-1} cm^2 eq^{-1}

[Ans. (a)]

[Hint: $\kappa = C \times \frac{l}{A} = \frac{1}{250} \times 1.15 = 4.6 \times 10^{-3}$ ohm^{-1} cm^{-1}

$\Lambda_e = \kappa \times \frac{1000}{N} = 4.6 \times 10^{-3} \times \frac{1000}{1} = 4.6$ ohm^{-1} cm^2 eq^{-1}]

16. Resistance of a conductivity cell filled with a solution of an electrolyte of concentration 0.1 M is 100 ohm. The conductivity of this solution is 1.29 S m^{-1}. Resistance of the same cell when filled with 0.2 M of the same solution is 520 ohm. The molar conductivity of 0.02 M solution of the electrolyte will be: **(AIEEE 2006)**

(a) 124×10^{-4} S m^2 mol^{-1} (b) 1240×10^{-4} S m^2 mol^{-1}

(c) 1.24×10^{-4} S m^2 mol^{-1} (d) 12.4×10^{-4} S m^2 mol^{-1}

[Ans. (a)]

[Hint:

$$\kappa = \frac{1}{R} \times \frac{l}{A}$$

$$1.29 = \frac{1}{100} \times \frac{l}{A}$$

$$\frac{l}{A} = 129 \text{ m}^{-1}$$

$$\Lambda_m = \kappa \times \frac{1000}{M}$$

$$= \left(\frac{1}{R} \times \frac{l}{A}\right) \times \frac{1000}{M}$$

[Ans. (b)]

[Hint: $\Lambda^\circ_{NaNO_3} = \Lambda^\circ_{NaCl} + \Lambda^\circ_{KNO_3} - \Lambda^\circ_{KCl}$

$= 128 + 111 - 152 = 87$ S cm^2 mol^{-1}]

SECTION III : ELECTROCHEMICAL CELL

12.10 ELECTROCHEMICAL CELL

Electrochemical cell is a system or arrangement in which two electrodes are fitted in the same electrolyte or in two different electrolytes which are joined by a salt bridge. Electrochemical cells are of two types:

(a) Electrolytic cell
(b) Galvanic or voltaic cell

(a) Electrolytic Cell

It is a device in which electrolysis (chemical reaction involving oxidation and reduction) is carried out by using electricity or in which conversion of electrical energy into chemical energy is done.

(b) Galvanic or Voltaic Cell

It is a device in which a redox reaction is used to convert chemical energy into electrical energy, *i.e.*, electricity can be obtained with the help of oxidation and reduction reaction. The chemical reaction responsible for production of electricity takes place in two separate compartments. Each compartment consists of a suitable electrolyte solution and a metallic conductor. The metallic conductor acts as an electrode. The compartments containing the electrode and the solution of the electrolyte are called **half-cells.** When the two compartments are connected by a salt bridge and electrodes are joined by a wire through galvanometer the electricity begins to flow. This is the simple form of voltaic cell.

12.11 DANIELL CELL

It is designed to make use of the spontaneous redox reaction between zinc and cupric ions to produce an electric current (Fig. 12.7). It consists of two half-cells. The half-cell on the left contains a zinc metal electrode dipped in $ZnSO_4$ solution. The half-cell on the right consists of copper metal electrode in a solution of $CuSO_4$. The half-cells are joined by a salt bridge that prevents the mechanical mixing of the solution.

When the zinc and copper electrodes are joined by a wire, the following observations are made:

(i) There is a flow of electric current through the external circuit.
(ii) The zinc rod loses its mass while the copper rod gains in mass.
(iii) The concentration of $ZnSO_4$ solution increases while the concentration of copper sulphate solution decreases.
(iv) The solutions in both the compartments remain electrically neutral.

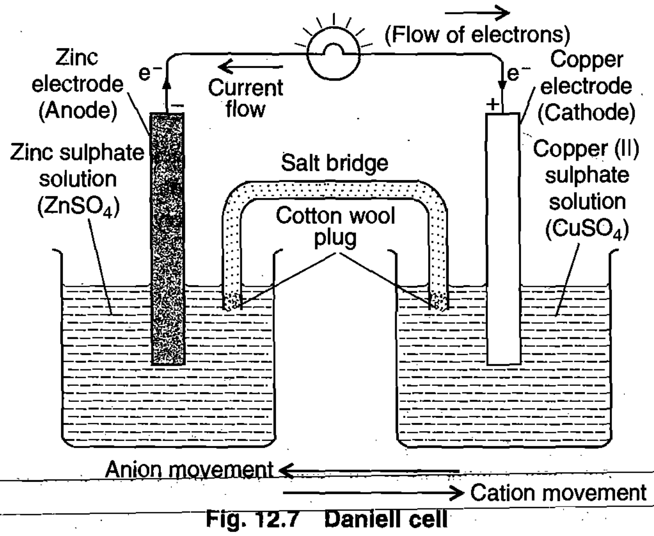

Fig. 12.7 Daniell cell

During the passage of electric current through external circuit, electrons flow from the zinc electrode to the copper electrode. At the zinc electrode, the zinc metal is oxidised to zinc ions which go into the solution. The electrons released at the electrode travel through the external circuit to the copper electrode where they are used in the reduction of Cu^{2+} ions to metallic copper which is deposited on the electrode. Thus, the overall redox reaction is:

$$Zn(s) + Cu^{2+}(aq.) \longrightarrow Cu(s) + Zn^{2+}(aq.)$$

Thus, indirect redox reaction leads to the production of electrical energy. At the zinc rod, oxidation occurs. It is the anode of the cell and is negatively charged while at copper electrode, reduction takes place; it is the cathode of the cell and is positively charged.

Thus, the above points can be summed up as:

(i) Voltaic or Galvanic cell consists of two **half-cells.** The reactions occurring in half-cells are called **half-cell reactions.** The half-cell in which oxidation occurs is called **oxidation half-cell** and the reaction taking place in it is called **oxidation half-cell reaction.** Similarly, the half-cell in which reduction occurs is called **reduction half-cell** and the reaction taking place in it is called **reduction half-cell reaction.**
(ii) The electrode where oxidation occurs is called anode and the electrode where reduction occurs is termed cathode.
(iii) Electrons flow from anode to cathode in the external circuit.
(iv) Overall ion movement during the operation of the galvanic cell shows that negative ions (anions) move away from cathode where they are present in excess, towards anode, where they are needed to balance the charge of the positive ions (cations) formed. Similarly, cations move away from the anode where they are in excess, towards the cathode, where they balance the anions left in excess.

Example : An $Au(NO_3)_3$ solution containing a gold electrode is connected by means of salt bridge to a $PbCl_2$ solution containing lead electrode. The cell can be correctly represented as,

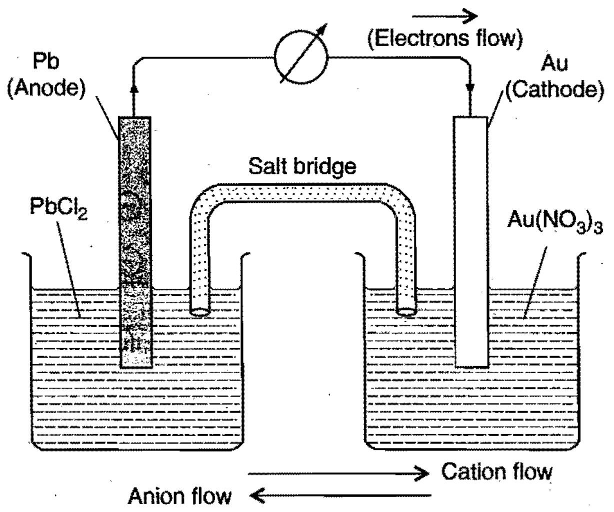

Fig. 12.8

(v) Chemical energy is converted into electrical energy.

(vi) The net reaction is the sum of two half-cell reactions. The reactions in Daniell cell can be represented as:

Oxidation half reaction, $\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(aq.) + 2e^-$

Reduction half reaction, $\mathrm{Cu}^{2+}(aq.) + 2e^- \longrightarrow \mathrm{Cu}(s)$

Net reaction $\mathrm{Zn}(s) + \mathrm{Cu}^{2+}(aq.) \longrightarrow \mathrm{Zn}^{2+}(aq.) + \mathrm{Cu}(s)$

Electrode Signs

The signs of the anode and cathode in the voltaic or galvanic cells are opposite to those in the electrolytic cells (Fig. 12.9).

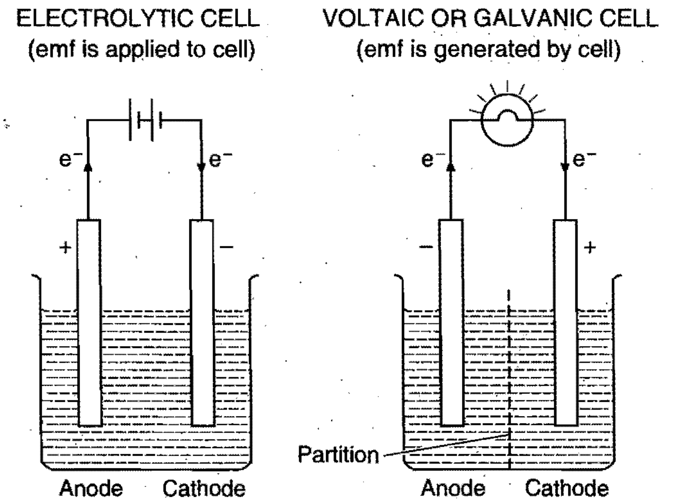

Fig. 12.9

	Electrolytic cell		**Voltaic or Galvanic cell**	
	Anode	**Cathode**	**Anode**	**Cathode**
Sign	+	−	−	+
Electron flow	out	in	out	in
Half reaction	oxidation	reduction	oxidation	reduction

Difference in electrolytic cell and galvanic cell

	Electrolytic cell	**Galvanic cell**
1.	Electrical energy is converted into chemical energy.	Chemical energy is converted into electrical energy.
2.	Anode is positive electrode. Cathode is negative electrode.	Anode is negative electrode. Cathode is positive electrode.
3.	Ions are discharged on both the electrodes.	Ions are discharged only on the cathode.
4.	If the electrodes are inert, concentration of the electrolyte decreases when the electric current is circulated.	Concentration of the anodic half-cell increases while that of cathodic half-cell decreases when the two electrodes are joined by a wire.
5.	Both the electrodes can be fitted in the same compartment.	The electrodes are fitted in different compartments.

12.12 SALT BRIDGE AND ITS SIGNIFICANCE

Salt bridge is usually an inverted U-tube filled with concentrated solution of inert electrolytes. An inert electrolyte is one whose ions are neither involved in any electrochemical change nor do they react chemically with the electrolytes in the two half-cells. Generally salts like KCl, KNO_3, NH_4NO_3, etc., are used. For the preparation of salt bridge, gelatin or agar-agar is dissolved in a hot concentrated aqueous solution of an inert electrolyte and the solution thus formed is filled in the U-tube. On cooling the solution sets in the form of a gel in the U-tube. The ends of the U-tube are plugged with cotton wool as to minimise diffusion effects. This is used as a salt bridge.

Significance of salt bridge: The following are the functions of the salt bridge:

(i) It connects the solutions of two half-cells and completes the cell circuit.

(ii) It prevents transference or diffusion of the solutions from one half-cell to the other.

(iii) It keeps the solutions in two half-cells electrically neutral. In anodic half-cell, positive ions pass into the solution and there shall be accumulation of extra positive charge in the solution around the anode which will prevent the flow of electrons from anode. This does not happen because negative ions are provided by salt bridge. Similarly, in cathodic half-cell, negative ions will accumulate around cathode due to deposition of positive ions by reduction. To neutralise these negative ions, sufficient number of positive ions are provided by salt bridge. Thus, salt bridge maintains electrical neutrality.

(iv) It prevents liquid-liquid junction-potential, *i.e.*, the potential difference which arises between two solutions when in contact with each other.

A broken vertical line or two parallel vertical lines in a cell reaction indicates the salt bridge.

$$\mathrm{Zn} \mid \mathrm{Zn}^{2+} \parallel \mathrm{Cu}^{2+} \mid \mathrm{Cu}$$

Salt bridge can be replaced by a porous partition which allows the migration of ions without allowing the solutions to intermix.

12.13 REPRESENTATION OF AN ELECTROCHEMICAL CELL (Galvanic Cell)

The following universally accepted conventions are followed in representing an electrochemical cell:

(i) The anode (negative electrode) is written on the left hand side and cathode (positive electrode) on the right hand side.

(ii) A vertical line or semicolon (;) indicates a contact between two phases. The anode of the cell is represented by writing metal first and then the metal ion present in the electrolytic solution. Both are separated by a vertical line or a semicolon. For example,

$$\mathrm{Zn} \mid \mathrm{Zn}^{2+} \text{ or } \mathrm{Zn};\mathrm{Zn}^{2+}$$

The molar concentration or activity of the solution is written in brackets after the formula of the ion. For example,

$$\mathrm{Zn} \mid \mathrm{Zn}^{2+}(1\,M) \text{ or } \mathrm{Zn} \mid \mathrm{Zn}^{2+}(0.1\,M)$$

(iii) The cathode of the cell is represented by writing the cation of the electrolyte first and then metal. Both are separated by a vertical line or semicolon. For example,

$$\mathrm{Cu}^{2+} \mid \mathrm{Cu} \text{ or } \mathrm{Cu}^{2+};\mathrm{Cu} \text{ or } \mathrm{Cu}^{2+}(1\,M) \mid \mathrm{Cu}$$

(iv) The salt bridge which separates the two half-cells is indicated by two parallel vertical lines.

(v) Sometimes negative and positive signs are also put on the electrodes.

The Daniell cell can be represented as:

$$\overset{-}{\mathrm{Zn}} \mid \mathrm{ZnSO_4}(aq.) \parallel \mathrm{CuSO_4}(aq.) \mid \overset{+}{\mathrm{Cu}}$$

Anode Salt bridge Cathode
Oxidation half-cell Reduction half-cell

or $$\mathrm{Zn} \mid \mathrm{Zn}^{2+} \parallel \mathrm{Cu}^{2+} \mid \mathrm{Cu}$$

or $$\mathrm{Zn} \mid \mathrm{Zn}^{2+}(1\,M) \parallel \mathrm{Cu}^{2+}(1\,M) \mid \mathrm{Cu}$$

12.14 ELECTRODE POTENTIAL

When a metal is placed in a solution of its ions, the metal acquires either a positive or negative charge with respect to the solution. On account of this, a definite potential difference is developed between the metal and the solution. This potential difference is called **electrode potential.** For example, when a plate of zinc is placed in a solution having Zn^{2+} ions, it becomes negatively charged with respect to solution and thus a potential difference is set-up between zinc plate and the solution. This potential difference is termed the electrode potential of zinc. Similarly, when copper is placed in a solution having Cu^{2+} ions, it becomes positively charged with respect to solution. A potential difference is set-up between the copper plate and the solution. The potential difference thus developed is termed as electrode potential of copper. The potential difference is established due to the formation of electrical double layer at the interface of metal and the solution. The development of negative charge (as on zinc plate) or positive charge (as on copper plate) can be explained in the following manner. When a metal rod is dipped in its salt solution, two changes occur:

$$M(s) \longrightarrow M^{n+}(aq.) + ne^-$$

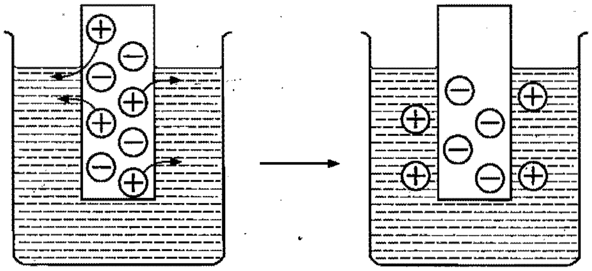

Fig. 12.10 (a)

$$M^{n+}(aq.) + ne^- \longrightarrow M(s)$$

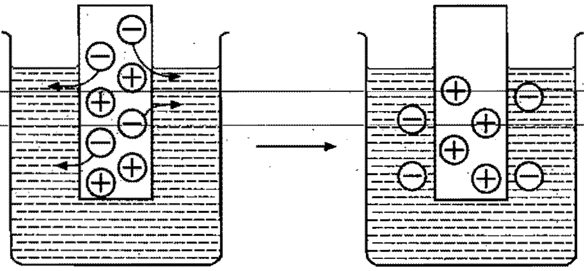

Fig. 12.10 (b)

(a) Oxidation : Metal ions pass from the electrode into solution leaving an excess of electrons and thus a negative charge on the electrode.

(b) Reduction : Metal ions in solution gain electrons from the electrode leaving a positive charge on the electrode.

(i) The conversion of metal atoms into metal ions by the attractive force of polar water molecules.

$$M \longrightarrow M^{n+} + ne^-$$

The metal ions go into the solution and the electrons remain on the metal making it negatively charged. The tendency of the metal to change into ions is known as **electrolytic solution pressure.**

(ii) Metal ions start depositing on the metal surface leading to a positive charge on the metal.

$$M^{n+} + ne^- \longrightarrow M$$

This tendency of the ions is termed **osmotic pressure.**

In the beginning, both these changes occur with different speeds but soon an equilibrium is established.

$$M \rightleftharpoons M^{n+} + ne^-$$

In practice, one effect is greater than the other, if first effect is greater than the second, the metal acquires a negative charge with respect to solution and if the second is greater than the first, it acquires positive charge with respect to solution, thus in both the cases a potential difference is set-up.

The magnitude of the electrode potential of a metal is a measure of its relative tendency to lose or gain electrons, *i.e.*, it is a measure of the relative tendency to undergo oxidation (loss of electrons) or reduction (gain of electrons). The magnitude of potential depends on the following factors:

(i) Nature of the electrode,
(ii) Concentration of the ions in solution,
(iii) Temperature.

Depending on the nature of the metal electrode to lose or gain electrons, the electrode potential may be of two types:

(i) Oxidation potential: When electrode is negatively charged with respect to solution, *i.e.*, it acts as anode. Oxidation occurs.

$$M \longrightarrow M^{n+} + ne^-$$

(ii) Reduction potential: When electrode is positively charged with respect to solution, *i.e.*, it acts as cathode. Reduction occurs.

$$M^{n+} + ne^- \longrightarrow M$$

It is not possible to measure the absolute value of the single electrode potential directly. Only the difference in potential between two electrodes can be measured experimentally. It is, therefore, necessary to couple the electrode with another electrode whose potential is known. This electrode is termed as **reference electrode.** The emf of the resulting cell is measured experimentally. The emf of the cell is equal to the sum of potentials on the two electrodes.

Emf of the cell = $E_{\text{Anode}} + E_{\text{Cathode}}$
= Oxidation potential of anode
+ Reduction potential of cathode

Knowing the value of reference electrode, the value of other electrode can be determined.

12.15 STANDARD ELECTRODE POTENTIAL

In order to compare the electrode potentials of various electrodes, it is necessary to specify the concentration of the ions present in solution in which the electrode is dipped and the temperature of the half-cell. The potential difference developed between metal electrode and the solution of its ions of unit molarity (1 *M*) at 25° C (298 K) is called **standard electrode potential.**

According to the IUPAC convention, the reduction potential alone can be called as the electrode potential ($E°$), *i.e.*, the given value of electrode potential can be regarded as reduction potential unless it is specifically mentioned that it is oxidation potential. Standard reduction potential of an electrode means that reduction reaction is taking place at the electrode. If the reaction is reversed and written as oxidation reaction, the numerical value of electrode potential will remain same but the sign of standard potential will have to be reversed. Thus,

Standard reduction potential = – Standard oxidation potential

or Standard oxidation potential = – Standard reduction potential

12.16 REFERENCE ELECTRODE (Standard Hydrogen Electrode, SHE or NHE)

Hydrogen electrode is the primary standard electrode. It consists of a small platinum strip coated with platinum black as to adsorb hydrogen gas. A platinum wire is welded to the platinum strip and sealed in a glass tube as to make contact with the outer circuit through mercury. The platinum strip and glass tube is surrounded by an outer glass tube which has an inlet for hydrogen gas at the top and a number of holes at the base for the escape of excess of hydrogen gas. The platinum strip is placed in an acid solution which has H^+ ion concentration 1 *M*. Pure hydrogen gas is circulated at one atmospheric pressure. A part of the gas is adsorbed and the rest escapes through holes. This gives an equilibrium between the adsorbed hydrogen and hydrogen ions in the solution.

$$H_2 \rightleftharpoons 2H^+ + 2e^-$$

The temperature of the cell is maintained at 25° C. By international agreement the standard hydrogen electrode is arbitrarily assigned a potential of exactly ± 0.000... volt.

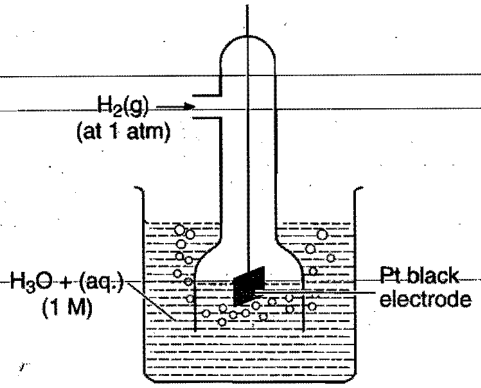

Fig. 12.11 Hydrogen electrode

The hydrogen electrode thus obtained forms one of two half-cells of a voltaic cell. When this half-cell is connected with any other half-cell, a voltaic cell is constituted. The hydrogen electrode can act as cathode or anode with respect to other electrode.

SHE half reaction	**Electrode potential**
$H_2 \longrightarrow 2H^+ + 2e^-$	0.0 V (Anode)
$2H^+ + 2e^- \longrightarrow H_2$	0.0 V (Cathode)

12.17 MEASUREMENT OF ELECTRODE POTENTIAL

The measurement of electrode potential of a given electrode is made by constituting a voltaic cell, *i.e.*, by connecting it with a standard hydrogen electrode (SHE) through a salt bridge. 1 *M* solution is used in hydrogen half-cell and the temperature is maintained at 25° C. The emf of the cell is measured either by a calibrated potentiometer or by a high resistance voltmeter, *i.e.*, a valve voltmeter. The reading of the voltmeter gives the electrode potential of the electrode in question with respect to the hydrogen electrode. The standard electrode potential of a metal may be determined as it is the potential difference in volt developed in a cell consisting of two electrodes: the pure metal is in contact with a molar solution of one of its ions and the standard hydrogen electrode.

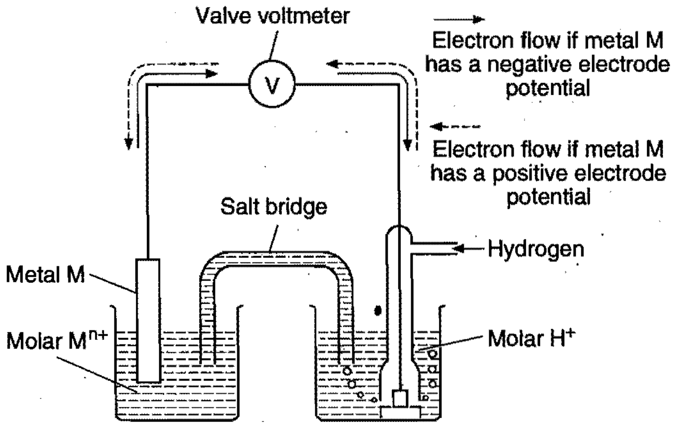

Fig. 12.12

(i) Determination of standard electrode potential of Zn / Zn^{2+} electrode: A zinc rod is dipped in 1 *M* zinc sulphate solution. This half-cell is combined with a standard hydrogen electrode through a salt bridge. Both the electrodes are connected with a voltmeter as shown in Fig. 12.13. The deflection of the voltmeter indicates that current is flowing from hydrogen electrode to metal electrode or the electrons are moving from zinc rod to hydrogen electrode. The zinc electrode acts as an anode and the hydrogen electrode as cathode and the cell can be represented as

$$\underset{\text{Anode } (-)}{\underline{Zn \mid Zn^{2+}(aq.)}} \,||\, \underset{\text{Cathode } (+)}{\underline{2H^+(aq.) \mid H_2(g)}}$$

$$\underset{\text{(Oxidation)}}{Zn \longrightarrow Zn^{2+} + 2e^-} \;;\; \underset{\text{(Reduction)}}{2H^+ + 2e^- \longrightarrow H_2\uparrow}$$

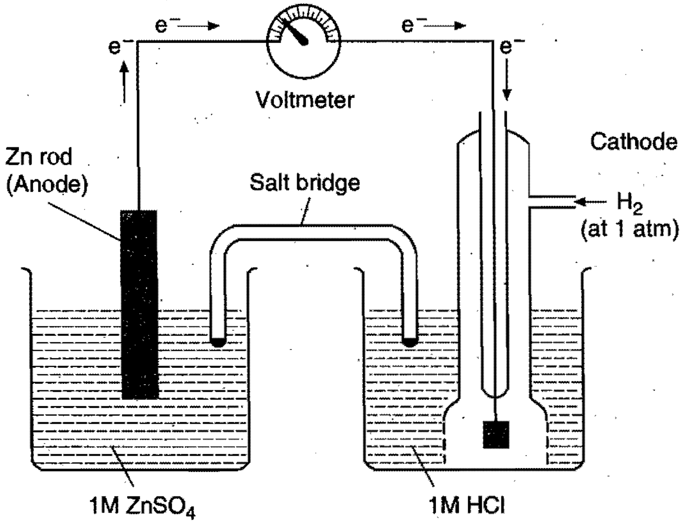

Fig. 12.13 $Zn–H_2$ electrochemical cell

The emf of the cell is 0.76 volt

$$E^\circ_{Cell} = E^\circ_{Anode} + E^\circ_{Cathode}$$

$$0.76 = E^\circ_{Anode} + 0 \text{ or } E^\circ_{Anode} = +0.76\text{ V}$$

As the reaction on the anode is oxidation, *i.e.*,

$$Zn \longrightarrow Zn^{2+} + 2e,$$

E°_{Anode} is the standard oxidation potential of zinc. This potential is given the positive sign.

$$E^\circ_{ox}(Zn / Zn^{2+}) = +0.76\text{ volt}$$

So, standard reduction potential of Zn, *i.e.*, $E^\circ(Zn^{2+} / Zn)$

$$= -E^\circ_{ox} = -(+0.76)$$

$$= -0.76\text{ volt}$$

The emf of such a cell gives the positive value of standard oxidation potential of metal *M*. The standard reduction potential (E°) is obtained by reversing the sign of standard oxidation potential.

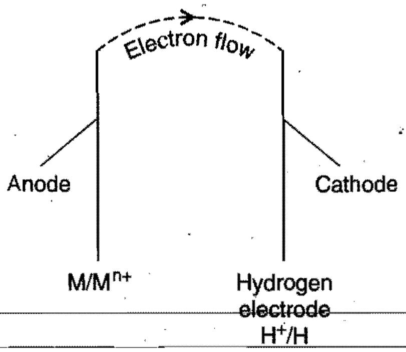

Fig. 12.14

(ii) Determination of standard electrode potential of Cu^{2+} / Cu, electrode: A copper rod is dipped in 1 *M* solution of $CuSO_4$. It is combined with hydrogen electrode through a salt bridge. Both the electrodes are joined through a voltmeter. The deflection of the voltmeter indicates that current is flowing from copper electrode towards hydrogen electrode, *i.e.*, the electrons are moving from hydrogen electrode to copper electrode. The hydrogen electrode acts as an anode and the copper electrode as a cathode. The cell can be represented as

$$\underset{\text{Anode } (-)}{H_2(g) \mid 2H^+(aq.)} \,||\, \underset{\text{Cathode } (+)}{Cu^{2+}(aq.) \mid Cu}$$

$$\underset{\text{Oxidation}}{H_2 \longrightarrow 2H^+ + 2e^-} \;;\; \underset{\text{Reduction}}{Cu^{2+} + 2e^- \longrightarrow Cu}$$

The emf of the cell is 0.34 volt.

$$E^\circ_{Cell} = E^\circ_{Anode} + E^\circ_{Cathode}$$

$$0.34 = 0 + E^\circ_{Cathode}$$

Since, the reaction on the cathode is reduction, *i.e.*, $Cu^{2+} + 2e^- \longrightarrow Cu$, $E^\circ_{Cathode}$ is the standard reduction potential of copper. This is given the + ve sign.

E°, *i.e.*, standard reduction potential of $Cu^{2+}/Cu = 0.34$ volt

So, E°_{ox} (standard oxidation potential of copper) = – 0.34 volt

The emf of such a cell gives positive value of reduction potential of metal electrode. The standard oxidation potential of this electrode is obtained by reversing the sign of standard reduction potential.

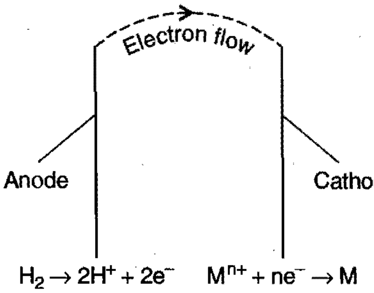

Fig. 12.15

It is thus concluded that at the metal electrode which acts as anode with respect to hydrogen electrode (cathode), the reduction potential is given the minus sign and at the metal electrode which acts as cathode with respect to hydrogen electrode (anode), the reduction potential is given the positive sign.

The standard electrode potentials (oxidation or reduction) of various elements can be measured by combining the electrode in question with a standard hydrogen electrode and measuring the emf of the cell constituted.

12.18 EMF OF A GALVANIC CELL

Every galvanic or voltaic cell is made up of two half-cells, the oxidation half-cell (anode) and the reduction half-cell (cathode). The potentials of these half-cells are always different. On account of this difference in electrode potentials, the electric current moves from the electrode at higher potential to the electrode at lower potential, *i.e.*, from cathode to anode. The direction of the flow of electrons is from anode to cathode.

$$\text{Anode} \underset{\text{Flow of current}}{\overset{\text{Flow of electrons}}{\rightleftarrows}} \text{Cathode}$$

The difference in potentials of the two half-cells is known as the electromotive force **(emf) of the cell or cell potential.**

The emf of the cell or cell potential can be calculated from the values of electrode potentials of the two half-cells constituting the cell. The following three methods are in use:

(i) When oxidation potential of anode and reduction potential of cathode are taken into account:

$$E^\circ_{\text{cell}} = \text{Oxidation potential of anode} + \text{Reduction potential of cathode}$$
$$= E^\circ_{\text{ox}}\ (\text{anode}) + E^\circ_{\text{red}}\ (\text{cathode})$$

(ii) When reduction potentials of both electrodes are taken into account:

$$E^\circ_{\text{cell}} = \text{Standard Reduction potential of cathode} - \text{Standard Reduction potential of anode}$$
$$= E^\circ_{\text{Cathode}} - E^\circ_{\text{Anode}}$$
$$= E^\circ_{\text{right}} - E^\circ_{\text{left}}$$

(iii) When oxidation potentials of both electrodes are taken into account:

$$E^\circ_{\text{cell}} = \text{Oxidation potential of anode} - \text{Oxidation potential of cathode}$$
$$= E^\circ_{\text{ox}}\ (\text{anode}) - E^\circ_{\text{ox}}\ (\text{cathode})$$

Difference between emf and potential difference: The potential difference is the difference between the electrode potentials of the two electrodes of the cell under any condition while emf is the potential generated by a cell when there is zero electron flow, *i.e.*, it draws no current. The points of difference are given ahead:

Emf	Potential difference
1. It is the potential difference between two electrodes when no current is flowing in the circuit.	It is the difference of the electrode potentials of the two electrodes when the cell is under operation.
2. It is the maximum voltage that the cell can deliver.	It is always less than the maximum value of voltage which the cell can deliver.
3. It is responsible for the steady flow of current in the cell.	It is not responsible for the steady flow of current in the cell.

12.19 REVERSIBLE AND IRREVERSIBLE CELLS

Daniell cell has the emf value 1.09 volt. If an opposing emf exactly equal to 1.09 volt is applied to the cell, the cell reaction,

$$Zn + Cu^{2+} \longrightarrow Cu + Zn^{2+}$$

stops but if it is increased infinitesimally beyond 1.09 volt, the cell reaction is reversed.

$$Cu + Zn^{2+} \longrightarrow Zn + Cu^{2+}$$

Such a cell is termed a **reversible cell.** Thus, the following are the two main conditions of reversibility:

(i) The chemical reaction of the cell stops when an exactly equal opposing emf is applied.

(ii) The chemical reaction of the cell is reversed and the current flows in opposite direction when the opposing emf is slightly greater than that of the cell.

Any other cell which does not obey the above two conditions is termed as **irreversible.** A cell consisting of zinc and copper electrodes dipped into the solution of sulphuric acid is irreversible. Similarly, the cell

$$Zn \mid H_2SO_4(aq.) \mid Ag$$

is also irreversible because when the external emf is greater than the emf of the cell, the cell reaction,

$$Zn + 2H^+ \longrightarrow Zn^{2+} + H_2$$

is not reversed but the cell reaction becomes

$$2Ag + 2H^+ \longrightarrow 2Ag^+ + H_2$$

12.20 SOME OTHER REFERENCE ELECTRODES

Since, a standard hydrogen electrode is difficult to prepare and maintain, it is usually replaced by other reference electrodes, which are known as secondary reference electrodes. These are convenient to handle and are prepared easily. Two important secondary reference electrodes are described here.

(i) **Calomel electrode:** It consists of mercury at the bottom over which a paste of mercury-mercurous chloride is placed. A solution of potassium chloride is then placed over the paste. A platinum wire sealed in a glass tube helps in making the electrical contact. The electrode is connected with the help of the side tube on the left through a salt bridge with the other electrode to make a complete cell.

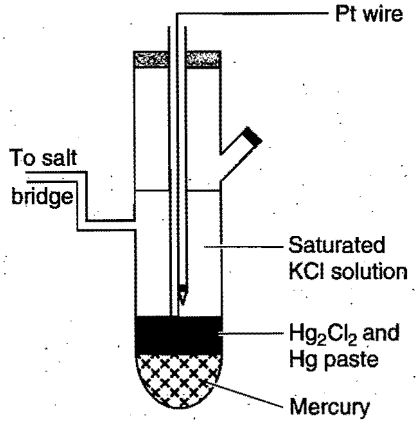

Fig. 12.16 Calomel electrode

The potential of the calomel electrode depends upon the concentration of the potassium chloride solution. If potassium chloride solution is saturated, the electrode is known as saturated calomel electrode (SCE) and if the potassium chloride solution is 1 N, the electrode is known as normal calomel electrode (NCE) while for 0.1 N potassium chloride solution, the electrode is referred to as decinormal calomel electrode (DNCE). The electrode reaction when the electrode acts as cathode is:

$$\frac{1}{2}\mathrm{Hg_2Cl_2} + e^- \rightleftharpoons \mathrm{Hg} + \mathrm{Cl^-}$$

The reduction potentials of the calomel electrodes on hydrogen scale at 298 K are as follows:

Saturated KCl	0.2415 V
1.0 N KCl	0.2800 V
0.1 N KCl	0.3338 V

The electrode potential of any other electrode on hydrogen scale can be measured when it is combined with calomel electrode. The emf of such a cell is measured. From the value of electrode potential of calomel electrode, the electrode potential of the other electrode can be evaluated.

(ii) Silver-silver chloride electrode: This is another widely used reference electrode. It is reversible and stable and can be combined with cells containing chlorides without inserting liquid junctions.

Silver chloride is deposited electrolytically on a silver or platinum wire and it is then immersed in a solution containing chloride ions. Its standard electrode potential with respect to the standard hydrogen electrode is 0.2224 V at 298 K. The electrode is represented as:

$$\mathrm{Ag} \mid \mathrm{AgCl} \mid \mathrm{Cl^-}$$

The electrode reaction is:

$$\mathrm{AgCl} + e^- \longrightarrow \mathrm{Ag} + \mathrm{Cl^-}$$

12.21 PREDICTION FOR OCCURRENCE OF A REDOX REACTION

Any redox reaction would occur spontaneously if the free energy change (ΔG) is negative. The free energy is related to cell emf in the following manner:

$$\Delta G^\circ = -nFE^\circ$$

where, n is the number of electrons involved, F is the value of Faraday and E° is the cell emf. ΔG can be negative if E° is positive.

When E° is positive, the cell reaction is spontaneous and serves as a source of electrical energy.

To predict whether a particular redox reaction will occur or not, write down the redox reaction into two half reactions, one involving oxidation reaction and the other involving reduction reaction. Write the oxidation potential value for oxidation reaction and reduction potential value for reduction reaction. Add these two values, if the algebraic summation gives a positive value, the reaction will occur, otherwise not.

[**Note :** The true conditions for operating voltaic cells are :
$\Delta G < 0,\ E > 0$]

12.22 ELECTRODE AND CELL POTENTIALS—NERNST EQUATION

The electrode potential and the emf of the cell depend upon the nature of the electrode, temperature and the activities (concentrations) of the ions in solution. The variation of electrode and cell potentials with concentration of ions in solution can be obtained from thermodynamic considerations. For a general reaction such as

$$m_1A + m_2B + \ldots \rightleftharpoons n_1X + n_2Y + \ldots \qquad \ldots \text{(i)}$$

occurring in the cell, the Gibbs free energy change is given by the equation

$$\Delta G = \Delta G^\circ + 2.303RT\log_{10}\frac{a_X^{n_1} \times a_Y^{n_2}\ldots}{a_A^{m_1} \times a_B^{m_2}\ldots} \qquad \ldots \text{(ii)}$$

where, 'a' represents the activities of reactants and products under a given set of conditions and ΔG° refers to free energy change for the reaction when the various reactants and products are present at standard conditions. The free energy change of a cell reaction is related to the electrical work that can be obtained from the cell, *i.e.*, $\Delta G = -nFE_{\text{cell}}$ and $\Delta G^\circ = -nFE^\circ$. On substituting these values in eq. (ii), we get

$$-nFE_{\text{cell}} = -nFE^\circ_{\text{cell}} + 2.303RT\log_{10}\frac{a_X^{n_1} \times a_Y^{n_2}\ldots}{a_A^{m_1} \times a_B^{m_2}\ldots} \qquad \ldots \text{(iii)}$$

or
$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{2.303RT}{nF}\log_{10}\frac{a_X^{n_1} \times a_Y^{n_2}\ldots}{a_A^{m_1} \times a_B^{m_2}\ldots} \qquad \ldots \text{(iv)}$$

This equation is known as Nernst equation.

Putting the values of $R = 8.314\ \mathrm{JK^{-1}\ mol^{-1}}$, $T = 298$ K and $F = 96500$ C, eq. (iv) reduces to

$$E = E^\circ - \frac{0.0591}{n}\log_{10}\frac{a_X^{n_1} \times a_Y^{n_2}\ldots}{a_A^{m_1} \times a_B^{m_2}\ldots} \qquad \ldots \text{(v)}$$

$$= E^\circ - \frac{0.0591}{n}\log_{10}\frac{[\text{Products}]}{[\text{Reactants}]} \qquad \ldots \text{(vi)}$$

Potential of single electrode (Anode): Consider the general oxidation reaction,

$$M \longrightarrow M^{n+} + ne^-$$

Applying Nernst equation,

$$E_{\text{ox}} = E^{\circ}_{\text{ox}} - \frac{0.0591}{n} \log_{10} \frac{[M^{n+}]}{[M]}$$

where, E_{ox} is the oxidation potential of the electrode (anode), E°_{ox} is the standard oxidation potential of the electrode.

[**Note:** The concentration of pure solids and liquids are taken as unity.]

$$E_{\text{ox}} = E^{\circ}_{\text{ox}} - \frac{0.0591}{n} \log_{10} [M^{n+}]$$

Let us consider a Daniell cell to explain the above equations. The concentrations of the electrolytes are not 1 *M*.

$$\text{Zn}(s) + \text{Cu}^{2+}(aq.) \rightleftharpoons \text{Zn}^{2+}(aq.) + \text{Cu}(s)$$

$$\text{Zn}(s) \mid \text{Zn}^{2+}(aq.) \mid\mid \text{Cu}^{2+}(aq.) \mid \text{Cu}$$

Potential at zinc electrode (Anode)

$$E_{\text{ox}} = E^{\circ}_{\text{ox}} - \frac{0.0591}{n} \log_{10} [\text{Zn}^{2+}]$$

Potential at copper electrode (Cathode)

$$E_{\text{red}} = E^{\circ}_{\text{red}} + \frac{0.0591}{n} \log_{10} [\text{Cu}^{2+}]$$

Emf of the cell

$$\begin{aligned} E_{\text{cell}} &= E_{\text{ox}} + E_{\text{red}} \\ &= (E^{\circ}_{\text{ox}} + E^{\circ}_{\text{red}}) - \frac{0.0591}{n} \log_{10} \left[\frac{\text{Zn}^{2+}}{\text{Cu}^{2+}}\right] \\ &= E^{\circ}_{\text{cell}} - \frac{0.0591}{n} \log_{10} \left[\frac{\text{Zn}^{2+}}{\text{Cu}^{2+}}\right] \end{aligned}$$

The value of $n = 2$ for both zinc and copper.

Let us consider an example, in which the values of *n* for the two ions in the two half-cells are not same. For example, in the cell

$$\text{Cu} \mid \text{Cu}^{2+} \mid\mid \text{Ag}^+ \mid \text{Ag}$$

The cell reaction is:

$$\text{Cu}(s) + 2\text{Ag}^+ \longrightarrow \text{Cu}^{2+} + 2\text{Ag}$$

The two half-cell reactions are:

$$\text{Cu} \longrightarrow \text{Cu}^{2+} + 2e^-$$

$$\text{Ag}^+ + e^- \longrightarrow \text{Ag}$$

The second equation is multiplied by 2 to balance the number of electrons.

$$2\text{Ag}^+ + 2e^- \longrightarrow 2\text{Ag}$$

$$E_{\text{ox}} = E^{\circ}_{\text{ox}} - \frac{0.0591}{2} \log_{10} [\text{Cu}^{2+}]$$

$$E_{\text{red}} = E^{\circ}_{\text{red}} + \frac{0.0591}{2} \log_{10} [\text{Ag}^+]^2$$

$$\begin{aligned} E_{\text{cell}} = E_{\text{ox}} + E_{\text{red}} &= E^{\circ}_{\text{ox}} + E^{\circ}_{\text{red}} - \frac{0.0591}{2} \log_{10} \frac{[\text{Cu}^{2+}]}{[\text{Ag}^+]^2} \\ &= E^{\circ}_{\text{cell}} - \frac{0.0591}{2} \log_{10} \frac{[\text{Cu}^{2+}]}{[\text{Ag}^+]^2} \end{aligned}$$

SOME SOLVED EXAMPLES

Example 31. *Construct the cells in which the following reactions are taking place. Which of the electrodes shall act as anode (negative electrode) and which one as cathode (positive electrode)?*

(*a*) $Zn + CuSO_4 = ZnSO_4 + Cu$

(*b*) $Cu + 2AgNO_3 = Cu(NO_3)_2 + 2Ag$

(*c*) $Zn + H_2SO_4 = ZnSO_4 + H_2$

(*d*) $Fe + SnCl_2 = FeCl_2 + Sn$

Solution: It should always be kept in mind that the metal which goes into solution in the form of its ions undergoes oxidation and thus acts as negative electrode (anode) and the element which comes into the free state undergoes reduction and acts as positive electrode (cathode):

(a) In this case Zn is oxidised to Zn^{2+} and thus acts as anode (negative electrode) while Cu^{2+} is reduced to copper and thus acts as cathode (positive electrode). The cell can be represented as

$$\text{Zn} \mid \text{ZnSO}_4 \mid\mid \text{CuSO}_4 \mid \text{Cu}$$

or

$$\underset{\text{Anode }(-)}{\text{Zn} \mid \text{Zn}^{2+}} \mid\mid \underset{\text{Cathode }(+)}{\text{Cu}^{2+} \mid \text{Cu}}$$

(b) In this case Cu is oxidised to Cu^{2+} and Ag^+ is reduced to Ag. The cell can be represented as

$$\text{Cu} \mid \text{Cu(NO}_3)_2 \mid\mid \text{AgNO}_3 \mid \text{Ag}$$

or

$$\underset{\text{Anode }(-)}{\text{Cu} \mid \text{Cu}^{2+}} \mid\mid \underset{\text{Cathode }(+)}{\text{Ag}^+ \mid \text{Ag}}$$

(c) In this case, Zn is oxidised to Zn^{2+} and H^+ is reduced to H_2. The cell can be represented as:

$$\text{Zn} \mid \text{ZnSO}_4 \mid\mid \text{H}_2\text{SO}_4 \mid \text{H}_2(\text{Pt})$$

or

$$\underset{\text{Anode }(-)}{\text{Zn} \mid \text{Zn}^{2+}} \mid\mid \underset{\text{Cathode }(+)}{2\text{H}^+ \mid \text{H}_2(\text{Pt})}$$

(d) Here, Fe is oxidised to Fe^{2+} and Sn^{2+} is reduced to Sn. The cell can be represented as:

$$\text{Fe} \mid \text{FeCl}_2 \mid\mid \text{SnCl}_2 \mid \text{Sn}$$

or

$$\underset{\text{Anode }(-)}{\text{Fe} \mid \text{Fe}^{2+}} \mid\mid \underset{\text{Cathode }(+)}{\text{Sn}^{2+} \mid \text{Sn}}$$

Note : Oxidation potential is $E^{\circ}_{M/M^{n+}}$ while reduction potential is represented as $E^{\circ}_{M^{n+}/M}$. The value of $E^{\circ}_{\text{Zn}/\text{Zn}^{2+}}$ (oxidation potential of Zn) is + 0.76 volt and the value of $E^{\circ}_{\text{Cu}^{2+}/\text{Cu}}$ (reduction potential of copper) is + 0.34 volt. The electrode having lower value of reduction potential acts as an anode while that having higher value of reduction potential acts as cathode.

Example 32. *Consider the reaction,*

$$2Ag^+ + Cd \longrightarrow 2Ag + Cd^{2+}$$

The standard electrode potentials for $Ag^+ \longrightarrow Ag$ *and* $Cd^{2+} \longrightarrow Cd$ *couples are* 0.80 *volt and* – 0.40 *volt respectively.*

(*i*) *What is the standard potential* E° *for this reaction?*

(*ii*) *For the electrochemical cell, in which this reaction takes place which electrode is negative electrode?*

Solution: (i) The half reactions are:

$$2Ag^+ + \underset{\text{(Cathode)}}{\underset{\text{Reduction}}{2e^-}} \longrightarrow 2Ag,$$

$$E^\circ_{Ag^+/Ag} = 0.80 \text{ volt} \qquad \text{(Reduction potential)}$$

$$Cd \longrightarrow \underset{\text{(Anode)}}{\underset{\text{Oxidation}}{Cd^{2+}}} + 2e^-,$$

$$E^\circ_{Cd^{2+}/Cd} = -0.40 \text{ volt} \quad \text{(Reduction potential)}$$

or $E^\circ_{Cd/Cd^{2+}} = +0.40$ volt

$$E^\circ = E^\circ_{Cd/Cd^{2+}} + E^\circ_{Ag^+/Ag} = 0.40 + 0.80 = 1.20 \text{ volt}$$

(ii) The negative electrode is always the electrode whose reduction potential has smaller value or the electrode where oxidation occurs. Thus, Cd electrode is the negative electrode.

Example 33. *Consider the cell,*

$$Zn \,|\, Zn^{2+}(aq.)(1.0M) \,||\, Cu^{2+}(aq.)(1.0M) \,|\, Cu$$

The standard electrode potentials are:

$$Cu^{2+} + 2e^- \longrightarrow Cu(aq.); \qquad E^\circ = 0.350 \text{ volt}$$

$$Zn^{2+} + 2e^- \longrightarrow Zn(aq.); \qquad E^\circ = -0.763 \text{ volt}$$

(*i*) *Write down the cell reaction.*

(*ii*) *Calculate the emf of the cell.*

Solution: (i) Reduction potential of Zn is less than copper, hence Zn acts as anode and copper as cathode.

At anode $Zn \longrightarrow Zn^{2+} + 2e^-$ (Oxidation)

At cathode $Cu^{2+} + 2e^- \longrightarrow Cu$ (Reduction)

Cell reaction $Zn + Cu^{2+} \longrightarrow Zn^{2+} + Cu$

(ii) $E^\circ_{cell} = E^\circ_{Zn/Zn^{2+}} + E^\circ_{Cu^{2+}/Cu}$

= Oxi. potential of zinc + Red. potential of copper

$$E^\circ_{Zn^{2+}/Zn} = -0.763 \text{ (Reduction potential)}$$

$$E^\circ_{Zn/Zn^{2+}} = +0.763 \text{ (Oxidation potential)}$$

and $E^\circ_{Cu^{2+}/Cu} = 0.350$ (Reduction potential)

So, $E^\circ_{cell} = 0.763 + 0.350 = 1.113$ volt

Example 34. *Write the electrode reactions and the net cell reactions for the following cells. Which electrode would be the positive terminal in each cell?*

(*a*) $Zn \,|\, Zn^{2+} \,||\, Br^-, Br_2 \,|\, Pt$ (*b*) $Cr \,|\, Cr^{3+} \,||\, I^-, I_2 \,|\, Pt$

(*c*) $Pt \,|\, H_2, H^+ \,||\, Cu^{2+} \,|\, Cu$ (*d*) $Cd \,|\, Cd^{2+} \,||\, Cl^-, AgCl \,|\, Ag$

Solution:

(a) Oxidation half reaction, $Zn \longrightarrow Zn^{2+} + 2e^-$

Reduction half reaction, $Br_2 + 2e^- \longrightarrow 2Br^-$

Net cell reaction $Zn + Br_2 \longrightarrow Zn^{2+} + 2Br^-$

Positive terminal—Cathode Pt

(b) Oxidation half reaction, $[Cr \longrightarrow Cr^{3+} + 3e^-] \times 2$

Reduction half reaction, $[I_2 + 2e^- \longrightarrow 2I^-] \times 3$

Net cell reaction $2Cr + 3I_2 \longrightarrow 2Cr^{3+} + 6I^-$

Positive terminal—Cathode Pt

(c) Oxidation half reaction, $H_2 \longrightarrow 2H^+ + 2e^-$

Reduction half reaction, $Cu^{2+} + 2e^- \longrightarrow Cu$

Net cell reaction $H_2 + Cu^{2+} \longrightarrow Cu + 2H^+$

Positive terminal—Cathode Cu

(d) Oxidation half reaction, $Cd \longrightarrow Cd^{2+} + 2e^-$

Reduction half reaction,

$$[AgCl + e^- \longrightarrow Ag + Cl^-] \times 2$$

Net cell reaction $Cd + 2AgCl \longrightarrow Cd^{2+} + 2Ag + 2Cl^-$

Positive terminal—Cathode Ag

Example 35. *Will Fe be oxidised to* Fe^{2+} *by reaction with* 1.0 *M HCl?* E° *for* $Fe/Fe^{2+} = +0.44$ *volt.*

Solution: The reaction will occur if Fe is oxidised to Fe^{2+}.

$$Fe + 2HCl \longrightarrow FeCl_2 + H_2$$

Writing two half reactions,

$$Fe \longrightarrow Fe^{2+} + 2e^- \quad \text{Oxidation; } E^\circ_{Fe/Fe^{2+}} = 0.44 \text{ volt}$$

$$2H^+ + 2e^- \longrightarrow H_2 \qquad \text{Reduction; } E^\circ_{H^+/H} = 0.0 \text{ volt}$$

Adding; emf = 0.44 volt

Since, emf is positive, the reaction shall occur.

Example 36. *The values of* E° *of some of the reactions are given below:*

$$I_2 + 2e^- \longrightarrow 2I^-; \qquad E^\circ = +0.54 \text{ volt}$$

$$Cl_2 + 2e^- \longrightarrow 2Cl^-; \qquad E^\circ = +1.36 \text{ volt}$$

$$Fe^{3+} + e^- \longrightarrow Fe^{2+}; \qquad E^\circ = +0.76 \text{ volt}$$

$$Ce^{4+} + e^- \longrightarrow Ce^{3+}; \qquad E^\circ = +1.60 \text{ volt}$$

$$Sn^{4+} + 2e^- \longrightarrow Sn^{2+}; \qquad E^\circ = +0.15 \text{ volt}$$

On the basis of the above data, answer the following questions:

(*a*) *Whether* Fe^{3+} *oxidises* Ce^{3+} *or not?*

(*b*) *Whether* I_2 *displaces chlorine from KCl?*

(*c*) *Whether the reaction between* $FeCl_3$ *and* $SnCl_2$ *occurs or not?*

Solution: (a) Chemical reaction,

$$Fe^{3+} + Ce^{3+} \longrightarrow Ce^{4+} + Fe^{2+}$$

Two half reactions,

$$Fe^{3+} + e \longrightarrow Fe^{2+}; \quad \text{Reduction; } E^\circ = 0.76 \text{ volt}$$

$$Ce^{3+} \longrightarrow Ce^{4+} + e^-; \quad \underline{\text{Oxidation; } E^\circ_{ox} = -1.60 \text{ volt}}$$

$$\text{Adding; emf} = -0.84 \text{ volt}$$

Since, emf is negative, the reaction does not occur, *i.e.*, Fe^{3+} does not oxidise Ce^{3+}.

(b) Chemical reaction,

$$I_2 + 2KCl = 2KI + Cl_2$$

Half reactions,

$$I_2 + 2e^- \longrightarrow 2I^-; \quad \text{Reduction; } E^\circ = 0.54 \text{ volt}$$

$$2Cl^- \longrightarrow Cl_2 + 2e^-; \quad \underline{\text{Oxidation; } E^\circ_{ox} = -1.36 \text{ volt}}$$

$$\text{Adding; emf} = -0.82 \text{ volt}$$

Since, emf is negative, the reaction does not occur, *i.e.*, I_2 does not displace Cl_2 from KCl.

(c) Chemical reaction,

$$SnCl_2 + 2FeCl_3 \longrightarrow SnCl_4 + 2FeCl_2$$

Half reactions,

$$Fe^{3+} + e^- \longrightarrow Fe^{2+}; \quad \text{Reduction; } E^\circ = 0.76 \text{ volt}$$

$$Sn^{2+} \longrightarrow Sn^{4+} + 2e^-; \quad \underline{\text{Oxidation; } E^\circ = -0.15 \text{ volt}}$$

$$\text{Adding; emf} = +0.61 \text{ volt}$$

Since, emf is positive, the reaction will occur.

Example 37. *Calculate the electrode potential at a copper electrode dipped in a* 0.1 *M solution of copper sulphate at* 25° *C. The standard electrode potential of* Cu^{2+}/Cu *system is* 0.34 *volt at* 298 *K.*

Solution: We know that, $E_{red} = E^\circ_{red} + \dfrac{0.0591}{n} \log_{10}[\text{ion}]$

Putting the values of $E^\circ_{red} = 0.34$ V, $n = 2$ and $[Cu^{2+}] = 0.1 M$

$$E_{red} = 0.34 + \frac{0.0591}{2} \log_{10}[0.1]$$

$$= 0.34 + 0.02955 \times (-1)$$

$$= 0.34 - 0.02955 = 0.31045 \text{ volt}$$

Example 38. *What is the single electrode potential of a half-cell for zinc electrode dipping in* 0.01 *M* $ZnSO_4$ *solution at* 25° *C? The standard electrode potential of* Zn/Zn^{2+} *system is* 0.763 *volt at* 25° *C.*

Solution: We know that, $E_{ox} = E^\circ_{ox} - \dfrac{0.0591}{n} \log_{10}[\text{ion}]$

Putting the value of $E^\circ_{ox} = 0.763$ V, $n = 2$ and $[Zn^{2+}] = 0.01$ *M*,

$$E_{ox} = 0.763 - \frac{0.0591}{2} \log_{10}[0.01]$$

$$= 0.763 - 0.02955 \times (-2)$$

$$= (0.763 + 0.0591) \text{ volt} = 0.8221 \text{ volt}$$

Example 39. *The standard oxidation potential of zinc is* 0.76 *volt and of silver is* − 0.80 *volt. Calculate the emf of the cell:*

$$Zn \mid \underset{0.25\,M}{Zn(NO_3)_2} \parallel \underset{0.1\,M}{AgNO_3} \mid Ag$$

at 25° *C.*

Solution: The cell reaction is

$$Zn + 2Ag^+ \longrightarrow 2Ag + Zn^{2+}$$

$$E^\circ_{ox} \text{ of Zn} = 0.76 \text{ volt}$$

$$E^\circ_{red} \text{ of Ag} = 0.80 \text{ volt}$$

$$E^\circ_{cell} = E^\circ_{ox} \text{ of Zn} + E^\circ_{red} \text{ of Ag} = 0.76 + 0.80 = 1.56 \text{ volt}$$

We know that, $E_{cell} = E^\circ_{cell} - \dfrac{0.0591}{n} \log \dfrac{[\text{Products}]}{[\text{Reactants}]}$

$$= E^\circ_{cell} - \frac{0.0591}{2} \log \frac{0.25}{0.1 \times 0.1}$$

$$= 1.56 - \frac{0.0591}{2} \times 1.3979$$

$$= (1.56 - 0.0413) \text{ volt}$$

$$= 1.5187 \text{ volt}$$

Alternative method: First of all, the single electrode potentials of both the electrodes are determined on the basis of given concentrations.

$$E_{ox\,(\text{Zinc})} = E^\circ_{ox} - \frac{0.0591}{2} \log 0.25$$

$$= 0.76 + 0.0177 = 0.7777 \text{ volt}$$

$$E_{red\,(\text{Silver})} = E^\circ_{red} + \frac{0.0591}{1} \log 0.1$$

$$= 0.80 - 0.0591 = 0.7409 \text{ volt}$$

$$E_{cell} = E_{ox\,(\text{Zinc})} + E_{red\,(\text{Silver})}$$

$$= 0.7777 + 0.7409 = 1.5186 \text{ volt}$$

Example 40. *The emf* (E°) *of the following cells are:*

$$Ag \mid Ag^+(1M) \parallel Cu^{2+}(1M) \mid Cu; \quad E^\circ = -0.46 \text{ volt}$$

$$Zn \mid Zn^{2+}(1M) \parallel Cu^{2+}(1M) \mid Cu; \quad E^\circ = +1.10 \text{ volt}$$

Calculate the emf of the cell:

$$Zn \mid Zn^{2+}(1M) \parallel Ag^+(1M) \mid Ag$$

Solution: $Zn \mid Zn^{2+}(1M) \parallel Ag^+(1M) \mid Ag$

$$E_{cell} = E_{ox\,(Zn/Zn^{2+})} + E_{red\,(Ag^+/Ag)}$$

With the help of the following two cells, the above equation can be obtained:

$$Ag \mid Ag^+(1M) \parallel Cu^{2+}(1M) \mid Cu; E^\circ = -0.46 \text{ volt}$$

or $Cu \mid Cu^{2+}(1M) \parallel Ag^+(1M) \mid Ag$; E° will be + 0.46 volt or $$+0.46 = E_{\text{ox (Cu/Cu}^{2+})} + E_{\text{red (Ag}^{+}/\text{Ag)}} \quad \text{... (i)}$$

$$\text{Zn} \mid \text{Zn}^{2+}(1\,M) \,||\, \text{Cu}^{2+} \mid \text{Cu};\; E^\circ = +1.10\,\text{volt}$$

$$+1.10 = E_{\text{ox (Zn/Zn}^{2+})} + E_{\text{red (Cu}^{2+}/\text{Cu)}} \quad \text{... (ii)}$$

Adding eqs. (i) and (ii),

$$+1.56 = E_{\text{ox (Cu/Cu}^{2+})} + E_{\text{red (Ag}^{+}/\text{Ag)}} + E_{\text{ox (Zn/Zn}^{2+})} + E_{\text{red (Cu}^{2+}/\text{Cu)}}$$

Since, $E_{\text{ox (Cu/Cu}^{2+})} = -E_{\text{red (Cu}^{2+}/\text{Cu)}}$

So, $$+1.56 = E_{\text{ox (Zn/Zn}^{2+})} + E_{\text{red (Ag}^{+}/\text{Ag)}}$$

Thus, the emf of the following cell is

$$\text{Zn} \mid \text{Zn}^{2+}(1\,M) \,||\, \text{Ag}^{+}(1\,M) \mid \text{Ag is } +1.56\text{ volt}$$

Example 41. *Calculate the emf of the cell.*

$$Mg(s) \mid Mg^{2+}(0.2\,M) \,||\, Ag^{+}(1\times 10^{-3}) \mid Ag$$

$$E^\circ_{Ag^{+}/Ag} = +0.8\,volt,\; E^\circ_{Mg^{2+}/Mg} = -2.37\,volt$$

What will be the effect on emf if concentration of Mg^{2+} ion is decreased to 0.1 M?

Solution: $$E^\circ_{\text{Cell}} = E^\circ_{\text{Cathode}} - E^\circ_{\text{Anode}}$$

$$= 0.80 - (-2.37) = 3.17\text{ volt}$$

Cell reaction, $\text{Mg} + 2\text{Ag}^{+} \longrightarrow 2\text{Ag} + \text{Mg}^{2+}$

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{n}\log\frac{\text{Mg}^{2+}}{[\text{Ag}^{+}]^2}$$

$$= 3.17 - \frac{0.0591}{2}\log\frac{0.2}{[1\times 10^{-3}]^2}$$

$$= 3.17 - 0.1566 = 3.0134\text{ volt}$$

when $\text{Mg}^{2+} = 0.1\,M$

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{2}\log\frac{0.1}{(1\times 10^{-3})^2}$$

$$= (3.17 - 0.1477)\text{ volt}$$

$$= 3.0223\text{ volt}$$

Example 42. *To find the standard potential of M^{3+}/M electrode, the following cell is constituted:*

$$Pt \mid M \mid M^{3+}(0.0018\,mol^{-1}L) \,||\, Ag^{+}(0.01\,mol^{-1}L) \mid Ag$$

The emf of this cell is found to be 0.42 volt. Calculate the standard potential of the half reaction $M^{3+} + 3e^{-} \longrightarrow M$. $E^\circ_{Ag^{+}/Ag} = 0.80\,volt$.

Solution: The cell reaction is

$$M + 3\text{Ag}^{+} \longrightarrow 3\text{Ag} + M^{3+}$$

Applying Nernst equation,

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{3}\log\frac{[M^{3+}]}{[\text{Ag}^{+}]^3}$$

$$0.42 = E^\circ_{\text{cell}} - \frac{0.0591}{3}\log\frac{(0.0018)}{(0.01)^3} = E^\circ_{\text{cell}} - 0.064$$

$$E^\circ_{\text{cell}} = (0.42 + 0.064) = 0.484\text{ volt}$$

$$E^\circ_{\text{Cell}} = E^\circ_{\text{Cathode}} - E^\circ_{\text{Anode}}$$

or $$E^\circ_{\text{Anode}} = E^\circ_{\text{Cathode}} - E^\circ_{\text{Cell}}$$

$$= (0.80 - 0.484) = 0.32\text{ volt}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

19. The oxidation potential of hydrogen electrode at pH = 10 and $\text{pH}_2 = 1$ atm is:

(a) 0.51 V (b) 0.00 V (c) + 0.59 V (d) 0.059 V

[Ans. (c)]

[Hint: $$E_{\text{ox}} = E^\circ_{\text{ox}} - \frac{0.0591}{n}\log\frac{[\text{H}^{+}]}{\text{pH}_2}$$

$$= 0 - \frac{0.0591}{1}\log\frac{10^{-10}}{1} = 0.59\text{ V}\,]$$

20. The value of equilibrium constant for a feasible cell reaction is:

(a) < 1 (b) = 1 (c) > 1 (d) zero

[Ans. (c)]

[Hint: $K = \text{antilog}\left(\dfrac{nE^\circ}{0.0591}\right)$

For feasible cell, E° is positive; hence from the above equation, $K > 1$ for feasible cell reaction.]

21. E° for the electrochemical cell

$$\text{Zn}(s) \mid \text{Zn}^{2+}\,1\,M\,(aq.) \,||\, \text{Cu}^{2+}\,1\,M\,(aq.) \mid \text{Cu}(s)$$

is 1.10 V at 25°C. The equilibrium constant for the cell reaction,

$$\text{Zn}(s) + \text{Cu}^{2+}(aq.) \rightleftharpoons \text{Zn}^{2+}(aq.) + \text{Cu}(s)$$

will be:

(a) 10^{-37} (b) 10^{37}

(c) 10^{-39} (d) 10^{39}

[Ans. (b)]

[Hint: $$K = \text{antilog}\left[\frac{nE^\circ}{0.0591}\right]$$

$$= \text{antilog}\left[\frac{2\times 1.10}{0.0591}\right] = 1.67\times 10^{37}\,]$$

22. The value of the reaction quotient Q, for the cell

$$\text{Zn}(s) \mid \text{Zn}^{2+}(0.01\,M) \,||\, \text{Ag}^{+}\,(1.25\,M) \mid \text{Ag}(s)$$

is:

(a) 156 (b) 125

(c) 1.25×10^{-2} (d) 6.4×10^{-3}

[Ans. (d)]

[Hint: $\text{Zn}(s) \longrightarrow \text{Zn}^{2+} + 2e^{-}$ (Anodic process)

$2\text{Ag}^{+} + 2e^{-} \longrightarrow 2\text{Ag}(s)$ (Cathodic process)

$\text{Zn}(s) + 2\text{Ag}^{+} \rightleftharpoons 2\text{Ag}(s) + \text{Zn}^{2+}$

$$Q = \frac{[\text{Zn}^{2+}]}{[\text{Ag}^{+}]^2} = \frac{0.01}{(1.25)^2} = 6.4\times 10^{-3}\,]$$

23. Calculate the emf of the following concentration cell at 25°C:

$Ag(s) \mid AgNO_3\ (0.01\,M) \parallel AgNO_3\ (0.05\,M) \mid Ag(s)$

(a) − 0.414 V (b) 0.828 V
(c) 0.414 V (d) 0.0414 V

[**Ans.** (d)]

[**Hint:** $E = E^\circ - \frac{0.0591}{n}\log_{10} Q$

($\because E^\circ = 0$ for all concentration cells)

$$= 0 - \frac{0.0591}{1}\log_{10}\left(\frac{0.01}{0.05}\right) = 0.0414\ \text{V}\ ]$$

24. The equilibrium constant of the reaction:

$Cu(s) + 2Ag^+(aq.) \rightleftharpoons Cu^{2+}(aq.) + 2Ag(s)$

$E^\circ = 0.46$ V at 298 K is: [CBSE (Med.) 2007]

(a) 2.0×10^{10} (b) 4.0×10^{10}
(c) 4.0×10^{15} (d) 2.4×10^{10}

[**Ans.** (c)]

[**Hint:** $K = \text{antilog}\left[\frac{nE^\circ}{0.059}\right] = \text{antilog}\left[\frac{2 \times 0.46}{0.059}\right]$

$= \text{antilog } 15.593$

$= 3.9 \times 10^{15}$

$\approx 4 \times 10^{15}$]

25. The cell reaction of a cell is:

$Mg(s) + Cu^{2+}(aq.) \rightleftharpoons Cu(s) + Mg^{2+}(aq.)$

If the standard reduction potentials of Mg and Cu are − 2.37 and + 0.34 V respectively. The emf of the cell is: [JEE (WB) 2007]

(a) 2.03 V (b) − 2.03 V (c) + 2.71 V (d) − 2.71 V

[**Ans.** (c)]

[**Hint:** $E^\circ_{\text{Cell}} = E^\circ_{\text{Cathode}} - E^\circ_{\text{Anode}}$

$= E^\circ_{\text{Reduced species}} - E^\circ_{\text{Oxidised species}}$

$= 0.34 - (-2.37) = +2.71$ V]

26. The equilibrium constant of the following redox reaction at 298 K is 1×10^8

$2Fe^{3+}(aq.) + 2I^-(aq.) \rightleftharpoons 2Fe^{2+}(aq.) + I_2(s)$

If the standard reduction potential of iodine becoming iodide is + 0.54 V. What is the standard reduction potential of Fe^{3+}/Fe^{2+}? [PMT (Kerala) 2008]

(a) + 1.006 V (b) − 1.006 V
(c) + 0.77 V (d) − 0.77 V
(e) − 0.652 V

[Ans. (c)]

[**Hint:** $E^\circ = \frac{0.059}{n}\log_{10} K$

$= \frac{0.059}{2}\log_{10} 10^8 = 0.236$

$E^\circ_{\text{Cell}} = E^\circ_{\text{Reduced species}} - E^\circ_{\text{Oxidised species}}$

$0.236 = E^\circ_{Fe^{3+}/Fe^{2+}} - 0.54$

$E^\circ_{Fe^{3+}/Fe^{2+}} = 0.77\text{V}$]

12.23 ELECTROCHEMICAL SERIES

By measuring the potentials of various electrodes *versus* standard hydrogen electrode (SHE), a series of standard electrode potentials has been established. When the electrodes (metals and non-metals) in contact with their ions are arranged on the basis of the values of their standard reduction potentials or standard oxidation potentials, the resulting series is called the **electrochemical** or **electromotive** or **activity series** of the elements.

By international convention, the standard potentials of electrodes are tabulated for reduction half reactions, indicating the tendencies of the electrodes to behave as cathodes towards SHE. Those with positive E° values for reduction half reactions do in fact act as cathodes *versus* SHE, while those with negative E° values of reduction half reactions behave instead as anodes *versus* SHE. The electrochemical series is shown in the given table:

Standard Aqueous Electrode Potentials at 25° C
'The Electrochemical Series'

Element	Electrode Reaction (Reduction)	Standard Electrode Reduction potential E°, volt
Li	$Li^+ + e^- = Li$	− 3.05
K	$K^+ + e^- = K$	− 2.925
Ca	$Ca^{2+} + 2e^- = Ca$	− 2.87
Na	$Na^+ + e^- = Na$	− 2.714
Mg	$Mg^{2+} + 2e^- = Mg$	− 2.37
Al	$Al^{3+} + 3e^- = Al$	− 1.66
Zn	$Zn^{2+} + 2e^- = Zn$	− 0.7628
Cr	$Cr^{3+} + 3e^- = Cr$	− 0.74
Fe	$Fe^{2+} + 2e^- = Fe$	− 0.44
Cd	$Cd^{2+} + 2e^- = Cd$	− 0.403
Ni	$Ni^{2+} + 2e^- = Ni$	− 0.25
Sn	$Sn^{2+} + 2e^- = Sn$	− 0.14
H_2	$2H^+ + 2e^- = H_2$	0.00
Cu	$Cu^{2+} + 2e^- = Cu$	+ 0.337
I_2	$I_2 + 2e^- = 2I^-$	+ 0.535
Ag	$Ag^+ + e^- = Ag$	+ 0.799
Hg	$Hg^{2+} + 2e^- = Hg$	+ 0.885
Br_2	$Br_2 + 2e^- = 2Br^-$	+ 1.08
Cl_2	$Cl_2 + 2e^- = 2Cl^-$	+ 1.36
Au	$Au^{3+} + 3e^- = Au$	+ 1.50
F_2	$F_2 + 2e^- = 2F^-$	+ 2.87

↓ Increasing tendency to accept electrons
Increasing strength as oxidising agent

↑ Increasing strength as reducing agent
Increasing tendency to lose electrons

Characteristics of Electrochemical Series

(i) The negative sign of standard reduction potential indicates that an electrode when joined with SHE acts as anode and oxidation occurs on this electrode. For example, standard reduction potential of zinc is − 0.76 volt. When zinc electrode is joined with SHE, it acts as anode (–ve electrode), *i.e.*, oxidation occurs on this electrode. Similarly, the +ve sign of standard reduction potential indicates that the electrode when joined with SHE acts as cathode and reduction occurs on this electrode.

(ii) The substances which are stronger reducing agents than hydrogen are placed above hydrogen in the series and have negative values of standard reduction potentials. All those substances which have positive values of reduction potentials and placed below hydrogen in the series are weaker reducing agents than hydrogen.

(iii) The substances which are stronger oxidising agents than H^+ ion are placed below hydrogen in the series.

(iv) The metals on the top (having high negative values of standard reduction potentials) have the tendency to lose electrons readily. These are active metals. The activity of metals decreases from top to bottom. The non-metals on the bottom (having high positive values of standard reduction potentials) have the tendency to accept electrons readily. These are active non-metals. The activity of non-metals increases from top to bottom.

Applications of Electrochemical Series

(i) Reactivity of metals: The activity of the metal depends on its tendency to lose electron or electrons, *i.e.*, tendency to form cation (M^{n+}). This tendency depends on the magnitude of standard reduction potential. The metal which has high negative value (or smaller positive value) of standard reduction potential readily loses the electron or electrons and is converted into cation. Such a metal is said to be chemically active.

The chemical reactivity of metals decreases from top to bottom in the series. The metal higher in the series is more active than the metal lower in the series. For example,

(a) Alkali metals and alkaline earth metals having high negative values of standard reduction potentials are chemically active. These react with cold water and evolve hydrogen. These readily dissolve in acids forming corresponding salts and combine with those substances which accept electrons.

(b) Metals like Fe, Pb, Sn, Ni, Co, etc., which lie a little down in the series do not react with cold water but react with steam to evolve hydrogen.

(c) Metals like Cu, Ag and Au which lie below hydrogen are less reactive and do not evolve hydrogen from water.

(ii) Electropositive character of metals: The electropositive character also depends on the tendency to lose electron or electrons. Like reactivity, the electropositive character of metals decreases from top to bottom in the electrochemical series. On the basis of standard reduction potential values, metals are divided into three groups:

(a) Strongly electropositive metals: Metals having standard reduction potential near about –2.0 volt or more negative like alkali metals, alkaline earth metals are strongly electropositive in nature.

(b) Moderately electropositive metals: Metals having values of reduction potentials between 0.0 and about –2.0 volt are moderately electropositive. Al, Zn, Fe, Ni, Co, etc., belong to this group.

(c) Weakly electropositive metals: The metals which are below hydrogen and possess positive values of reduction potentials are weakly electropositive metals. Cu, Hg, Ag, etc., belong to this group.

(iii) Displacement reactions:

(a) To predict whether a given metal will displace another, from its salt solution: A metal higher in the series will displace the metal from its solution which is lower in the series, *i.e.*, **the metal having low standard reduction potential will displace the metal from its salt's solution which has higher value of standard reduction potential.** A metal higher in the series has greater tendency to provide electrons to the cations of the metal to be precipitated.

(b) Displacement of one non-metal from its salt solution by another non-metal: A non-metal higher in the series (towards bottom side), *i.e.*, having high value of reduction potential will displace another non-metal with lower reduction potential, *i.e.*, occupying position above in the series. The non-metals which possess high positive reduction potentials have the tendency to accept electrons readily. These electrons are provided by the ions of the non-metal having low value of reduction potential. Thus, Cl_2 can displace bromine and iodine from bromides and iodides.

$$Cl_2 + 2KI \longrightarrow 2KCl + I_2$$

$$2I^- \longrightarrow I_2 + 2e^- \qquad \text{(Oxidation)}$$

$$Cl_2 + 2e^- \longrightarrow 2Cl^- \qquad \text{(Reduction)}$$

[The activity or electronegative character or oxidising nature of the non-metal increases as the value of reduction potential increases.]

(c) Displacement of hydrogen from dilute acids by metals: The metal which can provide electrons to H^+ ions present in dilute acids for reduction, evolve hydrogen from dilute acids.

$$Mn \longrightarrow Mn^{n+} + ne^- \qquad \text{(Oxidation)}$$

$$2H^+ + 2e^- \longrightarrow H_2 \qquad \text{(Reduction)}$$

The metal having negative values of reduction potential possess the property of losing electron or electrons.

- **Thus, the metals occupying top positions in the electrochemical series readily liberate hydrogen from dilute acids and on descending in the series tendency to liberate hydrogen gas from dilute acids decreases.**

The metals which are below hydrogen in electrochemical series like Cu, Hg, Au, Pt, etc., do not evolve hydrogen from dilute acids.

(d) Displacement of hydrogen from water: Iron and the metals above iron are capable of liberating hydrogen from water. The tendency decreases from top to bottom in electrochemical series.

Alkali and alkaline earth metals liberate hydrogen from cold water but Mg, Zn and Fe liberate hydrogen from hot water or steam.

(iv) Reducing power of metals: Reducing nature depends on the tendency of losing electron or electrons. More the negative reduction potential, more is the tendency to lose electron or electrons. **Thus, reducing nature decreases from top to bottom in the electrochemical series.** The power of the reducing agent increases as the standard reduction potential becomes more and more negative.

Sodium is a stronger reducing agent than zinc and zinc is a stronger reducing agent than iron.

Element	Na	Zn	Fe
Reduction potential	−2.71	− 0.76	− 0.44

$\xrightarrow{\hspace{6em}}$

Reducing nature decreases

Alkali and alkaline earth metals are strong reducing agents.

(v) Oxidising nature of non-metals: Oxidising nature depends on the tendency to accept electron or electrons. More the value of reduction potential, higher is the tendency to accept electron or electrons. **Thus, oxidising nature increases from top to bottom in the electrochemical series.** The strength of an oxidising agent increases as the value of reduction potential becomes more and more positive.

F_2 (Fluorine) is a stronger oxidant than Cl_2, Br_2 and I_2.

Cl_2 (Chlorine) is a stronger oxidant than Br_2 and I_2.

Element	I_2	Br_2	Cl_2	F_2
Reduction potential	+ 0.53	+ 1.06	+ 1.36	+ 2.85

$\xrightarrow{\hspace{6em}}$

Oxidising nature increases

Thus, in electrochemical series

Top (Strongest reducing agent)
Highest negative reduction potential
or
(Minimum reduction potential)
Bottom (Strongest oxidising agent)
Highest positive value of reduction potential

Oxidising nature ↓
Reducing nature ↑

(vi) Thermal stability of metallic oxides: The thermal stability of the metal oxide depends on its electropositive nature. As the electropositivity decreases from top to bottom, the thermal stability of the oxide also decreases from top to bottom. The oxides of metals having high positive reduction potentials are not stable towards heat. The metals which come below copper form unstable oxides, *i.e.*, these are decomposed on heating.

$$Ag_2O \xrightarrow{\text{Heat}} 2Ag + \frac{1}{2}O_2$$

$$2HgO \xrightarrow{\text{Heat}} 2Hg + O_2$$

$$\left.\begin{matrix} BaO \\ Na_2O \\ Al_2O_3 \end{matrix}\right] \xrightarrow{\text{Heat}} \text{No decomposition}$$

(vii) Products of electrolysis: In case, two or more types of positive and negative ions are present in solution, during electrolysis certain ions are discharged or liberated at the electrodes in preference to others. **In general, in such competition the ion which is stronger oxidising agent (high value of standard reduction potential) is discharged first at the cathode.** The increasing order of deposition of few cations is:

$$K^+, Ca^{2+}, Na^+, Mg^{2+}, Al^{3+}, Zn^{2+}, Fe^{2+}, H^+, Cu^{2+}, Ag^+, Au^{3+}$$

$\xrightarrow{\hspace{20em}}$

Increasing order of deposition

Similarly, the anion which is stronger reducing agent (low value of standard reduction potential) is liberated first at the anode.

The increasing order of discharge of few anions is:

$$SO_4^{2-}, NO_3^-, OH^-, Cl^-, Br^-, I^-$$

$\xrightarrow{\hspace{14em}}$

Increasing order of discharge

Thus, when an aqueous solution of NaCl containing Na^+, Cl^-, H^+ and OH^- ions is electrolysed, H^+ ions are discharged at cathode and Cl^- ions at the anode, *i.e.*, H_2 is liberated at cathode and chlorine at anode.

When an aqueous solution of $CuSO_4$ containing Cu^{2+}, SO_4^{2-}, H^+ and OH^- ions is electrolysed, Cu^{2+} ions are discharged at cathode and OH^- ions at the anode.

$$Cu^{2+} + 2e^- \longrightarrow Cu \qquad \text{(Cathodic reaction)}$$

$$4OH^- \longrightarrow O_2 + 2H_2O + 4e^- \quad \text{(Anodic reaction)}$$

Cu is deposited on cathode while O_2 is liberated at anode.

(viii) Latimer diagram: Redox chemistry of an element can be understand by comparing the standard electrode potentials of the various oxidation states of the element. Latimer diagram showing relative stabilities of different oxidation states are given below :

Acid Medium

$$Fe \xrightarrow{E^\circ_{Fe/Fe^{2+}} = +0.44\text{ V}} Fe^{2+} \xrightarrow{E^\circ_{Fe^{2+}/Fe^{3+}} = -0.77\text{ V}} Fe^{3+}$$

Alkaline Medium

$$Fe \xrightarrow{E^\circ_{Fe/Fe^{2+}} = +0.88\text{ V}} Fe^{2+} \xrightarrow{E^\circ_{Fe^{2+}/Fe^{3+}} = +0.56\text{ V}} Fe^{3+}$$

In acid medium, the positive value of $E^\circ_{Fe/Fe^{2+}}$ indicates that iron will dissolve in acid medium to form Fe^{2+} ion; since $E^\circ_{Fe^{2+}/Fe^{3+}}$ is negative, hence +2 state of iron will be more state than +3 state in acid medium.

When the potential on right of a species is more positive (less negative) than that on the left, then the species will tend to undergo disproportionation.

Example :

Alkaline Medium

$$Cl^- \xrightarrow{E^\circ_{Cl^-/Cl_2} = -1.35\text{ V}} \frac{1}{2}Cl_2 \xrightarrow{E^\circ_{Cl_2/ClO^-} = -0.4\text{ V}} ClO^-$$

Thus, Cl_2 will undergo disproportionation into Cl^- and ClO^- ions in basic medium.

$$Cl_2 + 2OH^- \longrightarrow Cl^- + ClO^- + H_2O$$

(ix) Corrosion of metals: Corrosion is defined as the deterioration of a substance because of its reaction with its environment. This is also defined as the process by which metals have the tendency to go back to their combined state, *i.e.*, reverse of extraction of metals.

Thus, the process of weathering away of the metal due to attack of the atmospheric gases on the surface of the metal *resulting into the formation of compounds such as oxides, sulphates, sulphides, carbonates, etc., is called corrosion.*

The process of corrosion of iron is called rusting. Rust is chemically the hydrated oxide of iron having the formula $Fe_2O_3 \cdot xH_2O$. Other examples of corrosion of metals are tarnishing of silver and those of copper and bronze etc. Corrosion of copper and bronze forms a green coating on the surface. The corrosion of metals, particularly iron, causes damage to buildings, dams, bridges, etc., and we lose a lot of money every year.

Mechanism of Corrosion : Corrosion is a redox process by which metals are oxidised by oxygen in presence of moisture. The mechanism can be understood by taking the example of rusting of iron. The theory of rusting is called **electrochemical theory.** In this theory the process of rusting can be explained on the basis of formation of electrochemical cell on the surface of an iron object.

Rusting of iron involves the following steps :

Step 1 : The water vapours present in contact with iron surface have dissolved CO_2 and O_2 from air.

$$H_2O(l) + CO_2(g) \longrightarrow H_2CO_3(l)$$

Thus, the surface of iron is covered with an aqueous solution of carbonic acid, which undergoes dissociation to a small extent.

$$H_2CO_3 \rightleftharpoons 2H^+ + CO_3^{2-} \quad \text{(Ionisation of carbonic acid)}$$

$$H_2O \rightleftharpoons H^+ + OH^- \quad \text{(Ionisation of water)}$$

Step 2 : Second step involves oxidation of iron. Oxidation of metal takes place at the point of strain. For example, a steel nail first corrodes at the tip and head. The tip of the nail acts as anode where iron is oxidised to ferrous ion.

$$Fe(s) \longrightarrow Fe^{2+} + 2e^- \quad \text{(Anodic process, oxidation)} \quad \ldots\text{(i)}$$

$$(E^\circ_{Fe^{2+}/Fe} = -0.44 \text{ volt})$$

Step 3 : The electrons flow along the nail to the areas containing impurities which act as cathode where oxygen (dissolved in water) is reduced to hydroxyl ions.

$$O_2(g) + 2H_2O(l) + 4e^- \longrightarrow 4OH^-$$

$$\text{(Cathodic process, reduction)}$$

$$(E^\circ_{red} = 1.23 \text{ volt})$$

The process of reduction involves the following two steps :

First of all H^+ ions are reduced to hydrogen atoms.

$$H^+ + e^- \longrightarrow [H] \quad \ldots\text{(ii)}$$

These hydrogen atoms combine with oxygen dissolved in water or from air.

$$4[H] + O_2 \longrightarrow 2H_2O \quad \ldots\text{(iii)}$$

Combining (ii) and (iii), we get

$$O_2 + 4H^+ + 4e^- \longrightarrow 2H_2O(l) \quad \ldots\text{(iv)}$$

$$(E^\circ_{red} = 1.23 \text{ volt})$$

Adding equations (i) and (iv), we get, the overall reactions of microcells established on the surface of iron.

$$2Fe(s) + O_2(g) + 4H^+(aq) \longrightarrow 2Fe^{2+}(aq) + 2H_2O(l)$$

$$(E^\circ_{cell} = 1.67 \text{ volt})$$

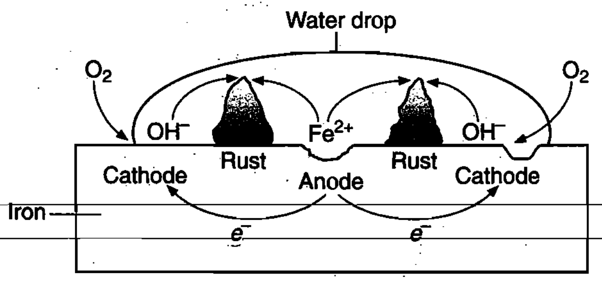
Step 4 : The ferrous ions (Fe^{2+}) formed in the previous step reacts with dissolved oxygen or oxygen from air to form ferric oxide (Fe_2O_3).

$$4Fe^{2+} + O_2 + 4H_2O \longrightarrow 2Fe_2O_3 + 8H^+(aq)$$

Hydration of ferric oxide gives rust.

$$Fe_2O_3 + xH_2O \longrightarrow Fe_2O_3 \cdot xH_2O$$

The process of rusting may be diagrammatically represented as in Fig. 12.17.



Oxidation : $Fe(s) \longrightarrow Fe^{2+}(aq.) + 2e^-$

Reduction : $O_2 + 4H^+(aq.) + 4e^- \longrightarrow 2H_2O(l)$

Atmospheric $4Fe^{2+} + O_2 + 4H_2O(l) \longrightarrow 2Fe_2O_3(s) + 8H^+(aq.)$

Oxidation $Fe_2O_3 + xH_2O \longrightarrow \underset{\text{Rust}}{Fe_2O_3 . xH_2O}$

Fig. 12.17 Rusting of iron

Factors Affecting Corrosion

1. Standard reduction potential : Lesser is the standard reduction potential, greater is the tendency of corrosion. In other words, more is the reactivity of metal, greater is the tendency of corrosion.

2. Strains and corrosion : Corrosion of metals occurs more readily at points of strain, bend, nick and scratches.

3. Impurity of metal and corrosion : Presence of impurity in metals increases the probability of their corrosion. Pure metals, *e.g.*, pure iron does not undergo rusting.

4. Salinity of water and corrosion : If water is saline, it helps in the flow of current in microelectrochemical cells on the surface of iron and hence, increases the process of corrosion.

5. Pollution and corrosion : The acidic oxides like CO_2, SO_2, NO_2 etc., present in air act as catalysts for corrosion. It should be noted that if iron is placed in vacuum, it does not undergo rusting.

Prevention of Rusting : Prevention of rusting is not only important from the point of view of economy but also from the point of view of safety. Prevention of corrosion not only saves money but also prevents accidents due to collapse of bridges and buildings.

Some important methods for preventing corrosion are described below:

1. Using antirust solution : Alkaline phosphate and alkaline chromate solutions are the commonly used antirust solutions. Alkaline phosphates tend to form an insoluble film of iron phosphate on the surface of iron, thereby protecting it from corrosion. In addition, the alkaline nature of an antirust solution decreases the availability of H^+ ions which facilitate the oxidation of Fe to Fe^{2+}. These solutions are used to prevent rusting of radiators of cars and water coolers.

2. Barrier protection : It is one of the simplest methods of preventing corrosion. In this method a barrier or coating is applied to prevent the surface of the metallic object from come in contact with the atmosphere. This can be achieved by the following methods :

(i) Oil paints on the surface of metal prevents its contact with moist air.

(ii) By applying grease or oil on the surface of iron tools and other objects, rusting can be prevented.

(iii) Nichrome (Ni + Cr) plating on the surface of iron also acts as a barrier between metal and atmosphere.

(iv) Bisphenol is an important chemical which can be applied on the surface of the metal to avoid its corrosion.

3. Sacrificial protection : In this method, the surface of iron is coated with a more active metal than iron. This active metal loses electrons, *i.e.*, undergo oxidation in preference to iron and hence, prevents the rusting of iron. So, long as the surface of iron is covered with such metals the corrosion of iron is prevented. If the surface is scratched or the coating is broken, even then the rusting of iron does not start.

Zinc metal is the most stable metal to cover iron surfaces. **The process of coating the iron surface by zinc is called galvanization.** Zinc metal present on the surface of iron forms a thin protective layer of basic zinc carbonate, *i.e.*, $ZnCO_3 \cdot Zn(OH)_2$ due to the reaction between zinc, oxygen, CO_2 and moisture in air.

$$Zn^{2+} + 2e^- \longrightarrow Zn(s); \qquad E^\circ_{Zn^{2+}/Zn} = -0.76 \text{ volt}$$

$$Fe^{2+} + 2e^- \longrightarrow Fe(s); \qquad E^\circ_{Fe^{2+}/Fe} = -0.44 \text{ volt}$$

(Zinc will undergo oxidation in preference to iron.)

Since, standard reduction potential of zinc is less than iron, hence, iron will not undergo corrosion (oxidation) even when the zinc coating is broken due to scratches or some other mechanical stress.

Sometimes an iron surface is coated with tin metal and this process is known as **tinning** or tin plating. This method is not as effective as **galvanization.**

$$Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s); \quad E^\circ_{Sn^{2+}/Sn} = -0.14 \text{ volt}$$

$$Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s); \quad E^\circ_{Fe^{2+}/Fe} = -0.44 \text{ volt}$$

(Iron will undergo oxidation in preference to tin.)

Tinning is effective in checking the rusting of iron so long as the surface of iron is fully covered by tin. Once the tin coating is broken or scratched then rusting will start because standard reduction potential of iron is less than that of tin.

4. Electrical or Cathodic protection : If a buried steel pipe is connected to an active metal, *i.e.*, highly electropositive metal, say magnesium, a voltaic cell is formed; the active metal is the anode and iron becomes the cathode. Wet soil or moisture forms the electrolyte and the electrode reactions are :

$$Mg(s) \longrightarrow Mg^{2+}(aq) + 2e^-; \quad E^\circ_{Mg^{2+}/Mg} = -2.37 \text{ V}$$

$$O_2(g) + 2H_2O(l) + 4e^- \longrightarrow 4OH^-(aq); \quad E^\circ_{red} = 1.23 \text{ V}$$

Overall: $2Mg(s) + O_2(g) + 2H_2O(l) \longrightarrow 2Mg^{2+} + 4OH^-; \quad E^\circ_{cell} = 3.60 \text{ V}$

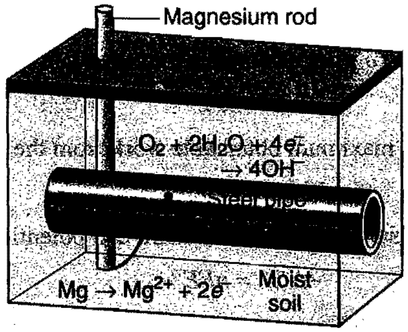


Fig. 12.18 Cathodic protection of a buried steel pipe

As the cathode, the iron containing steel pipe is protected from oxidation. Of course, the magnesium rod is eventually consumed and must be replaced, but this is cheaper than digging up the pipe line. This method is used to prevent the rusting of submarines and base line of oil refineries.

(x) Extraction of metals: A more electropositive metal can displace a less electropositive metal from its salt's solution. This principle is applied for the extraction of Ag and Au by cyanide process. Silver from the solution containing sodium argento cyanide, $NaAg(CN)_2$, can be obtained by the addition of zinc as it is more electropositive than Ag.

$$2NaAg(CN)_2 + Zn \longrightarrow Na_2Zn(CN)_4 + 2Ag$$

Concept of Equilibrium in Electrochemical Cell

In an electrochemical cell a reversible redox process takes place, *e.g.*, in Daniell cell:

$$Zn(s) + Cu^{2+}(aq.) \rightleftharpoons Zn^{2+}(aq.) + Cu(s)$$

(1) At equilibrium mass action ratio becomes equal to equilibrium constant,

i.e., $Q = K_e$

(2) Oxidation potential of anode = − Reduction potential of cathode

i.e., emf = Oxidation potential of anode + Reduction potential of cathode = 0

Cell is fully discharged.

According to Nernst equation:

$$E = E^\circ - \frac{0.0591}{n} \log_{10} Q \text{ at } 25^\circ\text{C}$$

At equilibrium, $E = 0, \ Q = K$

$$0 = E^\circ - \frac{0.0591}{n} \log_{10} K$$

$$K = \text{antilog}\left[\frac{nE^\circ}{0.0591}\right]$$

Work done by the Cell

Let n faraday charge be taken out of a cell of emf E; then work done by the cell will be calculated as:

$$\text{Work} = \text{Charge} \times \text{Potential}$$
$$= nFE$$

Work done by the cell is equal to decrease in free energy.

$$-\Delta G = nFE$$

Similarly, maximum obtainable work from the cell will be

$$W_{\max} = nFE^\circ$$

where, E° = standard emf or standard cell potential.

$$-\Delta G^\circ = nFE^\circ$$

The Relationship among K, ΔG° and E° Cell

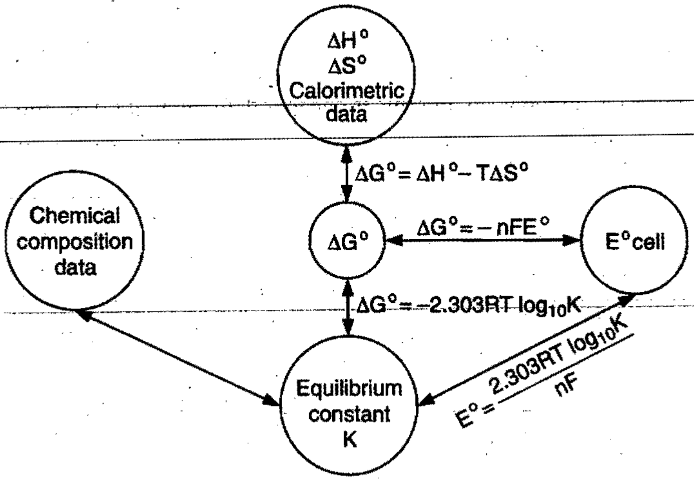

Fig. 12.19

Heat of Reaction in an Electrochemical Cell

Let n faraday charge flows out of a cell of emf E,

Then $$-\Delta G = nFE \quad \text{... (i)}$$

Gibbs-Helmholtz equation from thermodynamics may be given as:

$$\Delta G = \Delta H + T\left(\frac{\partial \Delta G}{\partial T}\right)_P \quad \text{... (ii)}$$

From equations (i) and (ii), we get

$$-nFE = \Delta H + T\left[\frac{\partial(-nFE)}{\partial T}\right]_P = \Delta H - nFT\left(\frac{\partial E}{\partial T}\right)_P$$

$$\Delta H = -nFE + nFT\left(\frac{\partial E}{\partial T}\right)_P$$

Here, $\left(\frac{\partial E}{\partial T}\right)_P$ = Temperature coefficient of cell

Case I: When $\left(\frac{\partial E}{\partial T}\right)_P = 0$, then $\Delta H = -nFE$

Case II: When $\left(\frac{\partial E}{\partial T}\right) > 0$, then $nFE > \Delta H$, *i.e.*, process inside the cell is endothermic.

Case III: When $\left(\frac{\partial E}{\partial T}\right) < 0$, then $nFE < \Delta H$, *i.e.*, process inside the cell is exothermic.

12.24 PRIMARY VOLTAIC CELL (The Dry Cell)

In this cell, once the chemicals have been consumed, further reaction is not possible. It cannot be regenerated by reversing the current flow through the cell using an external direct current source of electrical energy. The most common example of this type is dry cell.

The container of the dry cell is made of zinc which also serves as one of the electrodes. The other electrode is a carbon rod in the centre of the cell. The zinc container is lined with a porous paper. A moist mixture of ammonium chloride, manganese dioxide, zinc chloride and a porous inert filler occupy the space between the paper lined zinc container and the carbon rod. The cell is sealed with a material like wax.

As the cell operates, the zinc is oxidised to Zn^{2+}

$$Zn \longrightarrow Zn^{2+} + 2e^- \quad \text{(Anode reaction)}$$

The electrons are utilized at carbon rod (cathode) as the ammonium ions are reduced.

$$2NH_4^+ + 2e^- \longrightarrow 2NH_3 + H_2 \quad \text{(Cathode reaction)}$$

The cell reaction is

$$Zn + 2NH_4^+ \longrightarrow Zn^{2+} + 2NH_3 + H_2$$

Hydrogen is oxidised by MnO_2 in the cell.

$$2MnO_2 + H_2 \longrightarrow 2MnO(OH)$$

Ammonia produced at cathode combines with zinc ions to form complex ion.

$$Zn^{2+} + 4NH_3 \longrightarrow [Zn(NH_3)_4]^{2+}$$

E_{cell} is 1.6 volt.

Alkaline dry cell is similar to ordinary dry cell. It contains potassium hydroxide. The reactions in alkaline dry cell are:

$$Zn + 2OH^- \longrightarrow Zn(OH)_2 + 2e^- \quad \text{(Anode reaction)}$$

$$2MnO_2 + 2H_2O + 2e^- \longrightarrow 2MnO(OH) + 2OH^- \quad \text{(Cathode reaction)}$$

$$Zn + 2MnO_2 + 2H_2O \longrightarrow Zn(OH)_2 + 2MnO(OH) \quad \text{(Overall)}$$

E_{cell} is 1.5 volt.

Button cell : The button cells are usually pallet type flat in construction and look like a button in shape. Owing to their small sizes, they are used in small electronic devices like hearing aids, electronic watches etc. These cells are basically primary cells. Mercuric oxide button cell is the most commonly used button cell. In this cell, zinc anode and mercuric oxide plus carbon paste cathode is used. The electrolyte is a paste of ZnO and KOH.

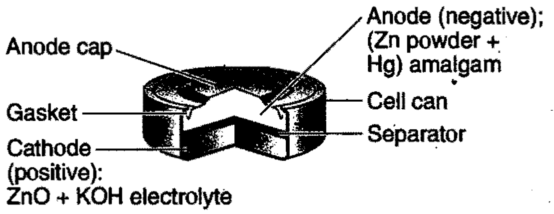

Fig. 12.20

The cell process is given below :

Anode : $$\underset{\text{(Amalgam)}}{Zn} + 2OH^- \longrightarrow ZnO(s) + H_2O + 2e^-$$

Cathode: $$HgO(s) + H_2O + 2e^- \longrightarrow Hg(l) + 2OH^-$$

Overall : $$\underset{\text{Amalgam}}{Zn} + HgO(s) \longrightarrow ZnO(s) + Hg(l)$$

The potential of this cell is approximately 1.35 volt and it remains constant during its life because overall reaction does not involve any ion whose concentration can change during the process.

12.25 SECONDARY VOLTAIC CELL (Lead Storage Battery)

The cell in which original reactants are regenerated by passing direct current from external source, *i.e.*, it is recharged, is called secondary cell. Lead storage battery is the example of this type.

It consists of a group of lead plates bearing compressed spongy lead, alternating with a group of lead plates bearing lead dioxide, PbO_2. These plates are immersed in a solution of about 30% H_2SO_4. When the cell discharges, it operates as a voltaic cell. The spongy lead is oxidised to Pb^{2+} ions and lead plates acquire a negative charge.

$$Pb \longrightarrow Pb^{2+} + 2e^- \qquad \text{(Anode reaction)}$$

Pb^{2+} ions combine with sulphate ions to form insoluble lead sulphate, $PbSO_4$, which begins to coat lead electrode.

$$Pb^{2+} + SO_4^{2-} \longrightarrow PbSO_4 \qquad \text{(Precipitation)}$$

The electrons are utilised at PbO_2 electrode.

$$PbO_2 + 4H^+ + 2e^- \longrightarrow Pb^{2+} + 2H_2O \qquad \text{(Cathode reaction)}$$

$$Pb^{2+} + SO_4^{2-} \longrightarrow PbSO_4 \qquad \text{(Precipitation)}$$

Overall cell reaction is:

$$Pb + PbO_2 + 4H^+ + 2SO_4^{2-} \longrightarrow 2PbSO_4 + 2H_2O$$

E_{cell} is 2.041 volt.

When a potential slightly greater than the potential of battery is applied, the battery can be recharged.

$$2PbSO_4 + 2H_2O \longrightarrow Pb + PbO_2 + 2H_2SO_4$$

After many repeated charge-discharge cycles, some of the lead sulphate falls to the bottom of the container, the sulphuric acid concentration remains low and the battery cannot be recharged fully.

Nickel-Cadmium storage cell : It is also a common storage battery. It is more expensive than the lead storage battery but it is light, therefore, used in calculators, portable power tools, etc.

It is a voltaic cell consisting of an anode of cadmium and a cathode of hydrated nickel oxide on nickel. The electrolyte in the cell is aqueous solution of potassium hydroxide. Electrode processes are given below :

Anode: $$Cd(s) + 2OH^-(aq) \longrightarrow Cd(OH)_2 + 2e^-$$

Cathode: $$NiO_2(s) + 2H_2O(l) + 2e^- \longrightarrow Ni(OH)_2 + 2OH^-$$

$$Cd(s) + NiO_2(s) + 2H_2O(l) \longrightarrow Cd(OH)_2 + Ni(OH)_2$$

In the recharging of the cell the process is reversed.

$$Cd(OH)_2 + Ni(OH)_2 \longrightarrow Cd(s) + NiO_2(s) + 2H_2O(l)$$

12.26 FUEL CELL

Fuel cells are another means by which chemical energy may be converted into electrical energy. The main disadvantage of a primary cell is that it can deliver current for a short period only. This is due to the fact that the quantity of oxidising agent and reducing agent is limited. But the energy can be obtained indefinitely from a fuel cell as long as the outside supply of fuel is maintained. One of the examples is the hydrogen-oxygen fuel cell. The cell consists of three compartments separated by a porous electrode. Hydrogen gas is introduced into one compartment and oxygen gas is fed into another compartment. These gases then diffuse slowly through the electrodes and react with an electrolyte that is in the central compartment. The electrodes are made of porous carbon and the electrolyte is a resin containing concentrated aqueous sodium hydroxide solution. Hydrogen is oxidised at anode and oxygen is reduced at cathode. The overall cell reaction produces water. The reactions which occur are:

Anode $$[H_2(g) + 2OH^-(aq.) \longrightarrow 2H_2O(l) + 2e^-] \times 2$$

Cathode $$O_2(g) + 2H_2O(l) + 4e^- \longrightarrow 4OH^-(aq.)$$

Overall $$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$$

This type of cells are used in space-crafts. Fuel cells are efficient and pollution free.

Thermodynamic efficiency of fuel cells is the ratio of the electrical free energy to the enthalpy of the reaction.

$$\eta = \frac{\Delta G}{\Delta H}$$

12.27 CONCENTRATION CELLS

If two plates of the same metal are dipped separately into two solutions of the same electrolyte and are connected with a salt bridge, the whole arrangement is found to act as a galvanic cell. In general, there are two types of concentration cells:

(i) Electrode concentration cells: In these cells, the potential difference is developed between two like electrodes at different concentrations dipped in the same solution of the electrolyte. For example, two hydrogen electrodes at different gas pressures in the same solution of hydrogen ions constitute a cell of this type.

$$\underset{\text{Anode}}{\underline{\text{Pt, } H_2 \text{ (Pressure } p_1)}} \,|H^+|\, \underset{\text{Cathode}}{\underline{H_2 \text{ (Pressure } p_2) \text{ Pt}}}$$

If $p_1 > p_2$, oxidation occurs at LHS electrode and reduction occurs at RHS electrode.

$$E_{\text{cell}} = \frac{0.0591}{2} \log \frac{(p_1)}{(p_2)} \quad \text{at } 25°\text{C}$$

In the amalgam cells, two amalgams of the same metal at two different concentrations are immersed in the same electrolytic solution.

$$M\,(\text{Hg } C_1)\,|M^{n+}|\,\text{Zn}(\text{Hg } C_2)$$

The emf of the cell is given by the expression

$$E_{\text{cell}} = \frac{0.0591}{n} \log \frac{C_1}{C_2} \quad \text{at } 25°\text{C}$$

(ii) Electrolyte concentration cells: In these cells, electrodes are identical but these are immersed in solutions of the same electrolyte of different concentrations. The source of electrical energy in the cell is the tendency of the electrolyte to diffuse from a solution of higher concentration to that of lower concentration. With the expiry of time, the two concentrations tend to become equal. Thus, at the start the emf of the cell is maximum and it gradually falls to zero. Such a cell is represented in the following manner:

(C_2 is greater than C_1).

$$M\,|\,M^{n+}(C_1)\,||\,M^{n+}(C_2)\,|\,M$$

or

$$\underset{\text{Anode}}{\underline{\text{Zn}\,|\,\text{Zn}^{2+}(C_1)}}\,||\,\underset{\text{Cathode}}{\underline{\text{Zn}^{2+}(C_2)\,|\,\text{Zn}}}$$

The emf of the cell is given by the following expression:

$$E_{\text{cell}} = \frac{0.0591}{n} \log \frac{C_{2\,(\text{RHS})}}{C_{1\,(\text{LHS})}} \quad \text{at } 25°\text{C}$$

The concentration cells are used to determine the solubility of sparingly soluble salts, valency of the cation of the electrolyte and transition point of the two allotropic forms of a metal used as electrodes, etc.

SOME SOLVED EXAMPLES

Example 43. *A cell contains two hydrogen electrodes. The negative electrode is in contact with a solution of 10^{-6} M hydrogen ions. The emf of the cell is 0.118 volt at 25° C. Calculate the concentration of hydrogen ions at the positive electrode.*

Solution: The cell may be represented as

$$\text{Pt}\,|\,H_2\,(1\text{ atm})\,|\,\underset{10^{-6}\,M}{H^+}\,||\,\underset{CM}{H^+}\,|\,H_2\,(1\text{ atm})\,|\,\text{Pt}$$

Anode	Cathode
(–ve)	(+ ve)
$H_2 \rightarrow 2H^+ + 2e^-$	$2H^+ + 2e^- \rightarrow H_2$

$$E_{\text{cell}} = \frac{0.0591}{2} \log \frac{[H^+]^2_{\text{Cathode}}}{[10^{-6}]^2}$$

$$0.118 = (0.0591) \log \frac{[H^+]}{10^{-6}}$$

$$\log \frac{[H^+]_{\text{Cathode}}}{10^{-6}} = \frac{0.118}{0.0591} = 2$$

$$\frac{[H^+]_{\text{Cathode}}}{10^{-6}} = 10^2$$

$$[H^+]_{\text{Cathode}} = 10^{-6} \times 10^2 = 10^{-4}\,M$$

Example 44. *The emf of the cell*

$Ag\,|\,AgI$ in 0.05 M $KI\,|$ Sol. $NH_4NO_3\,|$ 0.05 M $AgNO_3\,|\,Ag$

is 0.788 volt at 25° C. The activity coefficient of KI and silver nitrate in the above solution is 0.90 each. Calculate (i) the solubility product of AgI and (ii) the solubility of AgI in pure water at 25° C.

Solution: Ag^+ ion concentration on $AgNO_3$ side

$$= 0.9 \times 0.05 = 0.045\,M$$

Similarly I^- ion concentration in 0.05 M KI solution

$$= 0.05 \times 0.9 = 0.045\,M$$

$$E_{\text{cell}} = \frac{0.0591}{1} \log \frac{[Ag^+]_{\text{RHS}}}{[Ag^+]_{\text{LHS}}} = 0.0591 \log \frac{0.045}{[Ag^+]_{\text{LHS}}}$$

or

$$\log \frac{0.045}{[Ag^+]_{\text{LHS}}} = \frac{0.788}{0.0591} = 13.33$$

$$[Ag^+]_{\text{LHS}} = \frac{0.045}{2.138 \times 10^{13}}$$

$$= 2.105 \times 10^{-15}\,M$$

$$\text{Solubility product of AgI} = [Ag^+][I^-]$$

$$= 2.105 \times 10^{-15} \times 0.045$$

$$= 9.472 \times 10^{-17}$$

$$\text{Solubility of AgI} = \sqrt{\text{Solubility product of AgI}}$$

$$= \sqrt{9.472 \times 10^{-17}}$$

$$= 9.732 \times 10^{-9}\text{ g mol L}^{-1}$$

$$= 9.732 \times 10^{-9} \times 143.5\text{ g L}^{-1}$$

$$= 1.396 \times 10^{-6}\text{ g L}^{-1}$$

Example 45. *The observed emf of the cell,*

$Pt\,|\,H_2\,(1\,atm)\,|\,H^+(3 \times 10^{-4}\,M)\,||\,H^+(M_1)\,|\,H_2\,(1\,atm)\,|\,Pt$

is 0.154 V. Calculate the value of M_1 and pH of cathodic solution.

Solution: $E_{\text{cell}} = 0.0591 \log \dfrac{M_1}{3 \times 10^{-4}}$

or

$$\log \frac{M_1}{3 \times 10^{-4}} = \frac{0.154}{0.0591} = 2.6058$$

$$\frac{M_1}{3\times10^{-4}} = 4.034\times10^{2}$$

$$M_1 = 4.034\times10^{2}\times3\times10^{-4}\ M$$

$$= 0.121M$$

$$\text{pH} = -\log[H^+] = -\log 0.121 = 0.917$$

Example 46. *Calculate the emf of the following cell at 25° C:*

$$Pt\ \underset{2\ atm}{H_2}\,|HCl|\,\underset{10\ atm}{H_2}\ Pt$$

Solution:

$$E_{\text{cell}} = \frac{0.0591}{2}\log\frac{p_1}{p_2}$$

$$= \frac{0.0591}{2}\log\frac{2}{10}$$

$$= -\ 0.0206\ \text{volt}$$

Example 47. *In a fuel cell H_2 and O_2 react to produce electricity. In the process H_2 gas is oxidised at the anode and O_2 is reduced at the cathode. If 67.2 litre of H_2 at NTP reacts in 15 minute, what is the average current produced? If the entire current is used for electro-deposition of Cu from Cu^{2+}, how many g of Cu are deposited?*

Solution: Reaction at anode of fuel cell,

$$\underset{\substack{1\ \text{mole}\\22.4\ \text{L}}}{H_2(g)} \longrightarrow 2H^+ + \underset{\substack{2\ \text{mole}\\2\ \text{F}}}{2e^-}$$

$$67.2\ \text{L of}\ H_2\ \text{correspond} = \frac{2\times96500}{22.4}\times67.2\ \text{coulomb}$$

$$\text{Time} = 15\times60\ \text{second}$$

$$\text{Average current} = \frac{2\times96500\times67.2}{22.4\times15\times60} = 643.3\ \text{amp}$$

$$\text{Mass of copper deposited by}\ \frac{2\times96500}{22.4}\times67.2\ \text{coulomb}$$

$$= \frac{63.5}{2\times96500}\times\frac{2\times96500\times67.2}{22.4}$$

$$= 190.5\ \text{g}$$

Example 48. *Neglecting the liquid-liquid junction potential, calculate the emf of the following cell at 25° C:*

$$H_2(1\ atm)|\ 0.5\ M\ HCOOH\ ||\ 1M\ CH_3COOH\ |\ (1\ atm)\ H_2$$

K_a for HCOOH and CH_3COOH are 1.77×10^{-4} and 1.8×10^{-5} respectively.

Solution:

$$[H^+]\ \text{in HCOOH} = \sqrt{C\times K_a} = \sqrt{0.5\times1.77\times10^{-4}}$$

$$= 0.9407\times10^{-2}\ M$$

$$[H^+]\ \text{in}\ CH_3COOH = \sqrt{C\times K_a} = \sqrt{1\times1.8\times10^{-5}}$$

$$= 4.2426\times10^{-3}\ M$$

$$E_{\text{cell}} = 0.0591\log\frac{[H^+]_{\text{RHS}}}{[H^+]_{\text{LHS}}} = 0.0591\log\frac{4.2426\times10^{-3}}{0.9407\times10^{-2}}$$

$$= -\ 0.0204\ \text{volt}$$

Example 49. *During the discharge of a lead storage battery, density of H_2SO_4 fell from 1.294 to 1.139 g/mL. Sulphuric acid of density 1.294 is 39% H_2SO_4 by weight and that of density 1.139 g/mL is 20% H_2SO_4 by weight. The battery holds 3.5 litre of the acid and volume remains practically constant during discharge. Calculate ampere-hour of which the battery must have been used. The charging and discharging reactions are:*

$$Pb + SO_4^{2-} \longrightarrow PbSO_4 + 2e^- \quad (charging)$$

$$PbO_2 + 4H^+ + SO_4^{2-} + 2e^- \longrightarrow PbSO_4 + 2H_2O\ (discharging)$$

Solution:

$$\text{Weight of solution before discharge} = 3500\times1.294$$

$$= 4529\ \text{g}$$

$$\text{Weight of}\ H_2SO_4\ \text{before discharge} = \frac{39}{100}\times4529$$

$$= 1766.31\ \text{g}$$

$$\text{Weight of solution after discharge} = 3500\times1.139$$

$$= 3986.5\ \text{g}$$

$$\text{Weight of}\ H_2SO_4\ \text{after discharge} = \frac{20}{100}\times3986.5$$

$$= 797.3\ \text{g}$$

Loss in mass of H_2SO_4 during discharge

$$= 1766.31 - 797.3 = 969.01\ \text{g}$$

Now from first law of electrolysis,

$$W = \frac{Q\times E}{96500}$$

$$969.01 = \frac{Q\times98}{96500}$$

$$Q = 954178.21\ \text{coulomb}$$

$$\text{Ampere-hour} = \frac{\text{Coulomb}}{3600} = \frac{954178.21}{3600}$$

$$= 265.04\ \text{ampere-hour}$$

12.28 COMMERCIAL PRODUCTION OF CHEMICALS

The wide applications of electrolysis have been listed in section 12.4 of this chapter. A large number of chemicals are produced by electrolysis. A few of these are described below:

1. Manufacture of sodium

Sodium is obtained on large scale by two processes:

(i) Castner's process: In this process, electrolysis of fused sodium hydroxide is carried out at 330°C using iron as cathode and nickel as anode.

$$2NaOH \rightleftharpoons 2Na^+ + 2OH^-$$

At cathode: $2Na^+ + 2e \longrightarrow 2Na$

At anode: $4OH^- \longrightarrow 2H_2O + O_2 + 4e$

During electrolysis, oxygen and water are produced. Water formed at the anode gets partly evaporated and is partly broken down and hydrogen is discharged at cathode.

$$H_2O \rightleftharpoons H^+ + OH^-$$

At cathode: $2H^+ + 2e \longrightarrow 2H \longrightarrow H_2 \uparrow$

(ii) Down's process: Now-a-days sodium metal is manufactured by this process. It involves the electrolysis of fused sodium chloride containing calcium chloride and potassium fluoride using iron as cathode and graphite as anode at about 600°C (Fig. 12.21).

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

At cathode: $Na^+ + e \longrightarrow Na$

At anode: $2Cl^- \longrightarrow Cl_2 + 2e$

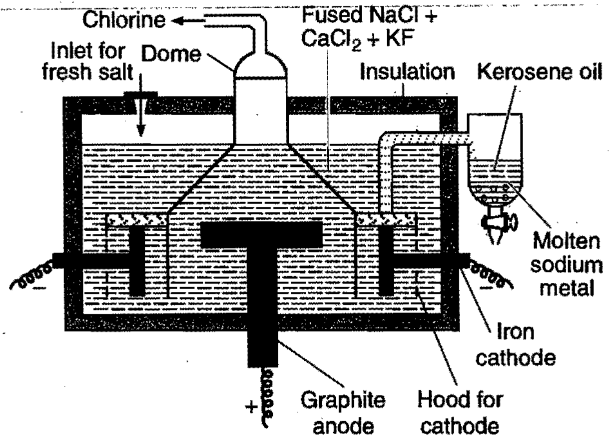

Fig. 12.21 Down's cell for extraction of sodium

The electrolysis of pure NaCl presents the following difficulties:

(a) The fusion temperature of NaCl is high, *i.e.*, 803°C. At this temperature both sodium and chlorine are corrosive.

(b) Sodium forms a metallic fog at this temperature.

To remove above difficulties, the fusion temperature is reduced to 600°C by adding $CaCl_2$ and KF. This is a cheaper method and **chlorine is obtained as a byproduct.** The sodium obtained is of high purity (about 99.5%).

2. Sodium hydroxide (Caustic soda), NaOH

Caustic soda is manufactured by the electrolysis of aqueous solution of sodium chloride in an electrolytic cell.

Principle: A sodium chloride solution contains Na^+, H^+, Cl^- and OH^- ions.

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

$$H_2O \rightleftharpoons H^+ + OH^-$$

On passing electricity, Na^+ and H^+ ions move towards cathode and Cl^- and OH^- ions move towards anode. The discharge potential of H^+ ions is less than Na^+ ions, thus hydrogen ions get discharged easily and hydrogen is liberated. Similarly, at anode Cl^- ions are easily discharged as their discharge potential is less than that of OH^- ions. Cl_2 gas is, therefore, liberated at anode.

The solution on electrolysis becomes richer in Na^+ and OH^- ions.

Since, chlorine reacts with sodium hydroxide solution even in the cold forming sodium chloride and sodium hypochlorite, it is necessary that chlorine should not come in contact with sodium hydroxide during electrolysis.

$$2NaOH + Cl_2 \longrightarrow NaCl + NaClO + H_2O$$

To overcome this problem, the anode is separated from the cathode in the electrolytic cell either by using a porous diaphragm or by using a mercury cathode.

(i) Porous diaphragm process (Nelson cell process): Nelson cell consists of a perforated steel tube lined inside with asbestos. The tube acts as a cathode (Fig. 12.22). It is suspended in a steel tank. A graphite rod dipped in sodium chloride solution serves as anode. On passing electric current, chlorine is liberated at the anode and let out through the outlet. Sodium ions penetrate through the asbestos and reach the cathode where hydrogen and OH^- ions are formed by reduction of water. Sodium ions combine with OH^- ions to form NaOH which is collected in the outer tank while hydrogen is drawn off through the outlet. The steam blown during the process keeps the electrolyte warm and helps to keep perforation clear.

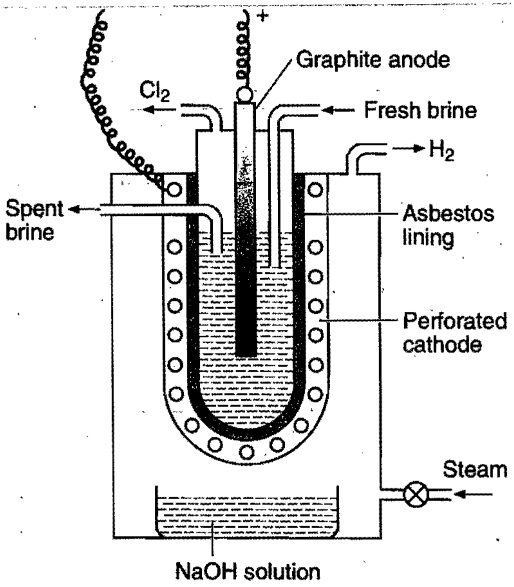

Fig. 12.22 Nelson cell

$$NaCl \rightleftharpoons Na^+ + Cl^- \quad \text{(in solution)}$$

At cathode: $2H_2O + 2e \rightleftharpoons H_2 + 2OH^-$

$$Na^+ + OH^- \rightleftharpoons NaOH$$

At anode: $2Cl^- \longrightarrow Cl_2 + 2e$

The solution containing NaOH and NaCl as impurity is taken out and evaporated to dryness.

(ii) Castner-Kellner cell: This is the common cell in which mercury is used as cathode. The advantage of using Hg as a cathode is that the discharge potential of Na^+ ions is less than that of H^+ ions. Na^+ ions get discharged on mercury and the sodium so deposited combines with mercury to form sodium amalgam. The cell consists of a large rectangular trough divided into three compartments by slate partitions which do not touch the bottom of the cell but dipping in mercury as shown in the Fig. 12.23.

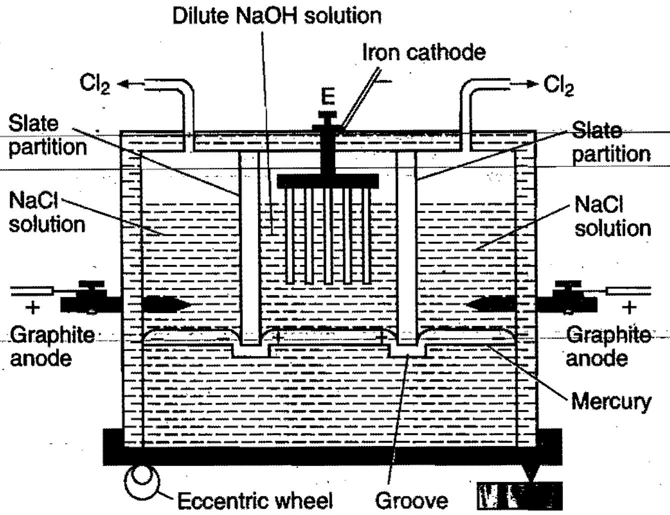

Fig. 12.23 Castner-Kellner cell

The mercury can flow from one compartment into other but the solution kept in one compartment cannot flow into other. Sodium chloride solution is placed in the two outer compartments and a dilute solution of sodium hydroxide in the inner compartment. Two graphite electrodes which act as anodes are fixed in the outer compartments and a series of iron rods fitted in the inner compartment acts as cathode. Mercury in the outer compartments acts as cathode while in the inner compartment it acts as anode by induction. The cell is kept rocking with the help of an eccentric wheel.

When electricity is circulated, sodium chloride in the outer compartments is electrolysed. Chlorine is evolved at the graphite anode while Na^+ ions are discharged at the Hg cathode. The liberated sodium forms amalgam with mercury.

$$NaCl \rightleftharpoons Na^+ + Cl^-$$

At anode: $2Cl^- \longrightarrow 2Cl + 2e \longrightarrow Cl_2$

At cathode: $Na^+ + e \longrightarrow Na$

$$Na + Hg \longrightarrow \text{Amalgam}$$

The sodium amalgam thus formed comes in the inner compartment due to rocking. Here, the sodium amalgam acts as the anode and iron rods acts as cathode.

At anode: $\text{Na-amalgam} \longrightarrow Na^+ + Hg + e$

At cathode: $2H_2O + 2e \longrightarrow H_2\uparrow + 2OH^-$

The concentrated solution of sodium hydroxide (about 20%) is taken out from the inner compartment and evaporated to dryness to get solid NaOH.

(iii) Kellner-Solvay cell: This is the modified cell. This cell has no compartments. The flowing mercury as shown in Fig. 12.24 acts as cathode. A number of graphite rods dipping in sodium chloride solution act as anode. A constant level of sodium chloride solution is maintained in the cell. On electrolysis chlorine gas is liberated and Na^+ ions are discharged at cathode (mercury). Sodium discharged dissolves in Hg and forms amalgam. This amalgam flows out in a vessel containing water. Sodium hydroxide is formed with evolution of hydrogen.

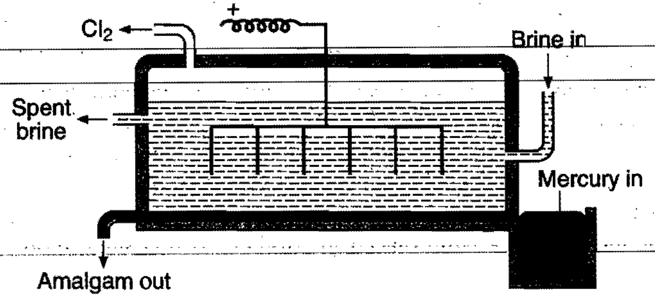

Fig. 12.24 Kellner-Solvay cell

Preparation of pure sodium hydroxide: Commercial sodium hydroxide is purified with the help of alcohol. Sodium hydroxide dissolves in alcohol while impurities like NaCl, Na_2CO_3, Na_2SO_4, etc., remain insoluble. The alcoholic filtrate is distilled. The alcohol distills off while pure solid sodium hydroxide is left behind.

3. Manufacture of aluminium

Aluminium is manufactured from pure bauxite ore by electrolysis. The bauxite ore usually contains impurities such as iron oxide, silica, etc. These impurities are first removed by the application of the following methods in order to get pure alumina, *i. e.*, pure bauxite ore:

(a) Hall's process; (b) Baeyer's process; (c) Serpeck's process.

Electrolytic reduction of pure alumina: The electrolysis of pure alumina faces two difficulties: (i) Pure alumina is a bad conductor of electricity and (ii) The fusion temperature of pure alumina is about 2000°C and at this temperature when the electrolysis is carried of the fused mass, the metal formed vapourises as the boiling point of aluminium is 1800°C.

The above difficulties are overcome by using a mixture containing alumina, cryolite (Na_3AlF_6) and fluorspar (CaF_2) in the ratio of 20 : 60 : 20. The fusion temperature of this mixture is 900°C and it is a good conductor of electricity.

The electrolysis is carried out in an iron box lined inside with gas carbon which acts as cathode. The anode consists of carbon rods which dip in the fused mixture of the electrolyte from above. The fused electrolyte is covered with a layer of coke (Fig. 12.25).

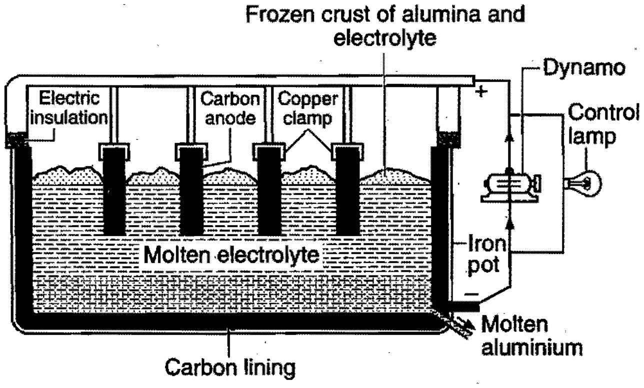

Fig. 12.25

The current passed through the cell serves two purposes: (i) Heating of the electrolyte: The temperature of the cell is automatically maintained at 900 – 950°C. (ii) Electrolysis: On passing current, aluminium is discharged at cathode. Aluminium being heavier than the electrolyte sinks to the bottom and is tapped out periodically from a tapping hole. Oxygen is liberated at anode. It attacks the carbon rods forming CO and CO_2. The process is continuous. When the concentration of the electrolyte decreases, the resistance of the cell increases. This is indicated by the glowing of a lamp placed in parallel. At this stage more of alumina is added.

The exact mechanism of the electrolysis is not yet known. Two concepts have been proposed.

First concept: AlF_3 from cryolite ionises as:

$$AlF_3 \rightleftharpoons Al^{3+} + 3F^-$$

Al^{3+} ions are discharged at cathode and F^- ions at anode.

$$Al^{3+} + 3e \longrightarrow Al \text{ (at cathode)}$$

$$2F^- \longrightarrow F_2 + 2e \text{ (at anode)}$$

The liberated fluorine reacts with alumina to form AlF_3 and O_2. The oxygen attacks the carbon anodes to form CO and CO_2.

$$Al_2O_3 + 3F_2 \longrightarrow 2AlF_3 + \frac{3}{2}O_2$$

$$2C + O_2 \longrightarrow 2CO$$

$$C + O_2 \longrightarrow CO_2$$

Anodes are replaced frequently.

Second concept: Alumina (Al_2O_3) ionises as:

$$Al_2O_3 \rightleftharpoons \underset{\text{Cathode}}{Al^{3+}} + \underset{\text{Anode}}{AlO_3^{3-}}$$

$$Al^{3+} + 3e \longrightarrow Al \text{ (at cathode)}$$

At anode AlO_3^- is oxidised.

$$4AlO_3^{3-} \longrightarrow 2Al_2O_3 + 3O_2 + 12e \text{ (at anode)}$$

Thus, the overall chemical reaction taking place during electrolysis is,

$$2Al_2O_3 \longrightarrow 4Al + 3O_2$$

Aluminium of 99.8% purity is obtained from this process.

Refining of aluminium by Hoope's electrolytic method: Aluminium is further purified by Hoope's process. The electrolytic cell consists of an iron box lined inside with carbon. The cell consists of three layers which differ in specific gravities. The upper layer is of pure aluminium which acts as cathode. The middle layer consists of a mixture of the fluorides of Al, Ba and Na. The lowest layer consists of impure aluminium which acts as anode. The middle layer works as electrolyte.

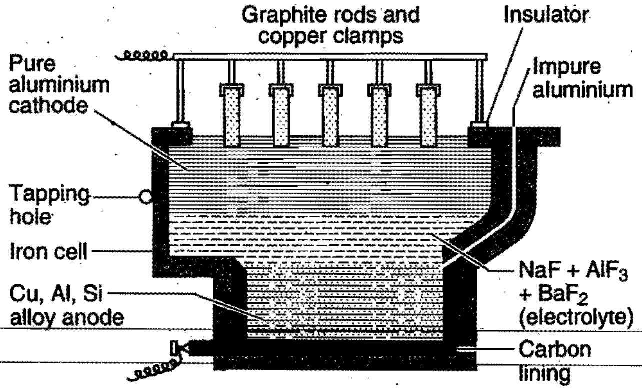

Fig. 12.26

The graphite rods are dipped in pure aluminium and Cu-Al alloy rods at the bottom of impure aluminium work as conductors. On electrolysis, aluminium is deposited at the cathode from the middle layer and an equivalent amount of aluminium is taken up by the middle layer from the bottom layer (impure aluminium). Therefore, aluminium is transferred from bottom to the top layer through middle layer while impurities are left behind. Aluminium thus obtained is 99.98%.

4. Isolation of fluorine

Fluorine presented many difficulties in its isolation. It remained a difficult problem in chemistry for many years and after a hard labour of many chemists for about 75 years it could be isolated finally by **Moissan** in 1886. **The reasons for its late discovery were its high reactivity and non-conducting nature of hydrofluoric acid.** Fluorine attacked the material of the vessels used for its isolation. Carbon vessel was attacked with formation of CF_4 and platinum vessel was reduced to chocolate powder. The vessels of other metals were also affected. Platinum and carbon could not be used as electrodes. Another difficulty experienced was that when the electrolysis of aqueous hydrofluoric acid was carried out, hydrogen and oxygen (ozone) were obtained and when anhydrous hydrofluoric acid was tried it was found to be a bad conductor of electricity.

Moissan finally solved the problem and isolated fluorine by the electrolysis of anhydrous hydrofluoric acid in the presence of potassium hydrogen fluoride using Pt-Ir alloy vessel at –23°C. The electrodes used were also of Pt-Ir alloy.

Modern methods of isolation: In modern methods, fluorine is prepared by electrolysis of a fused fluoride (usually potassium hydrogen fluoride, KHF_2). The electrolytic cells are made of copper, nickel or monel metal. The anode is generally of graphite and the fluorine set free contains some carbon tetrafluoride.

Reactions in the electrolytic cell

$$KHF_2 \longrightarrow KF + HF$$

$$\Downarrow$$

$$K^+ + F^-$$

Cathode	Anode
$K^+ + e \rightarrow K$	$F^- \rightarrow F + e$
$K + HF \rightarrow KF + H$	$2F \rightarrow F_2$
$2H \rightarrow H_2$	

The following precautions should be taken in the preparation of fluorine:

(i) The electrolyte must be completely dry. In presence of moisture, the evolved fluorine reacts with moisture to form O_2 and O_3.

(ii) The parts of the apparatus which come in contact with fluorine must be free from oil and grease.

(iii) The vessel in which fluorine is collected should also be absolutely dry.

(iv) The gas must be made free from HF before storing by passing through sodium fluoride (NaF), otherwise HF will attack the vessel.

Note: HF is more corrosive and reactive than fluorine.

Dennis method: The electrolytic cell used in this method consists of a V-shaped copper tube (5 cm in diameter) fitted with copper caps. Graphite electrodes through these caps are sealed and insulated in the tube by bakelite cement which is not affected by fluorine. The cell is covered with an insulating layer of asbestos cement over which is wound a resistance wire for electrical heating. The tube is thickly lagged to prevent the loss of heat.

The electrolyte consists of fused potassium hydrogen fluoride which has already been dried for 48 hours at 130°C. The electrolyte is kept in fused state by electrical heating externally. For electrolysis, a current of 5 ampere and 12 volt is used. On electrolysis fluorine is liberated at anode. To make the liberated fluorine free from HF vapours, it is passed through copper U-tubes containing sodium fluoride.

$$NaF + HF \longrightarrow NaHF_2$$

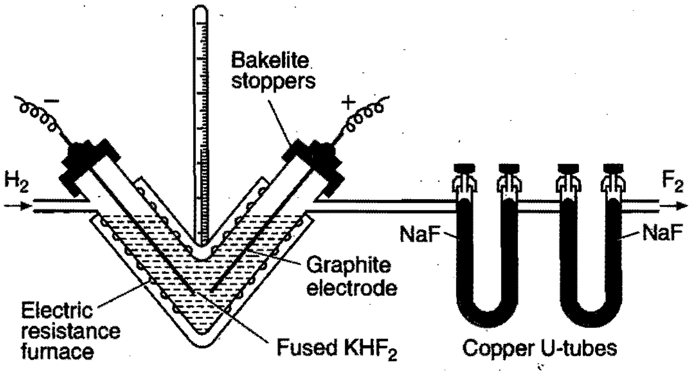

Fig. 12.27

The following difficulty is experienced in this method: The liberated fluorine at anode does not escape fast enough due to narrow exit. The escape is further hindered due to frothing in the electrolyte. There are, thus, chances of mixing of H_2 and F_2 which may result in explosion. To avoid this, a modified apparatus has been devised by Whytlaw-Gray.

Whytlaw-Gray method: It consists of a copper cell wound with resistance wire for electrical heating. The pure graphite anode is enclosed in a copper cylinder which is perforated at the bottom (Fig. 12.28). The electrolysis of fused KHF_2 is carried out in this cell. The escape of fluorine is fast enough and thus no frothing in the electrolyte occurs. There are no chances of mixing of H_2 and F_2 in this cell.

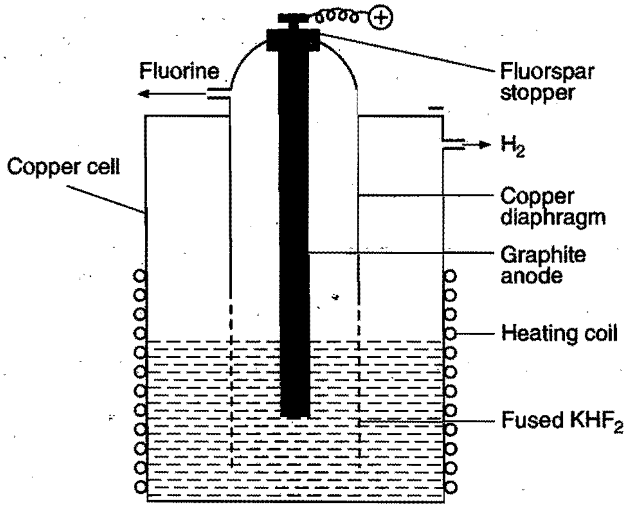

Fig. 12.28

MISCELLANEOUS NUMERICAL EXAMPLES

Example 1. *Anodic oxidation of ammonium hydrogen sulphate produces ammonium persulphate.*

$$NH_4HSO_4 \longrightarrow NH_4SO_4^- + H^+$$

$$2NH_4SO_4^- \longrightarrow (NH_4)_2S_2O_8 + 2e^- \ (Anodic\ oxidation)$$

$$2H^+ + 2e^- \longrightarrow H_2 \ (Cathodic\ reduction)$$

Hydrolysis of ammonium persulphate forms H_2O_2.

$$(NH_4)_2S_2O_8 + 2H_2O \longrightarrow 2NH_4HSO_4 + H_2O_2$$

Current efficiency in electrolytic process is 60%. Calculate the amount of current required to produce 85 g of H_2O_2 per hour. Hydrolysis reaction shows 100% yield.

Solution: Given,

$$\underset{228\,\text{g}}{(\text{NH}_4)_2\text{S}_2\text{O}_8} + \text{H}_2\text{O} \longrightarrow 2\text{NH}_4\text{HSO}_4 + \underset{34\,\text{g}}{\text{H}_2\text{O}_2}$$

$\because$ 34 g H_2O_2 is produced by 228 g $(\text{NH}_4)_2\text{S}_2\text{O}_8$

$\therefore$ 85 g H_2O_2 will be produced by $\frac{228}{24} \times 85$ g $(\text{NH}_4)_2\text{S}_2\text{O}_8$

$$= 570\,\text{g}$$

Equivalent mass of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ may be calculated using the following reaction:

$$2\text{NH}_4\text{SO}_4^- \longrightarrow (\text{NH}_4)_2\text{S}_2\text{O}_8 + 2e$$

$$\text{Equivalent mass of } (\text{NH}_4)_2\text{S}_2\text{O}_8 = \frac{\text{Mol. mass}}{2} = \frac{228}{2} = 114$$

From first law of electrolysis,

$$W = \frac{ItE}{96500}$$

$$570 = \frac{I \times 3600 \times 114}{96500}$$

$$I = 134.0277 \text{ ampere}$$

Given that, current efficiency is 60%, the actual amount of current

$$= \frac{100}{60} \times 134.0277$$

$$= 223.379 \text{ ampere}$$

Example 2. *In a zinc manganese dioxide dry cell, the anode is made up of zinc and cathode of a carbon rod surrounded by a mixture of MnO_2, carbon, NH_4Cl and $ZnCl_2$ in aqueous base.*

The cathodic reaction may be represented as:

$$2MnO_2(s) + Zn^{2+} + 2e^- \longrightarrow ZnMn_2O_4(s)$$

Let there be 8 g MnO_2 in the cathodic compartment. How many days will the dry cell continue to give a current of 4×10^{-3} ampere?

Solution: When MnO_2 will be used up in cathodic process, the dry cell will stop to produce current.

Cathodic process:

$$2\overset{+4}{\text{MnO}_2}(s) + \text{Zn}^{2+} + 2e^- \longrightarrow \text{Zn}\overset{+3}{\text{Mn}}_2\text{O}_4$$

$$\text{Equivalent mass of MnO}_2 = \frac{\text{Molecular mass}}{\text{Change in oxidation state}}$$

$$= \frac{87}{1} = 87$$

From first law of electrolysis,

$$W = \frac{ItE}{96500}$$

$$8 = \frac{4 \times 10^{-3} \times t \times 87}{96500}$$

$$t = 2218390.8 \text{ second}$$

$$= \frac{2218390.8}{3600 \times 24} = 25.675 \text{ day}$$

Example 3. *Ten gram of a fairly concentrated solution of cupric sulphate is electrolysed using 0.01 faraday of electricity. Calculate:*

(*i*) *The mass of the resulting solution;*

(*ii*) *The number of equivalents of acid or alkali in the solution.*

Solution: Electrode process during electrolysis of aqueous CuSO_4 may be given as:

$$\text{Cu}^{2+} + 2e^- \longrightarrow \text{Cu (Cathode)}$$

$$2\text{OH}^- \longrightarrow \text{H}_2\text{O} + \tfrac{1}{2}\text{O}_2 + 2e^- \text{ (Anode)}$$

Mass of copper deposited at cathode by 0.01 faraday charge

$= 0.01 \times 31.75$

$= 0.3175$ g

(Here, 31.75 is the equivalent mass of Cu^{2+}.)

Mass of oxygen evolved by 0.01 faraday charge

$= 0.01 \times 8 = 0.08$ g

Total weight loss from solution $= 0.3175 + 0.08 = 0.3975$ g

Mass of resulting solution $= 10 - 0.3975$

$= 9.6025$ g

After deposition of Cu^{2+} and OH^- ions at the respective electrodes, H_2SO_4 will prevail in the solution. 0.01 faraday of electricity will result in 0.01 equivalent of acid.

Example 4. *A current of 40 microampere is passed through silver nitrate solution for 16 minutes using platinum electrodes. 50% of the cathode is occupied by a single atom thick silver layer. Calculate the total surface area of the cathode if one silver atom occupies 5.5×10^{-16} cm^2 surface area.*

Solution: Mass of silver deposited may be calculated according to Faraday's first law of electrolysis.

$$W = \frac{ItE}{96500}$$

$$= \frac{40 \times 10^{-6} \times 60 \times 16 \times 108}{96500}$$

$$= 42.976 \times 10^{-6} \text{ g}$$

Total number of deposited 'Ag' atoms

$$= \frac{42.976 \times 10^{-6}}{108} \times 6.023 \times 10^{23}$$

$$= 2.3967 \times 10^{17} \text{ atoms}$$

Surface occupied by deposited silver

= number of silver atoms × area occupied by a single atom

$= 2.3967 \times 10^{17} \times 5.5 \times 10^{-16}$

$= 131.818 \text{ cm}^2$

Since, deposited silver occupies 50% of total area of cathode, hence,

Total surface area of cathode $= 2 \times 131.818$

$$= 263.636 \text{ cm}^2$$

Example 5. *A pin of 2 cm length and 0.4 cm diameter was placed in $AgNO_3$ solution through which a 0.2 ampere current was passed for 10 minute to deposit silver on the pin. The pin was used by a surgeon in lachrymal duct operation. The density of silver and electrochemical equivalent are 1.05×10^4 kg m^{-1} and 1.118×10^{-6} kg/coulomb respectively. What is the thickness of silver deposited on the pin? Assume that the tip of the pin contains negligible mass of silver?*

Solution: From Faraday's first law,

$$W = ZIt$$

$$= 1.118 \times 10^{-6} \times 0.2 \times 10 \times 60 = 1.34 \times 10^{-4} \text{ kg}$$

$$V = \frac{W}{d} = \frac{1.34 \times 10^{-4}}{1.05 \times 10^4} = 1.277 \times 10^{-8} \text{ m}^3$$

$$= 1.277 \times 10^{-2} \text{ cm}^3 \quad \text{... (i)}$$

Surface area of pin $= 2\pi rh$

$$= 2 \times 3.14 \times 0.2 \times 2$$

$$= 2.512 \text{ cm}^2$$

Surface area may be treated as that of a rectangle of length 'h' and breadth $2\pi r$. Let the thickness of the coating be 'd' cm. Then

Volume of the occupied metal $= 2.512 \times d \text{ cm}^3$ ... (ii)

From equations (i) and (ii), we get

$$1.277 \times 10^{-2} = 2.512 \times d$$

$$d = 0.5083 \times 10^{-2} \text{ cm}$$

$$= 5.083 \times 10^{-5} \text{ metre}$$

Example 6. *The specific conductivity of a saturated solution of silver chloride is 2.30×10^{-6} mho cm^{-1}, at 25° C. Calculate the solubility of silver chloride at 25° C if $\lambda_{Ag^+} = 61.9$ mho cm^2 mol^{-1} and $\lambda_{Cl^-} = 76.3$ mho cm^2 mol^{-1}.*

Solution: Let the solubility of AgCl be s gram mole per litre

$$\text{Dilution} = \frac{1000}{S}$$

$$\Lambda^{\infty}_{AgCl} = \lambda_{Ag^+} + \lambda_{Cl^-}$$

$$= 61.9 + 76.3$$

$$= 138.2 \text{ mho cm}^2 \text{ mol}^{-1}$$

$$\text{Sp. conductivity} \times \text{dilution} = \Lambda^{\infty}_{AgCl} = 138.2$$

$$2.30 \times 10^{-6} \times \frac{1000}{S} = 138.2$$

$$S = \frac{2.30 \times 10^{-3}}{138.2} = 1.66 \times 10^{-5} \text{ mol per litre}$$

$$= 1.66 \times 10^{-5} \times 143.5 \text{ gL}^{-1}$$

$$= 2.382 \times 10^{-3} \text{ gL}^{-1}$$

Example 7. *Resistance of a solution (A) is 50 ohm and that of solution (B) is 100 ohm, both solutions being taken in the same conductivity cell. If equal volumes of solutions (A) and (B) are mixed, what will be the resistance of the mixture, using the same cell? Assume that there is no increase in the degree of dissociation of (A) and (B) on mixing.*

Solution: Let us suppose κ_1 and κ_2 are the specific conductances of solutions 'A' and 'B' respectively and cell constant is 'y'. We know that,

Specific conductance = Conductance × Cell constant

For (A), $\kappa_1 = \frac{1}{50} \times y$

For (B), $\kappa_2 = \frac{1}{100} \times y$

When equal volumes of (A) and (B) are mixed, the volume becomes double. Then,

$$\text{Specific conductance of mixture} = \frac{\kappa_1 + \kappa_2}{2}$$

$$\therefore \quad \frac{\kappa_1 + \kappa_2}{2} = \frac{1}{R} \times y$$

$$\frac{1}{2}\left[\frac{y}{50} + \frac{y}{100}\right] = \frac{1}{R} \times y$$

$$\frac{1}{100} + \frac{1}{200} = \frac{1}{R}$$

$$R = 200/3 = 66.66 \text{ ohm}$$

Example 8. *A big irregular shaped vessel contained water, specific conductance of which was 2.56×10^{-5} mho cm^{-1}. 500 g of NaCl was then added to the water and the specific conductance after the addition of NaCl was found to be*

3.1×10^{-5} mho cm^{-1}. Find the capacity of the vessel if it was fully filled with water. (Λ^{∞} NaCl $= 149.9$ ohm^{-1} cm^{2} eq^{-1})

Solution: Let us suppose the volume of vessel is V mL

Volume containing 1 equivalent

$$=\frac{\text{Volume}}{\text{Mass / equivalent mass}}$$

$$=\frac{V}{500/58.5}=\frac{V}{8.547}$$

Specific conductance of NaCl

= Specific conductance of NaCl solution − Specific conductance of water

$$=3.1\times10^{-5}-2.56\times10^{-5}$$

$$=0.54\times10^{-5}\ \text{mho cm}^{-1}$$

$\Lambda=\kappa\times$ volume containing 1 equivalent of electrolyte ...(i)

For very dilute solution, when the big vessel is fully filled

$$\Lambda^{\infty}_{\text{NaCl}}=149.9\ \text{ohm}^{-1}\ \text{cm}^2\ \text{eq}^{-1}$$

Thus, from eq. (i),

$$149.9=0.54\times10^{-5}\times\frac{V}{8.547}$$

$$V=237258.38\ \text{L}$$

Example 9. *A 0.05 N solution of a salt occupying a volume between two platinum electrodes separated by a distance of 1.72 cm and having an area of 4.5 cm^2 has a resistance of 250 ohm. Calculate the equivalent conductance of the solution.*

Solution:

Specific conductance = conductance × cell constant

$$\kappa=C\times\frac{l}{A}$$

$$=\frac{1}{R}\times\frac{l}{A}$$

$$=\frac{1}{250}\times\frac{1.72}{4.5}$$

$$=1.5288\times10^{-3}\ \text{ohm}^{-1}\ \text{cm}^{-1}$$

$$\Lambda_e=\kappa\times\frac{1000}{N}$$

$$=1.5288\times10^{-3}\times\frac{1000}{0.05}$$

$$=30.56\ \text{ohm}^{-1}\ \text{cm}^2\ \text{eq}^{-1}$$

Example 10. *At 18° C, the mobilities of NH_4^+ and ClO_4^- ions are 6.6×10^{-4} and 5.7×10^{-4} cm^2 volt^{-1} sec^{-1} at infinite dilution. Calculate the equivalent conductance of ammonium chlorate solution.*

Solution: $\Lambda^{\infty}_{NH_4ClO_4}=\lambda^{\infty}_{NH_4^+}+\lambda^{\infty}_{ClO_4^-}$

$$=(U^{\infty}_{NH_4^+}+U^{\infty}_{ClO_4})F$$

$$=(6.6\times10^{-4}+5.7\times10^{-4})\times96500$$

$$=118.69\ \text{ohm}^{-1}\ \text{cm}^2\ \text{eq}^{-1}$$

Example 11. *For the cell reaction,*

$$Mg\,|\,Mg^{2+}(aq.)\,||\,Ag^+(aq.)\,|\,Ag$$

calculate the equilibrium constant at 25° C and maximum work that can be obtained by operating the cell.

$$E^{\circ}_{Mg^{2+}/Mg}=-2.37\ \textit{volt}\ \text{ and }\ E^{\circ}_{Ag^+/Ag}=+0.80\ \textit{volt}$$

Solution: $E^{\circ}_{\text{cell}}=0.80+2.37=3.17$ volt

$$\log K_c=\frac{nE^{\circ}_{\text{cell}}}{0.0591}$$

$$=\frac{2\times3.17}{0.0591}=107.2758$$

$$K_c=1.89\times10^{107}$$

$$-\Delta G=\text{maximum work}$$

$$=nFE^{\circ}=2\times96500\times3.17$$

$$=611810\ \text{J}$$

Example 12. *Zinc granules are added in excess to 500 mL of 1.0 M nickel nitrate solution at 25° C until the equilibrium is reached. If the standard reduction potentials of Zn^{2+}/Zn and Ni^{2+}/Ni are −0.75 and −0.24 volt respectively, find out the concentration of Ni^{2+} ions in solution at equilibrium.* (IIT 1991)

Solution: The reaction to be considered is,

$$\text{Zn}(s)+\text{Ni}^{2+}(aq.)\rightleftharpoons\text{Zn}^{2+}(aq.)+\text{Ni}(s)$$

The cell involving this reaction would be,

$$\text{Zn}(s)\,|\,\text{Zn}^{2+}(aq.)\,||\,\text{Ni}^{2+}(aq.)\,|\,\text{Ni}(s)$$

$$E^{\circ}_{\text{cell}}=-0.24+0.75=0.51\ \text{volt}$$

$$\log K_{\text{eq}}=\frac{nFE^{\circ}}{2.303\,RT}=\frac{nE^{\circ}}{0.0591}=\frac{2\times0.51}{0.0591}=17.25$$

So, $K_{\text{eq}}=1.78\times10^{17}$

Let x be the concentration of Ni^{2+} that have been reduced to nickel at equilibrium.

$$\underset{(1.0-x)}{\text{Zn}(s)+\text{Ni}^{2+}(aq.)}\rightleftharpoons\underset{x}{\text{Zn}^{2+}(aq.)}+\text{Ni}(s)$$

$$K_{\text{eq}}=\frac{[\text{Zn}^{2+}]}{[\text{Ni}^{2+}]}=\frac{x}{(1-x)}=1.78\times10^{17}$$

$$x\approx1.0\,M$$

So, $(1-x)=[\text{Ni}^{2+}]=\dfrac{1.0}{1.78\times10^{17}}=5.6\times10^{-18}\ M$

Example 13. *The standard reduction potential of Cu^{2+}/Cu and Ag^+/Ag electrodes are 0.337 and 0.799 volt* *respectively. Construct a galvanic cell using these electrodes so that its standard emf is positive. For what concentration of* Ag^+ *will the emf of the cell at 25° C be zero if concentration of* Cu^{2+} *is* 0.01 *M?* (IIT 1990)

Solution: Given, $E^\circ_{Cu^{2+}/Cu} = 0.337$ volt and $E^\circ_{Ag^+/Ag} = 0.799$ volt. The standard emf will be positive if Cu / Cu^{2+} is anode and Ag^+ / Ag is cathode. The cell can be represented as:

$$Cu \mid Cu^{2+} \parallel Ag^+ \mid Ag$$

The cell reaction is,

$$Cu + 2Ag^+ \longrightarrow Cu^{2+} + 2Ag$$

$$E^\circ_{cell} = \text{Oxid. potential of anode} + \text{Red. potential of cathode}$$

$$= -0.337 + 0.799$$

$$= 0.462 \text{ volt}$$

Applying the Nernst equation,

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{2} \log \frac{[Cu^{2+}]}{[Ag^+]^2}$$

When, $E_{cell} = 0$

$$E^\circ_{cell} = \frac{0.0591}{2} \log \frac{[Cu^{2+}]}{[Ag^+]^2}$$

or $$\log \frac{[Cu^{2+}]}{[Ag^+]^2} = \frac{0.462 \times 2}{0.0591} = 15.6345$$

$$\frac{[Cu^{2+}]}{[Ag^+]^2} = 4.3102 \times 10^{15}$$

$$[Ag^+]^2 = \frac{0.01}{4.3102 \times 10^{15}}$$

$$= 0.2320 \times 10^{-17}$$

$$= 2.320 \times 10^{-18}$$

$$[Ag^+] = 1.523 \times 10^{-9}\ M$$

Example 14. *The standard reduction potential for the half- cell having reaction,*

$$NO_3^- (aq.) + 2H^+ (aq.) + e^- \longrightarrow NO_2 (g) + H_2O$$

is 0.78 *volt.*

(*i*) *Calculate the reduction potential in* 8 *M* H^+.

(*ii*) *What will be the reduction potential of the half-cell in a neutral solution?*

Assume all other species to be at unit concentration. (IIT [illegible])

Solution: (i) Applying the formula,

$$E_{red} = E^\circ_{red} + \frac{0.0591}{n} \log [H^+]^2$$

$$= 0.78 + \frac{0.0591}{2} \log 8^2$$

$$= 0.78 + 0.0591 \times 3 \times 0.3010$$

$$= 0.833 \text{ volt}$$

(ii) $$E_{red} = 0.78 + \frac{0.0591}{2} \log (10^{-7})^2$$

[For neutral solution $[H^+] = 10^{-7}\ M$]

$$= 0.78 - 0.0591 \times 7$$

$$= 0.367 \text{ volt}$$

Example 15. *The emf of a cell corresponding to the reaction,*

$$Zn + 2H^+ (aq.) \longrightarrow Zn^{2+}\ (0.1 M) + H_2 (g)\ 1\, atm$$

is 0.28 *volt at* 25° *C. Write the half-cell reactions and calculate the pH of the solution at the hydrogen electrode.*

$$E^\circ_{Zn^{2+}/Zn} = -0.76 \text{ volt} \quad \text{and} \quad E^\circ_{H^+/H_2} = 0$$

Solution: $E^\circ_{cell} = 0.76$ volt

Applying Nernst equation,

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{2} \log \frac{[Zn^{2+}][H_2]}{[H^+]^2}$$

$$0.28 = 0.76 - \frac{0.0591}{2} \log \frac{(0.1) \times 1}{[H^+]^2}$$

$$\log \frac{0.1}{[H^+]^2} = \frac{2 \times 0.48}{0.0591}$$

$$\log 0.1 - \log [H^+]^2 = 16.2436 \qquad [\text{Since, } -\log [H^+] = \text{pH}]$$

$$2\, \text{pH} = 16.2436 - \log 0.1$$

$$\text{pH} = \frac{17.2436}{2} = 8.6218$$

Example 16. *Calculate the solubility product constant of AgI from the following values of standard electrode potentials.*

$$E^\circ_{Ag^+/Ag} = 0.80 \text{ volt} \quad \text{and} \quad E^\circ_{I/AgI/Ag} = -0.15 \text{ volt} \quad \text{at } 25^\circ C.$$

Solution: Solubility product of AgI = $[Ag^+][I^-]$

[**Note:** See chapter 10 for solubility product.]

Two half reactions for the cell are:

$$Ag \longrightarrow Ag^+ + e^- \qquad \text{Anode (Oxidation)}$$

$$AgI + e^- \longrightarrow Ag + I^- \qquad \text{Cathode (Reduction)}$$

$$\text{Cell reaction} \qquad AgI \longrightarrow Ag^+ + I^-$$

Applying Nernst equation,

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{1} \log \frac{[Ag^+][I^-]}{[AgI]}$$

At equilibrium, $E_{cell} = 0$ and $[AgI] = 1$

So, $$\log [Ag^+][I^-] = \frac{E^\circ_{cell}}{0.0591}$$

$$E^\circ_{cell} = -0.80 - 0.15 = -0.95 \text{ volt}$$

$$\log[\mathrm{Ag^+}][\mathrm{I^-}] = -\frac{0.95}{0.0591} = -16.0744$$

Solubility product of AgI $= 8.4 \times 10^{-17}$

Example 17. *The standard reduction potential of Ag^+/Ag electrode at 298K is 0.799 volt. Given for AgI, $K_{sp} = 8.7 \times 10^{-17}$, evaluate the potential of the Ag^+/Ag electrode in a saturated solution of AgI. Also calculate the standard reduction potential of the $I^-/AgI/Ag$ electrode.* (IIT 1994)

Solution: In the saturated solution of AgI, the half-cell reactions are:

$$\mathrm{AgI} + e^- \longrightarrow \mathrm{Ag} + \mathrm{I^-} \quad \text{Cathode (Reduction)}$$

$$\mathrm{Ag} \longrightarrow \mathrm{Ag^+} + e^- \quad \text{Anode (Oxidation)}$$

$$\text{Cell reaction} \quad \mathrm{AgI} \longrightarrow \mathrm{Ag^+} + \mathrm{I^-}$$

$$E_{\mathrm{Ag^+/Ag}} = E^\circ_{\mathrm{Ag^+/Ag}} + 0.0591 \log[\mathrm{Ag^+}]$$

$$[\mathrm{Ag^+}][\mathrm{I^-}] = K_{sp}(\mathrm{AgI}) = [\mathrm{Ag^+}]^2 = [\mathrm{I^-}]^2$$

So, $[\mathrm{Ag^+}]^2 = 8.7 \times 10^{-17}$

$$[\mathrm{Ag^+}] = \sqrt{8.7 \times 10^{-17}} = 9.3 \times 10^{-9}$$

Substituting the value of $E^\circ_{\mathrm{Ag^+/Ag}}$ and $[\mathrm{Ag^+}]$ in the above equation.

$$\begin{aligned} E_{\mathrm{Ag^+/Ag}} &= 0.799 - 0.0591 \log(9.3 \times 10^{-9}) \\ &= 0.324 \text{ volt} \\ E^\circ_{\text{cell}} &= 0.0591 \log K_{sp}(\mathrm{AgI}) \\ &= 0.0591 \log(8.7 \times 10^{-17}) \\ &= -0.95 \text{ volt} \end{aligned}$$

$$E^\circ_{\text{cell}} = \text{Oxid. pot. of anode} + \text{Red. pot. of cathode}$$

$$\begin{aligned} \text{Red. pot. of cathode } E^\circ_{\mathrm{I^-/AgI/Ag}} &= -0.95 - (-0.799) \\ &= -0.95 + 0.799 \\ &= -0.151 \text{ volt} \end{aligned}$$

Example 18. *Calculate the pH of the following half-cells solutions:*

(*a*) $PtH_2(1\,atm) | H^+ (HCl)$; $E = 0.25$ *volt*

(*b*) $PtH_2(1\,atm) | H^+ (H_2SO_4)$; $E = 0.3$ *volt*

Solution: (a) $\mathrm{H_2} \longrightarrow 2\mathrm{H^+} + 2e$

$$E_{\mathrm{H_2/H^+}} = E^\circ_{\mathrm{H_2/H^+}} - \frac{0.0591}{2} \log \frac{[\mathrm{H^+}]^2}{P_{\mathrm{H_2}}}$$

$$= 0.0 - 0.0591 \log \frac{[\mathrm{H^+}]}{1}$$

$$0.25 = 0.0591\,\mathrm{pH}$$

$$\mathrm{pH} = \frac{0.25}{0.0591} = 4.23$$

(b)
$$E_{\mathrm{H_2/H^+}} = E^\circ_{\mathrm{H_2/H^+}} - \frac{0.0591}{2} \log \frac{[\mathrm{H^+}]^2}{P_{\mathrm{H_2}}}$$

$$= 0.0 - 0.0591 \log \frac{[\mathrm{H^+}]}{1}$$

$$0.3 = 0.0591\,\mathrm{pH}$$

$$\mathrm{pH} = \frac{0.3}{0.0591} = 5.076$$

Example 19. *The emf of the cells obtained by combining zinc and copper electrodes of the Daniell cell with calomel electrodes are 1.083 volt and – 0.018 volt respectively at 25°C. If the reduction potential of normal calomel electrode is + 0.28 volt, find the emf of the Daniell cell.*

Solution: For the cell Zn electrode || Calomel electrode

E_{cell} = Oxid. pot. of Zn electrode + Red. pot. of calomel electrode

So, oxid. pot. of Zn electrode = 1.083 – 0.28 = 0.803 volt

For the cell,

Cu electrode || Calomel electrode

E_{cell} = Oxid. pot. of Cu electrode + Red. pot. of calomel electrode

So, oxid. pot. of Cu electrode = – 0.018 – 0.28 = – 0.298 volt

For the Daniell cell,

Zn electrode || Cu electrode

E_{cell} = Oxid. pot. of Zn electrode + Red. pot. of copper electrode

= 0.803 + 0.298 = 1.101 volt

Example 20. *The Edison storage cell is represented as:*

$$Fe(s) | FeO(s) | KOH(aq.) | Ni_2O_3(s) | Ni(s)$$

The half-cell reactions are:

$$Ni_2O_3(s) + H_2O(l) + 2e^- \longrightarrow 2NiO(s) + 2OH^-; \quad E^\circ = +0.40\,volt$$

$$FeO(s) + H_2O(l) + 2e^- \longrightarrow Fe(s) + 2OH^-; \quad E^\circ = -0.87\,volt$$

(*a*) *What is the cell reaction?*

(*b*) *What is the emf of the cell? How does it depend on the concentration of KOH?*

(*c*) *What is the maximum amount of energy that can be obtained from one mole of Ni_2O_3?* (IIT 1994)

Solution: Actual half reactions are:

$$\mathrm{Fe} + 2\mathrm{OH^-} \longrightarrow \mathrm{FeO} + \mathrm{H_2O} + 2e^- \quad \text{Anode (Oxidation)}$$

$$\mathrm{Ni_2O_3} + \mathrm{H_2O} + 2e^- \longrightarrow 2\mathrm{NiO} + 2\mathrm{OH^-} \quad \text{Cathode (Reduction)}$$

Thus, the cell reaction is:

(a) $\mathrm{Fe} + \mathrm{Ni_2O_3} \longrightarrow \mathrm{FeO} + 2\mathrm{NiO}$

(b) $E_{\text{cell}} = E^\circ_{\text{cell}} - \dfrac{0.0591}{2} \log \dfrac{[\mathrm{NiO}]^2[\mathrm{FeO}]}{[\mathrm{Fe}][\mathrm{Ni_2O_3}]} = E^\circ_{\text{cell}}$

$$\left[\text{Since, } \frac{[\text{NiO}]^2[\text{FeO}]}{[\text{Fe}][\text{Ni}_2\text{O}_3]} = 1 \text{ as all are solids}\right]$$

$$= 0.87 + 0.40 = 1.27 \text{ volt}$$

The emf of the cell is independent of KOH concentration.

(c) Maximum amount of electrical energy

$$= nFE^\circ$$

$$= 2 \times 96500 \times 1.27$$

$$= 245.11 \text{ kJ}$$

Example 21. *The normal oxidation potential of zinc referred to the standard hydrogen electrode is 0.76 volt and that of copper is – 0.34 volt at 25° C. When excess of zinc is added to a solution of copper sulphate, the zinc displaces copper till equilibrium is reached. What is the ratio of concentration of Zn^{2+} to Cu^{2+} ions at equilibrium?*

Solution: The reaction is,

$$\text{Zn} + \text{CuSO}_4 \longrightarrow \text{Cu} + \text{ZnSO}_4$$

or

$$\text{Zn} + \text{Cu}^{2+} \longrightarrow \text{Cu} + \text{Zn}^{2+}$$

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]}$$

At equilibrium, $E_{\text{cell}} = 0$

$$E^\circ_{\text{cell}} = \frac{0.0591}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]}$$

or

$$\log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} = \frac{2 \times E^\circ_{\text{cell}}}{0.0591}$$

$$(E^\circ_{\text{cell}} = 0.76 + 0.34 = 1.10 \text{ volt})$$

$$= \frac{2 \times 1.10}{0.0591} = 37.225$$

$$\frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} = 1.679 \times 10^{37} : 1$$

Example 22. *An excess of liquid mercury is added to an acidified solution of 1.0×10^{-3} M Fe^{3+}. It is found that 5% of Fe^{3+} remains at equilibrium at 25° C. Calculate $E^\circ_{Hg_2^{2+}/Hg}$ assuming that the only reaction that occurs is*

$$2Hg + 2Fe^{3+} \longrightarrow Hg_2^{2+} + 2Fe^{2+}$$

(Given, $E_{Fe^{3+}/Fe^{2+}} = 0.77$ volt). (IIT 1995)

Solution:

$$\begin{array}{lcccc} & 2\text{Hg} + & 2\text{Fe}^{3+} \longrightarrow & \text{Hg}_2^{2+} + & 2\text{Fe}^{2+} \\ \text{At equilibrium, excess} & & \dfrac{10^{-3} \times 5}{100} & \dfrac{10^{-3} \times 95}{2 \times 100} & \dfrac{10^{-3} \times 95}{100} \end{array}$$

At equilibrium, $E_{\text{cell}} = 0$

$$0 = E^\circ_{\text{cell}} - \frac{0.0591}{2} \log \frac{[\text{Hg}_2^{2+}][\text{Fe}^{2+}]^2}{[\text{Fe}^{3+}]^2}$$

$$= (E^\circ_{\text{Hg}/\text{Hg}_2^{2+}} + E^\circ_{\text{Fe}^{3+}/\text{Fe}^{2+}}) - \frac{0.0591}{2} \log \frac{\left(\dfrac{10^{-3} \times 95}{2 \times 100}\right)\left(\dfrac{10^{-3} \times 95}{100}\right)^2}{\left(\dfrac{10^{-3} \times 5}{100}\right)^2}$$

$$E^\circ_{\text{Hg}/\text{Hg}_2^{2+}} = -0.77 + \frac{0.0591}{2} \log \frac{(95)^3 \times 10^{-5}}{25 \times 2}$$

$$= -(0.77 + 0.0226)$$

$$= -0.7926 \text{ volt}$$

$$E^\circ_{\text{Hg}_2^{2+}/\text{Hg}} = +0.7926 \text{ volt}$$

Example 23. *Prove that for two half reactions having potentials E_1 and E_2 which are combined to yield a third half reaction, having a potential E_3,*

$$E_3 = \frac{n_1 E_1 + n_2 E_2}{n_3}$$

Solution:

$$\Delta G_3 = \Delta G_1 + \Delta G_2$$

$$-n_3 FE_3 = -n_1 FE_1 - n_2 FE_2$$

or

$$n_3 E_3 = n_1 E_1 + n_2 E_2$$

or

$$E_3 = \frac{n_1 E_1 + n_2 E_2}{n_3}$$

Example 24. *What is the standard potential of the Tl^{3+}/Tl electrode?*

$$Tl^{3+} + 2e^- \longrightarrow Tl^+; \quad E^\circ = 1.26 \text{ volt}$$

$$Tl^+ + e^- \longrightarrow Tl; \quad E^\circ = -0.336 \text{ volt}$$

Solution:

$$\text{Tl}^{3+} + 2e^- \longrightarrow \text{Tl}^+; \quad nFE^\circ = 2 \times 1.26 \times F = 2.52F$$

$$\text{Tl}^+ + e^- \longrightarrow \text{Tl}; \quad nFE^\circ = 1 \times (-0.336) \times F = -0.336F$$

Adding

$$\text{Tl}^{3+} + 3e^- \longrightarrow \text{Tl}; \quad E^\circ = \frac{2.52F - 0.336F}{nF} = \frac{2.184}{3}$$

$$= 0.728 \text{ volt}$$

Example 25. *Calculate the minimum mass of NaOH required to be added in RHS to consume all the H^+ present in RHS of the cell of emf + 0.701 volt at 25° C before its use. Also report the emf of the cell after addition of NaOH.*

$$\underset{}{Zn} \mid \underset{0.1\,M}{Zn^{2+}} \parallel \underset{1\,litre}{HCl} \mid \underset{1\,atm}{Pt(H_2 g)}; \quad E^\circ_{Zn/Zn^{2+}} = 0.760\,V$$

Solution: The cell reaction is,

$$\text{Zn} + 2\text{H}^+ \longrightarrow \text{Zn}^{2+} + \text{H}_2$$

Applying Nernst equation,

$$E_{\text{cell}} = E^\circ - \frac{0.0591}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{H}^+]^2}$$

$$0.701 = 0.760 - \frac{0.0591}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{H}^+]^2}$$

So, $$\log \frac{[\text{Zn}^{2+}]}{[\text{H}^+]^2} = \frac{0.0591 \times 2}{0.0591} = 2$$

or $$\frac{[\text{Zn}^{2+}]}{[\text{H}^+]^2} = 10^2$$

$$[\text{H}^+]^2 = \frac{0.1}{10^2} = 10^{-3}$$

$$[\text{H}^+] = 0.0316 \text{ mol L}^{-1}$$

Thus, 0.0316 mol/litre of NaOH is required to neutralise H^+ ions.

$$\text{Mass of NaOH} = 0.0316 \times \text{Mol. mass of NaOH}$$
$$= 0.0316 \times 40 = 1.264 \text{ g}$$

After addition of NaOH, the solution becomes neutral, *i.e.*, the concentration of H^+ ions in cathodic solution becomes 10^{-7}.

Applying again Nernst equation,

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{0.0591}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{H}^+]^2}$$

$$= 0.760 - \frac{0.0591}{2} \log \frac{0.1}{(10^{-7})^2} = 0.3759 \text{ volt}$$

Example 26. *For the galvanic cell,*

$$Ag \mid AgCl(s), KCl\,(0.2\,M) \parallel KBr\,(0.001\,M), AgBr(s) \mid Ag$$

Calculate the emf generated and assign correct polarity to each electrode for the spontaneous process after taking into account the cell reaction at 25° C.

Given, $K_{sp\,AgCl} = 2.8 \times 10^{-10}$; $K_{sp\,AgBr} = 3.3 \times 10^{-13}$ **(IIT 1992)**

Solution:

$$E_{\text{cell}} = E_{\text{Oxid. pot. LHS electrode}} + E_{\text{Red. pot. RHS electrode}}$$

$$= E^\circ_{\text{Oxid. pot. Ag/Ag}^+} - 0.0591 \log [\text{Ag}^+]_{\text{LHS}} + E^\circ_{\text{Red. pot. Ag}^+/\text{Ag}} + 0.0591 \log [\text{Ag}^+]_{\text{RHS}}$$

$$= 0.0591 \log \frac{[\text{Ag}^+]_{\text{RHS}}}{[\text{Ag}^+]_{\text{LHS}}} \quad \left[\text{Since, } E^\circ_{\text{Ag/Ag}^+} + E^\circ_{\text{Ag}^+/\text{Ag}} = 0\right]$$

$$= 0.0591 \log \frac{\dfrac{K_{\text{sp AgBr}}}{[\text{Br}^-]}}{\dfrac{K_{\text{sp AgCl}}}{[\text{Cl}^-]}}$$

$$= 0.0591 \log \frac{3.3 \times 10^{-13}}{0.001} \times \frac{0.2}{2.8 \times 10^{-10}}$$

$$= -\,0.0371 \text{ volt}$$

The cell potential is negative; therefore, the cell reaction is non-spontaneous. For spontaneous reaction emf should be positive. Therefore, the correct cell reaction is

$$\underset{\text{Anode}}{\text{Ag} \mid \text{AgBr}; \text{KBr}} \parallel \underset{\text{Cathode}}{\text{KCl, AgCl}} \mid \text{Ag}$$

Example 27. *The following electrochemical cell has been set-up,*

$$Pt(1) \mid Fe^{3+}, Fe^{2+}\,(a = 1) \parallel Ce^{4+}, Ce^{3+}\,(a = 1) Pt(2)$$

$$E^\circ(Fe^{3+}/Fe^{2+}) = 0.77\ V;\ E^\circ(Ce^{4+}/Ce^{3+}) = 1.61 V$$

If an ammeter is connected between the two platinum electrodes, predict the direction of flow of current. Will the current increase or decrease with time? **(IIT 2000)**

Solution: Current will flow from higher reduction potential electrode to lower reduction potential electrode, *i.e.*, from Pt(2) electrode to Pt(1) electrode.

$$E^\circ_{\text{cell}} = 1.61 - 0.77 = 0.84 \text{ volt}$$

Example 28. *Copper sulphate solution (250 mL) was electrolysed using a platinum anode and a copper cathode. A constant current of 2 mA was passed for 16 minutes. It was found that after electrolysis the absorbance of the solution was reduced to 50% of its original value. Calculate the concentration of copper sulphate in the solution to begin with.* **(IIT 2000)**

Solution: Number of faraday passed through the aqueous solution of $CuSO_4$

$$= \frac{I \times t}{96500} = \frac{(2 \times 10^{-3}) \times 16 \times 60}{96500} = 1.98 \times 10^{-5}$$

Thus, number of equivalents of $CuSO_4$ involved in electrolysis from 1 litre solution

$$= 4 \times 1.98 \times 10^{-5} = 7.92 \times 10^{-5}$$

Since, after electrolysis, the absorbance reduces to 50% hence, initial number of equivalents of $CuSO_4$ per litre

$$= 2 \times 7.92 \times 10^{-5}$$
$$= 1.584 \times 10^{-4}$$

or Normality of $CuSO_4$ solution $= 1.584 \times 10^{-4}\ N$.

Example 29. *A silver electrode is immersed in saturated* $Ag_2SO_4(aq.)$. *The potential difference between silver and the standard hydrogen electrode is found to be 0.711 V. Determine* $K_{sp}(Ag_2SO_4)$. *(Given,* $E^\circ_{Ag^+/Ag} = 0.799 V$ *)* **(IIT 2000)**

Solution: The cell may be represented as:

$$\text{Pt}(\text{H}_2\ 1\text{atm}) \mid \text{H}^+(1\,M) \parallel \text{Ag}^+(\text{salt}) \mid \text{Ag}(s)$$

$$E^\circ_{\text{cell}} = E^\circ_{\text{Ag}^+/\text{Ag}} - E^\circ_{\text{H}^+/\text{H}_2}$$

$$= 0.799 - 0 = 0.799 \text{ V}$$

Given, emf of the cell = 0.711 V

$$H_2 + 2Ag^+ \longrightarrow 2Ag + 2H^+$$

$$Q = \frac{[Ag]^2[H^+]^2}{[H_2][Ag^+]^2} = \frac{1^2 \times 1^2}{1 \times [Ag^+]^2} = \frac{1}{[Ag^+]^2}$$

Applying Nernst equation,

$$E = E^\circ - \frac{0.0591}{n}\log_{10} Q$$

or $$0.711 = 0.799 - \frac{0.0591}{2}\log_{10}\frac{1}{[Ag^+]^2}$$

$$[Ag^+] = 0.03243 \text{ mol L}^{-1}$$

$$Ag_2SO_4 \rightleftharpoons \underset{0.03243}{2Ag^+} + \underset{0.016215}{SO_4^{2-}}$$

$$K_{sp} = [Ag^+]^2[SO_4^{2-}] = (0.03243)^2 \times (0.016215) = 1.705 \times 10^{-5}.$$

Example 30. *Calculate the equilibrium constant for the reaction,*

$$Fe^{2+} + Ce^{4+} \rightleftharpoons Ce^{3+} + Fe^{3+}$$

Given, $E^\circ_{Ce^{4+}/Ce^{3+}} = 1.44\ V$ *and* $E^\circ_{Fe^{3+}/Fe^{2+}} = 0.68\ V$

[IIT (July) 1997]

Solution: $$E^\circ_{cell} = \frac{0.059}{1}\log K_c$$

$$E^\circ_{cell} = E^\circ_{Fe^{2+}/Fe^{3+}} + E^\circ_{Ce^{4+}/Ce^{3+}}$$

$$= -0.68 + 1.44 = 0.76\text{ V}$$

$$\log_{10} K_c = \frac{0.76}{0.059} = 12.8814$$

$$K_c = 7.6 \times 10^{12}$$

Example 31. *Find the solubility product of a saturated solution of* Ag_2CrO_4 *in water at 298 K if the emf of the cell*

$$Ag \mid Ag^+ \text{ (satd. } Ag_2CrO_4 \text{ soln.)} \parallel Ag^+ (0.1\,M) \mid Ag$$

is 0.164 V at 298 K. (IIT 1998)

Solution: $$E_{cell} = \frac{0.059}{1}\log\frac{[Ag^+]_{RHS}}{[Ag^+]_{LHS}}$$

$$0.164 = \frac{0.059}{1}\log\frac{0.1}{[Ag^+]_{LHS}}$$

or $$[Ag^+]_{LHS} = 1.66 \times 10^{-4}\ M$$

So, $$[CrO_4^{2-}] = \frac{1.66 \times 10^{-4}}{2}$$

$$K_{sp(Ag_2CrO_4)} = [Ag^+]^2[CrO_4^{2-}]$$

$$= (1.66 \times 10^{-4})^2\left(\frac{1.66 \times 10^{-4}}{2}\right)$$

$$= 2.287 \times 10^{-12} \text{ mol}^3 \text{ L}^{-3}$$

Example 32. *The standard potential of the following cell is 0.23 V at 15°C and 0.21 V at 25°C*

$$PtH_2(g) \mid HCl(aq.) \parallel AgCl(s) \mid Ag(s)$$

(*i*) *Write cell reaction.*

(*ii*) *Calculate* ΔH° *and* ΔS° *for the cell reaction by assuming that these quantities remain unchanged in the range 15°C to 35°C.*

(*iii*) *Calculate the solubility of AgCl in water at 25°C. Given the standard reduction potential of the* Ag^+/Ag *couple is 0.80 volt at 25°C.* (IIT 2001)

Solution: (i) Electrode process:

$$\tfrac{1}{2}H_2 \longrightarrow H^+ + e^- \qquad \text{(Anode)}$$

$$AgCl + e^- \longrightarrow Ag + Cl^- \qquad \text{(Cathode)}$$

$$\tfrac{1}{2}H_2 + AgCl \rightleftharpoons H^+ + Ag + Cl^-$$

(ii) We know that, $\Delta G^\circ = \Delta H^\circ - T\,\Delta S^\circ$

$$-22195 = \Delta H^\circ - 288 \times \Delta S^\circ$$

$$-20265 = \Delta H^\circ - 308 \times \Delta S^\circ$$

On solving, $\Delta S^\circ = -96.5\text{ J}, \Delta H^\circ = 49.987\text{ kJ}$

(iii) $$E = E^\circ - \frac{0.0591}{n}\log_{10} Q$$

At equilibrium, $E = 0, Q = K = [Ag^+][Cl^-]$

$$0 = (0.8 - 0.22) + \frac{0.0591}{1}\log K_{sp}$$

$$\frac{(-0.8 + 0.22)}{0.0591} = \log K_{sp}$$

$$K_{sp} = 1.47 \times 10^{-10}$$

Solubility, $$S = \sqrt{K_{sp}}$$

$$= \sqrt{1.47 \times 10^{-10}} = 1.21 \times 10^{-5}\ M$$

Example 33. *Two students use same stock solution of* $ZnSO_4$ *and a solution of* $CuSO_4$*. The emf of one cell is 0.03 V higher than that of other. The concentration of* $CuSO_4$ *in the cell with higher emf value is 0.5 M. Find out the concentration of* $CuSO_4$ *in the other cell.* $\left(\frac{2.303\,RT}{F} = 0.06\right)$ (IIT 2003)

Solution: **Student I.**

$$Zn(s) \mid ZnSO_4\ (C_1) \parallel 0.5\,M\ CuSO_4 \mid Cu(s)$$

$$E_1 = E^\circ - \frac{0.06}{2}\log\frac{C_1}{0.5} \qquad \text{. . . (i)}$$

Student II. $Zn(s) \mid ZnSO_4(C_1) \parallel CuSO_4\ (C_2) \mid Cu(s)$

$$E_2 = E^\circ - \frac{0.06}{2}\log\frac{C_1}{C_2} \qquad \text{. . . (ii)}$$

$$E_1 - E_2 = \frac{0.06}{2}\left[\log\frac{C_1}{C_2} - \log\frac{C_1}{0.5}\right]$$

$$0.03 = \frac{0.06}{2}\left[\log\left(\frac{0.5}{C_2}\right)\right]$$

$$1 = \log\frac{0.5}{C_2}$$

$$C_2 = 0.05\,M$$

Example 34. *Find the equilibrium constant for the reaction,*

$$In^{2+} + Cu^{2+} \rightleftharpoons In^{3+} + Cu^{+} \text{ at } 298\,K$$

Given: $E_{Cu^{2+}/Cu^{+}} = 0.15\,V;\ E^{\circ}_{In^{2+}/In^{+}} = -0.4$ *volt*

$E^{\circ}_{In^{3+}/In^{+}} = -0.42$ *volt* (IIT 2004)

Solution: The given reversible reaction can be obtained as,

$$\mathrm{Cu}^{2+} + e^- \longrightarrow \mathrm{Cu}^{+}; \quad \Delta G^{\circ} = -0.15F \quad \because \Delta G^{\circ} = -nFE^{\circ}$$

$$\mathrm{In}^{2+} + e^- \longrightarrow \mathrm{In}^{+}; \quad \Delta G^{\circ} = +0.40F$$

$$\mathrm{In}^{+} \longrightarrow \mathrm{In}^{3+} + 2e^-; \Delta G^{\circ} = -0.84F$$

$$\mathrm{Cu}^{2+} + \mathrm{In}^{2+} \rightleftharpoons \mathrm{In}^{3+} + \mathrm{Cu}^{+}; \quad \Delta G^{\circ} = -0.59\,F$$

$$-nFE^{\circ} = -0.59\,F$$

$$E^{\circ} = 0.59 \text{ volt}$$

Equilibrium constant can be calculated as,

$$K = \text{antilog}\left[\frac{nE^{\circ}}{0.059}\right]$$

$$= \text{antilog}\left[\frac{1 \times 0.59}{0.059}\right] = 10^{10}$$

Example 35. *In which direction can the reaction,*

$$2Hg\,(l) + 2Ag^{+}(aq.) \rightleftharpoons 2Ag(s) + Hg_2^{2+}(aq.)$$

proceed spontaneously at the following concentrations of the ions participating in the reactions (i) and (ii)?

(*i*) $[Ag^{+}] = 10^{-4}\ mol\,L^{-1}$ *and* $[Hg_2^{2+}] = 10^{-1}\ mol\,L^{-1}$

(*ii*) $[Ag^{+}] = 10^{-1}\ mol\,L^{-1}$ *and* $[Hg_2^{2+}] = 10^{-4}\ mol\,L^{-1}$

Given: $E^{\circ}_{Hg_2^{2+}/Hg} = 0.79\,V;\ E^{\circ}_{Ag^{+}/Ag} = 0.80\,V$

[CBSE (Mains) Medical 2006]

Solution: (i) $Q = \dfrac{[\mathrm{Hg}_2^{2+}]}{[\mathrm{Ag}^{+}]^2} = \dfrac{10^{-1}}{[10^{-4}]^2} = 10^{7}$

$$E^{\circ} = E^{\circ}_{\mathrm{Ag^{+}/Ag}} - E^{\circ}_{\mathrm{Hg_2^{2+}/Hg}}$$

$$= 0.80 - 0.79 = 0.01\,\mathrm{V}$$

$$E = E^{\circ} - \frac{0.059}{n}\log Q$$

$$= 0.01 - \frac{0.059}{2}\log 10^{7}$$

$$= -0.1965\,\mathrm{V}$$

Negative value shows that the reaction will proceed from right to left, *i.e.*, in backward direction.

(ii) $Q = \dfrac{[\mathrm{Hg}_2^{2+}]}{[\mathrm{Ag}^{+}]^2} = \dfrac{10^{-4}}{[10^{-1}]^2} = 10^{-2}$

$$n = 2$$

$$E^{\circ} = 0.01 \text{ volt}$$

$$E = E^{\circ} - \frac{0.059}{n}\log_{10} Q$$

$$= 0.01 - \frac{0.059}{2}\log_{10} 10^{-2}$$

$$= 0.01 + 0.059\,\mathrm{V}$$

$$= 0.069\,\mathrm{V}$$

Since, the value of cell potential is positive, the reaction will proceed spontaneously in forward direction.

SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. **Electrochemistry** is a branch of physical chemistry which deals with the relationship between chemical energy and electrical energy and how one can be converted into another. The subject is divided into two categories: (i) use of electrical energy to produce chemical changes (electrolysis) and (ii) conversion of chemical energy into electrical energy (production of electricity by spontaneous redox reactions).

2. **Conductors** are the substances which allow the passage of electric current through them. Those which do not allow the flow of electric current through them are called **insulators.** Conductors are of two types:

(a) Metallic or electronic conductors are those which remain unchanged as current flows through them. These conductors transfer electric current by transfer of electrons without transfer of matter. Metals such as Cu, Ag, Al, Pt, etc., non- metals like carbon (graphite) and various alloys belong to this class.

(b) Electrolytic conductors are the conductors like aqueous solutions of acids, bases and salts or substance in molten state which allow the flow of electric current with chemical decomposition. These conductors are termed as **electrolytes.** The substances whose aqueous solutions do not conduct electric current are called **non-electrolytes.**

To pass the current through an electrolytic conductor, two metallic rods or plates are required. These are termed **electrodes.** The electrode which is connected with the positive terminal of battery or through which electric current enters the solution is termed **anode** and the electrode which is connected with negative terminal of battery or through which electric current leaves the solution is termed **cathode.** Actually the anode is the electrode where oxidation occurs and the cathode is the electrode where reduction takes place.

3. **Electrolysis** is the process of chemical decomposition of an electrolyte by passage of electric current through its aqueous solution or molten state. Molecules of the electrolyte when dissolved in water split up into cations and anions. On passing electric current these ions move towards their respective electrodes. On reaching electrodes these ions lose their charge either by losing or accepting electrons and thereby deposited at the respective electrodes or undergo a secondary change. The device in which electrolysis is carried out is known as **electrolytic cell.**

4. **Preferential discharge theory:** If more than one type of ion is attracted towards a particular electrode, then the ion discharged is the one which requires least energy.

The decreasing order of the discharge potential or the increasing order of deposition for the cations and anions is as follows:

Cations : $K^+, Na^+, Ca^{2+}, Mg^{2+}, Al^{3+}, Zn^{2+}, H^+, Cu^{2+}, Ag^+, Au^{3+}$.

Anions : $SO_4^{2-}, NO_3^-, OH^-, Cl^-, Br^-, I^-$.

5. **Faraday's laws of electrolysis:** These present the relationship between the quantity of electric charge and the amount of the substance deposited at the electrode. These were given by Faraday in 1834.

(i) First law: When an electric current is passed through an electrolyte, the amount of substance deposited is proportional to the quantity of electric charge which flows through the electrolyte.

Mathematically, $$W \propto Q$$

or $$W = ZQ = Z \times I \times t$$

where, Z is a constant, known as electrochemical equivalent, I is the current in amperes and t is the time in seconds. When $Q = 1$ coulomb or one ampere of current is passed for 1 second, $W = Z$. Z is thus the mass of the substance deposited by one coulomb.

(ii) Second law: When the same quantity of current is passed through different electrolytes, the masses of different substances deposited on the electrodes will be in the ratio of their equivalent masses. For example, if same quantity of current is passed through copper sulphate and silver nitrate solutions, then

$$\frac{\text{Mass of copper deposited}}{\text{Mass of silver deposited}} = \frac{\text{Equivalent mass of copper}}{\text{Equivalent mass of silver}}$$

One gram equivalent of any substance is deposited by passing same amount of charge, *i.e.*, 96500 coulomb (1 faraday).

$$E = Z \times 96500$$

or $$Z = \frac{E}{96500}$$

$$\text{The charge carried by an ion} = \frac{nF}{6.02 \times 10^{23}} \text{ coulomb}$$

When, $n = 1$,

$$\text{The fundamental unit of charge} = \frac{F}{6.02 \times 10^{23}} = \frac{96500}{6.02 \times 10^{23}}$$

$$= 1.6 \times 10^{-19} \text{ coulomb}$$

$$1 \text{ coulomb} = 6.24 \times 10^{18} \text{ electrons}$$

Charge on one mole of electrons

$$= 6.02 \times 10^{23} \times 1.6 \times 10^{-19}$$

$$\approx 96500 \text{ coulomb}$$

Applications of electrolysis: (i) Determination of equivalent masses of elements (ii) Electrometallurgy (iii) Manufacture of non-metals (iv) Electroplating of metal (v) Manufacture of compounds (vi) Electroplating—The process of coating an inferior metal with a superior metal by electrolysis.

6. **Arrhenius theory of electrolytic dissociation:** It was put forward by Arrhenius in 1884 to explain the properties of electrolytic solutions. The main points of the theory are:

(i) An electrolyte, when dissolved in water, breaks up into two types of charged particles called ions. The ion carrying positive charge is called **cation** and the ion carrying negative charge is called **anion.**

$$AB \rightleftharpoons A^+ \text{ (cation)} + B^- \text{ (anion)}$$

(ii) The process of splitting of the molecules of the electrolyte into ions is called **ionisation.** The fraction of the total number of molecules present in solution as ions is known as **degree of ionisation.**

It is denoted by 'α'.

$$\alpha = \frac{\text{Number of molecules dissociated into ions}}{\text{Total number of molecules dissolved}}$$

The degree of ionisation depends upon: (a) Nature of solute (b) Nature of solvent (c) Dilution and temperature.

(iii) Ions present in solution constantly reunite to form neutral molecules; thus, there is a state of dynamic equilibrium between ionised and unionised molecules.

$$AB \rightleftharpoons A^+ + B^-$$

$$\frac{[A^+][B^-]}{[AB]} = K \text{ (ionisation constant)}$$

(iv) The ions are discharged always in equivalent amounts when current is passed through electrolytic solution no matter what their relative speeds are.

(v) The electrolytic solution is always neutral in nature as the total charge on cations is equal to the total charge on anions. However, it is not necessary that the number of cations and anions should be always equal.

(vi) The properties of electrolytes in solution are the properties of ions present in the solution.

(vii) The ions act as molecules for colligative properties.

(viii) The conductivity of the solution depends on the nature and number of ions.

Evidences in favour of Arrhenius theory: (i) Ohm's law applicability: No part of the current is used in splitting up the molecules into ions. (ii) X-ray studies have shown that ions are present in solid electrolytes. The ionic compounds in molten state behave as good conductors. (iii) Ionic reactions are observed in the case of electrolytes. (iv) Constant value of heat of neutralisation. (v) Abnormal colligative properties in the case of electrolytes. (vi) Colour of compounds in solution. (vii) This theory explains satisfactorily various phenomena such as electrolysis, conductivity, salt hydrolysis, etc.

7. **Conductivity** is the property of the conductor which facilitates the flow of electricity through it. It is equal to the reciprocal of resistance.

$$\text{Conductivity} = \frac{1}{\text{Resistance}} = \frac{1}{R}$$

It is expressed as ohm^{-1} or mho.

Specific conductivity is defined as the reciprocal of specific resistance, *i.e.*, it is the conductance of 1 cm^3 of a conductor. It is represented by the symbol κ.

$$\kappa = \frac{1}{\rho} = \frac{l}{a} \times \text{conductivity}$$

where, l = distance between electrodes and a = area of cross-section of electrode.

In the case of electrolytic solutions, specific conductance is the conductance of a solution of definite dilution enclosed in a cell having two electrodes of unit area separated by one centimetre. The units of specific conductance are $\text{ohm}^{-1}\ \text{cm}^{-1}$. The ratio of l/a is called **cell constant.**

Equivalent conductance: Conductivity of a solution containing 1g equivalent of the electrolyte. It is denoted by 'Λ'. If the concentration of solution is C g equivalent per litre, then

$$\Lambda = \kappa \frac{1000}{C}$$

or $$\Lambda = \kappa \times V$$

where, V is the volume in mL containing 1g equivalent of the electrolyte. The unit of equivalent conductance is $\text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$.

Molar conductance: Conductance of a solution containing 1 g mole of an electrolyte. If V is volume in mL containing 1g mole, then

$$\text{Molar conductance, } \mu = \kappa \times V$$

If C is the concentration of the solution in g mole per litre, then

$$\mu = \kappa \times \frac{1000}{C}$$

Its unit is $\text{ohm}^{-1}\ \text{cm}^2\ \text{mol}^{-1}$.

$$\text{Equivalent conductance} = \frac{\text{Molar conductance}}{n}$$

where, $$n = \frac{\text{Molecular mass}}{\text{Equivalent mass}}$$

8. **Kohlrausch's law:** At infinite dilution, each ion makes a definite contribution towards equivalent conductance of the electrolyte. The value of equivalent conductance at infinite dilution for any electrolyte is the sum of conductances at infinite dilution of its constituent ions. Thus,

$$\Lambda_\infty = \Lambda_a + \Lambda_c$$

Λ_a and Λ_c are called the ionic conductances of anion and cation at infinite dilution respectively. It can be used to determine degree of dissociation.

$$\alpha = \frac{\Lambda}{\Lambda_\infty} = \frac{\text{Equivalent conductance at given concentration}}{\text{Equivalent conductance at infinite dilution}}$$

9. **Galvanic or Voltaic or Electrochemical cell:** It is the device in which chemical energy is converted into electrical energy. In this cell a redox reaction is carried out in an indirect manner and the decrease in free energy during the chemical process appears as electrical energy.

The common galvanic cell, dry cell and the lead storage battery are the devices for converting chemical energy into electrical energy. Daniell cell is the typical example of galvanic cell. It consists of two half-cells, one containing zinc electrode dipping in solution of zinc sulphate (1 M) and another containing copper electrode dipping in solution of copper sulphate (1 M). Zinc electrode acts as anode. At this electrode oxidation occurs. $Zn \rightarrow Zn^{2+} + 2e^-$. Copper electrode acts as cathode. At this electrode reduction occurs, $Cu^{2+} + 2e^- \rightarrow Cu$. When the two half-cells are connected by a salt bridge and the metal electrodes are joined externally, the electrons from zinc electrode (–ve electrode) move towards copper electrode (+ve electrode), *i.e.*, current flows from cathode to anode. The cell reaction is:

$$Zn + Cu^{2+} \rightarrow Zn^{2+} + Cu$$

Salt-bridge allows the flow of current by completing the circuit and maintains electrical neutrality. It also prevents liquid-liquid junction potential.

A galvanic cell is represented in the following manner:

Salt-bridge

LHS	RHS
Anode (–ve)	Cathode (+ve)
$Zn \mid Zn^{2+}\ (1\ M)$	$Cu^{2+}\ (1\ M) \mid Cu$
Oxidation half-cell	Reduction half-cell
$Zn \rightarrow Zn^{2+} + 2e^-$	$Cu^{2+} + 2e^- = Cu$

10. **Electrode potential:** When a metal is placed in a solution of its ions, the metal either acquires a positive charge or negative charge with respect to solution. On account of this a definite potential is developed between the metal and the solution. This potential difference is termed **electrode potential.** The magnitude of potential depends on the nature of electrode, concentration of ions and temperature. It is a measure of the tendency of the metal to lose or gain electrons or a measure of the relative tendency to undergo oxidation or reduction. Depending on the nature of the metal electrode, the electrode potential is of two types:

(i) Oxidation potential: When electrode is negatively charged with respect to solution, *i.e.*, oxidation occurs and the electrode acts as anode

$$M \rightarrow M^{n+} + ne^-$$

(ii) Reduction potential: When electrode is positively charged with respect to solution, *i.e.*, reduction occurs and the electrode acts as cathode,

$$M^{n+} + ne^- \rightarrow M$$

Standard electrode potential: The potential difference developed between metal electrode and the solution of its ions of unit molarity (1 *M*) at 25°C is called standard electrode potential.

It is not possible to measure the absolute value of single electrode potential directly. Only difference in potential of two electrodes can be measured experimentally. It is, therefore, necessary to couple the electrode with another electrode whose potential is known. This electrode is termed as **reference electrode.** The emf of the resulting cell is measured experimentally.

$$\text{Emf of the cell} = E_{\text{Anode}} + E_{\text{Cathode}}$$

$$= \text{Oxid. pot. of anode} + \text{Red. pot. of cathode}$$

Knowing the value of reference electrode, the value of other electrode can be determined.

Standard reduction potential = – (Standard oxidation potential)

Standard oxidation potential = – (Standard reduction potential)

11. Reference electrode (Standard hydrogen electrode, SHE): It is a primary standard electrode. It consists of a small platinum strip coated with platinum black as to adsorb hydrogen gas. A platinum wire is welded to the platinum strip and sealed in a glass tube as to make contact with outer circuit through mercury. The platinum strip and glass tube is surrounded by another glass tube which has an inlet for hydrogen gas and a number of holes at the base for the escape of excess of hydrogen gas. The platinum strip is placed in acid solution which has H^+ ion concentration 1 *M*. Pure hydrogen gas is circulated at 1 atmospheric pressure. The temperature of the cell is maintained at 25°C. By international agreement, the standard hydrogen electrode is arbitrarily assigned a potential of exactly ± 0.000... volt. This electrode can act as cathode or anode with respect to other electrode.

The electrode whose electrode potential is to be determined is connected with SHE and emf of such a cell is determined which is taken as the electrode potential of the given electrode. The metal electrode which acts as anode with respect to hydrogen electrode, the **oxidation potential** of the electrode is given positive sign and the metal electrode which acts as cathode with respect to hydrogen electrode, the reduction potential is given the positive sign.

12. Emf of a cell: The difference in potentials of two half-cells is known as the emf of the cell.

$$E^\circ_{\text{Cell}} = \text{Red. pot. cathode} - \text{Red. pot. anode } (E^\circ_{\text{right}} - E^\circ_{\text{left}})$$

$$= \text{Red. pot. cathode} + \text{Oxid. pot. anode}$$

$$= \text{Oxid. potential anode} - \text{Oxid. potential cathode}$$

13. Some more reference electrodes: Since, a hydrogen electrode is difficult to prepare and maintain, it is usually replaced by other reference electrodes which are known as **secondary** reference electrodes. These are convenient to handle and prepared easily. Calomel electrode and silver-silver chloride are used as reference electrodes. The potentials of these electrodes are fixed on hydrogen scale but their values depend on strong electrolyte concentration.

14. Reversible and irreversible cells: A cell is said to be reversible if the following two conditions are fulfilled:

(i) The chemical reaction of the cell stops when an exactly equal external emf is applied.

(ii) The chemical reaction of the cell is reversed and the current flows in opposite direction when the external emf is slightly higher than that of the cell.

Any other cell which does not obey the above two conditions is termed as irreversible. Daniell cell is reversible but $Zn\,|\,H_2SO_4\,|\,Ag$ cell is irreversible in nature.

15. Prediction for occurrence of a redox reaction: Any redox reaction would occur spontaneously if the free energy change (ΔG) is negative.

$\Delta G^\circ = -nFE^\circ$ where, '*n*' is the number of electrons involved, *F* is the value of faraday and E° is the cell emf. ΔG° can be negative if E° is positive.

When E° is positive, the cell reaction will be spontaneous and serves as a source of electrical energy.

16. Nernst equation: The potential of an electrode changes with the change in concentration of ions in solution in contact with the electrode. Increase in concentration of cations results in an increase of reduction potential of an electrode.

Consider $M^{n+} + ne^- \rightarrow M$

$$E_{\text{red}} = E^\circ_{\text{red}} - \frac{2.303RT}{nF}\log\frac{[\text{reduced form}]}{[\text{oxidised form}]}$$

At 25°C, $\dfrac{2.303RT}{F} = 0.0591$

and the concentration of metal is unity.

$$E_{\text{red}} = E^\circ_{\text{red}} + \frac{0.0591}{n}\log[M^{n+}]$$

Similarly, consider the electrode where oxidation occurs.

$$M \rightarrow M^{n+} + ne^-$$

$$E_{\text{oxid.}} = E^\circ_{\text{oxid.}} - \frac{0.0591}{n}\log[M^{n+}]$$

Cell potential depends on the potential of anode and cathode.

$$E_{\text{Cell}} = E_{\text{Anode}} + E_{\text{Cathode}}$$

$$= \text{Oxid. pot. of anode} - \text{Red. pot. of cathode}$$

$$= E^\circ_{\text{oxid.}} - \frac{0.0591}{n}\log[\text{Anodic ion conc.}]$$

$$+ E^\circ_{\text{red}} - \frac{0.0591}{n}\log[\text{Cathodic ion conc.}]$$

$$= E^\circ_{\text{oxid.}} + E^\circ_{\text{red}} - \frac{0.0591}{n}\log\frac{[\text{Anodic ion conc.}]}{[\text{Cathodic ion conc.}]}$$

$$= E^\circ_{\text{cell}} - \frac{0.0591}{n}\log\frac{[\text{Products}]}{[\text{Reactants}]}$$

or

$$= E^\circ_{\text{cell}} - \frac{0.0591}{n}\log\frac{[\text{ion}]_{\text{LHS}}}{[\text{ion}]_{\text{RHS}}}$$

17. Electrochemical series: When the electrodes (metals and non-metals) in contact with their ions are arranged on the basis of values of their standard reduction potentials or standard oxidation potentials, the resulting series is called the electrochemical or activity series of the elements.

Characteristics of Electrochemical Series

(i) The negative sign of reduction potential indicates that an electrode when joined with SHE acts as anode. Similarly the positive sign of reduction potential indicates that the electrode joined with SHE acts as cathode.

(ii) The substances which act as stronger reducing agents than hydrogen are placed above hydrogen in series. All those which have positive values of reduction potentials and placed below hydrogen are weaker reducing agents than hydrogen.

(iii) The substances which are stronger oxidising agents are placed below hydrogen in the series.

(iv) The metals at the top have the tendency to lose electrons readily. The activity of metals decreases from top to bottom while that of non-metals increases from top to bottom.

(v) A metal higher in the series will displace the metal from its solution which is lower in the series.

(vi) A non-metal higher in the series (towards bottom side) having high value of reduction potential will displace another non-metal with lower reduction potential.

(vii) The metals occupying top positions in the series readily liberate hydrogen from dilute acids.

(viii) Iron and metals above iron are capable of liberating hydrogen from water.

(ix) The oxides of metals having low reduction potentials are thermally stable while the oxides of metals having high reduction potentials are thermally not stable.

18. Relation between emf and equilibrium constant:

$$\Delta G^\circ = -2.303RT \log K$$

$$\Delta G^\circ = -nFE^\circ_{\text{cell}}$$

So,

$$nFE^\circ_{\text{cell}} = 2.303\,RT \log K$$

$$E^\circ_{\text{cell}} = \frac{2.303RT}{nF} \log K$$

$$= \frac{0.0591}{n} \log K \qquad (T = 298\text{ K})$$

19. Primary cells are those which have definite life and become dead over a time. These cannot be recharged. Examples are dry cell, mercury cell, etc.

Secondary cells are the cells which can be recharged by passing direct current through them. Lead storage battery and nickel-cadmium cell are examples of secondary cells. Lead storage battery consists of spongy lead as anode, a grid of lead packed with PbO_2 as cathode and an aqueous solution of H_2SO_4 (38% by mass or 20% H_2SO_4 of specific gravity 2.15) as electrolyte.

Reaction during discharging	**Reaction during charging**
$Pb + PbO_2 + 4H^+ + 2SO_4^{2-} \rightarrow 2PbSO_4 + 2H_2O$ Voltage 2.0 volt. The concentration of H_2SO_4 decreases during discharging.	$2PbSO_4 + 2H_2O \rightarrow Pb + PbO_2 + 4H^+ + 2SO_4^{2-}$

Name of cell	**Anode**	**Cathode**	**Electrolyte used**
Dry cell	Zn	Graphite	MnO_2 + C (around cathode) $NH_4Cl + ZnCl_2$ (around anode)
Mercury cell	Zn	Graphite	HgO + KOH (moist)
Lead storage battery	Pb	PbO_2	H_2SO_4 (38% by mass)
Lithium battery	Li	Metal sulphide	$LiClO_4$ in organic solvent
Ni-Cad cell	Cd	NiO	KOH solution
Fuel cell (H_2-O_2)	Porous carbon (with catalyst)	Porous carbon (with catalyst)	Conc. NaOH or KOH (*aq.*)

20. Fuel cell: The cells which convert chemical energy of fuels directly into electrical energy are known as fuel cells. One of such cells is fuel cell (H_2-O_2) in which electrical energy is generated by the use of H_2 and O_2. In fuel cell NaOH is used as an electrolyte and hydrogen gas is diffused at the anode made of porous carbon. At the cathode oxygen is diffused through a porous carbon. The following chemical reactions occur:

(i) At anode, $$H_2 \rightarrow 2H$$

$$2H + 2OH^- \rightarrow 2H_2O + 2e^-$$

(ii) At cathode, $O_2 + 2H_2O + 4e^- \rightarrow 4OH^-$

Net cell reaction $2H_2 + O_2 \rightarrow 2H_2O + \text{energy}$

Fuel cells are quite efficient, and free from pollution. These are used in spacecrafts.

21. Concentration cells: If two plates of the same metal are dipped separately into two solutions of the same electrolyte and are connected with a salt bridge, the whole arrangement is found to acts as galvanic cell. Such cells are known as concentration cells. These are of two types:

(i) Electrode concentration cells

$$\text{Pt, } H_2 \text{ (pressure } p_1) \mid H^+ \mid H_2 \text{ (pressure } p_2), \text{ Pt}$$

If $p_1 > p_2$ oxidation occurs at LHS electrode and reduction occurs at RHS electrode.

$$E_{\text{cell}} = \frac{0.0591}{2} \log \frac{(p_1)}{(p_2)} \text{ at } 25°\text{C}$$

(ii) Electrolyte concentration cells

$$M \mid M^{n+}(C_1) \parallel M^{n+}(C_2) \mid M$$

$$Zn \mid Zn^{n+}(C_1) \parallel Zn^{n+}(C_2) \mid Zn$$

C_2 is higher than C_1.

$$E_{\text{cell}} = \frac{0.0591}{n} \log \frac{C_2}{C_1} \text{ at } 25°\text{C}$$

Questions

1. Match the List-I with List-II and List-III:

List-I (Quantity)	**List-II (Symbol)**	**List-III (Unit)**
(a) Conductivity	(p) Λ_m	(u) mho cm^{-1}
(b) Cell constant	(q) κ	(v) cm^{-1}
(c) Molar conductance	(r) Λ_e	(w) $ohm^{-1}\ cm^2\ mol^{-1}$
(d) Equivalent conductance	(s) l/A	(x) $ohm^{-1}\ cm^2\ eq^{-1}$

2. Match the salts in the Column-I with their use in Column-II:

Column-I	**Column-II**
(a) Hg_2Cl_2	(p) Salt bridge
(b) Agar-agar	(q) Calomel electrode
(c) 0.1 N KCl	(r) Used in ice cream
(d) Quinhydrone	(s) Redox electrode

3. Match the Column-I with Column-II:

Column-I (Term)	**Column-II (Relation)**
(a) α (Degree of ionisation)	(p) λ^+/Λ
(b) t_+ (Transport number)	(q) Λ_m^c/Λ_m^0
(c) Fraction of a mole undergoing ionization	(r) $U^+/U^+ + U^-$
(d) NaCl	(s) Λ_e^c/Λ_e^0
	(t) $\Lambda_m = \Lambda_e$

4. Match the physical quantities in the List-I with their units in List-II:

List-I	**List-II**
(a) Resistance	(p) ohm
(b) Resistivity	(q) volt amp^{-1}
(c) Conductivity	(r) ohm m
(d) Specific conductance	(s) $ohm^{-1}\ m^{-1}$

5. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) Specific conductance, κ	(p) $\Lambda_m^c / \Lambda_m^\circ$
(b) Molar conductance, Λ_m	(q) Decreases with dilution
(c) Resistance of electrolyte solution R	(r) Increases with dilution
(d) Degree of ionization of weak electrolyte, α	(s) Increases with increase in the distance between parallel plates

6. Match Column-I with Column-II:

Column-I (Combination of half-cell reactions)	**Column-II (Potential of overall process)**
(a) $6OH^- + Br^- \rightleftharpoons BrO_3^- + 3H_2O + 6e^-$ $E° = -0.61$ V $2OH^- + Br^- \rightleftharpoons BrO^- + H_2O + 2e^-$ $E° = -0.76$ V $4OH^- + BrO^- \rightleftharpoons BrO_3^- + 2H_2O + 4e^-$ $E° = ?$	(p) $E° = 0.56$ V
(b) $H_2SO_3 + 4H^+ + 4e^- \rightleftharpoons S + 3H_2O$ $E° = 0.45$ V $SO_4^{2-} + 4H^+ + 2e^- \rightleftharpoons H_2SO_3 + H_2O$ $E° = 0.17$ V $SO_4^{2-} + 8H^+ + 6e^- \rightleftharpoons S + 4H_2O$ $E° = ?$	(q) $E° = -0.535$V
(c) $ClO_3^- + 6H^+ + 6e^- \rightleftharpoons Cl^- + 3H_2O$ $E° = +1.45$ V $Cl_2 + 2e^- \rightleftharpoons 2Cl^-$ $E° = +1.36$ V $ClO_3^- + 6H^+ + 5e^- \rightleftharpoons \frac{1}{2}Cl_2 + 3H_2O$ $E° = ?$	(r) $E° = +0.36$ V
(d) $Zn^{2+}_{(aq)} + 2e \longrightarrow Zn(s)$ $E° = -0.76$ V $Ag^+ + e^- \longrightarrow Ag(s)$ $E° = +0.80$ V $Zn(s) + 2Ag^+ \rightleftharpoons Zn^{2+}(aq) + 2Ag(s)$ $E° = ?$	(s) $E° = +1.47$ V

7. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) Concentration cell	(p) Fe is oxidised by Ni_2O_3
(b) Edison cell	(q) Zinc anode
(c) Mercury cell	(r) HgO cathode
(d) Dry cell	(s) $E° = 0$

8. Match the Column-I with Column-II:

Column-I (Electrode)	**Column-II (Type)**
(a) Calomel	(p) Reference
(b) Glass	(q) Redox
(c) Hydrogen	(r) Membrane
(d) Quinhydrone	(s) Gas

9. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) Kohlrausch law	(p) $\Lambda_m / \Lambda^\circ_m$
(b) Λ_m	(q) $\frac{1}{R} \times \frac{1}{A}$
(c) κ (kappa)	(r) $\Lambda^\circ_m Ca_3(PO_4)_2 = 3\lambda^\circ Ca^{2+} + 2\lambda^\circ PO_4^{3-}$
(d) α	(s) $\kappa \times \frac{1000}{M}$

10. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) $E^\circ = 0$	(p) Cell is discharged
(b) $E = 0$	(q) $Q = K$
(c) $\Delta G = 0$	(r) 96500 coulomb
(d) 1 Faraday	(s) 1 mol electrons
	(t) Concentration cell

Answers

1. (a—q, u), (b—s, v), (c—p, w), (d—r, x)
2. (a—q), (b—p, r), (c—p), (d—s)
3. (a—q, s), (b—p, r), (c—q, s), (d—t)
4. (a—p, q), (b—r), (c—s), (d—s)

• PRACTICE PROBLEMS •

1. How many coulombs are required for the following reductions?

(i) 1 mole of Ag^+ ions to Ag

(ii) 1 mole of Cu^{2+} ions to Cu

(iii) 1 mole of MnO_4^- ions to MnO_4^{2-}

[**Ans.** (i) 96500 coulomb (ii) 193000 coulomb (iii) 96500 coulomb]

2. How many faradays are needed to reduce 2 gram-mole of Cu^{2+} to Cu metal?

[**Ans.** 4 faraday]

3. How many faradays are released when 12.7 g of copper metal is changed into copper ions?

[**Ans.** 0.4 faraday]

[**Hint:** $\underset{\substack{1\text{ mole}\\63.5}}{Cu} \longrightarrow Cu^{2+} + \underset{\substack{2\text{ mole}\\2F}}{2e^-}$]

4. Calculate the number of coulombs required to deposit 40.5 g Al when the electrode reaction is:

$$Al^{3+} + 3e^- \longrightarrow Al$$

[**Ans.** 4.34×10^5 coulomb]

5. Calculate the number of coulombs required to deposit 50 g of silver at cathode from silver nitrate solution.
(Atomic mass of silver = 108)

[**Ans.** 44675.9 coulomb]

6. How much electric charge is required to produce 20.0 g of calcium from molten $CaCl_2$?

[**Ans.** 96500 coulomb]

7. If 3 faradays of electricity are passed through an iron (II) bromide solution, how many grams of iron metal will be deposited? (At. mass of iron = 56)

[**Ans.** 84 g]

8. A certain quantity of electricity deposits 0.54 g of Ag from silver nitrate solution. What volume of hydrogen will be liberated by the same quantity of electricity at 27°C and 750 mm of Hg pressure?

[**Hint:** $\dfrac{\text{Mass of } H_2}{\text{Mass of Ag}} = \dfrac{\text{Eq. mass of } H_2}{\text{Eq. mass of Ag}}$

$$\text{Mass of } H_2 = \frac{1 \times 0.54}{108} = 0.005 \text{ g}$$

$$\text{Volume of } H_2 = \frac{0.005 \times 0.0821 \times 300 \times 760}{2 \times 750} \quad \left(V = \frac{w}{M} \cdot \frac{RT}{P}\right)$$

$$= 0.06234 \text{ litre}$$]

9. In the electrolysis of an aqueous cupric bromide solution, how many grams of bromine are formed on passing a current of 1 ampere for 16 minutes and 5 seconds? Write the anode and the cathode half reactions.

[**Ans.** 0.80 g; cathode reaction $Cu^{2+} + 2e^- \longrightarrow Cu$;
anode reaction $2Br^- \longrightarrow Br_2 + 2e^-$]

10. A current of 1.5 amperes is passed through a solution of a salt of a bivalent metal for 30 minutes. Increase in mass of cathode is 0.8898 g. Find the atomic mass of the metal.

[**Ans.** 63.6]

11. A lead storage battery is discharged in which the following electrode reaction takes place:

$$Pb(s) + PbO_2(s) + 2H_2SO_4(l) \longrightarrow 2PbSO_4 + 2H_2O$$

The original volume in electrolyte is 1 litre. During discharge the concentration of H_2SO_4 changes from 34.6% by weight (density 1.261 g/mL) to 27% by weight. How many faradays have left the anodic half-cell? Water produced during electrolysis is used up.

[**Ans.** 1.254 faraday]

12. The chemical reaction given below:

$$Cl_2(g) + SO_2(g) + 2H_2O(l) \longrightarrow 2Cl^-(aq.) + 3H^+(aq.) + HSO_4^-(aq.)$$

proceeds readily in aqueous acid solution.

(i) Give the half-cell reactions.

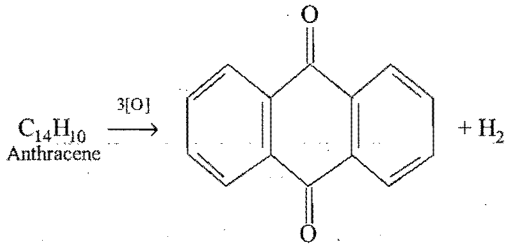
(ii) If a fully charged cell initially held 1 mole of Cl_2, for how many days could it sustain a current of 0.05 ampere, assuming the cell becomes non-operative when 90% of initial Cl_2 has been used up?

[**Ans.** 40.2 days]

13. A current of 80 microampere is passed through a solution of $AgNO_3$ for 32 minutes using platinum electrodes. A uniform single atom thick layer is deposited covering 86% of the cathode surface. If total surface area of cathode is 601.7 cm^2, calculate the area covered by one Ag atom.

[**Ans.** 5.4×10^{-16} cm^2]

14. Anthracene can be electrolytically oxidised to anthraquinone.



Anthraquinone

What mass of anthraquinone can be produced by the passage of 1 ampere current for an hour at 100% efficiency?

[**Ans.** 1.2932 g]

15. Dal lake has water 8.2×10^{12} litre approximately. A power reactor produces electricity at the rate of 1.5×10^6 coulomb per second at an appropriate voltage. How much time would it take to electrolyse the lake?

[**Ans.** 1.9 million year]

16. How many grams of H_2 and O_2 are produced during the electrolysis of water by a 1.30 ampere current for 5 hours? What volumes of dry gases are produced at NTP?

[**Ans.** 0.242 g H_2; 1.94 g O_2; 2.72 litre H_2; 1.36 litre O_2]

17. How many coulombs of electricity would be required to reduce the iron in 36.0 g of potassium hexacyano ferrate(III), $K_3Fe(CN)_6$, to metallic iron?
[**Ans.** 3.17×10^4 coulomb]
[**Hint:** Iron in the complex is Fe^{3+}.

$$\underset{1\text{ mole}}{K_3Fe(CN)_6} + \underset{3 \times 96500\text{ C}}{3e^-} \longrightarrow 3K^+ + 6CN^- + Fe\ ]$$

18. What current strength in ampere will be required to liberate 5 g of iodine from potassium iodide solution in 30 minutes?
[**Ans.** 2.11 ampere]

19. The mass of copper deposited from a solution of copper sulphate by a uniform current of 0.25 ampere flowing for one hour is 0.295 g. Find the equivalent mass of copper. (1 faraday = 96500 coulomb)
[**Ans.** 31.75]

20. The solution of a salt of a metal of atomic mass 112 was electrolysed for 15 minutes with a current of 1.5 ampere. The mass of the metal deposited was 0.788 g. Find the valency of the metal.
[**Ans.** 2]

21. If a monovalent metal ion carries 1.6×10^{-19} coulomb of electricity, what is the amount of electricity carried by one gram molecular mass of the metal ions?
[**Ans.** 9.6336×10^4 coulomb]

22. Calculate approximately how much current is necessary to produce oxygen gas at the rate of 1 mL per second?
[**Ans.** 17.23 ampere]
[**Hint:** 1 g-equivalent of oxygen or $\frac{22400}{4}$ mL is liberated by 96500 coulomb.]

23. 0.5 faraday of electricity was required to deposit all the copper in 500 mL of a copper sulphate solution. What is the normality of the copper sulphate solution?
[**Ans.** Normality = 1 *N*]

24. Copper is deposited at an electrode according to the reaction $Cu^{2+} \xrightarrow{+2e^-} Cu$. When a current of 1.34 ampere was passed through a solution of copper sulphate for 10 hours, 15.885 g of copper was deposited.
(i) How many coulombs of electricity were passed through the solution?
(ii) How many moles of copper were deposited?
(iii) How many coulombs are required for the deposition of 1 mole of copper?
(iv) If the charge on an electron is 1.6×10^{-19} coulomb, calculate the value of Avogadro's number.
[**Ans.** (i) 482.40 coulomb (ii) 0.25 mol (iii) 2×96500 coulomb (iv) 6.03×10^{23}]

25. Calculate the mass and volume at NTP of hydrogen and chlorine that will be formed by passing 10,000 coulomb of charge through an aqueous solution of potassium chloride. The cell reaction is:

$$2KCl + 2HOH \longrightarrow 2KOH + Cl_2 + H_2$$

[**Ans.** 0.1036 g H_2, volume 1.063 litre; 3.678 g Cl_2, volume 1.1603 litre]

26. Three electrolytic cells *A*, *B* and *C* containing electrolytes zinc sulphate, silver nitrate and copper sulphate respectively, were connected in series. A steady current of 1.50 ampere was passed through them until 1.45 g of silver was deposited at the cathode of cell *B*. How long did the current flow? What masses of copper and zinc were deposited?
(At. mass: Cu = 63.5, Zn = 65.4, Ag = 107.8)
[**Ans.** 865 second; 0.427 g Cu; 0.44 g Zn]

27. An electric current passing for 6 minutes through a dilute H_2SO_4 solution gave 40 mL of the electrolytic gas ($H_2 + O_2$) measured at NTP. What was the average value of current?
[**Ans.** 0.638 ampere]
[**Hint:** 96500 coulomb give 11.2 litre of H_2 and 5.6 litre of O_2, *i.e.*, 16.8 litre of electrolytic gas at NTP.]

28. The same quantity of electricity that liberated 2.158 g silver was passed through a solution of a gold salt and 1.314 g of gold was deposited. The equivalent mass of silver is 107.9. Calculate the equivalent mass of gold. What is the oxidation state of gold in this gold salt? (At. mass of gold = 197)
[**Ans.** Eq. mass = 65.7; Oxidation state = 3]

29. Calculate the volume of Cl_2 at NTP produced during electrolysis of $MgCl_2$ which produces 6.50 g Mg. (At. mass of Mg = 24.3)
[**Ans.** 5.99 litre]

30. How long does it take to deposit 100 g of Al from an electrolytic cell containing Al_2O_3 using a current of 125 ampere?
[**Ans.** 8577.8 second]

31. 10g fairly concentrated solution of $CuSO_4$ is electrolysed using 1.01 faraday of electricity. Calculate the mass of the resulting solution.
[**Ans.** 9.6025 g]

32. The density of copper is 8.94 g mL^{-1}. Find out the number of coulombs needed to plate an area $10 \times 10\ cm^2$ to a thickness of 10^{-2} cm using $CuSO_4$ solution as electrolyte. (At. mass of Cu = 63.6)
[**Ans.** 27129.2 coulomb]

33. What mass of Ag (At. mass 108) could be plated on a spoon from electrolysis of $AgNO_3$ solution by one ampere current for 10 minutes? (Dhanbad 1990)
[**Ans.** 0.6715 g]

34. If a current of 0.3 ampere is drawn from a Daniell cell for 1 hour, what would be the change in mass of electrodes? (At. mass of Cu = 63.5 and Zn = 65.37)
[**Ans.** 0.356 g Cu deposited, 0.366 g of Zn dissolves]

35. An element *A* (At. mass 112) and an element *B* (At. mass 27) form chlorides. Solutions of these chlorides are electrolysed separately and it is found that when the same quantity of electricity is passed, 5.6 g of *A* was deposited while in the other cell only 0.9 g of *B* was deposited. What is the valency of *A* if the valency of *B* is 3? (Dhanbad 1991)
[**Ans.** 2]

36. How many coulombs must be applied to a cell for the electrolytic production of 245 g $NaClO_4$ from $NaClO_3$. The anode efficiency for the desired reaction is 60%.
[**Ans.** 6.43×10^5 coulomb]

37. Calculate the mass of Hg_2Cl_2 which can be prepared by the reduction of mercury(II) ions in the presence of chloride ions by the passage of 5.0 ampere current for 3.0 hours.

[**Ans.** 132.34 g]

[**Hint:** $\underset{}{2Hg^{2+}} + 2Cl^- + \underset{2\,F}{2e^-} \longrightarrow \underset{1\text{ mole}}{Hg_2Cl_2}$]

38. How long will it take for a uniform current of 6.0 ampere to deposit 78.0 g gold from a solution of $AuCl_4^-$? What mass of chlorine gas will be formed simultaneously at the anode in the electrolytic cell?

[**Ans.** 19104 second; chlorine liberated = 42.17 g]

[**Hint:** $AuCl_4^- + \underset{3\,F}{3e^-} \longrightarrow \underset{1\text{ mole}}{Au} + 4Cl^-$ (Cathode)

$2Cl^- \longrightarrow \underset{1\text{ mole}}{Cl_2} + \underset{2\,F}{2e^-}$ (Anode)]

39. How long will it take 5 ampere of current to deposit 2 g of copper from a solution of copper sulphate?
(Given, CE of copper = 32, F = 96500 coulomb)
(Ranchi 1996)

[**Ans.** 20.1 minute]

40. The amount of lactic acid, $HC_3H_5O_3$, produced in a sample of muscle tissue was analysed by reaction with hydroxide ion. Hydroxide ion was produced in the sample mixture by electrolysis. The cathode reaction was,

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq.)$$

Hydroxide ion reacts with lactic acid as soon as it is produced. The end point of the reaction is detected with an acid-base indicator. It required 115 seconds for a current of 15.6 mA to reach end point. How many grams of lactic acid (a monoprotic acid) were present in the sample?

[**Ans.** 1.674×10^{-3} g]

[**Hint:** No. of moles of lactic acid = No. of moles of OH^- used
= No. of faraday used in electrolysis

$$\text{Number of faraday used} = \frac{I \times t}{96500} = \frac{15.6 \times 10^{-3} \times 115}{96500}$$
$$= 1.86 \times 10^{-5}$$

Mass of lactic acid = Number of moles × Molecular mass

$$= 1.86 \times 10^{-5} \times 90$$
$$= 1.674 \times 10^{-3}\text{ g}]$$

41. In what direction, can the reaction:

$$2NaCl + Fe_2(SO_4)_3 \rightleftharpoons 2FeSO_4 + Cl_2 + Na_2SO_4$$

proceed spontaneously?

(Given: $E^\circ_{Fe^{3+}/Fe^{2+}} = 0.77\text{ V}$; $E^\circ_{Cl^-/Cl_2} = 1.36\text{ V}$)
(BCECE 2005)

[**Ans.** Forward]

42. How many faradays of electricity will be required to completely electrolyse one mole of molten Al_2O_3 to produce Al metal and O_2 gas? **|JEE (West Bengal) 2005|**

[**Ans.** 3 F]

43. The resistance of 0.01 N solution at 25°C is 200 ohm. Cell constant of the conductivity cell is unity. Calculate the equivalent conductance of the solution.

[**Ans.** $500\text{ ohm}^{-1}\text{ cm}^2\text{ eq}^{-1}$]

44. A conductivity cell was filled with 0.01 M solution of KCl which was known to have a specific conductivity of 0.1413 $\text{ohm}^{-1}\text{ m}^{-1}$ at 298 K. Its measured resistance at 298 K was 94.3 ohm. When the cell was filled with 0.02 M $AgNO_3$ solution, its resistance was 50.3 ohm. Calculate (i) cell constant and (ii) the specific conductance of $AgNO_3$ solution.

[**Ans.** 13.32 m^{-1}; $2.648 \times 10^{-1}\text{ ohm}^{-1}\text{ m}^{-1}$]

45. A conductance cell was calibrated by filling it with a 0.02 M solution of potassium chloride. (specific conductance $= 0.2768\text{ ohm}^{-1}\text{ m}^{-1}$) and measuring the resistance at 298 K which was found to be 457.3 ohm. The cell was then filled with a calcium chloride solution containing 0.555 g of $CaCl_2$ per litre. The measured resistance was 1050 ohm. Calculate the molar conductivity of $CaCl_2$ solution.

[**Ans.** $0.0241\text{ mho m}^2\text{ mol}^{-1}$]

[**Hint:** Determine cell constant with KCl data. Its value is 126.6 m^{-1}.

$$\text{Sp. cond. of } CaCl_2 \text{ soln.} = \text{Cell const.} \times \frac{1}{\text{Resistance}}$$
$$= 126.6 \times \frac{1}{1050} = 0.1206\text{ ohm}^{-1}\text{ m}^{-1}$$
$$\text{Molar conductance} = \frac{\text{Sp. cond.}}{\text{Conc.}}$$
$$\text{Conc.} = \frac{0.555}{111.0} = 0.005\text{ mol dm}^{-3} = 5\text{ mol m}^{-3}]$$

46. The molar conductivities at infinite dilution of KCl, KNO_3 and $AgNO_3$ at 298 K are $0.01499\text{ mho m}^2\text{ mol}^{-1}$, $0.01250\text{ mho m}^2\text{ mol}^{-1}$ and $0.01334\text{ mho m}^2\text{ mol}^{-1}$ respectively. What is the molar conductivity of AgCl at infinite dilution at this temperature?

[**Ans.** $0.01383\text{ mho m}^2\text{ mol}^{-1}$]

47. The electrodes in a conductivity cell have area $1.2 \times 10^{-4}\text{ m}^2$ and they are fixed 3×10^{-3} m apart. A solution containing 200 g equivalent of the electrolyte per m^3 of the solution has a resistance of 60 ohm at 298 K. Calculate the equivalent conductivity of the solution.

[**Ans.** $2.09 \times 10^{-2}\text{ mho m}^2\text{ eq}^{-1}$]

48. The molar conductivities of NH_4^+ ion and Cl^- ion are 73.5 $\text{mho cm}^2\text{ mol}^{-1}$ and $76.2\text{ mho cm}^2\text{ mol}^{-1}$ respectively. The specific conductivity of 0.1 M NH_4Cl is $1.288 \times 10^{-2}\text{ mho cm}^{-1}$. What is the dissociation constant of NH_4Cl?

[**Ans.** 0.86]

49. The specific conductivity of a saturated solution of silver chloride at 18°C is 1.24×10^{-6} mho after subtracting that of water. Ionic conductances at infinite dilution of Ag^+ and Cl^- ions at this temperature are 53.8 and 65.3 respectively. Calculate the solubility of silver chloride in gram per litre.

[**Ans.** 1.494×10^{-3} g per litre]

50. Given:

$$\lambda^{\infty}\,[\tfrac{1}{2}\,Mg^{2+}] = 53.06\ ohm^{-1}\ cm^2\ mol^{-1}$$
$$\lambda^{\infty}\,[\tfrac{1}{2}\,SO_4^{2-}] = 80\ ohm^{-1}\ cm^2\ mol^{-1}$$
$$\lambda^{\infty}\,[\tfrac{1}{3}\,Al^{3+}] = 63\ ohm^{-1}\ cm^2\ mol^{-1}$$

Calculate the values of $\Lambda_m^{\infty}\,[Al_2(SO_4)_3]$ and $\Lambda^{\infty}\,[MgSO_4]$.

[**Ans.** 858 $ohm^{-1}\ cm^2\ mol^{-1}$, 266.12 $ohm^{-1}\ cm^2\ mol^{-1}$]

51. Hydrofluoric acid is a weak acid. At 25°C, the molar conductivity of 0.002 M HF is 176.2 $ohm^{-1}\ cm^2\ mol^{-1}$. If its $\Lambda_m^{\infty} = 405.2\ ohm^{-1}\ cm^2\ mol^{-1}$, calculate its degree of dissociation and equilibrium constant at the given concentration.

[**Ans.** $\alpha = 0.435, K = 6.7 \times 10^{-4}$]

52. For mercury at 0°C specific conductance,

$$\kappa = 1.062963 \times 10^6\ S/m.$$

(a) If the resistance of a cell containing mercury is 0.243166 ohm, what is the cell constant of the cell?

(b) If the same cell is filled with KCl solution at 0°C, the resistance of the cell is 3.966×10^4 ohm. What is the conductivity of KCl solution?

(c) If the average cross-sectional area of the cell is 0.9643 mm^2, what is the effective distance between the electrodes?

[**Ans.** (a) 2.58476×10^5 S/m; (b) 6.517 S/m; (c) 0.2492 m]

53. The mobility of the NH_4^+ ions is $7.623 \times 10^{-8}\ m^2/Vs$. Calculate:

(a) the molar conductivity of NH_4^+ ion;

(b) velocity of the ion if 15 volt are applied across the electrodes 25 cm apart.

[**Ans.** (a) $73.55 \times 10^{-4}\ S\ m^2/mol$; (b) 4.574 μm/s]

54. Construct electric cells for the following reactions:

(a) $Fe + Cu^{2+} \longrightarrow Cu + Fe^{2+}$

(b) $Cu + 2Ag^+ \longrightarrow 2Ag + Cu^{2+}$

(c) $6Fe^{2+} + Cr_2O_7^{2-} + 14H^+ \longrightarrow 6Fe^{3+} + 2Cr^{3+} + 7H_2O$

(d) $Cd + I_2 \longrightarrow Cd^{2+} + 2I^-$

(e) $2Fe^{3+} + 2Cl^- \longrightarrow 2Fe^{2+} + Cl_2$

[**Ans.** (a) $Fe \mid Fe^{2+} \parallel Cu^{2+} \mid Cu$

(b) $Cu \mid Cu^{2+} \parallel Ag^+ \mid Ag$

(c) $Pt \mid Fe^{2+}, Fe^{3+} \parallel H^+, Cr_2O_7^{2-}, Cr^{3+} \mid Pt$

(d) $Cd \mid Cd^{2+} \parallel I^-, I_2 \mid Pt$

(e) $Pt \mid Cl_2, Cl^- \parallel Fe^{3+}, Fe^{2+} \mid Pt$]

55. Predict whether the following reaction will occur spontaneously or not:

$$Co^{2+} + Sn \longrightarrow Co + Sn^{2+}$$

$E^{\circ}_{Co/Co^{2+}} = 0.277$ volt and $E^{\circ}_{Sn/Sn^{2+}} = 0.136$ volt

[**Ans.** No; E°_{cell} is negative = – 0.141 volt]

56. An iron wire is immersed in a solution containing $ZnSO_4$ and $NiSO_4$. Predict giving reasons which of the following reactions is likely to proceed?

(i) Iron reduces Zn^{2+} ions (ii) Iron reduces Ni^{2+} ions.

Given: $E^{\circ}_{Zn^{2+}/Zn} = -0.76$ volt; $E^{\circ}_{Fe^{2+}/Fe} = -0.44$ volt and $E^{\circ}_{Ni^{2+}/Ni} = -0.25$ volt.

[**Ans.** Iron reduces Ni^{2+} ions as the E°_{cell} in this case has positive value.]

57. Can a solution of 1 M $CuSO_4$ be stored in a vessel made of nickel metal?

Given: $E^{\circ}_{(Ni^{2+};\,Ni)} = -0.25$ volt

$E^{\circ}_{(Cu^{2+};\,Cu)} = 0.34$ volt

Ans. No; The reaction takes place between $CuSO_4$ and nickel s E°_{cell} is positive.]

58. Answer whether, under standard conditions, the following reactions are possible or not:

(i) Will copper reduce Ag^+ to Ag? Given: $E^{\circ}_{Ag^+/Ag} = 0.799$ volt; $E^{\circ}_{Cu^{2+}/Cu} = -0.337$ volt

(ii) Will Fe^{3+} be reduced to Fe^{2+} by Sn^{2+} ion? Given:

$Fe^{3+} \mid Fe^{2+} = 0.771$ volt;

$Sn^{2+} \mid Sn^{4+} = -0.250$ volt

(iii) Would you use a silver spoon to stir a solution of $Cu(NO_3)_2$?

[**Ans.** (i) Yes, E°_{cell} $Cu \mid Cu^{2+} \parallel Ag^+ \mid Ag$ is positive (+ 0.462 volt)

(ii) Yes, E°_{cell} $Pt \mid Sn^{4+}, Sn^{2+} \parallel Fe^{3+}, Fe^{2+} \mid Pt$ is positive (+0.621 volt)

(iii) Yes, the reaction does not occur.]

59. The electrode potentials of two half reactions are as follows:

$Fe^{3+} + e^- \longrightarrow Fe^{2+}$; $E^{\circ} = +0.76$ volt

$Ce^{4+} + e^- \longrightarrow Ce^{3+}$; $E^{\circ} = +1.60$ volt

Giving reason, describe if Ce^{3+} can be oxidised by Fe^{3+}.

[**Hint:** $Ce^{3+} + Fe^{3+} \longrightarrow Ce^{4+} + Fe^{2+}$

$Ce^{3+} \longrightarrow Ce^{4+} + e^-$ (oxidation); $E^{\circ} = -1.60$ volt

$Fe^{3+} + e^- \longrightarrow Fe^{2+}$ (reduction); $E^{\circ} = +0.76$ volt

Adding both, E° of the reaction = – 0.84 volt

The oxidation of Ce^{3+} by Fe^{3+} is not possible.]

60. Calculate the standard reduction potential of Ni^{2+}/Ni electrode when the emf of the cell

$$Ni \mid Ni^{2+}\,(1\,M) \parallel Cu^{2+}\,(1\,M) \mid Cu$$

is 0.59 volt and $E^{\circ}_{Cu^{2+}/Cu} = +0.34$ volt

[**Ans.** – 0.25 volt]

61. Calculate the half-cell potential at 298 K for the reaction,

$$Zn^{2+} + 2e^- \longrightarrow Zn$$

if $[Zn^{2+}] = 0.1\,M$ and $E^{\circ} = -0.76$ volt.

[**Ans.** – 0.789 volt]

62. A galvanic cell consists of a metallic zinc plate immersed in 0.1 M $Zn(NO_3)_2$ solution. Calculate the emf of the cell at 25°C. Write the chemical equations for the electrode reactions and represent the cell. (Given: $E^{\circ}_{Zn^{2+}/Zn} = -0.76$ volt and $E^{\circ}_{Pb^{2+}/Pb} = -0.13$ volt)

[**Ans.** $Zn \longrightarrow Zn^{2+} + 2e^-$, $\quad Pb^{2+} + 2e^- \longrightarrow Pb$

$$Zn \mid \underset{0.1\,M}{Zn^{2+}} \parallel \underset{0.02\,M}{Pb^{2+}} \mid Pb$$

$E^\circ_{cell} = 0.63$ volt $\quad E_{cell} = 0.609$ volt]

63. Calculate the cell potential of the cell at 25°C having the cell reaction:

$$2Ag^+ + Cu \rightleftharpoons 2Ag + Cu^{2+}$$

(Given that, $[Ag^+] = 1.0 \times 10^{-3}\,M$,

$[Cu^{2+}] = 1.0 \times 10^{-4}\,M$, $E^\circ_{cell} = 0.46$ volt)

[**Ans.** 0.40 volt]

64. Calculate the E and E° of the cell

$$Ni \mid Ni^{2+} \parallel Cu^{2+} \mid Cu$$

from the following half-cell reactions:

$Ni^{2+} + 2e^- \longrightarrow Ni$; $\quad E^\circ = -0.25$ volt

$Cu^{2+} + 2e^- \longrightarrow Cu$; $\quad E^\circ = +0.34$ volt

(Given: $[Ni^{2+}] = 1\,M$ and $[Cu^{2+}] = 10^{-3}\,M$)

[**Ans.** $E^\circ_{cell} = 0.59$ volt; $E_{cell} = 0.5015$ volt]

65. Use E° values to calculate ΔG° for the reaction

$$Fe^{2+} + Ag^+ \longrightarrow Fe^{3+} + Ag$$

$E^\circ_{Ag^+/Ag} = 0.80$ volt and $E^\circ_{Pt/Fe^{3+}, Fe^{2+}} = 0.77$ volt

[**Ans.** -2895 J]

[**Hint:** $E^\circ_{cell} = 0.03$ volt, $\Delta G^\circ = -nFE^\circ_{cell}$]

66. A piece of zinc metal is dipped in a 0.1 M solution of zinc salt. The salt is dissociated to the extent of 20%. Calculate the electrode potential of Zn^{2+}/Zn.

(Given: $E^\circ_{Zn^{2+}/Zn} = -0.76$ volt.)

[**Ans.** -0.8102 volt]

[**Hint:** $[Zn^{2+}] = 0.1 \times 0.2 = 0.02\,M$

$Zn^{2+} + 2e^- \longrightarrow Zn$ (Reduction)

$$E_{Zn^{2+}/Zn} = E^\circ_{Zn^{2+}/Zn} + \frac{0.0591}{2}\log_{10}[Zn^{2+}]\,]$$

67. Estimate the concentration limit beyond which the half-cell potential of $Cu^{2+} \mid Cu$ will be zero.

$$E^\circ_{Cu^{2+}/Cu} = 0.34 \text{ volt}$$

[**Ans.** 3.1×10^{-12} mol L^{-1}]

[**Hint:** $E^\circ_{Cu^{2+}/Cu} = \frac{0.0591}{2}\log[Cu^{2+}]$]

68. Calculate equilibrium constant for the following reaction:

$$Zn + CuSO_4 \longrightarrow ZnSO_4 + Cu$$

$E^\circ_{Zn/Zn^{2+}} = 0.765$ volt; $\quad E^\circ_{Cu^{2+}/Cu} = 0.347$ volt

[**Ans.** 1.862×10^{37}]

69. For the cell reaction,

$$Ni \mid Ni^{2+} \parallel Ag^+ \mid Ag$$

Calculate the equilibrium constant at 25°C. How much maximum work would be obtained by the operation of this cell?

[**Ans.** 3.98×10^{35}, Max. work = 202650 J]

70. Calculate the emf of the cell

$$Cr \mid Cr^{3+}\,(0.1\,M) \parallel Fe^{2+}\,(0.01\,M) \mid Fe$$

(Given: $E^\circ_{Cr^{3+}/Cr} = -0.75$ volt; $E^\circ_{Fe^{2+}/Fe} = -0.45$ volt)

[**Ans.** 0.261 volt]

71. Calculate the equilibrium constant for the reaction,

$$Zn(s) + Ag_2O(s) + H_2O(l) \longrightarrow 2Ag(s) + Zn^{2+}(aq.) + 2OH^-(aq.)$$

when $E^\circ_{cell} = 1.11$ at 298 K.

[**Ans.** $K_c = 3.499 \times 10^{37}$]

72. The standard reduction potential of $Ag^+ \mid Ag$ electrode is 0.80 volt. Calculate the standard electrode potential of $Cl^- \mid AgCl \mid Ag$ at 25°C. Given solubility product, $K_{sp}(AgCl) = 1.8 \times 10^{-10}$.

[**Hint:** Apply

$E^\circ_{cell} = 0.0591 \times \log[Ag^+][Cl^-] = 0.0591 \log K_{sp}(AgCl)$

$E^\circ_{cell} = -0.576$ volt

E°_{cell} = Oxid. pot. anode + Red. pot. cathode

Red. pot. cathode $[Cl^- \mid AgCl \mid Ag] = -0.576 - (-0.80)$

$= -0.576 + 0.80 = 0.224$ volt]

73. Derive Nernst equation for the cell.

$$Ni(s) \mid Ni^{2+}\,(aq.\ 0.1\,M) \parallel Ag^+\,(aq.\ 0.1\,M) \mid Ag(s)$$

and also find its cell potential. Given:

$E^\circ_{Ag^+/Ag} = 0.80$ volt and $E^\circ_{Ni^{2+}/Ni} = -0.25$ volt

[**Hint:** Cell reaction,

$Ni + 2Ag^+ \longrightarrow 2Ag + Ni^{2+}$; $\quad E^\circ_{cell} = 1.05$ volt

Nernst equation, $E_{cell} = E^\circ_{cell} - \frac{0.0591}{2}\log\frac{[Ni^{2+}]}{[Ag^+]^2}$

$\doteq (1.05 - 0.0295)$ volt

$= 1.02$ volt]

74. Determine the equilibrium constant of the following reaction at 298 K:

$$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$$

(Given: $E^\circ_{Sn^{4+}/Sn^{2+}} = 0.15$ volt, $E^\circ_{Fe^{3+}/Fe^{2+}} = 0.771$ volt)

[**Ans.** $K = 1.0 \times 10^{21}$]

[**Hint:** Calculate E°_{cell}. The value is 0.621 volt.

Apply $E^\circ_{cell} = \frac{0.0591}{2}\log K$]

75. The zinc-silver oxide cell is used in hearing aids and electric watches. From the following data:

$Zn^{2+} + 2e^- \longrightarrow Zn$; $\quad E^\circ = -0.76$ volt

$Ag_2O + H_2O + 2e^- \longrightarrow 2Ag + 2OH^-$; $\quad E^\circ = 0.334$ volt

Answer the following:

(a) Construct the cell and what will be its emf?

(b) What is its cell reaction and what will be ΔG° value of this cell reaction?

(c) Name the species which undergo oxidation and reduction when the cell is in operation.

[**Ans.** (a) Cell $Zn \mid Zn^{2+} \parallel OH^- \mid Ag_2O \mid Ag$

$E^\circ_{cell} = 1.104$ volt

(b) Cell reaction,

$$Ag_2O + H_2O + Zn \longrightarrow 2Ag + Zn^{2+} + 2OH^-$$

$$\Delta G^\circ = -nFE^\circ_{cell} = -2 \times 96500 \times 1.104 = -213072 \text{ J}$$

(c) Zinc is oxidised to Zn^{2+} and Ag_2O is reduced to Ag.]

76. An excess of Hg was added to 10^{-3} *M* acidified solution of Fe^{3+} ions. It was found that only 4.6% of the ions remained as Fe^{3+} at equilibrium at 25°C. Calculate E° for $2Hg / Hg_2^{2+}$ at 25°C for

$$2Hg + 2Fe^{3+} \rightleftharpoons Hg_2^{2+} + 2Fe^{2+}$$

[**Ans.** -0.7912 volt]

77. The emf of the cell,

$$Ag \mid AgI \ (0.05) \ M \ KI \parallel (0.05) \ M \ AgNO_3 \mid Ag$$

is 0.788 volt. Calculate the solubility product of AgI.

[**Ans.** 1.10×10^{-16}]

78. At equimolar concentrations of Fe^{2+} and Fe^{3+}, what must $[Ag^+]$ be so that the voltage of the galvanic cell made from Ag^+/Ag and Fe^{3+}/Fe^{2+} electrodes equals zero? The reaction is $Fe^{2+} + Ag^+ \rightleftharpoons Fe^{3+} + Ag$. Determine the equilibrium constant at 25°C for the reaction. (Given: $E^\circ_{Ag^+/Ag} = 0.799$ volt and $E^\circ_{Fe^{3+}/Fe^{2+}} = 0.771$ volt)

[**Hint:** $E^\circ_{cell} = E^\circ_{Fe^{2+}/Fe^{3+}} + E^\circ_{Ag^+/Ag}$

$$= -0.771 + 0.799 = 0.028 \text{ volt}$$

At equilibrium, $E_{cell} = 0$

$$0 = E^\circ_{cell} - \frac{0.0591}{1} \log \frac{[Fe^{3+}]}{[Fe^{2+}][Ag^+]}$$

$$= E^\circ_{cell} - 0.0591 \log \frac{1}{[Ag^+]}$$

$$[Ag^+] = 0.34$$

$$\log K = \frac{nE^\circ}{0.0591}$$

$$K = 3.0]$$

79. Using Nernst equation for the cell reaction,

$$Pb + Sn^{2+} \longrightarrow Pb^{2+} + Sn$$

Calculate the ratio $\frac{[Pb^{2+}]}{[Sn^{2+}]}$ for which $E_{cell} = 0$.

(Given: $E^\circ_{Pb/Pb^{2+}} = 0.13$ volt and $E^\circ_{Sn^{2+}/Sn} = -0.14$ volt)

[**Ans.** $\frac{[Pb^{2+}]}{[Sn^{2+}]} = 0.5$]

80. Determine the potential of a Daniell cell, initially containing 1.00 L each of 1.0 *M* copper(II) ion and 1.0 *M* zinc(II) ion, after passage of 10^5 coulomb charge. The E° of the Daniell cell is 1.10 volt.

[**Ans.** 1.09 volt]

[**Hint:** By passage of 10^5 coulomb charge, zinc ion concentration increases by 0.518 mole while copper ion concentration decreases by 0.518 mole.

Thus, $[Zn^{2+}] = 1.518 \, M$ and $[Cu^{2+}] = 0.482 \, M$

(Now apply Nernst equation)]

81. Calculate the standard potential for the reaction,

$$Hg_2Cl_2 + Cl_2 \longrightarrow 2Hg^{2+} + 4Cl^-$$

(Given:

$$Hg_2Cl_2 + 2e^- \longrightarrow 2Hg + 2Cl^-; \quad E^\circ = 0.270 \text{ volt}$$

$$Hg_2^{2+} \longrightarrow 2Hg^{2+} + 2e^-; \quad E^\circ = -0.92 \text{ volt}$$

$$2Hg \longrightarrow Hg_2^{2+} + 2e^-; \quad E^\circ = -0.79 \text{ volt}$$

$$Cl_2 + 2e^- \longrightarrow 2Cl^-; \quad E^\circ = 1.36 \text{ volt})$$

Ans. -0.08 volt]

[**Hint:** First determine E° for

$$Hg_2Cl_2 \longrightarrow 2Hg^{2+} + 2Cl^- + 2e^- \text{ electrode.}$$

It comes to -1.44 volt.

This electrode is now coupled with $Cl_2 + 2e^- \longrightarrow 2Cl^-$ electrode.]

82. Given:

$$Cu^{2+} + e^- \longrightarrow Cu^+; \quad E^\circ = 0.15 \text{ volt}$$

$$Cu^+ + e^- \longrightarrow Cu; \quad E^\circ = 0.5 \text{ volt}$$

Calculate potential for $Cu^{2+} + 2e^- \longrightarrow Cu$.

[**Ans.** 0.325 volt]

83. What is the standard electrode potential for the electrode MnO_4^-/MnO_2 in solution?

(Given: $E^\circ_{MnO_4^-/Mn^{2+}} = 1.51$ volt, $E^\circ_{MnO_2/Mn^{2+}} = 1.23$ volt)

[**Ans.** 1.7 volt]

[**Hint:**

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O; \ E^\circ = 1.51 \text{ volt}$$

$$MnO_2 + 4H^+ + 2e^- \longrightarrow Mn^{2+} + 2H_2O; \ E^\circ = 1.23 \text{ volt}$$

Subtracting

$$MnO_4^- + 4H^+ + 3e^- \longrightarrow MnO_2 + 2H_2O; \ E^\circ = ?$$

$$E^\circ = \frac{5 \times 1.51 - 2 \times 1.23}{3} = \frac{7.55 - 2.46}{3} = \frac{5.09}{3} = 1.70 \text{ volt}]$$

84. What ratio of Pb^{2+} to Sn^{2+} concentration is needed to reverse the following cell reaction?

$$Sn(s) + Pb^{2+}(aq.) \longrightarrow Sn^{2+}(aq.) + Pb(s)$$

$$E^\circ_{Sn^{2+}/Sn} = -0.136 \text{ volt} \quad \text{and} \quad E^\circ_{Pb^{2+}/Pb} = -0.126 \text{ volt}$$

[**Ans.** $\frac{[Pb^{2+}]}{[Sn^{2+}]} < 0.458$]

85. For the cell $Mg \mid Mg^{2+} \parallel Ag^+ \mid Ag$, calculate the equilibrium constant at 25°C and the maximum work that can be obtained during the operation of the cell.

(Given: $E^\circ_{Mg/Mg^{2+}} = 2.37$ volt and $E^\circ_{Ag^{2+}/Ag} = 0.80$ volt)

[**Ans.** $K = 2.86 \times 10^{107}$; $W_{max} = 6.118 \times 10^5$ J]

86. Determine the potential for the cell:

$$\text{Pt} \mid \text{Fe}^{2}, \text{Fe}^{3+} \parallel \text{Cr}_2\text{O}_7^{2-}, \text{Cr}^{3+}, \text{H}^+ \mid \text{Pt}$$

in which $[\text{Fe}^{2+}]$ and $[\text{Fe}^{3+}]$ are $0.5M$ and $0.75M$ respectively and $[\text{Cr}_2\text{O}_7^{2-}]$, $[\text{Cr}^{3+}]$ and $[\text{H}^+]$ are $2M$, $4M$ and $1M$ respectively. Given:

$$\text{Fe}^{3+} + e^- \longrightarrow \text{Fe}^{2+}; \qquad E° = 0.770 \text{ volt}$$

$$14\text{H}^+ + 6e^- + \text{Cr}_2\text{O}_7^{2-} = 2\text{Cr}^{3+} + 7\text{H}_2\text{O}; \qquad E° = 1.35 \text{ volt}$$

[**Ans.** 0.56 volt]

87. For the measurement of the solubility product of AgCl the following cell is constructed:

$$\text{Ag} \mid \text{AgCl} \parallel \text{KCl}\ (0.1\ M) \parallel \text{AgNO}_3\ (0.1\ M) \mid \text{Ag}$$

The emf of the cell is 0.45 volt. In the cell, KCl is dissociated to the extent of 83% and AgNO_3 is dissociated to the extent of 86%. Calculate the solubility product of AgCl at 298 K.

[**Ans.** 1.735×10^{-10}]

[**Hint:** $E_{\text{cell}} = E°_{\text{cell}} - 0.0591 \log \dfrac{[\text{Ag}^+]_{\text{Anode}}}{[\text{Ag}^+]_{\text{Cathode}}}$]

88. Excess of AgCl is added to 0.1 M solution of KBr at 298 K. Calculate the equilibrium concentrations of Br^- and Cl^- ions.

$$E°_{\text{Cl}^-/\text{AgCl}/\text{Ag}} = 0.222 \text{ volt} \quad E°_{\text{Br}^-/\text{AgBr}/\text{Ag}} = 0.095 \text{ volt}$$

[**Ans.** $[\text{Cl}^-] = 0.09929 \text{ mol L}^{-1}$, $[\text{Br}^-] = 0.00071 \text{ mol L}^{-1}$]

[**Hint:** $\underset{}{\text{AgCl}} + \underset{(0.1-x)}{\text{Br}^-} \rightleftharpoons \text{AgBr} + \underset{x}{\text{Cl}^-}$

At equilibrium

Apply $\log K = \dfrac{E°_{\text{cell}}}{0.0591}$

or $\log \dfrac{x}{(0.1-x)} = \dfrac{E°_{\text{cell}}}{0.0591}$]

89. The emf of the cell $\text{Cu} \mid \underset{a\,=\,0.1}{\text{CuSO}_4} \parallel \underset{x}{\text{CuSO}_4} \mid \text{Cu}$ is -0.03 V at 25°C. Calculate the activity of copper sulphate solution in the right hand side electrode.

[**Ans.** $0.009616 \text{ mol L}^{-1}$]

[**Hint:** Apply $E = (E°_{\text{Cu}} - E°_{\text{Cu}}) - \dfrac{0.0591}{2} \log \dfrac{0.1}{x}$]

90. The cell, $\text{Pt} \mid \text{H}_2\ (1 \text{ atm}) \parallel \text{H}^+\ (\text{pH} = x) \mid$ normal calomel electrode, has an emf of 0.67 volt as 25°C. Calculate the pH of the solution. The oxidation potential of calomel electrode on the hydrogen scale is -0.28 volt.

[**Ans.** pH = 6.61]

91. The emf of the cell,

$$\text{Ag} \mid \text{AgI}, \text{KI}\ (0.05\ M) \parallel \text{AgNO}_3\ (0.05\ M) \mid \text{Ag}$$

is 0.788 volt. Calculate the solubility product of AgI.

[**Ans.** 1.101×10^{-16}]

92. The standard reduction potential for Cu^{2+}/Cu is + 0.34 V. Calculate the reduction potential at pH = 14 for the above couple. K_{sp} of Cu(OH)_2 is 1.0×10^{-19}.

[**Ans.** -0.22 V] **(IIT 1996)**

93. Calculate the potential of a cell in which H electrode is immersed in a solution of pH 3.5 and in a solution of pH 10.7.

[**Ans.** 0.4255 volt]

94. Calculate the emf of the cell,

$$\text{Cl}_2\ (1 \text{ atm}) \mid \text{NaCl}\ (aq.) \mid \text{Cl}_2\ (0.1 \text{ atm})$$

[**Ans.** -0.0295 volt]

95. The standard free energy change for the reaction,

$$\text{H}_2(g) + 2\text{AgCl}(s) \longrightarrow 2\text{Ag}(s) + 2\text{H}^+(aq.) + 2\text{Cl}^-(aq.)$$

is $-10.26 \text{ kcal mol}^{-1}$ at 25°C. A cell using the above reaction is operated at 25°C under $P_{\text{H}_2} = 1$ atm, $[\text{H}^+]$ and $[\text{Cl}^-] = 0.1$. Calculate the emf of the cell.

[**Ans.** 0.340 volt]

96. For the reaction, $\text{Fe}^{3+} + 3e^- \rightleftharpoons \text{Fe}$. $E°$ is -0.036 volt and the standard electrode potential for $\text{Fe}^{3+} + e^- \rightleftharpoons \text{Fe}^{2+}$ is 0.771 volt. Calculate the $E°$ for $\text{Fe}^{2+} + 2e^- \rightleftharpoons \text{Fe}$.

[**Ans.** -0.4395 volt]

97. The standard reduction potential at 25°C of the reaction $2\text{H}_2\text{O} + 2e^- \longrightarrow \text{H}_2 + 2\text{OH}^-$ is -0.8277 volt. Calculate the equilibrium constant for the reaction,

$$2\text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^- \text{ at } 25°\text{C}$$

[**Ans.** $\approx 10^{14}$]

[**Hint:**

$$\text{H}_2\text{O} + e^- \longrightarrow \tfrac{1}{2}\text{H}_2 + \text{OH}^- \text{ (Cathode)}; \quad E° = -0.8277 \text{ volt}$$

$$\text{H}_2\text{O} + \tfrac{1}{2}\text{H}_2 \longrightarrow \text{H}_3\text{O}^+ + e^- \quad \text{(Anode)}; \quad E° = 0$$

$E°$ for the cell = -0.8277 volt

Apply now $E° = \dfrac{0.0591}{n} [\log K]$ $(n = 1)$]

98. Calculate the emf of the following cell:

$$\text{Pt(H}_2\ 1 \text{ atm}) \mid \text{CH}_3\text{CH}_2\text{COOH}\ (0.15\ M) \parallel 0.01\ M\ \text{NH}_4\text{OH} \mid \text{H}_2\ (1 \text{ atm})\ \text{Pt}$$

K_a for $\text{CH}_3\text{CH}_2\text{COOH} = 1.4 \times 10^{-5}$

K_b for $\text{NH}_4\text{OH} = 1.8 \times 10^{-5}$

[**Ans.** -0.4603 volt]

[**Hint:** $[\text{H}^+]$ in $\text{CH}_3\text{CH}_2\text{COOH} = \sqrt{C \times K_a} = \sqrt{0.15 \times 1.4 \times 10^{-5}}$
$= 1.449 \times 10^{-3}$

$[\text{OH}^-]$ in $\text{NH}_4\text{OH} = \sqrt{C \times K_b} = \sqrt{0.01 \times 1.8 \times 10^{-5}} = 0.4242 \times 10^{-3}$

$$[\text{H}^+] \text{ in NH}_4\text{OH} = \frac{10^{-14}}{0.4242 \times 10^{-3}} = 2.3573 \times 10^{-11}$$

$$E_{\text{cell}} = 0.0591 \log \frac{[\text{H}^+]_{\text{RHS}}}{[\text{H}^+]_{\text{LHS}}}$$]

99. Calculate equilibrium constant for

$$\text{I}_2 + \text{I}^- \rightleftharpoons \text{I}_3^-$$

at 298 K from the following information:

$$\text{I}_2(aq.) + 2e^- \longrightarrow 2\text{I}^-; \qquad E° = 0.6197 \text{ volt}$$

$$\text{I}_3^- + 2e^- \longrightarrow 3\text{I}^-; \qquad E° = 0.5355 \text{ volt}$$

[**Ans.** 706.9]

[**Hint:**

$$\text{I}_2 + 2e^- \longrightarrow 2\text{I}^-; \qquad E° = 0.6197 \text{ volt}$$

$$3\text{I}^- \longrightarrow \text{I}_3^- + 2e^-; \quad E° = -0.5355 \text{ volt}$$

$$\text{I}_2 + \text{I}^- \rightleftharpoons \text{I}_3^-; \qquad E° = 0.6197 - 0.5355$$

$$= 0.0842 \text{ volt}$$

$$K = \text{antilog}\left[\frac{nE^\circ}{0.0591}\right] = \text{antilog}\left[\frac{2 \times 0.0842}{0.0591}\right] = 706.9]$$

100. A lead storage battery has initially 200 g of lead and 200 g of PbO_2, plus excess H_2SO_4. How long could this cell deliver a current of 10 amp, without recharging, if it was possible to operate it so that the reaction goes to completion?

[**Ans.** 4.48 hour]

101. $Zn(s) + 2AgCl(s) \rightleftharpoons ZnCl_2\ (0.555\ M) + 2Ag(s)$

$$E_{0^\circ C} = 1.015 \text{ volt} \left(\frac{dE}{dT}\right)_P = -4.02 \times 10^{-4} \text{ volt per degree.}$$

Find $\Delta G, \Delta S$.

[**Ans.** $\Delta G = -195.895$ kJ, $\Delta S = -18.55$ cal]

[**Hint:** We know that,

$$\Delta H = nF\left[T\left(\frac{dE}{dT}\right)_P - E\right]$$

$$= 2 \times 96500\,[-273 \times 4.02 \times 10^{-4} - 1.015]$$

$$= -217075.98 \text{ joule} = -217.075 \text{ kJ}$$

$$\Delta G = -nFE = -2 \times 96500 \times 1.015 = -195895 \text{ J}$$

$$= -195.895 \text{ kJ}$$

$$\Delta G = \Delta H - T\Delta S$$

$$-195.895 = -217.075 - 273 \times \Delta S$$

$$\Delta S = -0.07758 \text{ kJ} = -77.58 \text{ J} = -18.55 \text{ cal}]$$

102. Calculate the equilibrium constant for the reaction,

$$2Fe^{3+} + 3I^- \rightleftharpoons 2Fe^{2+} + I_3^-$$

The standard reduction potentials in acidic conditions are 0.77 and 0.54 V respectively for Fe^{3+}/Fe^{2+} and I_3^-/I^- couples. (IIT 1998)

[**Ans.** 6.26×10^7]

103. Electrolysis of a solution of $MnSO_4$ in aqueous sulphuric acid is a method for the preparation of MnO_2 as the per reaction,

$$Mn^{2+}(aq.) + 2H_2O \longrightarrow MnO_2 + 2H^+(aq.) + H_2$$

Passing a current of 27 A for 24 hours gives one kg of MnO_2. What is the value of current efficiency? Write the reactions taking place at the cathode and at the anode. [IIT (May) 1997]

[**Hint:** Apply $w = \dfrac{E \times i \times t}{96500}$

$$1000 = \frac{87 \times i \times 24 \times 60 \times 60}{2 \times 96500}$$

$$i = 25.6 \text{ ampere}$$

$$\text{Current efficiency} = \frac{25.6}{27.0} \times 100 = 94.8\%$$

Reactions:

Anode: $Mn^{2+} \longrightarrow Mn^{4+} + 2e^-$

Cathode: $2H^+ + 2e^- \longrightarrow H_2$]

104. Calculate the number of kWh of electricity is necessary to produce 1 metric ton (1000 kg) of aluminium by Hall process in a cell operating at 15 V.

[**Ans.** 4.47×10^4 kWh]

105. What will be the value of Λ for a 0.001 M aqueous NH_3 solution?

$K_b = 1.6 \times 10^{-5}$ and $\Lambda_0 = 2.38 \times 10^{-2}$ ohm^{-1} m^2 mol^{-1}

[**Ans.** 2.998×10^{-3} ohm^{-1} cm^2 mol^{-1}]

[**Hint:**

$$K_b = C\alpha^2$$

$$1.6 \times 10^{-5} = 0.001 \times \alpha^2$$

$$\alpha = 0.126$$

$$\alpha = \frac{\Lambda_m^c}{\Lambda_m^\infty};$$

(Λ_m^c = molar conductance at concentration 'c' and Λ_m^∞ = molar conductance at infinite dilution)

$$0.126 = \frac{\Lambda_m^c}{2.38 \times 10^{-2}}$$

$$\Lambda_m^c = 2.998 \times 10^{-3} \text{ ohm}^{-1} \text{ cm}^2 \text{ mol}^{-1}]$$

106. A weak monobasic acid is 5% dissociated in 0.01 mol dm^{-3} solution. The limiting molar conductivity at infinite dilution is 4.00×10^{-2} ohm^{-1} m^2 mol^{-1}. Calculate the conductivity of a 0.05 mol dm^{-3} solution of the acid.

[**Ans.** 8.92×10^{-4} ohm^{-1} cm^2 mol^{-1}]

[**Hint:** Dissociation constant of acid $K_a = C\alpha^2$

$$= 0.01 \times (0.05)^2$$

$$= 2.5 \times 10^{-5}$$

$$K_a = C\alpha^2$$

$$2.5 \times 10^{-5} = 0.05 \times \alpha^2$$

$$\alpha = 0.0223$$

We know that, $\alpha = \dfrac{\Lambda_m^c}{\Lambda_m^\infty}$

$$0.0223 = \frac{\Lambda_m^c}{4 \times 10^{-2}}$$

$$\Lambda_m^c = 8.92 \times 10^{-4} \text{ ohm}^{-1} \text{ cm}^2 \text{ mol}^{-1}]$$

107. 1.05 g of a lead ore containing impurity of Ag was dissolved in quantity of HNO_3 and the volume was made 350 mL. A Ag electrode was dipped in the solution and E_{cell} of,

$$Pt(H_2) \mid H^+(1\,M) \parallel Ag^+ \mid Ag$$

was 0.503 V at 298 K. Calculate % of lead in the ore.

$$E^\circ_{Ag^+/Ag} = 0.80 \text{ V}$$

[**Ans.** 0.0339%]

[**Hint:** Anode $\frac{1}{2}H_2(g) \longrightarrow H^+(1\,M) + e^-$

Cathode $Ag^+(x) + e^- \longrightarrow Ag(s)$

$$\frac{1}{2}H_2(g) + Ag^+(x) \rightleftharpoons Ag(s) + H^+(1\,M) \qquad (n = 1)$$

$$E^\circ = 0.80 - 0 = 0.80 \text{ volt}$$

$$Q = \frac{[H^+]}{[Ag^+]} = \frac{1}{x}$$

$$E = E^\circ - \frac{0.0591}{n}\log_{10} Q$$

$$0.503 = 0.80 - \frac{0.0591}{1}\log_{10}\left(\frac{1}{x}\right)$$

$$x = 9.43 \times 10^{-6}\ M$$

Number of moles of Ag^+ in 350 mL

$$= \frac{MV}{1000} = \frac{9.43 \times 10^{-6} \times 350}{1000}$$

$$= 3.3 \times 10^{-6}$$

$$\text{Mass of Ag} = 3.3 \times 10^{-6} \times 108 = 3.56 \times 10^{-4}\ \text{g}$$

$$\%\ \text{Ag in the ore} = \frac{3.56 \times 10^{-4}}{1.05} \times 100 = 0.0339\%]$$

108. Calculate E° of the following half-cell reaction at 298 K:

$$Ag(NH_3)_2^+ + e^- \longrightarrow Ag + 2NH_3$$

$$Ag^+ + e^- \longrightarrow Ag; \qquad E^\circ_{Ag^+/Ag} = 0.80\ V$$

$$Ag(NH_3)_2^+ \rightleftharpoons Ag^+ + 2NH_3; \qquad K = 6 \times 10^{-8}$$

[**Ans.** 0.373 volt]

[**Hint:** Anode $Ag(s) \longrightarrow Ag^+ + e^-$; $E^\circ = 0.80$ volt

Cathode $[Ag(NH_3)_2]^+ + e^- \longrightarrow Ag(s) + 2NH_3$; $E^\circ = v$ volt

$$\overline{Ag(s) + [Ag(NH_3)_2]^+ \rightleftharpoons Ag(s) + Ag^+ + 2NH_3}$$

$$Q = \frac{[Ag^+][NH_3]^2}{[Ag(NH_3)_2]^+} = 6 \times 10^{-8} \qquad (n = 1)$$

$$E^\circ_{\text{cell}} = (v - 0.80)$$

At equilibrium, $E = 0$

$$\therefore \quad E = E^\circ - \frac{0.0591}{n} \log Q$$

$$0 = (v - 0.80) - \frac{0.0591}{1} \log (6 \times 10^{-8})$$

$$v = 0.373\ \text{volt}]$$

OBJECTIVE QUESTIONS

Set-1: Questions with single correct answer

1. An electrolyte is a substance which:
(a) conducts electricity
(b) decomposes on heating
(c) is acidic in nature
(d) when dissolved in water, dissociates into ions

2. The theory of ionisation was presented by:
(a) Faraday (b) Arrhenius (c) Ostwald (d) Rutherford

3. Dissociation of an electrolyte in water into negative and positive ions is called:
(a) ionisation (b) electrolysis
(c) decomposition (d) hydrolysis

4. Degree of ionisation is equal to:
(a) total number of moles of the electrolyte present in solution
(b) total number of moles of the electrolyte dissociated into ions
(c) number of moles dissociated /total number of moles dissolved
(d) total number of moles dissolved/number of moles dissociated

5. Conductivity of aqueous solution of an electrolyte depends on:
(a) molecular mass of the electrolyte
(b) boiling point of solvent
(c) degree of ionisation
(d) volume of the solvent

6. Degree of ionisation does not depend on:
(a) nature of the solvent
(b) nature of the electrolyte
(c) dilution
(d) molecular mass of the electrolyte

7. Substances which give good conducting aqueous solution are called:
(a) weak electrolytes (b) strong electrolytes
(c) non-electrolytes (d) catalysts

8. The number of ions given by one molecule of $K_4Fe(CN)_6$ after complete dissociation is:
(a) 5 (b) 11 (c) 2 (d) 10

9. The amount of electricity required to produce one mole of copper from copper sulphate solution will be : **(VITEEE 2008)**
(a) 1 faraday (b) 2.33 faraday
(c) 2 faraday (d) 1.33 faraday

[**Hint :** $Cu^{2+} + 2e^- \longrightarrow Cu\ (s)$

1 mole copper requires 2 mole electron, *i.e.*, 2 faraday charge.]

10. The process in which chemical change occurs on passing electricity is termed:
(a) ionisation (b) neutralisation
(c) electrolysis (d) hydrolysis

11. Which of the following condition is correct for operation of electrolytic cell?
(a) $\Delta G = 0, E = 0$ (b) $\Delta G < 0, E > 0$
(c) $\Delta G > 0, E < 0$ (d) $\Delta G > 0, E > 0$

12. Which one is the correct equation that represents the first law of electrolysis?
(a) $mZ = ct$ (b) $m = cZt$ (c) $mc = Zt$ (d) $c = mZt$

13. When one coulomb of electricity is passed through an electrolytic solution, the mass deposited on the electrode is equal to:
(a) equivalent weight (b) molecular weight
(c) electrochemical equivalent (d) one gram

14. One faraday is equal to:
(a) 9650 coulomb (b) 10,000 coulomb
(c) 19640 coulomb (d) 96500 coulomb

15. When one faraday of electric current is passed, the mass deposited is equal to:
(a) one gram equivalent (b) one gram mole
(c) electrochemical equivalent (d) half gram equivalent

16. On passing one faraday of electricity through a dilute solution of an acid, the volume of hydrogen obtained at NTP is:
(a) 22400 mL (b) 1120 mL
(c) 2240 mL (d) 11200 mL

17. *w* g of copper is deposited in a copper voltameter when an electric current of 2 ampere is passed for 2 hours. If one ampere of electric current is passed for 4 hours in the same voltameter, copper deposited will be:
(a) w (b) $w/2$ (c) $w/4$ (d) $2w$

18. Copper sulphate solution is electrolysed between two platinum electrodes. A current is passed until 1.6 g of oxygen is liberated at anode. The amount of copper deposited at the cathode during the same period is:
(a) 6.36 g (b) 63.6 g (c) 12.7 g (d) 3.2 g

19. When electricity is passed through a solution of $AlCl_3$, 13.5 g of Al is discharged. The amount of charge passed is:
(a) 1.5 F (b) 0.5 F (c) 1.0 F (d) 2.0 F

20. When the same electric current is passed through the solution of different electrolytes in series, the amounts of elements deposited on the electrodes are in the ratio of their:
(a) atomic numbers (b) atomic masses
(c) specific gravities (d) equivalent masses

21. Faraday's laws of electrolysis are related to:
(a) atomic number of the cation
(b) atomic number of the anion
(c) equivalent mass of the electrolyte
(d) speed of the cation

22. The specific conductance of a 0.01 *M* solution of KCl is 0.0014 ohm^{-1} cm^{-1} at 25°C. Its equivalent conductance is:
(a) 14 (b) 140 (c) 1.4 (d) 0.14

23. The equivalent conductivity of 0.1 *N* CH_3COOH at 25°C is 80 and at infinite dilution 400 ohm^{-1}. The degree of dissociation of CH_3COOH is:
(a) 1 (b) 0.2 (c) 0.1 (d) 0.5

24. The number of electrons involved when one faraday of electricity is passed through an electrolytic solution is:
(a) 96500 (b) 8×10^{6} (c) 12×10^{16} (d) 6×10^{23}

25. One faraday of charge was passed through the electrolytic cells placed in series containing solutions of Ag^+, Ni^{2+} and Cr^{3+} respectively. The amount of Ag (At. mass 108), Ni (At. mass 59) and Cr (At. mass 52) deposited will be:

	Ag	Ni	Cr
(a)	108 g	29.5 g	17.5 g
(b)	108 g	59.0 g	52.0 g
(c)	108 g	108.0 g	108.0 g
(d)	108 g	117.5 g	166.0 g

26. One faraday of electricity will liberate one gram mole of the metal from the solution of:
(a) $BaCl_2$ (b) $CuSO_4$
(c) $AlCl_3$ (d) NaCl

27. Strong electrolytes are those which:
(a) dissolve readily in water
(b) conduct electricity
(c) dissociate into ions even at high concentration
(d) dissociate into ions at high dilution

28. The extent of ionisation increases:
(a) with increase in concentration of the electrolyte
(b) on decreasing temperature of solution
(c) on addition of excess of water
(d) on stirring the solution vigorously

29. Molten sodium chloride conducts electricity due to the presence of:
(a) free electrons (b) free ions
(c) free molecules (d) free atoms of Na and Cl

30. When NaCl is dissolved in water, the sodium ion is:
(a) oxidised (b) reduced
(c) hydrolysed (d) hydrated

31. A solution of sodium sulphate in water is electrolysed using platinum electrodes. The products at cathode and anode are respectively:
(a) H_2, O_2 (b) O_2, H_2
(c) O_2, Na (d) O_2, SO_2

32. The electric conduction of a salt solution in water depends on the:
(a) shape of molecules (b) size of its molecules
(c) size of solvent molecules (d) extent of its ionisation

33. In electroplating, the article to be electroplated serves as:
(a) cathode (b) electrolyte
(c) anode (d) conductor

34. The amount of electricity that can deposit 108 g of silver from silver nitrate solution is: **(AFMC 1993)**
(a) 1 ampere (b) 1 coulomb
(c) 1 faraday (d) 2 ampere

35. A certain current liberated 0.504 g of hydrogen in 2 hours. How many grams of copper can be liberated by the same current flowing for the same time in $CuSO_4$ solution?
(a) 12.7 g (b) 15.9 g (c) 31.8 g (d) 63.5 g

36. If the specific resistance of a solution of concentration *C* g equivalent $litre^{-1}$ is *R*, then its equivalent conductance is:
(a) $\frac{100R}{C}$ (b) $\frac{RC}{1000}$ (c) $\frac{1000}{RC}$ (d) $\frac{C}{1000R}$

37. If the specific conductance and conductance of a solution are same, then its cell constant is equal to:
(a) 1 (b) 0 (c) 10 (d) 100

38. On increasing the dilution, the specific conductance: **(Jiwaji 1990)**
(a) increases (b) decreases
(c) remains constant (d) none of these

39. The distance between two electrodes of a cell is 2.5 cm and area of each electrode is 5 cm^2. The cell constant is: **(Jabalpur 1990)**
(a) 2 (b) 12.5 (c) 7.5 (d) 0.5

40. At 25°C, the molar conductances at infinite dilution for the strong electrolytes NaOH, NaCl and $BaCl_2$ are 248×10^{-4}, 126×10^{-4} and 280×10^{-4} $Sm^2\ mol^{-1}$ respectively. $\Lambda^{\circ}_{m}Ba(OH)_2$ in $S\ m^2\ mol^{-1}$: **(EAMCET 2009)**
(a) 52.4×10^{-4} (b) 524×10^{-4}
(c) 402×10^{-4} (d) 262×10^{-4}

[**Hint :** $\Lambda^{\circ}_{m}Ba(OH)_2 = \Lambda^{\circ}_{m}BaCl_2 + 2\Lambda^{\circ}_{m}NaOH - 2\Lambda^{\circ}_{m}NaCl$
$= 280\times10^{-4} + 2\times248\times10^{-4} - 2\times126\times10^{-4}$
$= 524\times10^{-4} S\ m^2\ mol^{-1}$]

41. The electrochemical cell stops working after some time because : **(VITEEE 2008)**
(a) electrode potential of both the electrodes becomes zero
(b) electrode potential of both the electrodes becomes equal
(c) one of the electrodes is eaten away
(d) the cell reaction gets reversed

42. Which reaction will take place at cathode when fused calcium chloride is electrolysed?
(a) $Ca^{2+} + 2e^- \longrightarrow Ca$ (b) $Cl^- \longrightarrow Cl + e^-$
(c) $Ca^{2+} - 2e^- \longrightarrow Ca$ (d) $Cl^- - e^- \longrightarrow Cl$

43. In electrolysis oxidation takes place at:
(a) both the electrodes (b) cathode
(c) anode (d) in the solution

44. The equation representing the process by which standard reduction potential of zinc can be defined is:
(a) $Zn^{2+}(s) + 2e^- \longrightarrow Zn$
(b) $Zn(g) \longrightarrow Zn^{2+}(g) + 2e^-$
(c) $Zn^{2+}(g) + 2e^- \longrightarrow Zn$
(d) $Zn^{2+}(aq.) + 2e^- \longrightarrow Zn(s)$

45. The measured potential for,

$$Mg^{2+} + 2e^- \rightleftharpoons Mg(s)$$

does not depend upon:
(a) raising the temperature
(b) increasing the concentration of Mg^{2+} ions
(c) making the magnesium plate bigger
(d) purity of magnesium plate

46. All cells do not contain:
(a) an anode (b) a cathode
(c) ions (d) a porous partition

47. When lead accumulator is charged, it is:
(a) an electrolytic cell (b) a galvanic cell
(c) a Daniell cell (d) none of these

48. The standard electrode potentials for the reactions,

$$Ag^+(aq.) + e^- \longrightarrow Ag(s)$$
$$Sn^{2+}(aq.) + 2e^- \longrightarrow Sn(s)$$

at 25°C are 0.80 volt and – 0.14 volt respectively. The emf of the cell,

$$Sn \mid Sn^{2+}(1\,M) \parallel Ag^+(1\,M) \mid Ag$$

is:
(a) 0.66 volt (b) 0.80 volt (c) 1.08 volt (d) 0.94 volt

49. The cathodic reaction in electrolysis of dilute H_2SO_4 with platinum electrode is:
(a) oxidation
(b) reduction
(c) both oxidation and reduction
(d) neutralization

50. Strongest reducing agent is:
(a) K (b) Mg (c) Al (d) I

51. The metal oxide which decomposes on heating, is:
(a) ZnO (b) HgO (c) Al_2O_3 (d) CuO

52. The reaction, $\frac{1}{2}H_2(g) + AgCl(s) = H^+(aq.) + Cl^-(aq.) + Ag(s)$ occurs in the galvanic cell: **(AFMC 2009)**
(a) $Ag \mid AgCl(s) \mid KCl\ (soln.) \parallel AgNO_3\ (soln.) \mid Ag$
(b) $Pt \mid H_2(g) \mid HCl\ (soln.) \parallel AgNO_3\ (soln.) \mid Ag$
(c) $Pt \mid H_2(g) \mid HCl\ (soln.) \parallel AgCl(s) \mid Ag$
(d) $Pt \mid H_2(g) \mid KCl\ (soln.) \parallel AgCl(s) \mid Ag$

53. The standard oxidation potentials, E°, for the half reactions are as,

$$Zn \longrightarrow Zn^{2+} + 2e^-; \quad E^\circ = +0.76 \text{ volt}$$
$$Fe \longrightarrow Fe^{2+} + 2e^-; \quad E^\circ = +0.41 \text{ volt}$$

The emf of the cell, $Fe^{2+} + Zn \longrightarrow Zn^{2+} + Fe$ is:
[CET (Karnataka) 2009]
(a) + 0.35 volt (b) – 0.35 volt
(c) +1.17 volt (d) –1.17 volt

54. The standard reduction potentials at 25°C for the following half reactions are given against each;

$$Zn^{2+}(aq.) + 2e^- \rightleftharpoons Zn(s); \quad -0.762$$
$$Cr^{3+}(aq.) + 3e^- \rightleftharpoons Cr(s); \quad -0.740$$
$$2H^+ + 2e^- \rightleftharpoons H_2(g); \quad 0.00$$
$$Fe^{3+} + e^- \rightleftharpoons Fe^{2+}; \quad 0.77$$

Which is the strongest reducing agent? **(VITEEE 2007)**
(a) Zn (b) Cr
(c) $H_2(g)$ (d) $Fe^{2+}(aq.)$

55. Hydrogen gas will not reduce heated:
(a) cupric oxide (b) ferric oxide
(c) stannic oxide (d) aluminium oxide

56. A solution containing one mole per litre of each $Cu(NO_3)_2$; $AgNO_3$; $Hg_2(NO_3)_2$ and $Mg(NO_3)_2$ is being electrolysed by using inert electrodes. The values of standard electrode potentials (reduction potentials) are $Ag/Ag^+ = 0.80$ volt, $2Hg/H_2^{2+} = 0.79$ volt, $Cu/Cu^{2+} = +0.24$ volt, $Mg/Mg^{2+} = -2.37$ volt. With increasing voltage, the sequence of deposition of metals on the cathode will be:
[PMT (Kerala) 2004]
(a) Ag, Hg, Cu (b) Cu, Hg, Ag
(c) Ag, Hg, Cu, Mg (d) Mg, Cu, Hg, Ag

57. Four colourless salt solutions are placed in separate test tubes and a strip of copper is dipped in each. Which solution finally turns blue?
(a) $Pb(NO_3)_2$ (b) $AgNO_3$ (c) $Zn(NO_3)_2$ (d) $Cd(NO_3)_2$

58. Red hot carbon will remove oxygen from the oxide *XO* and *YO* but not from *ZO*. *Y* will remove oxygen from *XO*. Use this evidence to deduce the order of activity of the three metals *X*, *Y* and *Z* putting the most active first:
(a) *XYZ* (b) *ZYX* (c) *YXZ* (d) *ZXY*

59. Which of the following metals does not give the following reaction?

$$M + \text{Water} \longrightarrow \text{Oxide or hydroxide} + H_2$$

(a) Iron (b) Sodium (c) Mercury (d) Magnesium

60. Which is the best reducing agent?

(a) F^- (b) Cl^- (c) Br^- (d) I^-

61. If a spoon of copper metal is placed in a solution of ferrous sulphate:

(a) Cu will precipitate out
(b) iron will precipitate
(c) Cu and Fe will precipitate
(d) no reaction will take place

62. Among Na, Hg, S, Pt and graphite, which can be used as electrodes in electrolytic cells having aqueous solutions?

(a) Hg and Pt (b) Hg, Pt and graphite
(c) Na and S (d) Na, Hg and S

63. The most reactive metal among the following is:

(a) Al (b) Ni (c) Pb (d) Cu

64. Which of the following metals is most readily corroded in moist air?

(a) Copper (b) Iron
(c) Silver (d) Nickel

65. Which one will liberate Br_2 from KBr?

(a) HI (b) I_2 (c) Cl_2 (d) SO_2

66. Which one of the following is not the correct representation?

(a) E°_{cell} = Red. pot. of cathode + Oxid. pot. of anode
(b) E°_{cell} = Red. pot. of cathode − Oxid. pot. of anode
(c) E°_{cell} = Red. pot. of cathode − Red. pot. of anode
(d) E°_{cell} = Oxid. pot. of cathode + Oxid. pot. of anode

67. Which of the following represents the potential of silver wire dipped into 0.1 M $AgNO_3$ solution at 25°C ?

(a) $E^\circ_{red.}$ (b) $(E^\circ_{red.} + 0.059)$
(c) $(E^\circ_{oxid.} - 0.059)$ (d) $(E^\circ_{red.} - 0.059)$

68. If the solution of the $CuSO_4$ in which copper rod is immersed is diluted to 10 times, the electrode potential:

(a) increases by 0.030 volt (b) decreases by 0.030 volt
(c) increases by 0.059 volt (d) decreases by 0.0059 volt

69. A solution of Cu(II) sulphate is reacted with KCl and KI. In which case will the Cu^{2+} be reduced to Cu^+?

(a) In both the cases
(b) When reacted with KCl
(c) When reacted with KI
(d) In both the cases but in presence of H^+

70. From the electrochemical series, it can be concluded that:

(a) Zn^{2+} will liberate H_2 from 1 M HCl
(b) Ag metal reacts spontaneously with Zn^{2+}
(c) Zn metal will liberate H_2 from 1 M HCl
(d) Ag metal will liberate H_2 from 1 M HCl

71. The potential of a hydrogen electrode at pH = 1 is:

(a) 0.059 volt (b) 0 volt
(c) −0.059 volt (d) 0.59 volt

72. Which is not true for a standard hydrogen electrode?

(a) The hydrogen ion concentration is 1 M
(b) Temperature is 25°C
(c) Pressure of hydrogen is 1 atmosphere
(d) It contains a metallic conductor which does not absorb hydrogen

73. The electrode potential becomes equal to standard electrode potential when reactants and products ratio is:

(a) equal to 1 (b) greater than 1
(c) less than 1 (d) none of these

74. For the half-cell reaction,

$$Au^{3+} + 3e^- \longrightarrow Au$$

the value of n used in Nernst equation is:

(a) 3 (b) 2 (c) 1 (d) 3 × 96500

75. When a piece of sodium metal is dropped in water, a reaction takes place to yield hydrogen because:

(a) sodium loses electrons
(b) sodium acts as an oxidising agent
(c) water loses electrons
(d) water acts as a reducing agent

76. Which one is the wrong statement about electrochemical series?

(a) Active metals have negative reduction potentials
(b) Active non-metals have positive reduction potentials
(c) Metals above hydrogen liberate hydrogen from acids
(d) Metals below hydrogen are strong reducing agents

77. The reduction potential values are given below:

$Al^{3+}/Al = -1.67$ volt, $Mg^{2+}/Mg = -2.34$ volt,
$Cu^{2+}/Cu = +0.34$ volt, $I_2/2I^- = +0.53$ volt.

Which one is the best reducing agent?

(a) Al (b) Mg
(c) Cu (d) I_2

78. From the values given in question No. 77, which one is the best oxidising agent?

(a) Al (b) Mg (c) I_2 (d) Cu

79. When iron is rusted, it is:

(a) reduced (b) oxidised
(c) evaporated (d) decomposed

80. Galvanization of iron denotes coating with:

(a) Cu (b) Sn (c) Zn (d) Al

81. The standard electrode potentials of four elements A, B, C and D are −3.05, 1.66, −0.40 and 0.80 volt. The highest chemical activity will be shown by:

(a) A (b) B (c) C (d) D

82. Which of the following methods does not liberate hydrogen?

(a) Zn + H_2SO_4 (dil.) (b) Mg + H_2SO_4 (dil.)
(c) Cu + H_2SO_4 (dil.) (d) Zn + HCl (dil.)

83. A depolarizer used in dry cell is:

(a) ammonium chloride (b) manganese dioxide
(c) potassium oxide (d) sodium phosphate

84. The oxide which can be reduced by hydrogen is:

(a) Na_2O (b) CaO (c) K_2O (d) CuO

85. The reference electrode is made from which of the following?

(a) $ZnCl_2$ (b) $CuSO_4$ (c) Hg_2Cl_2 (d) $HgCl_2$

86. Given, standard electrode potentials;

$$Fe^{3+} + 3e^- \longrightarrow Fe; \qquad E° = -0.036 \text{ volt}$$

$$Fe^{2+} + 2e^- \longrightarrow Fe; \qquad E° = -0.440 \text{ volt}$$

The standard electrode potential $E°$ for $Fe^{3+} + e^- \longrightarrow Fe^{2+}$ is: **[AMU (Medical) 2007; AIEEE 2009]**

(a) − 0.476 volt (b) − 0.404 volt

(c) 0.440 volt (d) − 0.772 volt

[**Hint:** Apply $\Delta G = -nFE$

$Fe^{2+} + 2e^- \longrightarrow Fe \ \Delta G = -2 \times F \times (-0.440 \text{ V}) = 0.88F$ ...(i)

$Fe^{3+} + 3e^- \longrightarrow Fe \ \Delta G = -3 \times F \times (-0.036) = 0.108F$ ...(ii)

Subtracting eq. (i) from eq. (ii),

$$Fe^{3+} + e^- \longrightarrow Fe^{2+}; \qquad \Delta G = 0.108F - 0.880F$$
$$= -0.772F$$

$$E° \text{ for the reaction} = -\frac{\Delta G}{nF} = -\frac{(-0.772F)}{1 \times F} = 0.772 \text{ volt}]$$

87. K, Ca and Li metals may be arranged in the decreasing order of their standard electrode potentials as:

(a) K, Ca and Li (b) Li, K and Ca

(c) Li, Ca and K (d) Ca, Li and K

88. In a galvanic cell energy changes occur like:

(a) chemical energy ⟶ electrical energy

(b) electrical energy ⟶ chemical energy

(c) chemical energy ⟶ internal energy

(d) internal energy ⟶ electrical energy

89. The reaction is spontaneous if the cell potential is:

(a) positive (b) negative

(c) zero (d) infinite

90. Is the reaction, $2Al + 3Fe^{2+} \rightleftharpoons 2Al^{3+} + 2Fe$ possible?

(a) No, because standard oxidation potential of Al < Fe

(b) Yes, because standard oxidation potential of Al > Fe

(c) Cannot be predicted

(d) Yes, because aluminium is a strong oxidising agent

91. In an experimental set-up for the measurement of emf of a half-cell using a reference electrode and a salt bridge, when the salt bridge is removed, the voltage:

(a) does not change (b) increases to maximum

(c) decreases half the value (d) drops to zero

92. More electronegative elements have:

(a) negative reduction potential

(b) tendency to lose electrons

(c) positive reduction potential

(d) positive oxidation potential

93. Which metal will be deposited in the galvanic cell?

$$Cu \mid Cu^{2+} \parallel Ag^+ \mid Ag$$

(a) Cu (b) Ag

(c) Both (d) None of these

94. In the cell $Zn \mid Zn^{2+} \parallel Cu^{2+} \mid Cu$, the negative electrode is:

(a) Cu (b) Cu^{2+} (c) Zn (d) Zn^{2+}

95. Which of the following gains electrons more easily?

(a) Na^+ (b) Zn^{2+}

(c) Al^{3+} (d) H^+

96. The potential of a hydrogen electrode at pH 10 is:

(a) 0.51 volt (b) 0 volt

(c) − 0.591 volt (d) 0.059 volt

97. The emf of the cell,

$$Ni \mid Ni^{2+} (1.0\,M) \parallel Ag^+ (1.0\,M) \mid Ag$$

($E°$ for $Ni^{2+}/Ni = -0.25$ volt, $E°$ for $Ag^+/Ag = 0.80$ volt) is given by:

(a) $-0.25 + 0.80 = 0.55$ volt

(b) $-0.25 - (+0.80) = -1.05$ volt

(c) $0 + 0.80 - (-0.25) = +1.05$ volt

(d) $-0.80 - (-0.25) = -0.55$ volt

98. The reaction for the cell,

$$Zn \mid Zn^{2+} (1.0\,M) \parallel Cd^{2+} (1.0\,M) \mid Cd$$

is:

(a) $Cd \longrightarrow Cd^{2+} + 2e^-$

(b) $Zn^{2+} \longrightarrow Zn - 2e^-$

(c) $Cd + Zn^{2+} \longrightarrow Cd^{2+} + Zn$

(d) $Zn + Cd^{2+} \longrightarrow Cd + Zn^{2+}$

99. The position of some metals in the electrochemical series in decreasing electropositive character is given as Mg > Al > Zn > Cu > Ag. What will happen if a copper spoon is used to stir a solution of aluminium nitrate?

(a) The spoon will get coated with aluminium

(b) An alloy of aluminium and copper is formed

(c) The solution becomes blue

(d) There is no reaction

100. The half-cell reaction is the one that:

(a) takes place at one electrode

(b) consumes half a unit of electricity

(c) involves half a mole of electrolyte

(d) goes half way to completion

Which Nernst equation is true to find out the potential of non-standard electrochemical cell from the following ?

$$Fe(s) \mid Fe^{2+} (xM) \parallel I^- (aq.) \mid I_2(s)\ (Pt)$$

[CET (Gujarat) 2008]

(a) $E_{cell} = E^\circ_{cell} - \frac{0.592}{n} \log_{10} [Fe^{2+}][I^-]^2$

(b) $E_{cell} = E^\circ_{cell} - \frac{0.0592}{n} \log_{10} [Fe^{2+}][I^-]^2$

(c) $E_{cell} = E^\circ_{cell} - \frac{0.0592}{n} \log_{10} [Fe^{2+}][I^-]$

(d) $E_{cell} = E^\circ_{cell} - \frac{0.0592}{nF} \log_{10} \frac{[Fe^{2+}][I^-]^2}{[Fe][I_2]}$

102. During the electrolysis of fused NaCl, which reaction occurs at anode?

(a) Chloride ions are oxidised

(b) Sodium ions are oxidised

(c) Chloride ions are reduced

(d) Sodium ions are reduced

103. $E°(Ni^{2+}/Ni) = -0.25$ volt, $E°(Au^{3+}/Au) = 1.50$ volt. The emf of the voltaic cell,

$$Ni \mid Ni^{2+}\ (1.0\ M) \parallel Au^{3+}\ (1.0\ M) \mid Au$$

is:

(a) 1.25 volt (b) −1.75 volt (c) 1.75 volt (d) 4.0 volt

104. Which of the following does not occur at cathode?

(a) $Ag^+ \longrightarrow Ag - e^-$ (b) $Fe^{2+} \longrightarrow Fe^{3+} + e^-$

(c) $Cu^{2+} + 2e^- \longrightarrow Cu$ (d) $2H^+ \longrightarrow H_2 - 2e^-$

105. The strong oxidising agent has:

(a) high value of reduction potential

(b) high value of oxidation potential

(c) low value of reduction potential

(d) high tendency to lose electrons

106. The passage of electricity in the Daniell cell when Zn and Cu electrodes are connected is from:

(a) Cu to Zn in the cell

(b) Cu to Zn outside the cell

(c) Zn to Cu outside the cell

(d) Zn to Cu in the cell

107. Which of the following can be used as an electrode?

(a) A glass rod (b) A wooden stick

(c) A nail (d) A soda straw

108. H^+ ions are reduced at platinum electrode prior to:

(a) Zn^{2+} (b) Cu^{2+} (c) Ag^+ (d) I_2

109. Which of the following statements is wrong?

(a) F_2 is the strongest oxidising agent as its reduction potential is high

(b) Li is the weakest reducing agent as its reduction potential is low

(c) Li is the strongest reducing agent as its oxidation potential is high

(d) F^- ion does not show reducing property

110. Out of Cu, Ag, Fe and Zn, the metal which can displace all others from their salt solution is:

(a) Ag (b) Cu (c) Fe (d) Zn

111. When the electric current is passed through a cell having an electrolyte, the positive ions move towards cathode and negative ions towards the anode. If the cathode is pulled out of the solution:

(a) the positive and negative ions will move towards anode

(b) the positive ions will start moving towards the anode while negative ions will stop moving

(c) the negative ions will continue to move towards anode while positive ions will stop moving

(d) the positive and negative ions will start moving randomly

112. The oxidation potentials of Zn, Cu, Ag, H_2 and Ni are 0.76, − 0.34, − 0.80, 0 and 0.25 volt respectively. Which of the following reactions will provide maximum voltage? **[PET (Kerala) 2007]**

(a) $Zn + Cu^{2+} \longrightarrow Cu + Zn^{2+}$

(b) $Zn + 2Ag^+ \longrightarrow 2Ag + Zn^{2+}$

(c) $H_2 + Cu^{2+} \longrightarrow 2H^+ + Cu$

(d) $H_2 + Ni^{2+} \longrightarrow 2H^+ + Ni$

(e) $Zn(s) + 2H^+(aq.) \rightleftharpoons Zn^{2+}(aq.) + H_2(g)$

113. Which one of the following will increase the voltage of the cell?

$$Sn + 2Ag^+ \longrightarrow Sn^{2+} + 2Ag$$

(a) Increase in the size of silver rod

(b) Increase in the concentration of Sn^{2+} ions

(c) Increase in the concentration of Ag^+ ions

(d) None of the above

114. A chemist wants to produce $Cl_2(g)$ from molten NaCl. How many grams could be produced if he uses a steady current of 2 ampere for 2.5 minutes?

(a) 3.55 g (b) 1.775 g (c) 0.110 g (d) 0.1775 g

115. In the electrolysis of $CuCl_2$ solution, the mass of cathode increased by 6.4 g. What occurred at copper anode?

(a) 0.224 litre of Cl_2 was liberated

(b) 1.12 litre of oxygen was liberated

(c) 0.05 mole Cu^{2+} passed into the solution

(d) 0.1 mole Cu^{2+} passed into the solution

116. Consider the reaction,

$$Cl_2(g) + 2Br^-(aq.) \longrightarrow 2Cl^-(aq.) + Br_2$$

The emf of the cell, when $[Cl^-] = [Br_2] = [Br^-] = 0.01\ M$ and Cl_2 gas is at 1 atm pressure, will be: (E° for the above reaction is 0.29 volt)

(a) 0.54 volt (b) 0.35 volt (c) 0.24 volt (d) − 0.29 volt

117. If λ°_c, λ°_a and λ° refer to equivalent conductance of a cation, an anion and equivalent conductance of the salt at infinite dilution, then according to Kohlrausch's law:

(a) $\lambda^\circ = \lambda^\circ_c + \lambda^\circ_a$ (b) $\lambda^\circ = \lambda^\circ_c - \lambda^\circ_a$

(c) $\lambda^\circ = \lambda^\circ_a - \lambda^\circ_c$ (d) $\lambda^\circ = \lambda^\circ_c / \lambda^\circ_a$

118. How much silver will be obtained by that quantity of current which displaces 5.6 litre of H_2? **[PMT (Pb.) 1993]**

(a) 54 g (b) 13.5 g (c) 20 g (d) 108 g

119. The specific conductance of a salt of 0.01 M concentration is 1.061×10^{-4}. Molar conductance of the same solution will be: **[PMT (Pb.) 1993]**

(a) 1.061×10^{-4} (b) 1.061 (c) 10.61 (d) 106.1

120. What is the number of coulombs required for the conversion of one mole of MnO_4^- to one mole of Mn^{2+}? **[MBBS (Orissa) 1993]**

(a) 5 × 96500 (b) 3 × 96500 (c) 96500 (d) 9650

121. Which of the following solutions of NaCl will have the highest specific conductance?

(a) 0.001 N (b) 0.1 N (c) 0.01 N (d) 1.0 N

122. The equivalent conductance of a 1 N solution of an electrolyte is nearly:

(a) 10^3 times its specific conductance

(b) 10^{-3} times its specific conductance

(c) 100 times its specific conductance

(d) the same as its specific conductance

123. Zinc is coated over iron to prevent rusting of iron because:

(a) it is cheaper than iron (b) $E^\circ_{(Zn^{2+}/Zn)} = E^\circ_{(Fe^{2+}/Fe)}$

(c) $E^\circ_{(Zn^{2+}/Zn)} < E^\circ_{(Fe^{2+}/Fe)}$ (d) $E^\circ_{(Zn^{2+}/Zn)} > E^\circ_{(Fe^{2+}/Fe)}$

124. Free energy change (ΔG) is related to the emf of the cell (E)

(a) $E = -nF\,\Delta G$ (b) $\Delta G = -nFE$

(c) $\Delta G = -\frac{RT}{n} F \log E$ (d) $\Delta G = -\frac{nF}{RT} \log E$

125. The standard reduction potentials at 25°C of Li^+/Li, Ba^{2+}/Ba, Na^+/Na and Mg^{2+}/Mg are – 3.05, – 2.73, – 2.71 and – 2.37 volt respectively. Which one of the following is the strongest oxidising agent?

(a) Na^+ (b) Li^+

(c) Ba^{2+} (d) Mg^{2+}

126. Three faradays of electricity was passed through an aqueous solution of iron(II) bromide. The mass of iron metal (At. mass 56) deposited at the cathode is: **(EAMCET 1991)**

(a) 56 g (b) 84 g (c) 112 g (d) 168 g

127. The standard electrode potentials of Zn, Ag and Cu are – 0.76, 0.80 and 0.34 volt respectively; then:

(a) Ag can oxidise Zn and Cu

(b) Ag can reduce Zn^{2+} and Cu^{2+}

(c) Zn can reduce Ag^+ and Cu^{2+}

(d) Cu can oxidise Zn and Ag

128. The standard emf for the cell reaction,

$$Zn + Cu^{2+} \longrightarrow Zn^{2+} + Cu$$

is 1.10 volt at 25°C. The emf for the cell reaction when 0.1 M Cu^{2+} and 0.1 M Zn^{2+} solutions are used at 25°C is: **(MLNR 1994)**

(a) 1.10 volt (b) 0.110 volt

(c) – 1.10 volt (d) – 0.110 volt

129. Three mole of electrons are passed through three solutions in succession containing $AgNO_3$, $CuSO_4$ and $AuCl_3$ respectively. The ratio of amounts of cations reduced at cathode will be:

(a) 1 : 2 : 3 (b) 2 : 1 : 3

(c) 3 : 2 : 1 (d) 6 : 3 : 2

130. In the electrolysis of an aqueous solution of NaOH, 2.8 litre of oxygen gas at NTP was liberated at anode. How much of hydrogen gas was liberated at cathode?

(a) 2.8 litre (b) 5.6 litre

(c) 11.2 litre (d) 22.4 litre

131. Two half-cells have potentials – 0.44 and 0.799 volt respectively. These two are coupled to make a galvanic cell. Which of the following will be true?

(a) Electrode of half-cell potential – 0.44 V will act as anode

(b) Electrode of half-cell potential – 0.44 V will act as cathode

(c) Electrode of half-cell potential 0.799 V will act as anode

(d) Electrode of half-cell potential – 0.44 V will act as a positive terminal

132. When a lead storage battery is charged:

(a) PbO_2 dissolves

(b) the lead electrode becomes coated with lead sulphate

(c) sulphuric acid is regenerated

(d) the amount of acid decreases

133. An example of a simple fuel cell is:

(a) lead storage battery (b) $H_2 — O_2$ cell

(c) Daniell cell (d) Lechlanche cell

134. For the cell reaction,

$$Mg(s) + 2Ag^+(aq.) \rightleftharpoons Mg^{2+}(aq.) + 2Ag(s).$$

E°_{cell} is +3.17 V at 298 K. The value of E_{cell}, ΔG° and Q at Ag^+ and Mg^{2+} concentrations of 0.001 M and 0.02 M respectively are: **(ISAT 2010)**

(a) 3.04 V, –605.8 kJ mol^{-1}, 20000

(b) 3.04 V, 611.8 kJ mol^{-1}, 20000

(c) 3.13 V, –604 kJ mol^{-1}, 20

(d) 3.04 V, –611.8 kJ, 20000

[**Hint:** $E^\circ = +3.17$ V, $n = 2$

$$Q = \frac{[Mg^{2+}]}{[Ag^+]^2} = \frac{0.02}{[0.001]^2} = 20000$$

$$\Delta G^\circ = -nFE^\circ$$
$$= -2 \times 96500 \times 3.17$$
$$= -611.8 \text{ kJ}$$
$$E = E^\circ - \frac{0.059}{n} \log_{10} Q$$
$$= 3.17 - \frac{0.059}{2} \log(20000)$$
$$= +3.04 \text{ V}]$$

135. Which of the following statements is correct?

(a) The temperature coefficient of electrolytic conductance is positive

(b) The temperature coefficient of electrolytic resistance is negative

(c) The resistance of an electrolyte decreases with decreasing temperature

(d) The resistance of electrolytic conductors is independent of temperature

136. Kohlrausch's law states that at: **[CBSE (PMT) 2008]**

(a) infinite dilution, each ion makes definite contribution to conductance of an electrolyte, whatever be the nature of the other ion of the electrolyte

(b) infinite dilution, each ion makes definite contribution to the equivalent conductance of an electrolyte, whatever be the nature of the other ion of the electrolyte

(c) finite dilution, each ion makes definite contribution to the equivalent conductance of an electrolyte, whatever be the nature of the other ion of the electrolyte

(d) infinite dilution, each ion makes definite contribution to equivalent conductance of an electrolyte depending on the nature of the other ion of the electrolyte

137. Which one of the following conditions will increase the voltage of the cell represented by the equation?

$Cu(s) + 2Ag^+(aq.) \rightleftharpoons Cu^{2+}(aq.) + 2Ag(s)$ **(KCET 2006)**

(a) Increase in the dimension of Cu electrode

(b) Increase in the dimension of Ag electrode

(c) Increase in the concentration of Cu^{2+} ion

(d) Increase in the concentration of Ag^+ ion

[**Hint:** Cell voltage will increase, either by increasing the concentration of Cu^{2+} ion or by decreasing the concentration of Ag^+.

$$Q = \frac{[Cu^{2+}]}{[Ag^+]}$$

Lesser is the value of Q, greater is the cell voltage.]

138. Which of the following reactions occurs at cathode during charging of storage battery? **(MGIMS 2007)**

(a) $Pb^{2+} + 2e^- \longrightarrow Pb$

(b) $Pb \longrightarrow Pb^{2+} + 2e^-$

(c) $Pb^{2+} + SO_4^{2-} \longrightarrow PbSO_4$

(d) $PbSO_4 + 2H_2O \longrightarrow PbO_2 + 4H^+ + SO_2^{2-} + 2e^-$

139. The amount of silver deposited on passing 2F of electricity through aqueous solution of $AgNO_3$ is: **(MHT-CET 2007)**

(a) 54 g (b) 108 g (c) 216 g (d) 324 g

140. Statements:

(i) Unit of specific conductivity is $ohm^{-1}\ cm^{-1}$.

(ii) Specific conductivity of strong electrolytes decreases on dilution.

(iii) The amount of an ion discharged during electrolysis does not depend upon resistance.

(iv) The unit of electrochemical equivalence is g/coulomb.

(a) All are correct

(b) All are wrong

(c) Only (i), (ii) and (iv) are correct

(d) Only (ii), (iii) and (iv) are correct

141. Which among the following expressions is/are not correct?

(a) $\mu^\infty = \gamma_+ \lambda_+^\infty + \gamma_- \lambda_-^\infty$

(b) $\lambda^\infty = \frac{1}{n^+}\lambda_+^\infty + \frac{1}{n_-}\lambda_-^\infty$

(c) $\lambda_{cation}^\infty = \mu_{cation}^\infty \times$ faraday

(d) $\lambda_{anion}^\infty = \mu_{cation}^\infty \times$ faraday

142. For the electrochemical cell, $M\,|\,M^+\,||\,X^-\,|\,X$, $E^\circ_{M^+/M} = 0.44$ V and $E^\circ_{X/X^-} = 0.33$ V. From this data we can deduce that: **[IIT (Screening) 2000]**

(a) $M + X \longrightarrow M^+ + X^-$ is the spontaneous reaction

(b) $M^+ + X^- \longrightarrow M + X$ is the spontaneous reaction

(c) $E_{cell} = 0.77$ V

(d) $E_{cell} = -0.77$ V

143. For the cell reaction,

$$\underset{(C_1)}{Cu^{2+}(aq.)} + Zn(s) \longrightarrow \underset{(C_2)}{Zn^{2+}(aq.)} + Cu(s)$$

the change in free energy (ΔG) at a given temperature is a function of: **(CBSE 1998)**

(a) $\ln C_1$ (b) $\ln\left(\frac{C_2}{C_1}\right)$

(c) $\ln(C_1 + C_2)$ (d) $\ln C_2$

144. The standard reduction potential values of three metallic cations X, Y and Z are 0.52, –3.03 and –1.18 V respectively. The order of reducing powers of the corresponding metals is: **(IIT 1998)**

(a) $Y > Z > X$ (b) $X > Y > Z$

(c) $Z > Y > X$ (d) $Z > X > Y$

145. A gas 'X' at 1 atm is bubbled through a solution containing a mixture of 1 $M\ Y^-$ and 1 $M\ Z^-$ at 25°C. If the reduction potential of $Z > Y > X$, then: **(IIT 1999)**

(a) Y will oxidise X and not Z

(b) Y will oxidise Z and not X

(c) Y will oxidise both Z and X

(d) Y will reduce both X and Z

146. The number of coulombs required for the deposition of 107.87 g of silver is: **[PMT (MP) 1998]**

(a) 48250 (b) 10000 (c) 96500 (d) 19300

147. At 25°C, the standard emf of a cell having reaction involving two electrons change is found to be 0.295 V. The equilibrium constant of the reaction is: **(IIT 1999)**

(a) 29.5×10^{-2} (b) 10

(c) 1×10^{10} (d) 29.5×10^{10}

148. The emf of the cell in which the following reaction,

$$Zn(s) + Ni^{2+}\ (0.1\ M) \longrightarrow Zn^{2+}\ (1.0\ M) + Ni(s)$$

occurs, is found to 0.5105 V at 298 K. The standard emf of the cell is: **(IIT 1998)**

(a) 0.4810 V (b) 0.5696 V

(c) – 0.5105 V (d) 0.5400 V

[Hint: $E_{cell} = E^\circ_{cell} - \frac{0.059}{2}\log\frac{1}{0.1}$]

149. The molar conductances of NaCl, HCl and CH_3COONa at infinite dilution are 126.45, 426.16 and 91 $ohm^{-1}\ cm^2\ mol^{-1}$ respectively. The molar conductance of CH_3COOH at infinite dilution is: **[CBSE 1997; DCE 2009]**

(a) 201.28 $ohm^{-1}\ cm^2\ mol^{-1}$ (b) 390.71 $ohm^{-1}\ cm^2\ mol^{-1}$

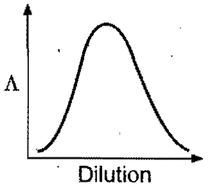
(c) 698.28 $ohm^{-1}\ cm^2\ mol^{-1}$ (d) 540.48 $ohm^{-1}\ cm^2\ mol^{-1}$

150. The specific conductance of a 0.1 N KCl solution at 23°C is 0.0112 $ohm^{-1}\ cm^{-1}$. The resistance of the cell containing the solution at the same temperature was found to be 55 ohm. The cell constant will be: **(CBSE 1999)**

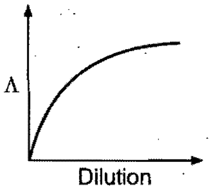
(a) 0.142 cm^{-1} (b) 0.918 cm^{-1}

(c) 1.12 cm^{-1} (d) 0.616 cm^{-1}

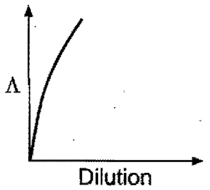
151. Which of the following plots represents correctly variation of equivalent conductance (Λ) with dilution for a strong electrolyte?



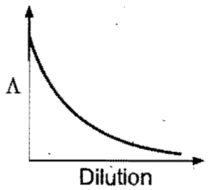
(a)



(b)



(c)



(d)

152. The standard reduction potential for Cu^{2+}/Cu and Cu^{2+}/Cu^{+} are 0.337 V and 0.153 V respectively. The standard electrode potential of Cu^{+}/Cu half cell is: **[AMU (PMT) 2009; CBSE (PMT) 2009]**

(a) 0.184 V (b) 0.827 V
(c) 0.521 V (d) 0.490 V

153. Solubility of a sparingly soluble salt S, specific conductance κ and the equivalent conductance Λ_0 are related as: **[IAS (Pre.) 1997]**

(a) $S = \frac{1000}{\kappa}\Lambda_0$ (b) $S = \kappa\Lambda_0$
(c) $S = \frac{\kappa}{1000\Lambda_0}$ (d) $S = \frac{1000\kappa}{\Lambda_0}$

154. $2Ag^{+}(aq.) + Cu(s) \rightleftharpoons Cu^{2+}(aq.) + 2Ag(s)$
($E^{\circ}_{cell} = +0.46$ V)
Which change will increase potential the most?

(a) Doubling the $[Ag^{+}]$
(b) Halving the $[Cu^{2+}]$
(c) Doubling the size of Cu electrode
(d) Halving the size of Ag electrode

155. As a lead storage battery is charged: **[PMT (MP) 1993, 2000]**

(a) lead dioxide dissolves
(b) sulphuric acid is regenerated
(c) lead electrode becomes coated with lead sulphate
(d) the concentration of sulphuric acid decreases

156. In the electrochemical reaction,

$$2Fe^{3+} + Zn \longrightarrow Zn^{2+} + 2Fe^{2+}$$

increasing the concentration of Fe^{2+}: **[CEE (Kerala) 2000]**

(a) increases the cell emf
(b) increases the current flow
(c) decreases the cell emf
(d) alters the pH of the solution

157. In the cell reaction,

$$Cu(s) + 2Ag^{+}(aq.) \longrightarrow Cu^{2+}(aq.) + 2Ag(s).$$

$E^{\circ}_{cell} = 0.46$ V. By doubling the concentration of Cu^{2+}, E°_{cell} is: **[MEE (Kerala) 2000]**

(a) doubled
(b) halved
(c) increased but less than double
(d) decreased by a small fraction

158. The conductivity of 0.01 mol/dm^3 aqueous acetic acid at 300 K is 19.5×10^{-5} ohm^{-1} cm^{-1} and the limiting molar conductivity of acetic acid at the same temperature is 390 ohm^{-1} cm^2 mol^{-1}. The degree of dissociation of acetic acid is: **[IAS (Pre.) 1995]**

(a) 0.5 (b) 0.05 (c) 5×10^{-3} (d) 5×10^{-7}

159. The ionization constant of a weak electrolyte is 25×10^{-6} while the equivalent conductance of its 0.01 M solution is 19.6 s cm^2 eq^{-1}. The equivalent conductance of the electrolyte at infinite dilution (in s cm^2 eq^{-1}) will be: **[IAS (Pre.) 1998]**

(a) 250 (b) 196
(c) 392 (d) 384

160. What is the amount of chlorine evolved when 2 ampere of current is passed for 30 minutes in an aqueous solution of NaCl? **(BHU 1998; AIIMS 1999)**

(a) 66 g (b) 1.32 g
(c) 33 g (d) 99 g

161. When 9.65 coulomb of electricity is passed through a solution of silver nitrate (Atomic mass of Ag = 108 g mol^{-1}), the amount of silver deposited is: **(KCET 2000)**

(a) 16.2 mg (b) 21.2 mg
(c) 10.8 mg (d) 6.4 mg

162. The quantity of electricity needed to deposit 127.08 g of copper is: **[CET (Pb.) 2000; PET (MP) 2004]**

(a) 1 faraday (b) 4 coulomb
(c) 4 faraday (d) 1 ampere

163. The charge required to deposit 9 g of Al from Al^{3+} solution is (At. wt. of Al = 27.0): **[MEE (Kerala) 2000]**

(a) 3216.3 C (b) 96500 C (c) 9650 C (d) 32163 C

164. The emf of the cell $Ni|Ni^{2+}(1.0\,M)\,||\,Au^{3+}(1.0\,M)|Au$ is (E° for $Ni^{2+}|Ni = -0.25$ V; E° for $Au^{3+}|Au = 1.5$ V): **[CET (Pb.) 2000; PMT (MP) 20[illegible]]**

(a) +1.25 V (b) +1.75 V (c) −1.25 V (d) −1.75 V

165. For the reduction of silver ions with copper metal, the standard cell potential was found to be +0.46 V at 25°C. The value of standard Gibbs energy, ΔG° will be :
($F = 96500$ C mol^{-1}) **(AIPMT 2010)**

(a) −89 kJ (b) −89 J
(c) −44.5 kJ (d) −98 kJ

166. In electrolysis of NaCl when Pt electrode is taken then H_2 is liberated at cathode while with Hg cathode it forms sodium amalgam: **[CBSE (PMT) 2002]**

(a) Hg is more inert than Pt
(b) more voltage is required to reduce H^{+} at Hg than at Pt
(c) Na is dissolved in Hg while it does not dissolve in Pt
(d) concentration of H^{+} ions is larger when Pt electrode is taken

167. Zn gives H_2 gas with H_2SO_4 and HCl but not with HNO_3 because: **[CBSE (PMT) 2002]**

(a) Zn acts as oxidising agent when reacts with HNO_3
(b) HNO_3 is weaker acid than H_2SO_4 and HCl
(c) in electrochemical series, Zn is above hydrogen
(d) NO_3^{-} is reduced in preference to hydronium ion

168. A current is passed through two voltameters connected in series. The first voltameter contains XSO_4 $(aq.)$ while the second voltameter contains Y_2SO_4 $(aq.)$. The relative atomic masses of X and Y are in the ratio 2 : 1. The ratio of the mass of X liberated to the mass of Y liberated is:

(a) 1 : 1 (b) 1 : 2
(c) 2 : 1 (d) none of these

169. Which of the following reactions is possible at anode? **(AIEEE 2002)**

(a) $2Cr^{3+} + 7H_2O \longrightarrow Cr_2O_7^{2-} + 14H^{+}$
(b) $F_2 \longrightarrow 2F^{-}$
(c) $\frac{1}{2}O_2 + 2H^{+} \longrightarrow H_2O$
(d) None of the above

170. When the sample of copper with zinc impurity is to be purified by electrolysis, the appropriate electrodes are: **(AIEEE 2002)**

	Cathode	**Anode**
(a)	Pure zinc	Pure copper
(b)	Impure sample	Pure copper
(c)	Impure zinc	Impure sample
(d)	Pure copper	Impure sample

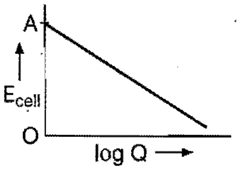
171. Conductivity (Unit Siemen's 'S') is directly proportional to area of the vessel and the concentration of the solution in it and is inversely proportional to the length of the vessel, then the unit of constant of proportionality is: **(AIEEE 2002)**

(a) $S\ \text{m mol}^{-1}$ (b) $S\ \text{m}^2\ \text{mol}^{-1}$

(c) $S^{-2}\ \text{m}^2\ \text{mol}$ (d) $S^2\ \text{m}^2\ \text{mol}^{-2}$

172. $Zn(s) + Cu^{2+}(aq.) \rightleftharpoons Cu(s) + Zn^{2+}(aq.)$

Reaction quotient $Q = \frac{[Zn^{2+}]}{[Cu^{2+}]}$, variation E_{cell} with Q is of the ne with $OA = 1.10$ volt. $E_{\text{cell}} = 1.1591$ volt when:



(a) $[Cu^{2+}]/[Zn^{2+}] = 0.01$ (b) $[Zn^{2+}]/[Cu^{2+}] = 0.01$

$[Zn^{2+}]/[Cu^{2+}] = 0.1$ (d) $[Zn^{2+}]/[Cu^{2+}] = 1$

173. In which of the following cells will the emf be independent of the activity of the chloride ions?

(a) $Zn\ |\ ZnCl_2(aq.)\ |\ Pt(Cl_2)$

(b) $Zn\ |\ ZnCl_2(aq.)\ ||\ KCl(aq.)\ |\ AgCl(s), Ag(s)$

(c) $Ag, AgCl(s)\ |\ KCl(aq.)\ |\ Pt(Cl_2)$

(d) $Hg, Hg_2Cl_2(s)\ |\ KCl(aq.)\ ||\ AgNO_3(aq.)\ |\ Ag(s)$

174. Standard electrode potential data are useful for understanding the suitability of an oxidant in a redox titration. Some half-cell reactions and their standard potentials are given below:

$MnO_4^-(aq.) + 8H^+(aq.) + 5e^- \longrightarrow Mn^{2+}(aq.) + 4H_2O(l);$ $E° = 1.51$ volt

$Cr_2O_7^{2-}(aq.) + 14H^+(aq.) + 6e^- \longrightarrow 2Cr^{3+}(aq.) + 7H_2O(l);$ $E° = 1.38$ volt

$Fe^{3+}(aq.) + e^- \longrightarrow Fe^{2+}(aq.);$ $E° = 0.77$ volt

$Cl_2(g) + 2e^- \longrightarrow 2Cl^-(aq.);$ $E° = 1.40$ volt

Identify the only incorrect statement regarding the quantitative estimation of aqueous $Fe(NO_3)_2$: **(IIT 2002)**

(a) MnO_4^- can be used in aqueous HCl

(b) $Cr_2O_7^{2-}$ can be used in aqueous HCl

(c) MnO_4^- can be used in aqueous H_2SO_4

(d) $Cr_2O_7^{2-}$ can be used in aqueous H_2SO_4

175. The standard reduction potential $E°$, for the half reaction are:

$Zn \longrightarrow Zn^{2+} + 2e^-;$ $E° = 0.76$ V

$Cu \longrightarrow Cu^{2+} + 2e^-;$ $E° = 0.34$ V

The emf for the cell reaction, $Zn(s) + Cu^{2+} \rightarrow Zn^{2+} + Cu(s)$ is: **[Bihar CECE (Pre.) 2004]**

(a) 0.42 V (b) − 0.42 V

(c) − 1.1 V (d) + 1.1 V

176. In a galvanic cell, the electrons flow from: **(KCET 2004)**

(a) anode to cathode through the solution

(b) cathode to anode through the solution

(c) anode to cathode through the external circuit

(d) cathode to anode through the external circuit

177. The standard emf of a galvanic cell involving cell reaction with $n = 2$ is found to be 0.295 V at 25°C. The equilibrium constant of the reaction would be:
Given: $F = 96500\ \text{C mol}^{-1}$; $R = 8.314\ \text{JK}^{-1}\ \text{mol}^{-1}$ **[CBSE (PMT) 2004; AIEEE 2004]**

(a) 2×10^{11} (b) 4×10^{12}

(c) 1×10^2 (d) 1×10^{10}

178. The emf of the cell,

$Zn\ |\ Zn^{2+}\ (0.01\ M)\ ||\ Fe^{2+}\ (0.001\ M)\ |\ Fe$

at 298 K is 0.2905 V then the value of equilibrium constant for the cell reaction is: **[IIT (S) 2004]**

(a) $e^{0.32/0.0295}$ (b) $10^{0.32/0.0295}$

(c) $10^{0.26/0.0295}$ (d) $10^{0.32/0.0591}$

179. The standard emf of the following electrodes are;

$$E^\circ_{Fe^{3+}/Fe^{2+}} = +0.77\ \text{V};\ E^\circ_{Sn^{2+}/Sn} = -0.14\ \text{V}$$

under standard conditions, the potential for the reaction,

$Sn(s) + 2Fe^{3+}(aq.) \longrightarrow 2Fe^{2+}(aq.) + Sn^{2+}(aq.)$ is: **(AIEEE 2004)**

(a) 1.68 V (b) 1.40 V (c) 0.91 V (d) 0.63 V

180. The highest electrical conductivity of the following aqueous solutions is of: **(AIEEE 2005)**

(a) 0.1 M acetic acid (b) 0.1 M chloroacetic acid

(c) 0.1 M fluoroacetic acid (d) 0.1 M difluoroacetic acid

181. Aluminium oxide may be electrolysed at 1000°C to furnish aluminium metal (Atomic mass = 27 amu; 1 faraday = 96500 coulomb). The cathode reaction is:

$$Al^{3+} + 3e^- \longrightarrow Al$$

To prepare 5.12 kg of aluminium metal by this method we would require: **(AIEEE 2005)**

(a) 5.49×10^7 C of electricity (b) 1.83×10^7 C of electricity

(c) 5.49×10^4 C of electricity (d) 5.49×10^{10} C of electricity

182. During the process of electrolytic refining of copper, some metals present as impurity settle as 'anode mud'. These are: **(AIEEE 2005)**

(a) Sn and Ag (b) Pb and Zn

(c) Ag and Au (d) Fe and Ni

183. When an acid cell is charged, then: **(AFMC 2005)**

(a) voltage of the cell increases

(b) electrolyte of the cell dilutes

(c) resistance of the cell increases

(d) none of the above

184. How many coulombs of electricity are required for the reduction of 1 mole of MnO_4^- to Mn^{2+}? **[PMT (Kerala) 2005]**

(a) 96500 C (b) 1.93×10^5 C

(c) 4.83×10^5 C (d) 9.65×10^6 C

(e) 5.62×10^5 C

185. The standard electrode potential of Ag^+/Ag is + 0.80 V and of Cu^{2+}/Cu is + 0.34 V. These electrodes are connected through a salt bridge and if: **[PET (Kerala) 2005]**

(a) copper electrode acts as cathode, then E°_{cell} is + 0.46 volt

(b) silver electrode acts as anode, then E°_{cell} is – 0.34 volt

(c) copper electrode acts as anode, then E°_{cell} is + 0.46 volt

(d) silver electrode acts as cathode, then E°_{cell} is – 0.34 volt

(e) silver electrode acts as anode, then E°_{cell} is + 1.14 volt

186. The half-cell reaction for the corrosion,

$$2H^+ + \frac{1}{2}O_2 + 2e^- \longrightarrow H_2O; \quad E^\circ = 1.23 \text{ V}$$

$$Fe^{2+} + 2e^- \longrightarrow Fe(s); \quad E^\circ = -0.44 \text{ V}$$

Find the ΔG° (in kJ) for the overall reaction: **[IIT (S) 2005]**

(a) – 76 kJ (b) – 322 kJ (c) – 161 kJ (d) – 152 kJ

[Hint:

$$Fe(s) \longrightarrow Fe^{2+} + 2e^-; \quad \Delta G_1^\circ$$

$$2H^+ + 2e^- + \frac{1}{2}O_2 \longrightarrow H_2O(l); \quad \Delta G_2^\circ$$

$$\underline{\overline{Fe(s) + 2H^+ + \frac{1}{2}O_2 \longrightarrow Fe^{2+} + H_2O; \ \Delta G_3^\circ}}$$

Applying $\Delta G_1^\circ + \Delta G_2^\circ = \Delta G_3^\circ$

$$\begin{aligned}\Delta G_3^\circ &= (-2F \times 0.44) + (-2F \times 1.23)\\ &= (-2 \times 96500 \times 0.44) + (-2 \times 96500 \times 1.23)\\ &= -322310 \text{ J} = -322 \text{ kJ}]\end{aligned}$$

187. What is the cell reaction occurring in Daniell cell (galvanic cell)? **[CET (J&K) 2006]**

(a) $Cu(s) + ZnSO_4(aq.) \longrightarrow CuSO_4(aq.) + Zn(s)$

(b) $Zn(s) + CuSO_4(aq.) \longrightarrow Cu(s) + ZnSO_4(aq.)$

(c) $Ni(s) + ZnSO_4(aq.) \longrightarrow NiSO_4(aq.) + Zn(s)$

(d) $2Na(s) + CdSO_4(aq.) \longrightarrow Na_2SO_4(aq.) + Cd(s)$

188. What are the units of equivalent conductivity of a solution? **[CET (J&K) 2006]**

(a) mho cm^{-1} (b) ohm cm^{-1} g $equiv^{-1}$

(c) mho cm^{-2} g $equiv^{-1}$ (d) mho cm^2 g $equiv^{-1}$

189. The amount of copper deposited by one faraday current will be maximum in an acidic solution of one litre of: **[PMT (Kerala) 2006]**

(a) 1 M Cu_2Cl_2 (b) 2 M $Cu(NO_3)_2$

(c) 5 M $CuSO_4$ (d) 5 M $Cu_3(PO_4)_2$

(e) 10 M CuF_2

[Hint: Greater is the equivalent mass, more is the amount deposited by 1 F charge.]

190. The reduction potential values of M, N and O are +2.46 V, – 1.13 V, – 3.13 V respectively. Which of the following orders is correct regarding their reducing property? **[JEE (Orissa) 2006]**

(a) $O > N > M$ (b) $O > M > N$

(c) $M > N > O$ (d) $M > O > N$

191. The molar conductivities of Λ°_{NaOAc} and Λ°_{HCl} at infinite dilution in water at 25°C are 91 and 426.2 S cm^2 mol^{-1} respectively. To calculate, Λ°_{HOAc}, the additional value required is: **(AIEEE 2006)**

(a) $\Lambda^\circ_{H_2O}$ (b) Λ°_{KCl}

(c) Λ°_{NaOH} (d) Λ°_{NaCl}

[Hint: $\Lambda^\circ_{HOAc} = \Lambda^\circ_{NaOAc} + \Lambda^\circ_{HCl} - \Lambda^\circ_{NaCl}$]

192. The equivalent conductances at infinite dilution of HCl and NaCl are 426.15 and 126.15 mho cm^2 g eq^{-1} respectively. It can be said that the mobility of: **[CET (Gujarat) 2006]**

(a) H^+ ions is much more than that of Cl^- ions

(b) Cl^- ions is much more than that of H^+ ions

(c) H^+ ions is much more than that of Na^+ ions

(d) Na^+ ions is much more than that of H^+ ions

193. The tendencies of the electrodes made up of Cu, Zn and Ag to release electrons when dipped in their respective salt solutions decrease in the order: **(VITEEE 2006)**

(a) Zn > Ag > Cu (b) Cu > Zn > Ag

(c) Zn > Cu > Ag (d) Ag > Cu > Zn

194. The electrode reaction that takes place at the anode of CH_4 — O_2 fuel cell is: **(VITEEE 2006)**

(a) $2O_2 + 8H^+ + 8e^- \longrightarrow 4H_2O$

(b) $CH_4 + 2H_2O \longrightarrow CO_2 + 8H^+ + 8e^-$

(c) $CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$

(d) $2H^+ + 2e^- \longrightarrow H_2$

195. The cell,

$$Zn(s) | Zn^{2+} (1\,M \| Cu^{2+} (1\,M) | Cu(s) \ (E^\circ_{cell} = +1.10 \text{ V})$$

was allowed to be completely discharged at 298K. The relative concentration of Zn^{2+} to Cu^{2+} $\left(\frac{[Zn^{2+}]}{[Cu^{2+}]}\right)$ is: **(AIEEE 2007)**

(a) 9.65×10^4 (b) antilog (24.08)

(c) 37.3 (d) $10^{37.3}$

[Hint:

$$E = E^\circ - \frac{0.059}{2}\log\frac{[Zn^{2+}]}{[Cu^{2+}]}$$

$$0 = 1.10 - \frac{0.059}{2}\log\frac{[Zn^{2+}]}{[Cu^{2+}]}$$

$$\log\frac{[Zn^{2+}]}{[Cu^{2+}]} = 37.3$$

$$\therefore \quad \frac{[Zn^{2+}]}{[Cu^{2+}]} = 10^{37.3}]$$

196. The efficiency of a cell is given by: **[CBSE (Med.) 2007]**

(a) $\frac{\Delta G}{\Delta S}$ (b) $\frac{\Delta G}{\Delta H}$

(c) $\frac{\Delta S}{\Delta G}$ (d) $\frac{\Delta H}{\Delta G}$

197. An electric current of 1 amp is passed through acidulated water for 160 minutes and 50 seconds. What is the volume of the hydrogen liberated at the anode (as reduced to NTP)? **(SCRA 2007)**

(a) 1.12 litre (b) 2.24 litre (c) 11.2 litre (d) 22.4 litre

[**Hint:** $V = \frac{I + V_e}{96500}$

$= \frac{1 \times 9650 \times 11.2}{96500} = 1.12$ litre]

198. The resistance of $N/10$ solution is found to be 2.5×10^3 ohm. The equivalent conductance of the solution is (cell constant $= 1.25\ \text{cm}^{-1}$): **[PMT (Kerala) 2007]**

(a) $2.5\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$ (b) $5\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$

(c) $2.5\ \text{ohm}^{-1}\ \text{cm}^{-2}\ \text{equiv}^{-1}$ (d) $5\ \text{ohm}^{-1}\ \text{cm}^{-2}\ \text{equiv}^{-1}$

(e) $1.25\ \text{ohm}^{-1}\ \text{cm}^2\ \text{equiv}^{-1}$

199. For strong electrolytes, the plot of molar conductance *versus* $\sqrt{C}$ is: **(VITEEE 2007)**

(a) parabolic (b) linear

(c) sinusoidal (d) circular

200. How long (in hours) must a current of 5 ampere be maintained to electroplate 60 g of calcium from molten $CaCl_2$? **(VITEEE 2007)**

(a) 27 hours (b) 8.3 hours (c) 11 hours (d) 16 hours

201. Emf of hydrogen electrode in term of pH is (at 1 atm pressure): **(MHT-CET 2007)**

(a) $E_{H_2} = \frac{RT}{F} \times \text{pH}$ (b) $E_{H_2} = \frac{RT}{F} \frac{1}{\text{pH}}$

(c) $E_{H_2} = \frac{2.303RT}{F}\text{pH}$ (d) $E_{H_2} = -0.0591\,\text{pH}$

202. The rusting of iron is catalysed by which of the following? **(MGIMS 2007)**

(a) Fe (b) O_2 (c) Zn (d) H^+

203. On the basis of $E°$ values, the strongest oxidising agent is :

$[Fe(CN)_6]^{4-} \longrightarrow [Fe(CN)_6]^{3-} + e^-$ $E° = -0.35$ V

$Fe^{2+} \longrightarrow Fe^{3+} + e^-$ $E° = -0.77$ V

[CBSE (PMT) 2008]

(a) Fe^{3+} (b) $[Fe(CN)_6]^{3-}$

(c) $[Fe(CN)_6]^{4-}$ (d) Fe^{2+}

204. Given $E^\circ_{Cr^{3+}/Cr} = -0.72\ \text{V}, E^\circ_{Fe^{2+}/Fe} = -0.42$ V

The potential for the cell, $Cr|Cr^{3+}(0.1M)\,||\,Fe^{2+}(0.01M)|Fe$ is: **(AIEEE 2008)**

(a) – 0.26 V (b) 0.26 V (c) 0.339 V (d) – 0.339 V

[**Hint:** $E^\circ_{\text{cell}} = -0.42 - (-0.72) = +0.30$ V

$2Cr(s) + 3Fe^{2+}(0.01M) \rightleftharpoons 2Cr^{3+}(0.1M) + 3Fe(s)$

$$Q = \frac{[Cr^{3+}]^2}{[Fe^{2+}]^3} = \frac{[0.1]^2}{[0.01]^2} = 10^4$$

According to Nernst equation,

$$E = E° - \frac{0.059}{n}\log_{10} Q$$

$$= 0.30 - \frac{0.059}{6}\log 10^4 \qquad (\because\ n = 6)$$

$= 0.261$ V]

205. Electrolysis of dilute aqueous NaCl solution was carried out by passing 10 milli ampere current. The time required to liberate 0.01 mole of H_2 gas at the cathode is: (1 faraday = 96500 C mol^{-1}) **(IIT 2008)**

(a) 9.65×10^4 sec (b) 19.3×10^4 sec

(c) 28.95×10^4 sec (d) 38.6×10^4 sec

[**Hint:** Mass of 0.01 mol H_2 = 0.02 g

$$W = \frac{ItE}{96500}$$

$$0.02 = \frac{10 \times 10^{-3} \times t \times 1}{96500}$$

$t = 19.3 \times 10^4$ sec]

206. The emf of a cell containing sodium/copper electrodes is 3.05 V, if the electrode potential of copper electrode is + 0.34 V, the electrode potential of sodium is: **[Comed (Karnataka) 2008]**

(a) – 2.71 V (b) + 2.71 V (c) – 3.71 V (d) + 3.71 V

207. What is the number of moles of oxygen gas evolved by electrolysis of 180 g of water? **(SCRA 2009)**

(a) 2.5 (b) 5.0 (c) 7.5 (d) 10.0

208. The Gibbs energy for the decomposition of Al_2O_3 at 500°C is as follows :

$$\frac{2}{3}Al_2O_3 \longrightarrow \frac{4}{3}Al + O_2;\ \Delta_rG = +966\ \text{kJ mol}^{-1}$$

The potential difference needed for the electrolytic reduction of Al_2O_3 at 500°C is at least : **(AIEEE 2010)**

(a) 2.5 V (b) 5.0 V (c) 4.5 V (d) 3.0 V

[**Hint:** In the given reaction,

$$\frac{2}{3}[2Al^{3+}] + 4e \longrightarrow \frac{4}{3}Al \quad (n = 4)$$

$\therefore$ $\Delta G = -nFE$

$$E = -\frac{\Delta G}{nF} = -\frac{966 \times 1000}{4 \times 96500}$$

$= -2.5$ V]

Set–2: The questions given below may have more than one correct answers

1. What is the difference between galvanic cell and electrolytic cell?
   (a) In galvanic cell, electrical energy is produced while in electrolytic cell electrical energy is consumed
   (b) In galvanic cell, anode is (–)ve while in electrolytic cell anode is (+)ve
   (c) In galvanic cell, cathode is (+)ve while in electrolytic cell anode is (–)ve
   (d) All are correct

2. $Ag\,|\,Ag^+, KI\,||\,AgI\,|\,Ag$ emf is E, then K_{sp} of AgI is given as:

   (a) $K_{sp} = \frac{nF}{2.303RT}\log E°$ (b) $\ln K_{sp} = nF\left[\frac{\delta E°}{\delta T} - E°\right]$

   (c) $\ln K_{sp} = \frac{nF}{E°}$ (d) $\log K_{sp} = \frac{nFE°}{2.303RT}$

3. A hydrogen electrode is placed in a buffer solution of acetic acid and sodium acetate in the ratio $y : x$ and $x : y$ has

electrode potential values E_1 and E_2 volts respectively. pK_a value for acetic acid is:

(a) $\frac{E_1 + E_2}{0.118}$ (b) $\frac{E_2 - E_1}{0.118}$

(c) $\frac{-(E_1 + E_2)}{0.118}$ (d) $\frac{E_1 - E_2}{0.118}$

(E_1 and E_2 are oxidation potentials)

4. For which electrolyte $\alpha = \frac{\lambda_v}{\lambda_\infty}$ doesn't hold good?

(a) CH_3OH (b) $HClO_4$

(c) HCOOH (d) $NaNH_2$

5. The main factors which affect corrosion are:

(a) position of metal in electrochemical series

(b) presence of CO_2 in water

(c) presence of impurities in metal

(d) presence of protective coating

6. Which is correct about silver plating?

(a) Anode—pure Ag

(b) Cathode—object to be electroplated

(c) Electrolyte—$Na[Ag(CN)_2]$

(d) Electrolyte—$AgNO_3$

7. Lead storage battery contains:

(a) Pb rod as anode

(b) Pb rod as cathode

(c) Pb plates coated with PbO_2 act as cathode

(d) electrolyte is H_2SO_4

8. During the electrolysis of $AgNO_3$ (using Pt electrodes) concentration around cathode as well as anode falls from $4M$ to $3M$. What will happen if this happened with Ag electrodes?

(a) Result will remain same

(b) Concentration around cathode will fall from $4M$ to $3M$ but around anode will increase from $4M$ to $5M$

(c) Reverse of statement (b)

(d) Concentration increases from $4M$ to $5M$ on both the electrodes

9. Emf of the cell $Pt \cdot H_2$ (1 atm) | $H^+(aq.)$ || AgCl|Ag is 0.27 V and 0.26 V at 25°C and 35°C. Heat of reaction occurring inside the cell at 25°C is:

(a) – 54.8 kJ (b) 26.05 kJ

(c) – 26.05 kJ (d) + 54.8 kJ

10. Given that,

$$Ni^{2+}/Ni = 0.25\ V,\ \ Cu^{2+}/Cu = 0.34\ V,$$
$$Ag^{+}/Ag = 0.80\ V \ \text{ and }\ Zn^{2+}/Zn = -0.76\ V$$

which of the following reactions under standard condition will not take place in the specified direction?

(a) $Ni^{2+}(aq.) + Cu(s) \longrightarrow Ni(s) + Cu^{2+}(aq.)$

(b) $Cu(s) + 2Ag^{+}(aq.) \longrightarrow Cu^{2+}(aq.) + 2Ag(s)$

(c) $Cu(s) + 2H^{+}(aq.) \longrightarrow Cu^{2+}(aq.) + H_2(g)$

(d) $Zn(s) + 2H^{+}(aq.) \longrightarrow Zn^{2+}(aq.) + 3H_2(g)$

11. Which of the following statements is/are correct?

(a) One faraday is the charge carried by one mole of electrons

(b) If same quantity of electricity flows through the solutions of 0.1 M $AgNO_3$ and 0.1 M $CuSO_4$ solutions, same weight of silver and copper will be deposited

(c) Electrochemical equivalent has the units of grams per coulomb

(d) Passage of one faraday of electricity produces one gram equivalent of the substance at the electrode

12. Which of the following statements is/are not correct?

(a) Zn-Cu cell is called Daniell cell

(b) Rust is Fe_2O_3

(c) Saline water slows down rusting

(d) Pure metals undergo corrosion faster than impure metals

13. In electrolysis of very dilute NaOH solution using platinum electrodes:

(a) H_2 is evolved at cathode

(b) H_2 is produced at anode

(c) Na is obtained at cathode

(d) O_2 is produced at anode

14. We observe blue colour if:

(a) Cu electrode is placed in the $AgNO_3$ solution

(b) Cu electrode is placed in the $ZnSO_4$ solution

(c) Cu electrode is placed in the dil. HNO_3

(d) Cu electrode is placed in dil. H_2SO_4

15. In which of the following cell (s); $E_{cell} = E^{\circ}_{cell}$?

(a) $Cu(s) \mid Cu^{2+}(0.01\ M) \parallel Ag^{+}(0.1\ M) \mid Ag(s)$

(b) $Pt(H_2) \mid pH = 1 \parallel Zn^{2+}(0.01\ M) \mid Zn(s)$

(c) $Pt(H_2) \mid pH = 1 \parallel Zn^{2+}(1\ M) \mid Zn(s)$

(d) $Pt(H_2) \mid H^{+} = 0.01\ M \parallel Zn^{2+}(0.01\ M) \mid Zn(s)$

16. Rusting on the surface of iron involves:

(a) $Fe(s) \longrightarrow Fe^{2+}(aq.) + 2e^-$ (at anodic site)

(b) $O_2(g) + 4H^{+}(aq.) + 4e^- \longrightarrow 2H_2O(l)$ (at cathodic site)

(c) $4Fe^{2+}(aq.) + O_2(g) + 4H_2O(l) \longrightarrow 2Fe_2O_3(s) + 8H^{+}$

(d) $Fe_2O_3(s) + xH_2O(l) \longrightarrow Fe_2O_3 \cdot xH_2O$

17. Fuel cell involves following reaction(s):

(a) $O_2(g) + 2H_2O(l) + 4e^- \longrightarrow 4OH^-(aq.)$ (at cathode)

(b) $O_2(g) + 2H_2O(l) + 4e^- \longrightarrow 4OH^-(aq.)$ (at anode)

(c) $2H_2(g) + 4OH^-(aq.) \longrightarrow 4H_2O(l) + 4e^-$ (at anode)

(d) $2H_2(g) + 4OH^-(aq.) \longrightarrow 4H_2O(l) + 4e^-$ (at cathode)

18. In the following question, more than one of the answers given may be correct. Select the correct answers and mark it according to the code:

Codes : **[BHU (Mains) 2008]**

(a) 1, 2 and 3 are correct (b) 1 and 2 are correct

(c) 2 and 4 are correct (d) 1 and 3 are correct

[**Hint :** In a cell $Zn(s) \mid Zn^{2+} \parallel H^{+} \mid H_2(Pt)$; the addition of H_2SO_4 to the cathode compartment, will:

1. decrease E
2. increase E
3. shift equilibrium to left
4. shift equilibrium to right]

19. For the reduction of NO_3^- in an aqueous solution, $E°$ is 0.96 V. Values of $E°$ for some metal ions are given below :

$$V^{2+}_{(aq)} + 2e^- \longrightarrow V \qquad E° = -1.19\text{ V}$$
$$Fe^{3+}_{(aq)} + 3e^- \longrightarrow Fe \qquad E° = -0.04\text{ V}$$
$$Au^{3+}_{(aq)} + 3e^- \longrightarrow Au \qquad E° = +1.40\text{ V}$$
$$Hg^{2+}_{(aq)} + 2e^- \longrightarrow Hg \qquad E° = +0.86\text{ V}$$

The pair(s) of metal that is(are) oxidised by NO_3^- in aqueous solution is(are) : **(IIT 2009)**

(a) V and Hg (b) Hg and Fe
(c) Fe and Au (d) Fe and V

[**Hint :** $E^\circ_{M^{n+}/M}$ for V, Fe and Hg are lower than that of NO_3^-, so, NO_3^- will oxidise V, Fe and Hg.]

Assertion-Reason TYPE QUESTIONS

The questions given below consist of an **'Assertion' (A)** and **'Reason' (R)**. Use the following keys to choose the appropriate answer:

(a) If both (A) and (R) are correct, and (R) is the correct explanation of (A).
(b) If both (A) and (R) are correct, but (R) is not the correct explanation of (A).
(c) If (A) is correct, but (R) is incorrect.
(d) If (A) is incorrect, but (R) is correct.

1. (A) When acidified zinc sulphate solution is electrolysed between zinc electrodes, it is zinc that is deposited at the cathode and hydrogen evolution does not take place.
(R) The electrode potential of zinc is more negative than hydrogen as the over voltage for the hydrogen evolution on zinc is quite large.

2. (A) In electrolysis, the quantity of electricity needed for depositing 1 mole of silver is different from that required for 1 mole of copper.
(R) The molecular weights of silver and copper are different. **(AIIMS 1996)**

3. (A) Equivalent conductance of all electrolytes decreases with increasing concentration.
(R) Lesser number of ions are available per gram equivalent at higher concentration. **(AIIMS 1999)**

4. (A) Zinc displaces copper from copper sulphate solution.
(R) The $E°$ is Zn of – 0.76 volt and that of copper is +0.34 volt. **(AIIMS 1999)**

5. (A) An electrochemical cell can be set-up only if the redox reaction is spontaneous.
(R) A reaction is spontaneous if free energy change is negative.

6. (A) If an aqueous solution of NaCl is electrolysed, the product obtained at the cathode is H_2 gas and not Na.
(R) Gases are liberated faster than the metals.

7. (A) Specific conductance decreases with dilution whereas equivalent conductance increases.
(R) On dilution, number of ions per cc decreases but total number of ions increases considerably.

8. (A) The cell constant of a cell depends upon the nature of the material of the electrodes.
(R) The observed conductance of a solution depends upon the nature of the material of the electrodes.

9. (A) The ratio of specific conductivity to the observed conductance does not depend upon the concentration of the solution taken in the conductivity cell.
(R) Specific conductivity decreases with dilution whereas observed conductance increases with dilution.

10. (A) Molar conductivity of a weak electrolyte at infinite dilution cannot be determined experimentally.
(R) Kohlrausch's law helps to find the molar conductivity of a weak electrolyte at infinite dilution.

11. (A) One coulomb of electric charge deposits weight equal to the electrochemical equivalent of the substance.
(R) One faraday deposits one mole of the substance.

12. (A) If standard reduction potential for the reaction, $Ag^+ + e^- \longrightarrow Ag$ is 0.80 volt, then for the reaction, $2Ag^+ + 2e^- \longrightarrow 2Ag$, it will be 1.60 volt.
(R) If concentration of Ag^+ ions is doubled, the electrode potential is also doubled.

13. (A) Gold chloride ($AuCl_3$) solution cannot be stored in a vessel made of copper, iron, nickel, chromium, zinc or tin.
(R) Gold is very precious metal.

14. (A) In the Daniell cell, if concentrations of Cu^{2+} and Zn^{2+} ions are doubled, the emf of the cell will be doubled.
(R) If the concentration of ions in contact with the metals is doubled, the electrode potential is doubled.

15. (A) $H_2 + O_2$ fuel cell gives a constant voltage throughout its life.
(R) In this fuel cell, H_2 reacts with OH^- ions, yet the overall concentration of OH^- ions does not change.

16. (A) Presence of CO_2 in the air accelerates corrosion.
(R) CO_2 is a poisonous gas.

17. (A) For the Daniell cell, $Zn \mid Zn^{2+} \parallel Cu^{2+} \mid Cu$ with $E_{cell} = 1.1$ volt, the application of opposite potential greater than 1.1 V results into flow of electrons from cathode to anode.
(R) Zn is deposited at anode and Cu is dissolved at cathode. **(AIIMS 2006)**

18. (A) A current of 96.5 ampere is passed into aqueous $AgNO_3$ solution for 100 second. The weight of silver deposited is 10.8 g. (Atomic weight of Ag = 108)
(R) The mass of a substance deposited during the electrolysis of an electrolyte is inversely proportional to the quantity of electricity passing through the electrolyte. **[EAMCET (Engg.) 2006]**

19. (A) According to Kohlrausch's law, the molar conductance of a strong electrolyte at infinite dilution is sum of molar conductivities of its ions.
(R) The current carried by cation and anion is always equal. **(AIIMS 2007)**

20. (A) The cell potential of mercury cell is 1.35 V, which remains constant.
(R) In mercury cell, the electrolyte is a paste of KOH and ZnO. **(AIIMS 2008)**

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS for IIT ASPIRANTS

1. When aluminium oxide (Al_2O_3) is electrolysed for the production of aluminium metal. For a given quantity of electricity, the number of moles of aluminium obtained if the volume of O_2 gas obtained is 201.6 litre measured at NTP, is:
(a) 9 (b) 6 (c) 12 (d) 4.5

[**Hint:** Number of equivalents of oxygen $= \frac{201.6}{5.6} = 36$

(Equivalent volume of oxygen = 5.6 litre at NTP)

$\therefore$ Number of equivalents of Al = 36

Mass of aluminium $= 36 \times 9$ g

Number of moles of aluminium $= \frac{36 \times 9}{27} = 12$]

2. A smuggler could not carry gold by depositing iron on the gold surface since:
(a) gold is denser
(b) iron rusts
(c) gold has higher reduction potential than iron
(d) gold has lower reduction potential than iron

3. On electrolysis, which of the following does not give out oxygen?
(a) Acidic water using Pt electrode
(b) Fused NaOH using Pt electrode
(c) Dilute H_2SO_4 using Pt electrode
(d) Dilute H_2SO_4 using Cu electrode

4. During electrolysis of a solution of $AgNO_3$, 9650 coulomb of charge pass through the electrolytic cell; the mass of silver deposited on the cathode will be:
(a) 21.6 g (b) 108 g (c) 10.8 g (d) 1.08 g

5. An electrolytic cell contains a solution of Ag_2SO_4 and has platinum electrodes. A current is passed until 1.6 g of O_2 has been liberated at anode. The amount of silver deposited at cathode will be:
(a) 108 g (b) 1.6 g (c) 0.8 g (d) 21.60 g

[**Hint:** Number of equivalents of oxygen $= \frac{1.6}{8} = 0.2$

$\therefore$ Number of equivalents of Ag deposited = 0.2

Mass of Ag deposited $= 0.2 \times 108 = 21.6$ g]

6. In the process of electroplating, *m* g of silver is deposited when 4 ampere of current flows for 2 minutes. The amount (in g) of silver deposited by 6 ampere of current flowing for 40 seconds will be:
(a) $4m$ (b) $\frac{m}{2}$ (c) $\frac{4m}{3}$ (d) $3m$

[**Hint:**
$$\frac{W_1}{W_2} = \frac{Q_1}{Q_2}$$
$$\frac{W_1}{W_2} = \frac{I_1 \times t_1}{I_2 \times t_2}$$
$$\frac{m}{W_2} = \frac{4 \times 2 \times 60}{6 \times 40}$$
$$W_2 = \frac{m}{2} \text{ g}]$$

7. If four moles of electrons are transferred from anode to cathode in an experiment on electrolysis of water, then total volume of the two gases produced at STP will be:
(a) 224 L (b) 72.6 L (c) 67.2 L (d) 89.4 L

[**Hint:** Equivalent volume of H_2 = 11.2 L

Equivalent volume of O_2 = 5.6 L

Volume of H_2 and O_2 evolved by 4 moles electrons or 4 faraday charge $= 4 \times 11.2 + 4 \times 5.6 = 67.2$ L]

8. When one faraday of electricity is passed through three electrolytic cells containing Ag^+, Ni^{2+} and Cr^{3+} ions respectively, the deposited Ag (At. mass = 108), Ni (At. mass = 59) and Cr (At. mass = 52) are:

	Ag	Ni	Cr
(a)	108 g	29.5 g	17.3 g
(b)	108 g	59 g	52 g
(c)	108 g	108 g	17.3 g
(d)	108 g	29.5 g	166 g

[**Hint:** Equivalent mass of Ag $= \frac{108}{1} = 108$

Equivalent mass of Ni $= \frac{59}{2} = 29.5$

Equivalent mass of Cr $= \frac{52}{3} = 17.3$

$\therefore$ Amount of these metals deposited by 1 faraday charge will be: 108 g Ag, 29.5 g Ni and 17.3 g Cr respectively.]

9. Which of the following reactions occur at the cathode during the charging of lead storage battery?
(a) $Pb^{2+} + 2e^- \longrightarrow Pb$
(b) $Pb^{2+} + SO_4^{2-} \longrightarrow PbSO_4$
(c) $Pb \longrightarrow Pb^{2+} + 2e^-$
(d) $PbSO_4 + 2H_2O \longrightarrow PbO_2 + 4H^+ + SO_4^{2-} + 2e^-$

10. A current of 2.6 amp was passed through $CuSO_4$ solution for 6 minutes and 20 seconds. The amount of copper deposited is:
(a) 0.3175 g (b) 0.0031 g (c) 6.35 g (d) 3.175 g

[**Hint:** $W = \frac{ItE}{96500} = \frac{2.6 \times 380 \times 31.75}{96500} \approx 0.32$ g]

11. In the electrolysis of fused salt, the weight of the substance deposited on an electrode will not depend on:
(a) temperature of the bath
(b) current intensity
(c) time of electrolysis
(d) electrochemical equivalent of the ions

12. When an aqueous solution of sodium chloride is electrolysed using platinum electrodes, the ions discharged at the electrodes are:

(a) sodium and hydrogen (b) sodium and chloride
(c) hydrogen and chloride (d) hydroxyl and chloride

13. How many coulombs are required for the oxidation of 1 mole of H_2O_2 to O_2?
(a) 9.65×10^4 C (b) 93000 C
(c) 1.93×10^5 C (d) 19.3×10^2 C

[**Hint:** $H_2O_2 \longrightarrow O_2 + 2H^+ + 2e^-$

$$1 \text{ mol } H_2O_2 \equiv 2 \text{ mol } e^-$$
$$\equiv 2 \times 96500 \text{ C}$$
$$\equiv 193000 \text{ C}$$
$$= 1.93 \times 10^5 \text{ C}]$$

14. A current of 2 amp when passed for 5 hours through a molten salt deposits 22.2 g of metal of atomic mass 177. The oxidation state of the metal in the metal salt is:
(a) +1 (b) +2 (c) +3 (d) +4

[**Hint:** $W = \frac{ItE}{96500}$

$$E = \frac{W \times 96500}{It} = \frac{22.2 \times 96500}{2 \times 5 \times 3600} = 59.5$$

$$\text{Equivalent mass} = \frac{\text{Atomic mass}}{\text{Oxidation state}}$$

$$59.5 = \frac{177}{n}$$

$\therefore$ $n \approx 3$]

15. When water is electrolysed, hydrogen and oxygen gases are produced. If 1.008 g of H_2 is liberated at cathode, what mass of O_2 is formed at the anode?
(a) 32 g (b) 16 g (c) 8 g (d) 4 g

[**Hint:** $\frac{W_1}{W_2} = \frac{E_1}{E_2}$

$$\frac{1.008}{W_2} = \frac{1.008}{8}$$

$\therefore$ $W_2 = 8$ g

where, E_1 and E_2 are equivalent mass of hydrogen and oxygen respectively.]

16. The cell potential (E) and the free energy change (ΔG) accompanying an electrochemical reaction are related by:
(a) $\Delta G = nF \log E$ (b) $\Delta G = nFE$
(c) $-\Delta G = nFE$ (d) $-\Delta G = nF \log E$

17. The units of conductivity are:
(a) siemens^{-1} cm^{-1} (b) siemens cm
(c) siemens cm^{-1} (d) siemens cm^{-2} mol^{-1}

18. The calomel electrode used as a reference electrode contains:
(a) PbO_2-$PbSO_4$ mixture (b) $HgCl_2$
(c) Hg_2Cl_2 (d) $ZnCl_2$

19. KCl is used in salt bridge because:
(a) it forms a good jelly with agar-agar
(b) it is a strong electrolyte
(c) it is a good conductor of electricity
(d) the transference number of K^+ and Cl^- ions are almost equal

[**Hint:** Only those electrolytes are used in salt bridge whose ions have same transference number in agar-agar gel.]

20. The increase in the equivalent conductance of a salt solution on dilution is due to increase in the:
(a) attraction between the ions
(b) degree of ionization of the salt
(c) molecular attraction
(d) association of the salt

21. When 96500 coulombs of electricity are passed through nickel sulphate solution, the amount of nickel deposited will be:
(a) 1 mol (b) 0.5 mol (c) 0.1 mol (d) 2 mol

[**Hint:** 1 faraday deposits 1 equivalent of nickel.
1 equivalent of Ni = 1/2 mole of nickel.]

22. $Al^{3+}(aq.) + 3e^- \longrightarrow Al(s); \; E° = -1.66$ V
$Cu^{2+}(aq.) + 2e^- \longrightarrow Cu(s); \; E° = +0.34$ V

What voltage is produced under standard conditions by combining the half reactions with these standard electrode potentials?
(a) 1.32 V (b) 2.00 V (c) 2.30 V (d) 4.34 V

[**Hint:** The cell will be:

$$Al(s) \,|\, Al^{3+}(aq.) \,||\, Cu^{2+}(aq.) \,|\, Cu(s)$$

$$E^\circ_{\text{Cell}} = E^\circ_{\text{Cathode}} - E^\circ_{\text{Anode}}$$
$$= E^\circ_{Cu^{2+}/Cu} - E^\circ_{Al^{3+}/Al}$$
$$= +0.34 - (-1.66) = +2.00 \text{ V}]$$

23. For which of these oxidation/reduction pairs will the reduction potential vary with pH?
I. AmO_2^{2+} / AmO_2^+ II. AmO_2^{2+} / Am^{4+} III. Am^{4+} / Am^{2+}
(a) I only (b) II only
(c) I and II only (d) I, II and III

[**Hint:** $4H^+ + AmO_2^{2+} + 2e^- \longrightarrow Am^{4+} + 2H_2O$
It includes H^+ ions; hence the electrode potential depends on pH.]

24. $2Ag^+(aq.) + Cu(s) \rightleftharpoons Cu^{2+}(aq.) + 2Ag(s)$
The standard potential $E°$ for this reaction is 0.46 V. Which change will increase the potential the most?
(a) Doubling the $[Ag^+]$
(b) Halving the $[Cu^{2+}]$
(c) Doubling the size of the Cu(s) electrode
(d) Decreasing the size of the Ag electrode by one-half

25. $10Cl^-(aq.) + 2MnO_4^-(aq.) + 16H^+(aq.) \rightleftharpoons 5Cl_2(g) + 2Mn^{2+}(aq.) + 8H_2O(l)$
The value of $E°$ for this reaction is 0.15 V. What is the value of the equilibrium constant (K) for this reaction?
(a) 2.4×10^{25} (b) 4.9×10^{12} (c) 1.2×10^5 (d) 3.4×10^2

[**Hint:** $K = \text{antilog}\left[\frac{nE^\circ}{0.059}\right]$

$$= \text{antilog}\left[\frac{10 \times 0.15}{0.059}\right]$$
$$\approx 2.4 \times 10^{25}]$$

26. What takes place when zinc metal is added to an aqueous solution containing magnesium nitrate and silver nitrate?

1. Zn is oxidised 2. Mg^{2+} is reduced

3. Ag^+ is reduced 4. No reaction takes place

(a) 1 and 2 only (b) 1 and 3 only

(c) 1, 2 and 3 only (d) 4 only

27. In the galvanizing process, iron is coated with zinc. The resulting chemical protection is most similar to that provided when:

(a) a magnesium bar is connected to an iron pipe

(b) an iron can is plated with tin

(c) copper pipes are connected using lead solder

(d) a copper pipe is covered with epoxy paint

28. What is the sign of $\Delta G°$ and the value of K for an electrochemical cell for which $E^\circ_{cell} = 0.80\,V$?

	$\Delta G°$	K
(a)	–	> 1
(b)	+	> 1
(c)	+	< 1
(d)	–	< 1

29. Consider a voltaic cell based on these half-cells:

$$Ag^+(aq.) + e^- \longrightarrow Ag(s); \; E° = +0.80\,V$$

$$Cd^{2+}(aq.) + 2e^- \longrightarrow Cd(s); \; E° = -0.40\,V$$

Identify the anode and give the voltage of this cell under standard conditions.

(a) Ag; $E_{cell} = 0.40\,V$ (b) Ag; $E_{cell} = 2.00\,V$

(c) Cd; $E_{cell} = 1.20\,V$ (d) Cd; $E_{cell} = 2.00\,V$

[**Hint:** Anode has lower standard reduction potential; thus Cd will be considered as anode.

$$E^\circ_{Cell} = E_{Cathode} - E_{Anode}$$

$$= E_{Ag^+/Ag} - E^\circ_{Cd^{2+}/Cd}$$

$$= 0.80 - (-0.40) = 1.20\,V\,]$$

30. If the E°_{cell} for a given reaction has a negative value, which gives the correct relationships for the values of $\Delta G°$ and K_{eq}?

(a) $\Delta G° > 0$; $K_{eq} < 1$ (b) $\Delta G° > 0$; $K_{eq} > 1$

(c) $\Delta G° < 0$; $K_{eq} > 1$ (d) $\Delta G° < 0$; $K_{eq} < 1$

31. Which of the following solutions is used as an anti-rusting solution?

(a) Na_2SO_4 (b) Na_3PO_4 (c) Na_3BO_3 (d) Na_2S

32. The pressure of hydrogen gas is increased from 1 atm to 100 atm. Keeping the H^+ (1 M) constant, the voltage of the hydrogen half-cell at 25°C will be:

(a) 0.059 V (b) 0.59 V (c) 0.0295 V (d) 0.118 V

33. Efficiency of the following cell is 84%.

$$A(s) + B^{2+}(aq.) \rightleftharpoons A^{2+}(aq.) + B(s); \; \Delta H = -285\,kJ$$

Then the standard electrode potential of the cell will be:

(a) 1.20 V (b) 2.40 V (c) 1.10 V (d) 1.24 V

[**Hint:** Efficiency $= \dfrac{\Delta G°}{\Delta H°} = \dfrac{-nFE°}{\Delta H°}$

$$0.84 = -\frac{2 \times E° \times 96500}{-285 \times 1000}$$

$$E° = +1.24\,V\,]$$

34. A chemical reaction will be spontaneous if:

(a) E°_{cell} is positive (b) $\Delta G°$ is negative

(c) reaction quotient, $Q < K$ (d) E°_{oxid} is negative

35. Match the List-I with List-II :

	List-I (Electrode)		**List-II (Type)**
1.	Calomel	(A)	Reference
2.	Glass	(B)	Redox
3.	Hydrogen	(C)	Membrane
4.	Quinhydrone	(D)	Gas

Codes:

(a)	1–A	2–C	3–D	4–B
(b)	1–B	2–A	3–D	4–C
(c)	1–C	2–B	3–A	4–D
(d)	1–D	2–A	3–C	4–B

36. The conductivity of saturated solution of $BaSO_4$ is 3.06×10^{-6} mho cm^{-1} and its equivalent conductance is 1.53 mho cm^2 eq^{-1}. The K_{sp} for $BaSO_4$ will be:

(a) $4 \times 10^{-12}\,M$ (b) $4 \times 10^{6}\,M$

(c) $4 \times 10^{-12}\,M^2$ (d) $4 \times 10^{-6}\,M^2$

37. The standard reduction potential of hydrogen is zero because:

(a) it is assumed

(b) hydrogen is easiest to oxidise

(c) hydrogen has single electron

(d) hydrogen is electronegative

In the following three questions, three statements I, II and III are given. Mark:

(a) if all the statements are correct

(b) if II and III are correct

(c) if I and III are correct

(d) if only II is correct **[BHU (Mains) 2007]**

38. I. Conductance of electrolyte solution increases with temperature.

II. Resistivity is reciprocal of molar conductivity of electrolyte.

III. Cell constant has unit cm^{-1}.

(a) (b) (c) (d)

39. I. The conductivity of molten NaCl is due to movement of Na^+ and Cl^- ions.

II. Solid NaCl is also conductor of electricity.

III. Molten sodium is a good conductor because of mobile electrons.

(a) (b) (c) (d)

40. I. Cathode is –ve terminal both in electrochemical and electrolytic cells.

II. Reduction occurs at cathode both in galvanic as well as electrolytic cells.

III. Chemical charge in electrolytic cell is non-spontaneous.

(a) (b) (c) (d)

41. In an experiment, 0.04 F was passed through 400 mL of a 1 *M* solution of NaCl. What would be the pH of the solution after the electrolysis? **[PMT (Kerala) 2007]**
(a) 8 (b) 10 (c) 13 (d) 6
(e) 9

[**Hint:** Electrolysis of *aq.* NaCl gives hydrogen gas at cathode and oxygen gas at anode, the electrolyte solution contains NaOH after electrolysis.

Number of equivalents of NaOH formed = 0.04

$$\text{Normality,}\quad N = \frac{0.04 \times 1000}{400} = 0.1$$

$$[OH^-] = 0.1M$$

$$pOH = 1 \qquad \therefore\ pH = 13]$$

42. An alloy of Pb-Ag weighing 1.08 g was dissolved in dilute HNO_3 and the volume made to 100 mL. A silver electrode was dipped in the solution and the emf of the cell set-up $Pt(s), H_2(g) | H^+ (1M) || Ag^+ (aq.) | Ag(s)$ was 0.62 V. If E°_{cell} is 0.80 V, what is the percentage of Ag in the alloy?
(At 25°C, $RT/F = 0.06$) **[PET (Kerala) 2007]**
(a) 25 (b) 2.50 (c) 10 (d) 1
(e) 50

[**Hint:** Overall cell reaction is:

$$H_2(g) + 2Ag^+ \rightleftharpoons 2Ag(s) + 2H^+(aq.)$$

$$E = E^\circ - \frac{0.06 \times 2.303}{2} \log \frac{[H^+]^2}{[Ag^+]^2\, pH_2}$$

$$0.62 = 0.80 + \frac{2 \times 0.06 \times 2.303}{2} \log [Ag^+]$$

$$[Ag^+] = 0.05\, M$$

Number of moles of Ag^+ in 100 mL

$$= \frac{MV}{1000} = \frac{0.05 \times 100}{1000} = 0.005$$

Mass of silver = 0.005 × 108 g

$$\text{Percentage of Ag in 1.08 g of alloy} = \frac{0.005 \times 108 \times 100}{1.08} = 50\%]$$

43. Select the correct statements about dry cell:
(a) It is also called Leclanche cell
(b) It is also called Daniell cell
(c) Electrolyte used is moist paste of NH_4Cl and $ZnCl_2$
(d) Cathodic process is:

$$2MnO_2(s) + 2NH_4^+(aq.) + 2e^- \rightarrow Mn_2O_3(s) + 2NH_3(g) + H_2O(l)$$

44. Given the standard oxidation potentials,

$$Fe \xrightarrow{+0.4\ V} Fe^{2+}(aq.) \xrightarrow{-0.8\ V} Fe^{3+}(aq.)$$

$$Fe \xrightarrow{+0.9\ V} Fe(OH)_2 \xrightarrow{0.6\ V} Fe(OH)_3$$

It is easier to oxidise Fe^{2+} to Fe^{3+} in:
(a) acid medium
(b) alkaline medium
(c) neutral medium
(d) both in acidic and alkaline mediums

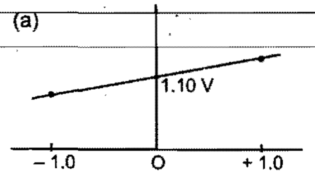
[**Hint:** $E^\circ_{Fe^{2+}/Fe^{3+}}$ is positive in alkaline solution, therefore, it is easier to oxidise Fe^{2+} to Fe^{3+} in alkaline medium.]

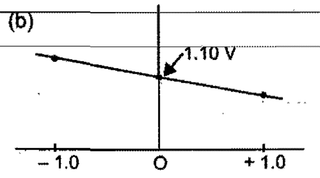
45. Dipping iron article into a strongly alkaline solution of sodium phosphate: **(VITEEE 2008)**
(a) does not affect the article
(b) forms $Fe_2O_3 \cdot xH_2O$ on the surface
(c) forms iron phosphate film
(d) forms ferric hydroxide

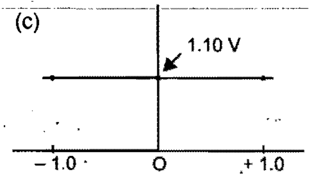
46. For the redox process,

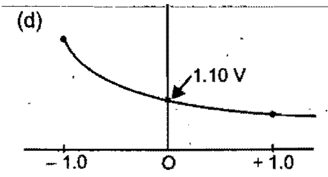
$$Zn(s) + Cu^{2+} \rightleftharpoons Zn^{2+} + Cu(s)\ E^\circ_{cell} = +1.10\ V$$

which graph correctly represents E_{cell} (*Y*-axis) as a function of $\log \frac{[Zn^{2+}]}{[Cu^{2+}]}$ (*X*-axis)?









47. A fuel cell involves combustion of the butane at 1 atm and 298 K

$$C_4H_{10}(g) + \frac{13}{2}O_2(g) \longrightarrow 4CO_2(g) + 5H_2O(l)$$

$$\Delta G^\circ = -2746\ \text{kJ/mol}$$

what is E° of a cell ?
(a) + 4.74 V (b) + 0.547 V (c) + 1.09 V (d) + 4.37 V

[**Hint :** In the reaction

$$\overset{-10}{C_4}\overset{+10}{H_{10}}(g) + \frac{13}{2}O_2(g) \longrightarrow 4\overset{+4}{C}\overset{-4}{O_2}(g) + 5H_2O(l)$$

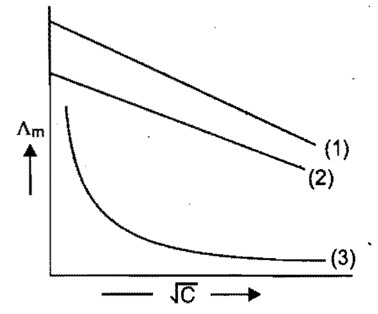
Change in oxidation number of carbon = + 16 – (– 10) = + 26

∴ Number of electrons involved in cell process will be 26.

$$E^\circ = \frac{-\Delta G^\circ}{nF} = -\frac{(-2746) \times 1000}{26 \times 96500}$$

$$= +1.09\ V]$$

48. Molar conductance Λ_m is plotted agains $\sqrt{C}$ (mol litre^{-1}) for three electrolytes (NaCl, HCl, NH_4OH)



which of the following is correct ?

	1	2	3
(a)	NaCl	HCl	NH_4OH
(b)	HCl	NaCl	NH_4OH
(c)	NH_4OH	NaCl	HCl
(d)	NH_4OH	HCl	NaCl

49. In the concentration cell

$$\mathrm{Pt(H_2)}\left|\begin{matrix}HA\ (0.1\,M)\\ \mathrm{Na}A\ (1M)\end{matrix}\right|\left|\begin{matrix}HA\ (1\,M)\\ \mathrm{Na}A\ (1M)\end{matrix}\right|\mathrm{(H_2)\ Pt}$$

(pK_a of $HA = 4$)
Cell potential will be:
(a) 0.03 V (b) 0.06 V (c) – 0.06 V (d) – 0.03 V

[**Hint :** $E_{cell} = \frac{0.0591}{1}\log_{10}\frac{[H^+]\text{ Cathode}}{[H^+]\text{ Anode}}$

$$E_{cell} = 0.06\,[\text{pH Anode} - \text{pH Cathode}] \qquad ...(1)$$

$$\text{pH Anode} = pK_a + \log\overline{[HA]} = 4 + \log\frac{0.1}{1} = 3$$

$$\text{pH Cathode} = 4 \ \text{(from eq. 1)}$$

$$E_{cell} = -\,0.06\text{ V}]$$

50. In the following process of disproportionation:

$$\underset{\text{Chlorate ion}}{2ClO_3^-} \rightleftharpoons ClO_2^- + \underset{\text{Per chlorate ion}}{ClO_4^-} \qquad E^\circ_{ClO_4^-/ClO_3^-} = +\,0.36\text{ V} \qquad E^\circ_{ClO_3^-/ClO_2^-} = +\,0.33\text{ V}$$

Initial concentration of chlorate ion was 0.1 *M*. The equilibrium concentration of per chlorate ion will be :
(a) 0.19 V (b) 0.1 *M* (c) 0.024 *M* (d) 0.019 *M*

[**Hint :**

$$ClO_3^-(aq.) + H_2O(l) \longrightarrow ClO_4^-(aq.) + 2H^+(aq.) + 2e^-$$
$$2H^+ + ClO_3^-(aq.) + 2e^- \longrightarrow ClO_2^-(aq.) + H_2O(l)$$
$$2ClO_3^-(aq.) \rightleftharpoons ClO_2^-(aq.) + ClO_4^-(aq.)$$

$$E^\circ_{cell} = 0.33 - 0.36 = -\,0.03\text{ V}$$

$$E = E^\circ - \frac{0.059}{n}\log Q$$

At equilibrium, $E = 0,\quad n = 2,\quad Q = K$

$$0 = -\,0.03 - \frac{0.059}{2}\log K$$

$$\log K = -\,1$$

$$K = \frac{1}{10} \qquad ...(1)$$

$$\begin{array}{llll} & 2ClO_3^-(aq.) \rightleftharpoons & ClO_2^-(aq.) + & ClO_4^-(aq.) \\ t_0 & 0.1 & 0 & 0 \\ t_{eq.} & 0.1 - 2x & x & x \end{array}$$

$$K = \frac{x \times x}{(0.1 - 2x)^2} = \frac{1}{10}$$

$$x = 0.019]$$

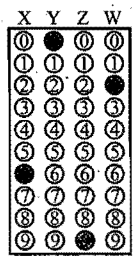
Integer Answer TYPE QUESTIONS

This section contains 10 questions. The answer to each of the questions is a single digit integer, ranging from 0 to 9. If the correct answers to question numbers X, Y, Z and W (say) are 6, 0, 9 and 2 respectively, then the correct darkening of bubbles will look like the given figure :



1. How many grams of water will be electrolysed by 96500 coulomb charge?
2. Number of faradays required to convert 1 mole of $Cr_2O_7^{2-}$ into Cr^{3+} ions is :
3. At what pH the potential of hydrogen electrode will be 0.059 V?
4. The ratio of $\left(\frac{\Lambda_m}{\Lambda_e}\right)$ for $Ca_3(PO_4)_2$ will be equal to :
5. $I_2(s)/I^-$ (0.1 M) half-cell is connected to $H^+(aq)/(H_2$ 1 atm) Pt half-cell and its cell potential is found to be 0.7714 V. If $E^\circ_{I_2/I^-} = 0.535$ V, the pH of H^+/H_2 half-cell will be :
6. If an aqueous solution of NaCl is electrolysed using platinum electrode by a current of 5 amp, then what volume of Cl_2 gas in litres at STP will be produced?
7. Charge of 6.24×10^{18} electrons will be (in coulomb) :
8. A current of 2 ~~amp when~~ passed for 5 hour through a molten salt deposits 22.2 g of metal of atomic mass 177. The positive oxidation state of the metal in the metal salt is :
9. $$Cr(s) \mid Cr^{3+} \parallel Fe^{2+} \mid Fe(s)$$
   In above cell, the value of n in the Nernst equation:
   i.e., $E = E^\circ - \frac{0.059}{n}\log_{10} Q$ will be :
10. In the Nernst Equation,
    $$E = E^\circ - \frac{2.303RT}{nF}\log_{10} Q$$
    Q will be equal to the equilibrium constant K_C, when the cell potential E is equal to :

Answers

LINKED COMPREHENSION TYPE QUESTIONS

• Passage 1

In a lead storage battery, Pb (anode) and PbO_2 (cathode) are used. Concentrated H_2SO_4 is used as electrolyte. The battery holds 3.5 litre acid with it. In the discharge process, the density of acid fell from 1.294 to 1.139 g/mL. The sulphuric acid of density 1.294 g mL^{-1} is 39% by mass and that of density 1.139 g/mL is 20% by mass.

Answer the following questions:

1. Equivalent mass of sulphuric acid in lead storage battery is:
   (a) 49 (b) 98
   (c) 24.5 (d) none of these
2. Normalities of sulphuric acid before and after discharge are:
   (a) 5.15, 2.32 (b) 2.32, 5.15 (c) 5.15, 5.15 (d) 2.32, 2.32
3. The number of ampere-hours for which the battery must have been used is:
   (a) 26504 amp-hrs (b) 2650.4 amp-hrs
   (c) 265.04 amp-hrs (d) 26.504 amp-hrs
4. The amount of charge which the battery must have been used is:
   (a) 9.88 F (b) 8.98 F (c) 8.89 F (d) 7.88 F
5. Which of the following takes place in discharge process at anode?
   (a) $PbO_2 + 4H^+ + SO_4^{2-} + 2e^- \longrightarrow PbSO_4 + 2H_2O$
   (b) $PbSO_4 + 2H_2O \longrightarrow PbO_2 + 4H^+ + SO_4^{2-} + 2e^-$
   (c) $Pb + SO_4^{2-} \longrightarrow PbSO_4 + 2e^-$
   (d) $PbSO_4 + 2e^- \longrightarrow Pb + SO_4^{2-}$

• Passage 2

Electrolysis is the process in which electrical energy is converted to chemical energy. In electrolytic cell, oxidation takes place at anode and reduction at cathode. Electrode process depends on the electrode taken for electrolysis. Amount of substance liberated at an electrode is directly proportional to the amount of charge passed through it. The mass of substance liberated at electrode is calculated using the following relation:

$$m = \frac{ItE}{96500}$$

Here, E represents the equivalent mass and 96500 C is called the Faraday constant. Faraday (96500 C) is the charge of 1 mole electron, i.e., 6.023×10^{23} electrons; it is used to liberate one gram equivalent of the substance.

Answer the following questions:

1. The platinum electrodes were immersed in a solution of cupric sulphate ($CuSO_4$) and electric current is passed through the solution. After sometime, it was observed that the colour of copper sulphate disappeared with evolution of a gas at the electrode. The colourless solution contains:
   (a) platinum sulphate (b) copper nitrate
   (c) copper sulphate (d) sulphuric acid
2. The passage of current liberates H_2 at cathode and Cl_2 at anode. The solution is:
   (a) copper chloride in water (b) NaCl in water
   (c) mercuric chloride in water (d) $AuCl_3$ in water
3. On electrolysis of dilute sulphuric acid using platinum electrodes, the product obtained at the anode will be:
   (a) hydrogen (b) oxygen
   (c) hydrogen sulphide (d) sulphur oxide
4. How many faradays are required to reduce 1 mol BrO_3^- to Br^-?
   (a) 3 (b) 5 (c) 6 (d) 4
5. Calculate the volume of gas liberated at the anode at STP during the electrolysis of a $CuSO_4$ solution by a current of 1 A passed for 16 minutes and 5 seconds:
   (a) 224 mL (b) 56 mL (c) 112 mL (d) 448 mL

[**Hint:** At anode: $2OH^- \longrightarrow H_2O + \frac{1}{2}O_2 + 2e^-$

(Oxygen gas is evolved)

Equivalent volume V_e of oxygen = 5.6 litre

$$\therefore \quad V = \frac{ItV_e}{96500} = \frac{1 \times 965 \times 5.6 \times 10^3}{96500} = 56 \text{ mL}]$$

6. The quantity of electricity required to liberate 112 cc hydrogen at S.T.P from acidified water is: **[Comed (Karnataka) 2008]**
   (a) 965 C (b) 9650 C (c) 96500 C (d) 4825 C

• Passage 3

The concentration of potassium ions inside a biological cell is at least twenty times higher than the outside. The resulting potential difference across the cell is important in several processes such as transmission of nerve impulses and maintaining the ion balance. A simple model for such a concentration cell involving a metal M is:

$$M(s) \mid M^+ (aq.\ 0.05 \text{ molar}) \parallel M^+ (aq;\ 1 \text{ molar}) \mid M(s)$$

For the above electrolytic cell, the magnitude of the cell potential $|E_{cell}| = 70$ mV.

Answer the following questions:

1. For the above cell
   (a) $E_{cell} < 0$; $\Delta G > 0$ (b) $E_{cell} > 0$; $\Delta G < 0$
   (c) $E_{cell} < 0$; $\Delta G^\circ > 0$ (d) $E_{cell} > 0$; $\Delta G^\circ < 0$
2. If the 0.05 molar solution of M^+ is replaced by a 0.0025 molar M^+ solution, then the magnitude of the cell potential would be:
   (a) 35 mV (b) 70 mV
   (c) 140 mV (d) 700 mV **[IIT 2010]**

[**Hint:** 1 (b) Electrolyte concentration cell will be spontaneous when the concentration in cathodic half cell is greater than that of anodic half cell. Thus, the given cell is spontaneous hence

$$\Delta G < 0, \ E_{cell} > 0$$

2. (c) $E^\circ_{cell} = 0$, for every concentration cell

$$E = 0 - \frac{0.059}{n}\log\frac{[M^+]_{anode}}{[M^+]_{cathode}}$$

$$= -\frac{0.059}{1}\log[0.0025]$$

$$= +153 \text{ mV}$$

It is close to 140 mV.]

• Passage 4

The driving force ΔG diminishes to zero on the way to equilibrium, just as in any other spontaneous process. Both ΔG and the corresponding cell potential $\left(E = -\frac{\Delta G}{nF}\right)$ are zero when the redox reaction comes to equilibrium. The Nernst equation for the redox process of the cell may be given as:

$$E = E^\circ - \frac{0.059}{n}\log Q$$

The key to the relationship is the standard cell potential E°, derived from the standard free energy change as:

$$E^\circ = -\frac{\Delta G^\circ}{nF}$$

At equilibrium, the Nernst equation is given as:

$$E^\circ = \frac{0.059}{n}\log K$$

Answer the following questions:

1. On the basis of information available for the reaction:

$$\frac{4}{3}\text{Al} + \text{O}_2 \longrightarrow \frac{2}{3}\text{Al}_2\text{O}_3;\ \Delta G = -827\ \text{kJ / mol of O}_2$$

the minimum emf required to carry out an electrolysis of Al_2O_3 is:
(Given: 1 F = 96500 C)
(a) 2.14 V (b) 4.28 V (c) 6.42 V (d) 8.56 V
[Hint: $\text{Al} \longrightarrow \text{Al}^{3+} + 3e^-$

$$\frac{4}{3}\text{ mol Al} \equiv \frac{4}{3}\times 3\text{ mol } e^-$$

$$\equiv 4\text{ mol } e^-$$

i.e., $n = 4$

$$\Delta G = -nFE$$

$$-827\times 1000 = -4\times 96500\times E$$

$$E = 2.14\text{ V}$$]

2. The equilibrium constant K_c will be equal to Q, when:
(a) $E = E^\circ$ (b) $RT/nF = 1$
(c) $E = 0$ (d) $E^\circ = 1$

3. The nature of graph of E°_{cell} against $\log K_c$ is a/an:
(a) straight line (b) parabola
(c) hyperbola (d) elliptical curve

4. The equilibrium constant K_c for the reaction:
$\text{Cu}(s) + 2\text{Ag}^+(aq.) \rightleftharpoons \text{Cu}^{2+}(aq.) + 2\text{Ag}(s)$ $(E^\circ_{\text{cell}} = 0.46\text{ V})$
will be:
(a) antilog 15.6 (b) antilog 2.5
(c) antilog 1.5 (d) antilog 12.2

5. E for the electrochemical cell,
$\text{Zn}(s) \mid \text{Zn}^{2+}(1\,M)\ aq. \parallel \text{Cu}^{2+}(1\,M)\ aq. \mid \text{Cu}(s)$ is 1.10 volt at 25°C.
The equilibrium constant for the cell reaction:

$$\text{Zn}(s) + \text{Cu}^{2+}(aq.) \rightleftharpoons \text{Cu}(s) + \text{Zn}^{2+}(aq.)$$

will be:
(a) 10^{-37} (b) 10^{37} (c) 10^{-39} (d) 10^{39}

• Passage 5

Conductors allow the passage of electric current through them. Metallic and electrolytic are the two types of conductors. Current carriers in metallic and electrolytic conductors are free electrons and free ions respectively. Specific conductance or conductivity of the electrolyte solution is given by the following relation:

$$\kappa = c\times\frac{l}{A}$$

where, $c = 1/R$ is the conductance and l/A is the cell constant. Molar conductance (Λ_m) and equivalence conductance (Λ_e) of an electrolyte solution are calculated using the following similar relations:

$$\Lambda_m = \kappa\times\frac{1000}{M}$$

$$\Lambda_e = \kappa\times\frac{1000}{N}$$

where, M and N are the molarity and normality of the solution respectively. Molar conductance of strong electrolyte depends on concentration:

$$\Lambda_m = \Lambda^\circ_m - b\sqrt{c}$$

where, Λ°_m = molar conductance at infinite dilution
c = concentration of the solution
b = constant

The degrees of dissociation of weak electrolytes are calculated as:

$$\alpha = \frac{\Lambda_m}{\Lambda^\circ_m} = \frac{\Lambda_e}{\Lambda^\circ_e}$$

Answer the following questions:

1. Which of the following decreases on dilution of electrolyte solution?
(a) Equivalent conductance (b) Molar conductance
(c) Specific conductance (d) Conductance

2. The correct order of equivalent conductances at infinite dilution of LiCl, NaCl and KCl is:
(a) LiCl > NaCl > KCl (b) KCl > NaCl > LiCl
(c) NaCl > KCl > LiCl (d) LiCl > KCl > NaCl

3. For which of the following electrolytic solutions Λ_m and Λ_e are equal?
(a) $BaCl_2$ (b) KCl (c) $Al_2(SO_4)_3$ (d) $CaCl_2$

4. The conductance of a solution of an electrolyte is equal to that of its specific conductance. The cell constant of the conductivity cell is equal to:
(a) resistance (b) faraday
(c) zero (d) unity

5. Which of the following equality holds good for the strong electrolytes?
(a) $\Lambda = \Lambda^\circ$ as $c \to 1$ (b) $\Lambda = \Lambda^\circ$ as $c \to 0$
(c) $\Lambda = \Lambda^\circ$ as $c \to \infty$ (d) $\Lambda = \Lambda^\circ$ as $c \to \sqrt{b}$

• Passage 6

At infinite dilution, when the dissociation of electrolyte is complete, each ion makes a definite contribution towards the molar conductance of electrolyte, irrespective of the nature of the other ion with which it is associated.

The molar conductance of an electrolyte at infinite dilution can be expressed as the sum of the contributions from its individual ions.

$$A_xB_y \longrightarrow xA^{y+} + yB^{x-}$$

$$\Lambda_m^\circ(A_xB_y) = x\lambda^\circ_{A^{y+}} + y\lambda^\circ_{B^{x-}}$$

where, x and y are the number of cations and anions respectively.

The degree of ionisation 'α' of weak electrolyte can be calculated as:

$$\alpha = \frac{\Lambda_m}{\Lambda_m^\circ}$$

Answer the following questions:

1. The ionic conductances of Al^{3+} and SO_4^{2-} ions at infinite dilution are x and y ohm^{-1} cm^2 mol^{-1} respectively. If Kohlrausch's law is valid, then molar conductance of aluminium sulphate at infinite dilution will be:
(a) $3x + 2y$ (b) $3y + 2x$ (c) $2x + 2y$ (d) $3x + 3y$
2. The molar conductances at infinite dilution for electrolytes BA and CA are 140 and 120 ohm^{-1} cm^2 mol^{-1}. If the molar conductance at infinite dilution of BX is 198 ohm^{-1} cm^2 mol^{-1}, then at infinite dilution, the molar conductance of CX is:
(a) 178 (b) 198 (c) 218 (d) 130
[**Hint:** $\Lambda^\circ_{CX} = \Lambda^\circ_{CA} + \Lambda^\circ_{BX} - \Lambda^\circ_{AB}$
$= 120 + 198 - 140 = 178$]
3. The molar conductance of 0.001 M acetic acid is 50 ohm^{-1} cm^2 mol^{-1}. The maximum value of molar conductance of acetic acid is 250 ohm^{-1} cm^2 mol^{-1}. What is the degree of dissociation (α) of acetic acid?
(a) 0.5 (b) 0.2 (c) 0.3 (d) 0.4
4. Which of the following solutions will have highest value of the molar conductance of CH_3COOH?
(a) 1 M CH_3COOH (b) 0.5 M CH_3COOH
(c) 0.3 M CH_3COOH (d) 0.1 M CH_3COOH
5. The unit of molar conductance of an electrolyte solution will be:
(a) ohm^{-1} cm^2 mol^{-1} (b) mho cm^2 mol^{-1}
(c) S cm^2 mol^{-1} (d) ohm^{-1} cm^{-1} mol^{-1}

• Passage 7

The potential associated with each electrode is known as electrode potential. If the concentration of each species taking part in the electrode reaction is unity (if any appears in the electrode reaction, it is confined to 1 atmospheric pressure) and further the reaction is carried out at 298 K, then the potential of each electrode is said to be the standard electrode potential. By convention, the standard electrode potential of hydrogen electrode is 0.0 volt. The electrode potential value for each electrode process is a measure of relative tendency of the active species in the process to remain in the oxidised/reduced form. A negative E° means that the redox couple is a stronger reducing agent than the H^+/H_2 couple. A positive E° means that the redox couple is a weaker reducing agent than the H^+/H_2 couple. The metal with greater positive value of standard reduction potential forms the oxide of greater thermal stability.

Answer the following questions:

1. Given the standard reduction potentials,
$E^\circ_{K^+/K} = -2.93$ V, $E^\circ_{Ag^+/Ag} = +0.80$ V, $E^\circ_{Hg^{2+}/Hg} = 0.79$ V
$E^\circ_{Mg^{2+}/Mg} = -2.37$ V, $E^\circ_{Cr^{3+}/Cr} = -0.74$ V.
The correct increasing order of reducing power is:
(a) K > Mg > Cr > Hg > Ag (b) Ag > Hg > Cr > Mg > K
(c) Mg > K > Cr > Hg > Ag (d) Cr > Hg > K > Mg > Ag
2. Which of the following oxides will be thermally most stable?
(a) ZnO (b) MgO (c) Cu_2O (d) Ag_2O
3. Which of the following reactions is not correct?
(a) $Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$
(b) $Fe + H_2SO_4 \longrightarrow FeSO_4 + H_2$
(c) $Mg + H_2SO_4 \longrightarrow MgSO_4 + H_2$
(d) $Cu + H_2SO_4 \longrightarrow CuSO_4 + H_2$
4. Which of the following couples will have highest value of emf ?
(a) $Mg \mid Mg^{2+} \parallel Ag^+ / Ag$ (b) $Zn \mid Zn^{2+} \parallel Cu^{2+} \mid Cu$
(c) $Zn \mid Zn^{2+} \parallel Ag^+ / Ag$ (d) $Cu \mid Cu^{2+} \parallel Ag^+ \mid Ag$
5. Which of the following metals will not displace hydrogen from water?
(a) Mg (b) Zn (c) Sn (d) Ag

• Passage 8

Chemical reactions involve interaction of atoms and molecules. A large number of atoms/molecules (approximately 6.023×10^{23}) are present in a few grams of any chemical compound varying with their atomic/molecular masses. To handle such large numbers conveniently, the mole concept was introduced. This concept has implications in diverse areas such as analytical chemistry, biochemistry, electrochemistry and radiochemistry. The following example illustrates a typical case, involving chemical/electrochemical reaction, which requires a clear understanding of the mole concept.

A 4.0 molar aqueous solution of NaCl is prepared and 500 mL of this solution is electrolysed. This leads to the evolution of chlorine gas at one of the electrodes (Atomic mass : Na = 23; Hg = 200; 1 Faraday = 96500 coulombs). **(IIT 2007)**

Answer the following questions:

1. The total number of moles of chlorine gas evolved is:
(a) 0.5 (b) 1.0 (c) 2.0 (d) 3.0
[**Hint:** Number of moles of NaCl $= \frac{MV}{1000} = \frac{4 \times 500}{1000} = 2$
$$2Cl^- \longrightarrow Cl_2 + 2e^-$$
2 mol Cl^- ions give 1 mol Cl_2]
2. If the cathode is a Hg electrode, the maximum weight (in g) of amalgam formed from this solution is:
(a) 200 (b) 225 (c) 400 (d) 446
[**Hint:** Electrolysis gives 2 mol sodium at cathode. Thus, amalgam (Na / Hg) will contain 2 mol of each sodium and Hg.
Mass of amalgam $= 2 \times 200 + 2 \times 23 = 446$]
3. The total charge (in coulombs) required for complete electrolysis is:
(a) 24125 (b) 48250 (c) 96500 (d) 193000
[**Hint:** 2 mol electrons will be required, therefore, required charge will be 2 faraday or 193000 coulombs.]

SELF ASSESSMENT

ASSIGNMENT NO. 12

SECTION-I

Straight Objective Type Questions

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. The specific conductance (κ) of an electrolyte of $0.1N$ concentration is related to equivalent conductance (Λ_e) by the following formula: **[CET (J&K) 2007]**

(a) $\Lambda_e = \kappa$ (b) $\Lambda_e = 10\kappa$
(c) $\Lambda_e = 100\kappa$ (d) $\Lambda_e = 10000\kappa$

2. The standard E°_{red} values of A, B and C are $+0.68$ V, -2.54 V, -0.50 V respectively. The order of their reducing power is: **(MHT-CET 2007)**

(a) $A > B > C$ (b) $A > C > B$ (c) $C > B > A$ (d) $B > C > A$

3. In the electrochemical reaction,

$$2Fe^{3+} + Zn \longrightarrow Zn^{2+} + 2Fe^{2+},$$

increasing the concentration of Fe^{2+}: **[JEE (WB) 2007]**

(a) increasing the cell emf
(b) increasing the current flow
(c) decrease the cell emf
(d) alter the pH of the solution

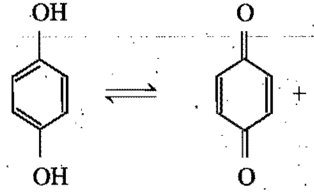
4. Fully charged lead storage battery contains 1.5 L of 5 M H_2SO_4. If 2.5 amp of current is taken from the cell for 965 minutes, then what will be the molarity of remaining H_2SO_4? Assume that volume of battery fluid to be constant:

(a) 4 M (b) 3.5 M (c) 2 M (d) 4.25 M

5. In a hydrogen-oxygen, 67.2 litre of H_2 at STP is used in 15 minutes. What is the average current produced?

(a) 549.4 amp (b) 643.33 amp
(c) 965 amp (d) 129.8 amp

6. The cell reaction involving quinhydrone electrode is:



$+ \ 2H^+ + 2e^-;\ E^\circ = 1.30$ volt

What will be the electrode potential at pH = 3 ?

(a) 1.48 V (b) 1.20 V (c) 1.10 V (d) 1.30 V

[Hint: $E = E^\circ - \dfrac{0.0591}{2}\log[H^+]^2$

$= 1.30 + 0.0591 \times 3 = 1.48$ V]

7. The standard reduction potential E° for OCl^- / Cl^- and for $Cl^- / 1/2Cl_2$ are 0.86 V and -1.10 volt respectively. The E° value of $OCl^- / 1/2Cl_2$ will be:

(a) $+1.96$ V (b) -1.96 V (c) $+0.24$ V (d) -0.24 V

[Hint:

$$OCl^- + H_2O + e^- \longrightarrow Cl^- + 2OH^- \qquad E^\circ_{\text{red}} = 0.86 \text{ V}$$

$$Cl^- \longrightarrow \frac{1}{2}Cl_2 + e^- \qquad E^\circ_{\text{oxi.}} = -1.10 \text{ V}$$

$$OCl^- + H_2O \longrightarrow \frac{1}{2}Cl_2 + 2OH^- \qquad E^\circ = 0.86 + (-1.10)$$

$= -0.24$ V]

8. The standard reduction potential for the following two reactions are given:

$AgCl + e^- \longrightarrow Ag(s) + Cl^-(aq.);\quad E^\circ = 0.22$ V ...(i)
$Ag^+(aq.) + e^- \longrightarrow Ag(s) \quad E^\circ = 0.80$ V ...(ii)

The solubility product of AgCl under standard condition will be:

(a) $1.613 \times 10^{-5}\ M^2$ (b) $1.535 \times 10^{-8}\ M^2$
(c) $3.213 \times 10^{-10}\ M^2$ (d) $1.535 \times 10^{-10}\ M^2$

[**Hint:** From eqs. (i) and (ii),

$AgCl(s) \rightleftharpoons Ag^+ + Cl^-; E^\circ = 0.22 - 0.80 = -0.58$ V

$$E_{cell} = E^\circ_{cell} - \frac{0.0591}{2} \log [Ag^+][Cl^-]$$

$$0 = -0.58 - \frac{0.0591}{2} \log [Ag^+][Cl^-]$$

$$K_{sp} = [Ag^+].[Cl^-] = 1.535 \times 10^{-10} M^2]$$

9. The equilibrium constant for the reaction,

$$Cu(s) + Cu^{2+}(aq.) \rightleftharpoons 2Cu^+(aq.)$$

$E^\circ_{Cu^{2+}/Cu} = 0.34$ V $\quad E^\circ_{Cu^{2+}/Cu} = 0.15$ V

(Given: log 3.72 = 0.571)

(a) 3.72×10^{-6} (b) 3.72×10^{-5}

(c) 3.72×10^{-7} (d) 3.72×10^{-8}

10. Cations absorb 6.023×10^{22} electrons for their reduction. How many equivalents of the ion are reduced?

(a) 0.1 (b) 0.01 (c) 0.001 (d) 0.0001

SECTION-II

Multiple Answers Type Objective Questions

11. In an electrolytic cell:

(a) anode is positively charged

(b) cathode is negatively charged

(c) oxidation takes place at anode

(d) reduction takes place at cathode

12. One gram equivalent of a substance is liberated at an electrode by:

(a) 6.023×10^{23} electrons

(b) 96500 C

(c) 1 amp current for 1 second

(d) 1 amp current for 96500 sec

13. If 9 gm H_2O is electrolysed completely with the current of 50% efficiency then:

(a) 96500 charge is required

(b) 2×96500 C charge is required

(c) 5.6 L of O_2 at STP will be formed

(d) 11.2 L of O_2 at STP will be formed

14. A galvanic cell involves the following reaction:

$Zn(s) + 2Ag^+(aq.) \rightleftharpoons Zn^{2+}(aq.) + 2Ag(s)$

Select the correct statements among the following:

(a) Zinc is negatively charged

(b) The given redox process is spontaneous

(c) $Ag^+ + e^- \longrightarrow Ag$, takes place at anode

(d) $Zn(s) \longrightarrow Zn^{2+} + 2e^-$, takes place at cathode

15. Given that,

$$E^\circ_{Ni^{2+}/Ni} = -0.25 \text{ V}, \; E^\circ_{Cu^{2+}/Cu} = +0.34 \text{ V}$$

$$E^\circ_{Ag^+/Ag} = +0.80 \text{ V} \; E^\circ_{Zn^{2+}/Zn} = -0.76 \text{ V}$$

Which of the following redox processes will not take place in specified direction?

(a) $Ni^{2+}(aq.) + Cu(s) \longrightarrow Ni(s) + Cu^{2+}(aq.)$

(b) $Cu(s) + 2Ag^+(aq.) \longrightarrow Cu^{2+}(aq.) + 2Ag(s)$

(c) $Cu(s) + 2H^+(aq.) \longrightarrow Cu^{2+}(aq.) + H_2(g)$

(d) $Zn(s) + 2H^+(aq.) \longrightarrow Zn^{2+}(aq.) + H_2(g)$

SECTION-III

Assertion-Reason Type Questions

This section contains 6 questions. Each question contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; statement-2 is true; statement-2 is a correct explanation for statement-1.

(b) Statement-1 is true; statement-2 is true; statement-2 is not a correct explanation for statement-1.

(c) Statement-1 is true; statement-2 is false.

(d) Statement-1 is false; statement-2 is true.

16. Statement-1: During the electrolysis of water, two faraday of charge will produce a total of 33.6 litre of gases at STP at electrodes.

Because

Statement-2: In the electrolysis of water, two faraday of charge will produce half mole of H_2 gas and one fourth mole of O_2 gas.

17. Statement-1: Aqueous solution of $CuSO_4$ turns colourless on complete electrolysis using platinum electrode.

Because

Statement-2: $CuSO_4$ is converted to $Cu(OH)_2$ on electrolysis.

18. Statement-1: Sodium ions are discharged at a mercury cathode in preference to hydrogen ion.

Because

Statement-2: Na^+ is stronger reducing agent than H^+.

19. Statement-1: KCl and NH_4Cl cannot be used in salt bridge of a cell containing Ag^+, Hg_2^{2+} and Tl^+ ions.

Because

Statement-2: Cell will be destroyed due to precipitation of metal chlorides.

20. Statement-1: The voltage of mercury cell remains constant for its life time.

Because

Statement-2: Overall cell reaction does not involve any ion.

21. Statement-1: In alkaline version of dry cell, NH_4Cl is replaced by KOH.

Because

Statement-2: Zinc container does not undergo corrosion in alkaline medium.

SECTION-IV

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

If the correct matches are (a-p,s); (b-q,r); (c-p,q) and (d-s); then correct bubbled 4 × 4 matrix should be as follows:

	p	q	r	s
a	●	ⓠ	ⓡ	●
b	ⓟ	●	●	ⓢ
c	●	●	ⓡ	ⓢ
d	ⓟ	ⓠ	ⓡ	●

22. Match the Column-I with Column-II:

Column-I	Column-II
(a) Nickel-Cadmium cell	(p) Used in auto vehicles
(b) Lithium battery	(q) Secondary cell
(c) $H_2 - O_2$ cell	(r) Fuel cell
(d) Lead storage battery	(s) Used in Apollo space craft

23. Match the Column-I with Column-II:

Column-I	Column-II
(a) Specific conductance, κ	(p) $\Lambda_m^c / \Lambda_m^\circ$
(b) Molar conductance, Λ_m	(q) Decreases with dilution
(c) Resistance of electrolyte solution, R	(r) Increases with dilution
(d) Degree of ionization of weak electrolyte, α	(s) Increases with increase in the distance between parallel plates

24. Match the Column-I with Column-II:

Column-I	Column-II
(a) Concentration cell	(p) Fe is oxidised by Ni_2O_3
(b) Edison cell	(q) Zinc anode
(c) Mercury cell	(r) HgO cathode
(d) Dry cell	(s) $E^\circ = 0$

SECTION-V

Linked Comprehension Type Questions

Redox reactions play a pivotal role in chemistry and biology. The values of standard redox potential (E°) of two half-cells reactions decide which way the reaction is expected to proceed. A simple example is a Daniell cell in which zinc goes into solution and copper gets deposited. Given below are a set of half-cell reactions (acidic medium) along with their E° (V with respect to normal hydrogen electrode) values.

$I_2 + 2e^- \longrightarrow 2I^-$; $E^\circ = 0.54$

$Cl_2 + 2e^- \longrightarrow 2Cl^-$; $E^\circ = 1.36$

$Mn^{3+} + e^- \longrightarrow Mn^{2+}$; $E^\circ = 1.50$

$Fe^{3+} + e^- \longrightarrow Fe^{2+}$; $E^\circ = 0.77$

$O_2 + 4H^+ + 4e^- \longrightarrow 2H_2O$; $E^\circ = 1.23$ **(IIT 2007)**

Answer the following questions:

25. Among the following, identify the correct statement:
(a) Chloride ion is oxidised by O_2
(b) Fe^{2+} is oxidised by iodine
(c) Iodide ion is oxidised by chlorine
(d) Mn^{2+} is oxidised by chlorine
[**Hint:** Species with greater reduction potential, oxidises other with lower reduction potential.]

26. While Fe^{3+} is stable, Mn^{3+} is not stable in acid solution because:
(a) O_2 oxidises Mn^{2+} to Mn^{3+}
(b) O_2 oxidises both Mn^{2+} and Fe^{2+}
(c) Fe^{3+} oxidises H_2O to O_2
(d) Mn^{3+} oxidises H_2O to O_2
[**Hint:** Mn^{3+} oxidises H_2O to O_2 because the standard reduction potential of ($Mn^{3+} \longrightarrow Mn^{2+}$) is greater than that of ($O_2 \longrightarrow H_2O$).]

Answers

1. (d) **2.** (d) **3.** (c) **4.** (a) **5.** (b) **6.** (a) **7.** (d) **8.** (b)
9. (c) **10.** (a) **11.** (a, b, c, d) **12.** (a, b, d) **13.** (b, c) **14.** (a, b) **15.** (a, c) **16.** (c)
17. (c) **18.** (b) **19.** (a) **20.** (a) **21.** (a) **22.** (a-q) (b-q) (c-r,s) (d-p,q)
23. (a-q) (b-r) (c-q,s) (d-p,r) **24.** (a-s) (b-p) (c-q,r) (d-q) **25.** (c) **26.** (d)

CHAPTER 13

ADSORPTION AND CATALYSIS

ADSORPTION

13.1 INTRODUCTION

There are several examples which reveal the fact that the surface of a solid (or liquid) has a tendency to attract and retain the molecules of other immiscible phase with which it is brought into contact. These molecules remain only at the surface and do not go deeper into the bulk. **This tendency of accumulation of molecular species at the surface than in the bulk of a solid (or liquid) is termed adsorption.** The molecular species or substance which concentrates or accumulates at the surface is termed **adsorbate** and the material on whose surface the adsorption has taken place is called **adsorbent.**

Adsorption is essentially a **surface phenomenon** and solids, particularly in finely divided state, have large surface area and, therefore, show this property to a much larger extent than liquids. Charcoal, silica gel, alumina gel, clay, Fuller's earth, colloids, metals in finely divided state, etc., act as good **adsorbents.**

The adsorption of gases on metal surfaces is called occlusion.

Examples of Adsorption

(i) If a gas like Cl_2, NH_3 or SO_2 is enclosed in presence of powdered charcoal in a closed vessel, it is observed that the pressure of the gas decreases. The gas molecules concentrate at the surface of the charcoal, *i.e.*, gases are adsorbed at the surface.

(ii) In a solution of an organic dye say methylene blue, when animal charcoal is added and the solution is well shaken, it is found that the filtrate obtained after filtration is colourless. The molecules of the dye, thus, concentrate on the surface of charcoal, *i.e.*, solute molecules from solution are adsorbed.

(iii) Water solution of raw sugar, when passed over beds of animal charcoal, becomes colourless as the colouring substances are adsorbed by animal charcoal.

(iv) The air becomes dry, *i.e.*, loses moisture in presence of silica gel. Molecules of water concentrate on the surface of gel, *i.e.*, are adsorbed.

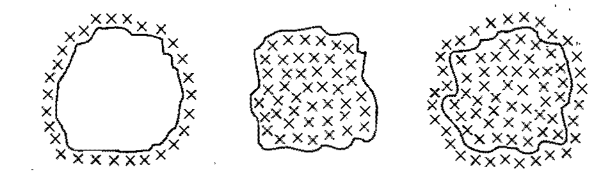
It is clear from the above examples that solid surfaces can hold the gas molecules, liquid molecules and also solid molecules by virtue of adsorption. **The process of removing an adsorbed substance from a surface on which it is adsorbed is called desorption.**

13.2 DISTINCTION BETWEEN ADSORPTION AND ABSORPTION

There are two similar sounding terms adsorption and absorption. Both the terms have different meanings. In adsorption, the substance is concentrated only at the surface and does not penetrate through the surface to go deep inside the bulk of the adsorbent, while in absorption, the substance is uniformly distributed throughout the bulk of the solid or liquid. For example, when a chalk stick is dipped in ink, the surface attains the colour of the ink due to adsorption of coloured molecules while the solvent of the ink goes deeper into the stick due to absorption. On breaking the chalk stick it is found that it is white from inside. Water vapours are absorbed by anhydrous calcium chloride while these are adsorbed by silica gel. **In other words, in adsorption the concentration of the adsorbate increases only at the surface of the adsorbent, while in absorption the concentration is uniform throughout the bulk of the solid.**

Both adsorption and absorption take place simultaneously. **Mc Bain** introduced a general term **sorption** to describe both the

Note: Rate of adsorption is high at the beginning and then decreases till equilibrium is attained. On the other hand, rate of absorption remains same throughout the process.



Adsorption Absorption Sorption

Fig. 13.1

processes. However, adsorption is instantaneous, *i.e.*, a fast process while absorption is a slow process, *e.g.*,

(i) If silica gel is placed in a vessel containing water vapours, the latter are adsorbed on the former. On the other hand, if anhydrous $CaCl_2$ is kept in place of silica gel, absorption takes place as the water vapours are uniformly distributed in $CaCl_2$ to form hydrated calcium chloride ($CaCl_2 \cdot 2H_2O$).

(ii) Dyes get adsorbed as well as absorbed in the cotton fibres, *i.e.*, sorption takes place.

13.3 MECHANISM OF ADSORPTION

Adsorption is due to the fact that the surface particles of the adsorbent are in different state than the particles inside the bulk. Inside the adsorbent all the forces acting between the particles are mutually balanced but on the surface the particles are not surrounded by atoms or molecules of their kind on all sides and hence they possess unbalanced or residual attractive forces. These forces of the adsorbent are responsible for attracting the adsorbate particles on its surface.

The extent of adsorption increases with the increase of surface area per unit mass of the adsorbent at a given temperature and pressure. This shows that with increase of surface area, the unbalanced attractive forces of the surface are also increased.

Another important factor regarding adsorption is the **heat of adsorption.** During adsorption, there is always decrease in residual forces of the surface, *i.e.*, there is decrease in surface energy which appears as heat. **Adsorption, therefore, is invariably accompanied by evolution of heat,** *i.e.*, it is an exothermic process. In other words, ΔH of adsorption is always negative. When a gas is adsorbed, the freedom of movement of its molecules becomes restricted. This amounts to decrease in the entropy of the gas after adsorption, *i.e.*, ΔS is negative. **Adsorption is thus accompanied by decrease in enthalpy as well as decrease in entropy of the system.** For a process to be instantaneous, the thermodynamic requirement is that ΔG must be negative, *i.e.*, there is decrease in free energy. On the basis of equation, $\Delta G = \Delta H - T\Delta S$, ΔG can be negative if ΔH has sufficiently high negative value as $-T\Delta S$ is positive.

Thus, in an adsorption process, which is spontaneous,

ΔS is negative,

ΔH is also sufficiently negative,

and as a combination of these two factors,

ΔG is negative.

ΔH becomes less and less negative as adsorption proceeds further and further. Ultimately ΔH becomes equal to $T\Delta S$ and ΔG becomes zero. This is the state at which equilibrium is attained.

13.4 TYPES OF ADSORPTION
(Adsorption of Gases)

There are two main types of adsorption of gases on solids.

If accumulation of gas on the surface of a solid occurs on account of weak van der Waals' forces, the adsorption is termed as physical adsorption or physisorption. When the gas molecules or atoms are held to the solid surface by chemical bonds, the adsorption is termed **chemical adsorption** or **chemisorption.** The chemical bonds may be covalent or ionic in nature. Chemisorption has a rather high energy of activation and is, therefore, often referred to as **activated adsorption.** Sometimes these two processes occur simultaneously and it is not easy to ascertain the type of adsorption. A physical adsorption at low temperature may pass into chemisorption as the temperature is increased. For example, hydrogen is first adsorbed on nickel by van der Waals' forces. Molecules of hydrogen then dissociate and hydrogen atoms are held on the surface by chemisorption.

Some of the important characteristics of both types of adsorption are described below:

1. Characteristics of physical adsorption

(i) Lack of specificity: The surface of an adsorbent does not show very strong attraction for a particular gas as the van der Waals' forces are universal.

(ii) Nature of gas: The amount of gas adsorbed by a solid depends on the nature of gas. In general, more easily liquefiable gases (*i.e.*, higher critical temperatures) are readily adsorbed as van der Waals' forces are stronger near the critical temperatures. Thus, 1g of activated charcoal adsorbs 380 mL of sulphur dioxide (critical temp. 157° C), 16 mL of methane (critical temp. − 83° C) and 4.5 mL of hydrogen (critical temp. −240° C).

Gas	H_2	N_2	CO	CH_4	CO_2	HCl	NH_3	SO_2
Volume adsorbed (c.c.)	4.5	8	9.3	16.2	48	72	181	380
Critical temperature (K)	33	126	134	190	304	324	406	430

(iii) Reversible nature: Physical adsorption of a gas by a solid is generally reversible. The gas adsorbed can be removed by reversing the conditions of temperature and pressure. Thus,

$$\text{Gas} \rightleftharpoons \text{Gas/ Solid} + \text{Heat}$$

More of gas is adsorbed when pressure is increased as the volume of the gas decreases (Le-Chatelier's principle) and it can be removed by decreasing pressure.

Since, the adsorption process is exothermic, the physical adsorption occurs readily at low temperature and decreases with increasing temperature (Le-Chatelier's principle). As the activation energy in the physical adsorption is more or less zero, the rate of adsorption is not affected even at low temperature.

(iv) Surface area of adsorbent: The extent of adsorption increases with increase of surface area of the adsorbent. Thus, finely divided metals and porous substances having large surface areas are good adsorbents.

(v) Heat of adsorption: No doubt, physical adsorption is an exothermic process but its heat of adsorption is quite low

(20 – 40 kJ mol^{-1} or about 5 kcal mol^{-1}) since the attraction between gas molecules and solid surface is due to weak van der Waals' forces.

2. Characteristics of chemisorption

(i) High specificity: Chemisorption is highly specific and it will only occur if there is some possibility of chemical bonding. For example, oxygen is adsorbed on metals by virtue of oxide formation and hydrogen is adsorbed by transition metals with unpaired *d*-orbitals leading to hydride formation.

(ii) Nature of gas: Chemisorption will occur if there is some possibility of chemical action between the gas and the solid adsorbent.

(iii) Irreversibility: As chemisorption involves compound formation, it is commonly irreversible in nature. Chemisorption is also an exothermic process but the process is very slow at low temperature on account of high energy of activation. Like most chemical changes, it often increases with rise of temperature. A gas adsorbed at low temperature by physical adsorption may change into chemisorption at high temperature.

High pressure is favourable for chemisorption.

(iv) Surface area: Like physical adsorption, chemisorption also increases with increase of surface area of the adsorbent.

(v) Heat of adsorption: Heat of adsorption is high enough (40–400 kJ/mol) as chemisorption involves bond formation.

Comparison of physisorption and chemisorption

	Physical adsorption	Chemical adsorption
1.	It is caused by intermolecular van der Waals' forces.	It is caused by chemical bond formation.
2.	It is not specific.	It is highly specific.
3.	It is reversible.	It is irreversible.
4.	It depends on the nature of gas. More easily liquefiable gases are adsorbed readily.	It depends on the nature of gas. Gases which form compounds with the adsorbent exhibit chemisorption.
5.	Heat of adsorption is low.	Heat of adsorption is high.
6.	Low temperature is favourable. It decreases with increase of temperature.	High temperature is favourable. It increases with increase of temperature.
7.	No appreciable activation energy is involved.	High activation energy is involved.
8.	High pressure is favourable. Decrease of pressure causes desorption.	High pressure is favourable. Decrease of pressure does not cause desorption.
9.	It depends on the surface area. It increases with increase of surface area.	It also depends on the surface area. It increases with increase of surface area.
10.	It forms multilayers on adsorbent surface under high pressure.	It forms unimolecular layer.

Adsorption of N_2 on the Surface of Iron

Nature of adsorption of nitrogen on the surface of iron depends on the temperature. At 83 K, nitrogen is physisorbed on iron surface as N_2 molecules. The degree of adsorption decreases rapidly as the temperature increases. At room temperature, there is no adsorption of N_2 on iron. When temperature is further increased up to 773 K and above, then nitrogen is chemisorbed on the iron surface as nitrogen atom.

Activation of Adsorption

Adsorbing power of an adsorbent can be increased by a number of ways. Some important methods are described below:

(i) Metallic adsorbents are activated by rubbing the surface.

(ii) Activity of adsorbent can be increased by taking it in powdered state because in the powdered state the surface area is maximum.

(iii) Adsorbing power of adsorbent can be increased by heating with superheated steam. For example, the charcoal is activated by heating between 650 K and 1330 K in vacuum, air or superheated steam.

13.5 ADSORPTION ISOTHERMS

The variation of the amount of the gas adsorbed by the adsorbent with pressure at constant temperature can be expressed by means of a curve. This curve is termed as **adsorption isotherm** at the particular temperature.

Freundlich adsorption isotherm: Freundlich, in 1909, gave an empirical relationship between the quantity of gas adsorbed by unit mass of solid adsorbent and pressure at a particular temperature. The relationship can be expressed by the following equation:

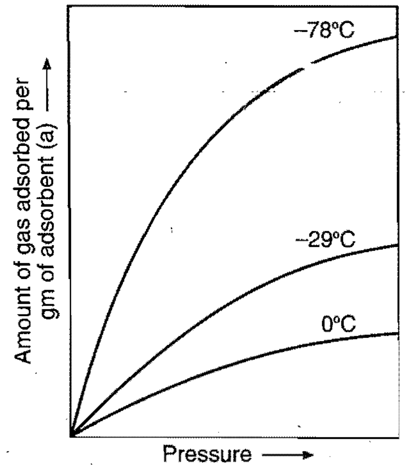


Fig. 13.2 Adsorption isotherm

$$\frac{x}{m} = k \cdot P^{1/n} \qquad \ldots (i)$$

where '*x*' is the mass of the gas adsorbed on a mass '*m*' of the adsorbent at a pressure *P*. *k* and *n* are constants which depend on the nature of the adsorbent and the gas at a particular temperature. The relationship is generally represented in the form of a curve when mass of the gas adsorbed per gram of the adsorbent is plotted against the pressure (Fig. 13.2). These curves indicate that at a fixed pressure, there is decrease in physical adsorption with increase in temperature. These curves always seem to approach saturation at high pressure.

Taking logarithm of equation (i),

$$\log \frac{x}{m} = \log k + \frac{1}{n} \log P \qquad \text{. . . (ii)}$$

This is the equation of a straight line. The validity of Freundlich isotherm can be verified by plotting $\log \frac{x}{m}$ on y-axis (ordinate) and $\log P$ on x-axis (abscissa). If it comes to be a straight line, the Freundlich isotherm is valid, otherwise not [Fig. 13.3(a)]. The slope of the straight line gives the value of $1/n$.

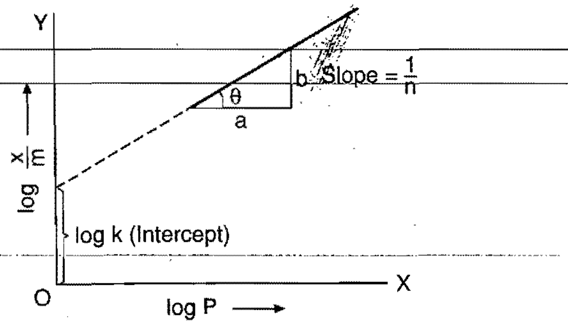

Fig. 13.3 (a) Freundlich isotherm

$$\tan \theta = \frac{b}{a} = \frac{1}{n}$$

The intercept on the y-axis gives the value of $\log k$.

Freundlich isotherm explains the behaviour of adsorption in an approximate manner. The factor $1/n$ can have values between 0 and 1 (probable range 0.1 to 0.5). Thus, equation (i) holds good over a limited range of pressure.

When $1/n = 0$, $x/m =$ constant which shows that adsorption is independent of pressure. When, $1/n = 1$, $x/m = kP$, *i.e.*, $x/m \propto P$. The adsorption varies directly with pressure. See graph in Fig. 13.3(b).

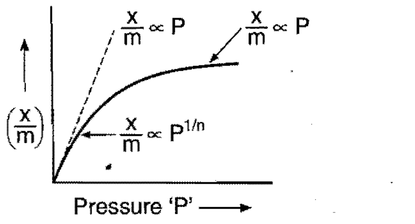

Fig. 13.3(b)

Both the above conditions are supported by experimental results. The experimental isotherms always seem to approach saturation at high pressure. This cannot be explained by Freundlich isotherm. Thus, it fails at high pressure.

Shortcomings of Freundlich adsorption isotherm:

(i) Concept of Freundlich adsorption is purely empirical.

(ii) It does not consider the role of surface area of adsorbent in the process of adsorption.

(iii) It is unable to explain, why the degree of adsorption is constant at higher pressure.

(iv) It is applicable for only physical adsorption because it considers multimolecular layer of adsorption.

The Freundlich adsorption isotherm was modified by Langmuir in 1916.

Langmuir adsorption isotherm: Langmuir (1916) derived a simple adsorption isotherm. He postulated the following theory of adsorption:

(i) Gases form unimolecular layer of adsorption on the surface of adsorbate.

(ii) Gases undergoing adsorption behave ideally.

(iii) Adjacent adsorbed molecules do not interact. In other words, adsorption of a gas molecule at a particular site is independent, whether the neighbouring sites are adsorbed or not.

(iv) Dynamic equilibrium exists on the surface of adsorbent, *i.e.*, two opposite processes take place simultaneously on the surface of adsorbent.

(a) Adsorption or condensation of gas molecules on the surface of solid or adsorbent.

(b) Desorption or evaporation of gas molecules from the surface of adsorbent.

At the stage of adsorption equilibrium, the rate of adsorption becomes equal to the rate of desorption.

Let us derive mathematical relation of adsorption isotherm. Let θ is the fraction of surface area of adsorbent covered by the gas molecules, then $(1-\theta)$ will be the fraction of surface area base which is available for adsorption. Rate of adsorption depends on the fraction of surface area base and the pressure of gas on the surface of adsorbent.

$$\text{Rate of adsorption} = k_1 (1-\theta)P \qquad \text{. . . (i)}$$

Rate of desorption is directly proportional to the fraction of surface area of adsorbent occupied.

$$\text{Rate of desorption} = k_2\theta \qquad \text{. . . (ii)}$$

At equilibrium,

$$\text{Rate of adsorption} = \text{Rate of desorption}$$

$$k_1 (1-\theta)P = k_2\theta$$

$$\theta = \frac{k_1 P}{k_2 + k_1 P}$$

$$\theta = \frac{(k_1/k_2)P}{1+\left(\frac{k_1}{k_2}\right)P} = \frac{KP}{1+KP}$$

where, $K = \frac{k_1}{k_2} = \text{constant}$

According to Langmuir, the degree of adsorption is directly proportional to the θ, *i.e.*, fraction of surface area occupied.

$$\frac{x}{m} \propto \theta = \frac{k\,KP}{1+KP} = \frac{K'P}{1+KP} \qquad \text{. . . (iii)}$$

where, $K' = kK$

Equation (iii) can be rearranged as:

$$\frac{P}{(x/m)} = \frac{1}{K'} + \left(\frac{K}{K'}\right)P$$

It is of the form $y = c + mx$, *i.e.*, equation of straight line but not passing through origin. By plotting $\frac{P}{(x/m)}$ against 'P' we get a straight line.

Slope of the line $AB = \frac{K}{K'} = \tan\theta$

Intercept of the line $= \frac{1}{K'} =$ length OA

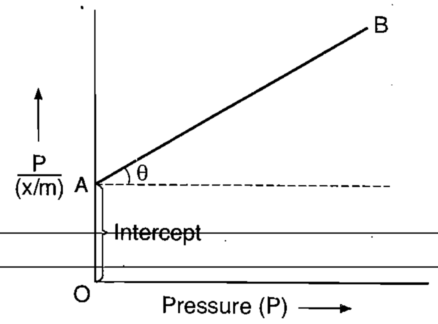

Fig. 13.3(c) Plot of Langmuir adsorption isotherm

Interpretation of Langmuir adsorption isotherm: Let us consider the mathematical relation

$$\frac{x}{m} = \frac{K'P}{1+KP}$$

Case I. When pressure is very high then $1 + KP \approx KP$

$$\therefore \quad \frac{x}{m} = \frac{K'P}{KP} = \text{constant}$$

Thus, at high pressure, the degree of adsorption approaches a limiting value.

Case II. When pressure is low then $1 + KP \approx 1$

$$\therefore \quad \frac{x}{m} = K'P$$

Thus, degree of adsorption is directly proportional to pressure.

Case III. When pressure is moderate then expression is of the form $\frac{x}{m} = KP^{1/n}$; where, $\frac{1}{n}$ lies between 0 and 1.

Alternatively,

If Langmuir adsorption isotherm is expressed as:

$$\frac{x}{m} = \frac{aP}{1+bP} \quad \text{...(i)}$$

then,

$$\frac{P}{(x/m)} = \frac{1}{a} + \frac{b}{a}P \quad \text{...(ii)}$$

Thus, a plot of $\frac{P}{(x/m)}$ against will be a straight line with slope $\frac{b}{a}$ and intercept $\frac{1}{a}$.

Equation (i) may also be taken as:

$$\frac{m}{x} = \frac{b}{a} + \frac{1}{a} \times \frac{1}{P}$$

When, $\left(\frac{m}{x}\right)$ is plotted against $\frac{1}{P}$, we get straight line with slope $\left(\frac{1}{a}\right)$ and intercept $\left(\frac{b}{a}\right)$.

13.6 ADSORPTION FROM SOLUTION PHASE

Solids can adsorb solutes from solutions also. When a solution of acetic acid in water is shaken with charcoal, a part of the acid is adsorbed by the charcoal and the concentration of the acid decreases in the solution. The litmus solution when shaken with charcoal becomes colourless. The precipitate of $Mg(OH)_2$ attains blue colour when precipitated in presence of magneson. The colour is due to adsorption of magneson. The following observations have been made in the case of adsorption from solution phase:

(i) The extent of adsorption decreases with the increase of temperature.

(ii) The extent of adsorption increases with the increase of surface area of the adsorbent.

(iii) The extent of adsorption depends on the concentration of the solute in solution.

(iv) The extent of adsorption depends on the nature of the adsorbent and the adsorbate.

When the concentration of adsorbate is more on the surface of the adsorbent than in the bulk, it is called positive adsorption. If the concentration of the adsorbate is less relative to its concentration in the bulk, it is called negative adsorption.

The precise mechanism of adsorption from solution is not known. Freundlich's equation approximately describes the behaviour of adsorption from solution with the difference that instead of pressure, concentration of the solution is taken into account, *i.e.*,

$$\frac{x}{m} = kC^{1/n}$$

(C is the equilibrium concentration, *i.e.*, when adsorption is complete.)

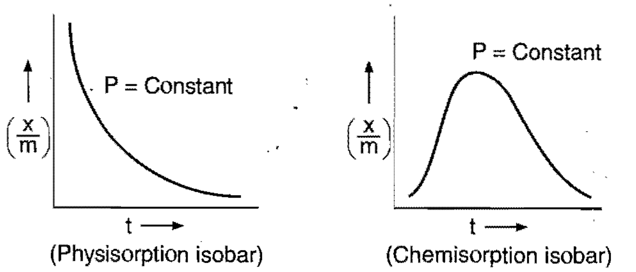
On taking logarithm of the above equation, we have

$$\log\frac{x}{m} = \log k + \frac{1}{n}\log C$$

Plotting $\log x/m$ against $\log C$ a straight line is obtained which shows the validity of Freundlich isotherm. This can be tested experimentally by taking solutions of different concentrations of acetic acid. Equal volumes of solutions are added to equal amounts of charcoal in different flasks. The final concentration is determined in each flask after adsorption. The difference in the initial concentration and final concentration gives the value of x. Using the above equation, validity of Freundlich isotherm can be established.

13.7 ADSORPTION ISOBARS AND ISOSTERE

A graph drawn between degree of adsorption (x/m) and temperature 't' at a constant pressure of adsorbate gas is known as adsorption isobar.



(Physisorption isobar) (Chemisorption isobar)

Fig. 13.4

Adsorption isobars of physical and chemical adsorptions show an important difference and this difference is helpful in distinguishing these two types of adsorption.

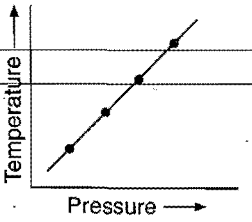


Fig. 13.5

Adsorption Isostere: Degree of adsorption depends on temperature as well as on pressure. When temperature increases, the extent of adsorption decreases. A linear relationship should exist between temperature and pressure with a certain amount of adsorption. *The plot of temperature versus pressure for a given amount of adsorption is called adsorption isostere.*

Preferential Adsorption OR Competing Adsorption

Whenever a mixture is allowed to come in contact with a particular adsorbent under the same conditions, the more strongly adsorbable adsorbate is adsorbed to a greater extent irrespective of its amount present. A preferentially adsorbable adsorbate can displace a weakly adsorbed substance from the surface of the adsorbent.

Determination of Surface Area of Adsorbent

If V litre of a gas is adsorbed at temperature T and pressure 'P' then number of gas molecules adsorbed will be:

$$\text{Number of molecules} = \left(\frac{PV}{RT}\right) \times 6.023 \times 10^{23} \quad \ldots\text{(i)}$$

If monomolecular layer of adsorption is formed then:

Surface area of adsorbent

= Number of molecules × Area of cross-section of a molecule

Area of cross section of molecule is usually determined from the density of the liquefied or solidified adsorbate.

$$\text{Volume of gas molecule} = \frac{M}{\rho \times 6.023 \times 10^{23}}$$

$$\frac{4}{3}\pi r^3 = \frac{M}{\rho N_A}$$

$$r = \left[\frac{3}{4\pi}\frac{M}{\rho N_A}\right]^{1/3}$$

$$\text{Area of cross-section} = \pi r^2 = \pi\left[\frac{3}{4\pi}\frac{M}{\rho N_A}\right]^{2/3}$$

13.8 APPLICATIONS OF ADSORPTION

The phenomenon of adsorption finds a number of applications. Important ones are given here:

1. **Production of high vacuum:** A bulb of charcoal cooled in liquid air is connected to a vessel which has already been exhausted as far as possible by a vacuum pump. The remaining traces of air are adsorbed by the charcoal. This results in a very high vacuum.

2. **Gas masks:** Gas mask is a device which consists of activated charcoal or a mixture or adsorbents. This apparatus is used to adsorb poisonous gases and thus purify the air for breathing.

3. **Humidity control:** Silica and aluminium gels are used as adsorbents for removing moisture. These gels are used for controlling humidity of rooms. Silica gel is also used in desiccators.

4. **Removal of colouring matter from solution:** Animal charcoal removes colours of solutions by adsorbing coloured impurities. Animal charcoal is used as decolouriser in the manufacture of cane sugar.

5. **Heterogeneous catalysis:** Adsorption of reactants on the solid surface of the catalysts affects the rate of reaction between the reactants. The reaction proceeds more rapidly after adsorption. There are many gaseous reactions of industrial importance involving solid catalysts. Manufacture of ammonia using iron as a catalyst, manufacture of H_2SO_4 by contact process and use of finely divided nickel in the hydrogenation of oils are excellent examples of heterogeneous catalysis.

6. **Separation of inert gases:** Due to the difference in degree of adsorption of gases by charcoal, a mixture of inert gases can be separated by adsorption on coconut charcoal at different low temperatures.

7. **Softening of hard water:** The hard water is made to pass through a column packed with zeolite (sodium aluminium silicate). Ca^{2+} and Mg^{2+} ions, which are responsible for hardness, get adsorbed on zeolite, exchanging sodium ions.

$$Na_2Al_2Si_2O_8 + CaCl_2 \longrightarrow CaAl_2Si_2O_8 + 2NaCl$$

The exhausted zeolite is regenerated with 10% of sodium chloride solution.

$$CaAl_2Si_2O_8 + 2NaCl \longrightarrow Na_2Al_2Si_2O_8 + CaCl_2$$

8. **Deionisation of water:** Water can be deionised by removing all dissolved salts with the help of cation and anion-exchanger resin. Cation-exchanger is an organic synthetic resin such as polystyrene containing a macroanion ($R—SO_3^-$) which has adsorbed H^+ ions. A resin containing a basic group ($—N^+R_3$) which has adsorbed OH^- ions acts as anion-exchanger. The water containing dissolved salts is first passed through cation-exchanger and then through anion-exchanger. The cation-exchanger removes the cations by exchange with H^+ ions while anion-exchanger removes the anions by exchange with OH^- ions:

$$\underset{\text{Cation-exchanger}}{R^- - - - H^+} + Na^+ \longrightarrow R^- - - - Na^+ + H^+$$

$$\underset{\text{Anion-exchanger}}{R^+ - - - OH^-} + Cl^- \longrightarrow R^+ - - - Cl^- + OH^-$$

The H^+ and OH^- ions thus produced react with each other to form water molecules.

$$H^+ + OH^- \longrightarrow H_2O$$

9. In curing diseases: A number of drugs are adsorbed on the germs and kill them or these are adsorbed on the tissues and heat them.

10. Cleaning agents: Soaps and detergents get adsorbed on the interface and thus reduce the surface tension between dirt and cloth, subsequently the dirt is removed from the cloth.

11. Froth floatation process: A low grade sulphide ore is concentrated by separating it from silica and other earthy matter by this method. The finely divided ore is added to water containing pine oil and foaming agent. The air is bubbled through the mixture. The foam formed rises to the surface on which mineral particles wetted with oil are adsorbed while earthy matter settles down at the bottom.

12. Adsorption indicators: Surfaces of certain precipitates such as silver halides have the property of adsorbing some dyes like eosin, fluorescein, etc. In the case of precipitation titrations (for example $AgNO_3$ *versus* NaCl) the indicator is adsorbed at the end point producing a characteristic colour on the precipitate.

13. Chromatographic analysis: The phenomenon of adsorption has given an excellent technique of analysis known as chromatographic analysis. The technique finds a number of applications in analytical and industrial fields.

14. Surfactants: Surfactants work as emulsifier in the manufacture of emulsion. The emulsifiers work on the principle of adsorption.

15. Adsorption and kinetics: Many reactions that occur on a metal surface are of zero-order, *e.g.*, decomposition of N_2O on platinum surface. It is because the rate determining step occurs on the surface itself. Once the surface of adsorbent gets covered by the reactant, the rate of reaction becomes independent of concentration of the reactant.

CATALYSIS

13.9 INTRODUCTION

Potassium chlorate when strongly heated decomposes slowly giving oxygen. The decomposition occurs in the temperature range of 380–600°C.

$$2KClO_3 \longrightarrow 2KCl + 3O_2$$

However, when a little of manganese dioxide is added, the decomposition takes place at a considerable lower temperature range, *i.e.*, 200–360°C at a much accelerated rate. The manganese dioxide added remains unchanged with regard to its mass and composition.

In a similar manner, the rates of a number of chemical reactions can be altered by the mere presence of a foreign substance. The systematic study of the effect of various foreign substances on the rates of chemical reactions was first made by **Berzelius,** in 1835. He suggested the name **catalyst,** for such substances.

Substances which thus alter the velocity of a reaction, themselves remaining chemically and quantitatively unchanged after the reaction, are known as **catalysts** and the phenomenon is known as **catalysis.** Ostwald (1895), defined a catalyst as: *a substance which changes the reaction rate without affecting the overall energetics of the reaction.*

13.10 HOMOGENEOUS AND HETEROGENEOUS CATALYSIS

Catalytic reactions can be broadly divided into two groups:

1. Homogeneous catalysis: When the reactants and the catalyst are in the same phase, *i.e.*, solid, liquid or gas, the catalysis is said to be **homogeneous.** The following are some of the examples of homogeneous catalysis:

(i) Oxidation of sulphur dioxide into sulphur trioxide with oxygen in the presence of oxides of nitrogen as the catalyst in the lead chamber process.

$$2SO_2(g) + O_2(g) \xrightarrow{NO(g)} 2SO_3(g)$$

The reactants sulphur dioxide and oxygen are in gaseous state. The catalyst nitric oxide is also in gaseous state, *i.e.,* all are in the same phase.

(ii) Hydrolysis of methyl acetate is catalysed by H^+ ions furnished by hydrochloric acid.

$$CH_3COOCH_3(l) + H_2O(l) \xrightarrow{HCl(l)} CH_3COOH(l) + CH_3OH(l)^*$$

Both the reactants and catalyst are in the same phase.

(iii) Hydrolysis of sugar is catalysed by H^+ ions furnished by sulphuric acid.

$$\underset{\text{Solution}}{C_{12}H_{22}O_{11}(l)} + H_2O(l) \xrightarrow{H_2SO_4(l)} \underbrace{\underset{\text{Glucose}}{C_6H_{12}O_6(l)} + \underset{\text{Fructose}}{C_6H_{12}O_6(l)}}_{\text{Solution}}$$

Both the reactants and the catalyst are in the same phase.

2. Heterogeneous catalysis: The catalytic process in which the reactants and the catalyst are in different phases is known as **heterogeneous catalysis.** Some of the examples of heterogeneous catalysis are given below:

(i) Oxidation of sulphur dioxide into sulphur trioxide in the presence of platinum metal or vanadium pentoxide as catalyst in the contact process for the manufacture of sulphuric acid.

$$2SO_2(g) + O_2(g) \xrightarrow{Pt(s)} 2SO_3(g)$$

The reactants are in gaseous state while the catalyst is in solid state.

(ii) Combination between nitrogen and hydrogen to form ammonia in the presence of finely divided iron in Haber process.

$$N_2(g) + 3H_2(g) \xrightarrow{Fe(s)} 2NH_3(g)$$

The reactants are in gaseous state while the catalyst is in solid state.

(iii) Oxidation of ammonia into nitric oxide in the presence of platinum gauze as a catalyst in Ostwald's process.

$$4NH_3(g) + 5O_2(g) \xrightarrow{Pt(s)} 4NO(g) + 6H_2O(g)$$

---

*(l) represents liquid or solution in chemical reactions.

The reactants are in gaseous state while the catalyst is in the solid state.

(iv) Hydrogenation of vegetable oils in the presence of finely divided nickel as catalyst.

$$\text{Vegetable oils }(l) + H_2(g) \xrightarrow{\text{Ni}(s)} \text{Vanaspati ghee}(s)$$

One of the reactants is in liquid state and the other in gaseous state while the catalyst is in solid state.

13.11 TYPES OF CATALYSIS

Catalytic reactions are of the following types:

1. Positive catalysis: When the rate of reaction is accelerated by the foreign substance, it is said to be a **positive catalyst** and the phenomenon as **positive catalysis.**

Examples of positive catalysis:

(i) Decomposition of H_2O_2 in presence of colloidal platinum.

$$2H_2O_2(l) \xrightarrow{\text{Pt}} 2H_2O(l) + O_2(g)$$

(ii) Decomposition of $KClO_3$ in presence of manganese dioxide.

$$2KClO_3(s) \xrightarrow[270°C]{MnO_2(s)} 2KCl(s) + 3O_2(g)$$

(iii) Oxidation of ammonia in presence of platinum gauze.

$$4NH_3(g) + 5O_2(g) \xrightarrow[300°C]{\text{Pt}(s)} 4NO(g) + 6H_2O(g)$$

(iv) Oxidation of sulphur dioxide in presence of nitric oxide.

$$2SO_2(g) + O_2(g) \xrightarrow{NO(g)} 2SO_3(g)$$

(v) Oxidation of sulphur dioxide in presence of platinized asbestos or vanadium pentoxide.

$$2SO_2(g) + O_2(g) \xrightarrow[\text{or Pt}(s)]{V_2O_5(s)} 2SO_3(g)$$

(vi) Oxidation of hydrochloric acid into chlorine by Deacon's process in presence of $CuCl_2$.

$$4HCl(g) + O_2(g) \xrightarrow[450°C]{CuCl_2(s)} 2Cl_2(g) + 2H_2O(g)$$

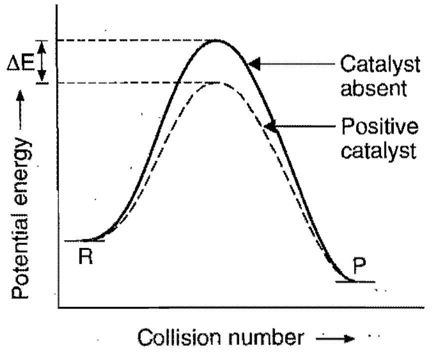

Fig. 13.6

(vii) Hydrogenation of vegetable oil in presence of nickel.

$$\text{Vegetable oil}(l) + H_2(g) \xrightarrow{\text{Ni}(s)} \text{Vanaspati ghee}(s)$$

(viii) Synthesis of ammonia by Haber process in presence of a mixture of iron and molybdenum.

$$N_2(g) + 3H_2(g) \xrightarrow[450\text{-}500°C]{\text{Fe}(s)} 2NH_3(g)$$

(ix) Manufacture of methyl alcohol in presence of ZnO/Cr_2O_3.

$$CO(g) + 2H_2(g) \xrightarrow[Cr_2O_3(s)]{ZnO(s),\ 250°C} CH_3OH(g)$$

(x) Formation of methane in presence of nickel.

$$CO(g) + 3H_2(g) \xrightarrow{\text{Ni}(s)} CH_4(g) + H_2O(g)$$

Positive catalyst increases the rate by lowering activation energy of reaction. Catalyst changes the mechanism by changing the intermediate, *i.e.*, an intermediate of low energy is formed. It increases the rate by converting some inactive molecules into active ones.

From chemical kinetics:

$$\frac{k_p}{k_a} = e^{\Delta E/RT}$$

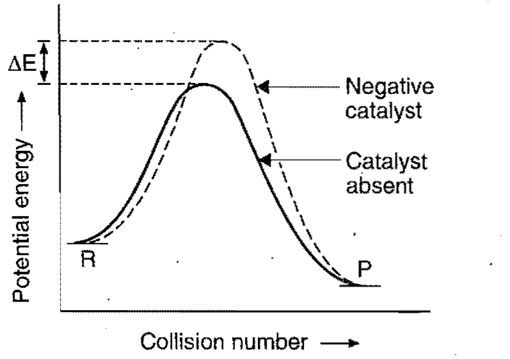
where, k_p = rate constant in presence of catalyst, k_a = rate constant in absence of catalyst.

ΔE = Lowering of activation energy

$$\log_e\left(\frac{k_p}{k_a}\right) = \frac{\Delta E}{RT}$$

$$\frac{k_p}{k_a} = \text{antilog}\left[\frac{\Delta E}{2.303\,RT}\right]$$

2. Negative catalysis: There are certain substances which, when added to the reaction mixture, retard the reaction rate instead of increasing it. These are called **negative catalysts** or **inhibitors** and the phenomenon is known as **negative catalysis.**



ΔE = Increased activation energy

Fig. 13.7

Examples of negative catalysis:

(i) The oxidation of sodium sulphite by air is retarded by alcohol.

$$2Na_2SO_3(s) + O_2(g) \xrightarrow{\text{Alcohol}(l)} 2Na_2SO_4(s)$$

Alcohol acts as a negative catalyst.

(ii) The decomposition of hydrogen peroxide decreases in presence of glycerine. Thus, in this reaction glycerine acts as a negative catalyst.

$$2H_2O_2(l) \xrightarrow{\text{Glycerine}(l)} 2H_2O(l) + O_2(g)$$

(iii) The oxidation of chloroform by air is retarded if some alcohol is added to it.

$$2CHCl_3(l) + O_2(g) \xrightarrow{\text{Alcohol}(l)} 2COCl_2(g) + 2HCl(g)$$

(iv) The oxidation of benzaldehyde is retarded if some diphenyl amine is added. It acts as a negative catalyst.

$$2C_6H_5CHO(l) + O_2(g) \xrightarrow{\text{Diphenyl amine}(l)} 2C_6H_5COOH(l)$$

(v) Tetraethyl lead (TEL) acts as an antiknocking agent in the case of petrol. Thus, it decreases knocking of petrol and acts as a negative catalyst.

(vi) Addition of small amount of acetanilide shows slow decomposition of hydrogen peroxide.

Negative catalysts decrease the rate by increasing the activation energy of reaction. Mechanism is altered by altering the intermediate; the new intermediate lies at high energy state.

3. Autocatalysis: In certain reactions, one of the products acts as a catalyst. In the initial stages the reaction is slow but as soon as the products come into existence, the reaction rate increases. This type of phenomenon, in which one of the products itself acts as a catalyst, is known as **autocatalysis.**

Examples of autocatalysis:

(i) The rate of oxidation of oxalic acid by acidified potassium permanganate increases as the reaction progresses. This acceleration is due to the presence of Mn^{2+} ions which are formed during reaction. Thus, Mn^{2+} ions act as autocatalyst.

$$5H_2C_2O_4 + 2KMnO_4 + 3H_2SO_4 \longrightarrow 2MnSO_4 + K_2SO_4 + 10CO_2 + 8H_2O$$

(ii) When nitric acid is poured on copper, the reaction is very slow in the beginning; gradually the reaction becomes faster due to the formation of nitrous acid during the reaction which acts as an autocatalyst.

(iii) In hydrolysis of ethyl acetate, acetic acid and ethyl alcohol are formed. The reaction is initially very slow but gradually its rate increases. This is due to the formation of acetic acid which acts as an autocatalyst in this reaction.

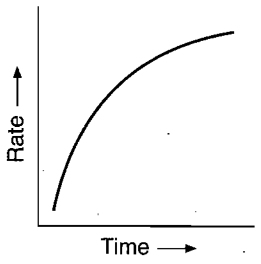


Fig. 13.8

$$CH_3COOC_2H_5 + H_2O \longrightarrow CH_3COOH + C_2H_5OH$$

In the case of homogeneous autocatalytic reactions, rate increases with passage of time because in such cases rate of reaction is directly proportional to concentration of catalyst, *e.g.*,

$$CH_3COOC_2H_5 + H_2O \longrightarrow CH_3COOH + C_2H_5OH$$

$$\text{Rate} = k\,\underset{\text{Reactant}}{[CH_3COOC_2H_5]}\,\underset{\text{Catalyst}}{[CH_3COOH]}$$

4. Induced catalysis: When one reaction influences the rate of other reaction, which does not occur under ordinary conditions, the phenomenon is known as **induced catalysis.**

Examples of induced catalysis:

(i) Sodium arsenite solution is not oxidised by air. If, however, air is passed through a mixture of the solution of sodium arsenite and sodium sulphite, both of them undergo simultaneous oxidation. The oxidation of sodium sulphite, thus, induces the oxidation of sodium arsenite.

$$Na_2SO_3 + \frac{1}{2}O_2 \longrightarrow Na_2SO_4$$

$$Na_3AsO_3 + \frac{1}{2}O_2 \longrightarrow Na_3AsO_4$$

(ii) The reduction of mercuric chloride ($HgCl_2$) with oxalic acid is very slow, but potassium permanganate is reduced readily with oxalic acid. If, however, oxalic acid is added to a mixture of potassium permanganate and mercuric chloride, both are reduced simultaneously. The reduction of potassium permanganate, thus, induces the reduction of mercuric chloride.

13.12 CHARACTERISTICS OF CATALYSIS

The following are the characteristics which are common to most of the catalytic reactions:

(i) A catalyst remains unchanged in mass and chemical composition at the end of the reaction: The amount of the catalyst found at the completion of the reaction is the same as taken at the start of the reaction. There is also no change in its composition. However, it is observed that in some cases the physical state may change. For example, manganese dioxide used in the granular form as a catalyst in the decomposition of $KClO_3$ is left as a fine powder at the completion of the reaction.

(ii) A small quantity of the catalyst is generally sufficient to catalyse almost unlimited reaction: For example, in the decomposition of hydrogen peroxide, one gram of colloidal platinum can catalyse 10^8 litre of hydrogen peroxide. One mole of Cu^{2+} in 10^6 litre can catalyse the oxidation of sodium sulphite by atmospheric oxygen.

However, in some reactions the rate of the reaction is proportional to the concentration of the catalyst. For the acid and alkaline hydrolysis of an ester, the rate of reaction is proportional to the concentration of H^+ or OH^- ions.

$$RCOOR'(l) + H_2O(l) \xrightarrow[OH^-]{H^+ \text{ or}} RCOOH(l) + R'OH(l)$$

In Friedel-Crafts reaction, anhydrous aluminium chloride is required in relatively large amount to the extent of 30% of the mass of benzene.

$$C_6H_6(l) + C_2H_5Cl(l) \xrightarrow{AlCl_3(s)} C_6H_5C_2H_5(l) + HCl(l)$$

It is also observed that in certain heterogeneous reactions, the rate of reaction increases with the increase of area of the catalytic surface.

(iii) The catalyst cannot initiate the reaction: The function of a catalyst is to alter the speed of the reaction rather than to start it. The reaction in presence of a positive catalyst adopts some alternative path which requires less amount of activation energy.

However, there are certain instances where it is observed that the reaction cannot be started in absence of a catalyst. For example, there is no reaction between H_2 and O_2 at room temperature but the reaction occurs very readily in presence of platinum black.

$$2H_2(g)+O_2(g)\xrightarrow{\text{Room temp.}}\text{No reaction}$$

$$2H_2(g)+O_2(g)\xrightarrow{\text{Pt black}}2H_2O(g)$$

Similarly, combination of dry chlorine with dry hydrogen is not possible unless water vapours are added. Water vapours which act as a catalyst might be thought to start the reaction.

$$H_2(g)+Cl_2(g)\xrightarrow{\text{Water vapour}}2HCl(g)$$

The concept is still disputed.

(iv) The catalyst is generally specific in nature: A substance, which acts as a catalyst for a particular reaction, fails to catalyse the other reactions. Different catalysts for the same reactants may form different products. Manganese dioxide which acts as a catalyst for the decomposition of potassium chlorate fails to catalyse the decomposition of potassium perchlorate. Ethanol yields ethene when passed over alumina but in presence of hot copper, acetaldehyde is formed.

$$C_2H_5OH(l)\xrightarrow{Al_2O_3}C_2H_4(g)+H_2O(g)\ \text{(Dehydration)}$$

$$C_2H_5OH(l)\xrightarrow{Cu}CH_3CHO(g)+H_2(g)\ \text{(Dehydrogenation)}$$

Similarly, in the case of formic acid, different products are formed using Cu or Al_2O_3 as catalysts.

$$HCOOH(l)\xrightarrow{Cu}CO_2(g)+H_2(g)\ \text{(Dehydrogenation)}$$

$$HCOOH(l)\xrightarrow{Al_2O_3}CO(g)+H_2O(g)\ \text{(Dehydration)}$$

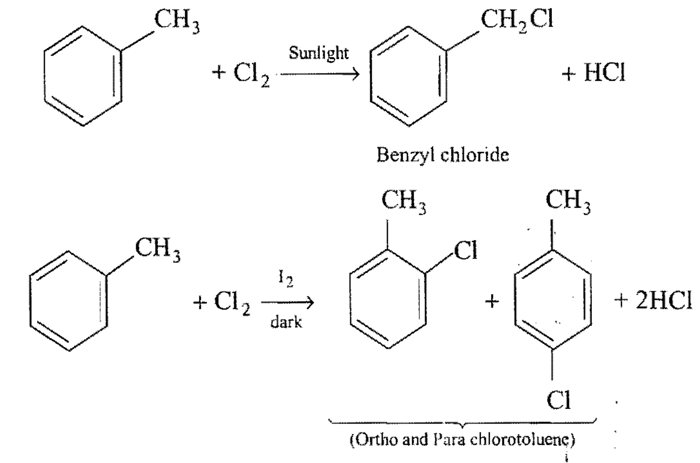
Carbon monoxide and hydrogen combine to form CH_4, CH_3OH, HCHO depending on the nature of the catalyst used.

$$CO(g)+3H_2(g)\xrightarrow{Ni}CH_4(g)+H_2O$$

$$CO(g)+2H_2\xrightarrow{ZnO+Cr_2O_3}CH_3OH$$

$$CO(g)+H_2(g)\xrightarrow{Cu}HCHO$$

Sometimes catalyst may alter the reaction product:



Enzymes have also specific action. However, transition metals like Fe, Co, Ni, Pt, Pd, etc., can catalyse reactions of various types.

(v) The catalyst cannot change the position of equilibrium: In the case of reversible reactions, the concentrations of the products and reactants cannot be affected by the catalyst if the equilibrium has been established. However, the use of a catalyst can help to achieve the equilibrium state in lesser time as forward and backward reactions are influenced to the same extent by the catalyst.

Let us consider a reversible reaction,

$$A+BC\rightleftharpoons AB+C$$

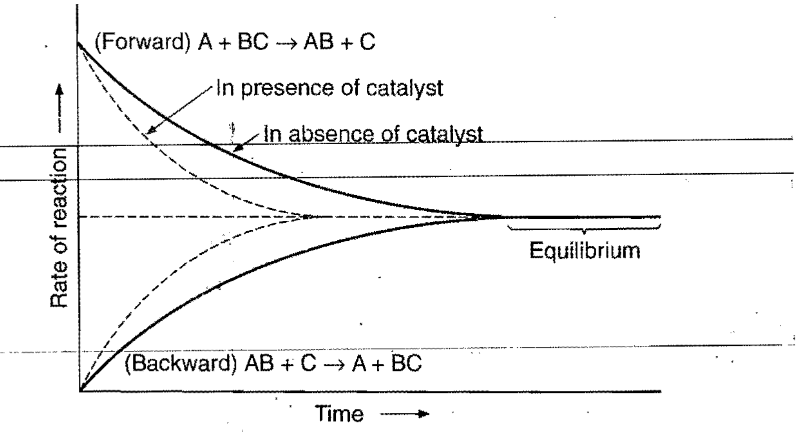


Fig. 13.9 Equilibrium state and catalyst

(vi) Catalytic promoters: Substances which themselves are not catalysts, but when mixed in small quantities with the catalysts increase their efficiency, are called as **promoters** or **activators.** Some examples of the promoters are given below:

(a) In the Haber process for the synthesis of ammonia, traces of molybdenum increase the activity of finely divided iron which acts as a catalyst. Oxides of aluminium and thorium are also used as promoter in this reaction.

(b) In the manufacture of methyl alcohol from water gas ($CO+H_2$), chromic oxide (Cr_2O_3) is used as a promoter with the catalyst zinc oxide (ZnO).

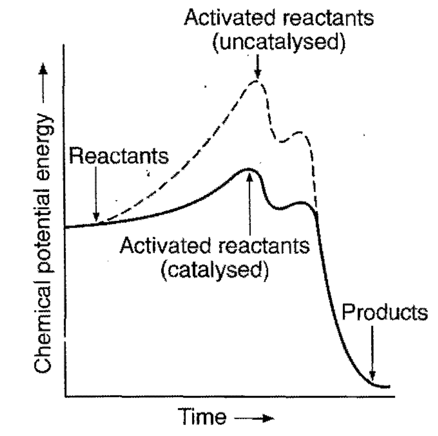

Fig. 13.10

(c) In the hydrogenation of oils, the activity of the catalyst nickel increases on adding small amount of copper and tellurium.

(vii) Catalytic poisons: Substances which destroy the activity of the catalyst by their presence are known as **catalytic poisons.** Some of the examples are:

(a) The presence of traces of arsenious oxide (As_2O_3) in the reacting gases reduces the activity of platinized asbestos which is used as catalyst in contact process for the manufacture of sulphuric acid.

(b) The activity of iron catalyst is destroyed by the presence of H_2S or CO in the synthesis of ammonia by Haber process.

(c) The platinum catalyst used in the oxidation of hydrogen is poisoned by CO.

The poisoning of a catalyst is probably due to the preferential adsorption of poison on the surface of the catalyst, thus reducing the space available for the adsorption of reacting molecules.

(viii) Change of temperature alters the rate of catalytic reaction as it does for the same reaction in absence of a catalyst: By increasing the temperature, there is an increase in the catalytic power of a catalyst but after a certain temperature its power begins to decrease. A catalyst has, thus, a particular temperature at which its catalytic activity is maximum. This temperature is termed as **optimum temperature.**

However, in the case of colloidal solutions acting as catalysts, the catalytic activity decreases by the rise of temperature as it may cause coagulation of the colloidal solution.

(ix) A positive catalyst lowers the activation energy: According to collision theory, a reaction occurs on account of effective collisions between the reacting molecules. For effective collision, it is necessary that the molecules must possess a minimum amount of energy known as activation energy (E_a). Under this condition, molecules after collision form an activated complex which dissociates to yield the product molecules.

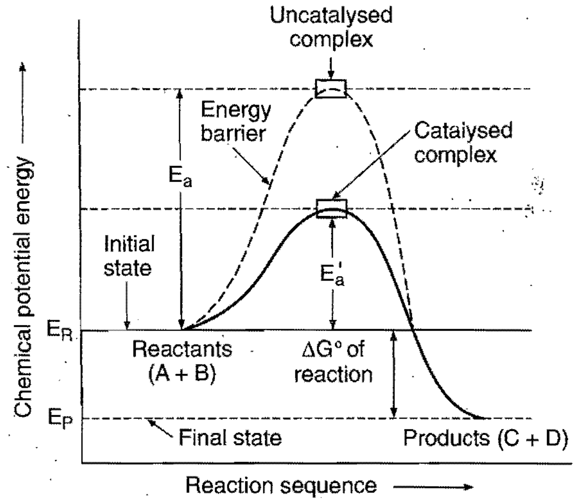

Fig. 13.11 (a)

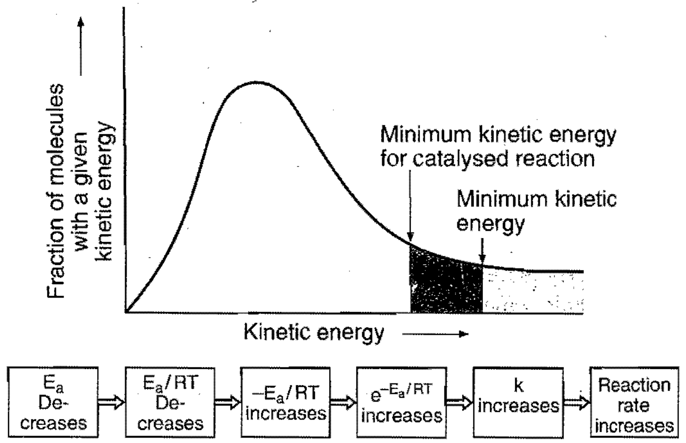

Fig. 13.11 (b) Lowering of energy barrier by the catalyst

The catalyst provides a new pathway involving lower amount of activation energy. Thus, larger number of effective collisions occur in the presence of a catalyst in comparison to effective collisions at the same temperature in absence of a catalyst. Hence, the presence of a catalyst makes the reaction to go faster.

Fig. 13.11 (a) shows that activation energy, E_a, in absence of a catalyst is higher than the activation energy, E'_a, in presence of a catalyst. E_R and E_P represent the average energies of reactants and products. The difference gives the value of ΔG, *i.e.*,

$$\Delta G = E_R - E_P$$

13.13 THEORIES OF CATALYSIS

It is not possible to give a uniform explanation of the mechanism of the phenomenon of catalysis as catalytic reactions are of varied nature. However, two broad theories of catalytic action have been proposed. First theory known as **intermediate compound formation theory** explains successfully the homogeneous catalysis while second theory termed as **adsorption theory** explains the heterogeneous catalysis.

1. Intermediate compound formation theory: This theory was proposed by **Clement** and **Desormes** in 1806.

According to this theory, **the catalyst first forms an intermediate compound with one of the reactants. The intermediate compound is formed with less energy consumption than needed for the actual reaction. The intermediate compound being unstable combines with other reactant to form the desired product and the catalyst is regenerated.**

For example, a reaction of the type

$$A + B \overset{K}{=} AB$$

which occurs in presence of a catalyst K, may take place as,

$$A + \underset{\text{Catalyst}}{K} = \underset{\substack{\text{Intermediate}\\\text{compound}}}{AK} \qquad \text{(Slow reaction)}$$

$$AK + B = \underset{\text{Product}}{AB} + \underset{\text{Catalyst}}{K} \qquad \text{(Fast reaction)}$$

$$\text{Rate} = K'[A][K \text{ catalyst}]$$

Many catalytic reactions can be explained on the basis of this theory:

(i) The catalytic oxidation of sulphur dioxide to sulphur trioxide in the lead chamber process probably takes place as:

$$\underset{\text{Catalyst}}{2NO} + O_2 \longrightarrow \underset{\text{Intermediate product}}{2NO_2}$$

$$NO_2 + SO_2 \longrightarrow \underset{\text{Product}}{SO_3} + \underset{\text{Catalyst}}{NO}$$

(ii) The catalytic action of manganese dioxide on the decomposition of $KClO_3$ was proposed by McLeod. The reaction probably takes place as follows:

$$2MnO_2 + 2KClO_3 \longrightarrow 2KMnO_4 + Cl_2 + O_2$$

$$2KMnO_4 \longrightarrow K_2MnO_4 + MnO_2 + O_2$$

$$K_2MnO_4 + Cl_2 \longrightarrow 2KCl + MnO_2 + O_2$$

$$\overline{2KClO_3 + [2MnO_2] \longrightarrow 2KCl + 3O_2 + [2MnO_2]}$$

The reaction accounts for the fact that oxygen given out is often contaminated with a little of chlorine.

(iii) The formation of methyl benzene (toluene) from benzene and methyl chloride in presence of a catalyst anhydrous aluminium chloride can be explained in the following way:

$$\underset{\text{Catalyst}}{AlCl_3} + CH_3Cl \longrightarrow \underset{\text{Intermediate compound}}{(CH_3)^+(AlCl_4)^-}$$

$$C_6H_6 + (CH_3)^+(AlCl_4)^- \longrightarrow \underbrace{C_6H_5CH_3 + HCl}_{\text{Products}} + \underset{\text{Catalyst}}{AlCl_3}$$

(iv) The formation of diethyl ether from ethyl alcohol using sulphuric acid as a catalyst can be explained as:

$$C_2H_5OH + \underset{\text{Catalyst}}{H_2SO_4} \longrightarrow \underset{\text{Intermediate compound}}{C_2H_5HSO_4}$$

$$C_2H_5HSO_4 + HOC_2H_5 \longrightarrow \underset{\text{Product}}{C_2H_5OC_2H_5} + \underset{\text{Catalyst}}{H_2SO_4}$$

(v) The decomposition of acetaldehyde which occurs as follows,

$$CH_3CHO \xrightarrow{I_2} CH_4 + CO$$

can be explained as shown below:

$$CH_3CHO + \underset{\text{Catalyst}}{I_2} \longrightarrow \underset{\text{Intermediate}}{CH_3I} + HI + CO$$

$$CH_3I + HI \longrightarrow CH_4 + I_2$$

$$\overline{CH_3CHO \longrightarrow CH_4 + CO}$$

This theory explains why a catalyst remains unchanged in mass and chemical composition at the end of the reaction and is effective even in small quantities. The scope of this theory is, however, limited as the formation of intermediate compound is possible in the case of homogeneous catalysis only. It also fails to explain the action of catalytic promoters, catalytic poisons and action of finely divided catalysts.

(vi) Variable oxidation state of transition metals makes them efficient catalysts. For example, Fe^{3+} catalyses the reaction between iodide and persulphate ions.

$$2I^- + S_2O_8^{2-} \xrightarrow{Fe^{3+}} I_2 + 2SO_4^{2-}$$

The catalytic action can be explained as,

$$2Fe^{3+} + 2I^- \longrightarrow 2Fe^{2+} + I_2$$

$$2Fe^{2+} + S_2O_8^{2-} \longrightarrow 2Fe^{3+} + 2SO_4^{2-}$$

2. Adsorption theory: This theory explains the mechanism of heterogeneous catalysis. The old point of view was that when a catalyst is in solid state and the reactants are in gaseous state or in solutions, the molecules of the reactants are adsorbed on the surface of the catalyst. The increased concentration of the reactants on the surface influences the rate of reaction (law of mass action). Adsorption being an exothermic process, the heat of adsorption is taken up by the surface of the catalyst which is utilised in enhancing the chemical activity of the reacting molecules. The view does not explain the specificity of a catalyst.

Adsorption is broadly of two types: physical and chemical. The chemical adsorption is specific and involves chemical combination on the surface of the catalyst. The modern adsorption theory is the combination of intermediate compound formation theory and the old adsorption theory. The catalytic activity is localised on the surface of the catalyst. The mechanism involves five steps:

(i) Diffusion of reactants to the surface of the catalyst.

(ii) Some form of association between the catalyst surface and the reactants occurs. This is assumed to be adsorption.

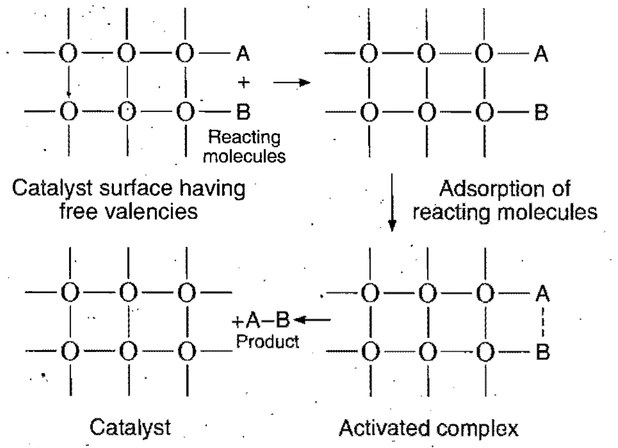

Fig. 13.12 Adsorption of reacting molecules, formation of activated complex and adsorption of products

(iii) Occurrence of chemical reaction on the catalyst surface.

(iv) Desorption of reaction products away from the catalyst surface.

(v) Diffusion of reaction products away from the catalyst surface.

The catalyst surface is a seat of chemical forces of attraction. There are free valencies on the surface of a catalyst. When a gas comes in contact with such a surface, its molecules are held up there due to loose chemical combination. If different molecules are adsorbed side by side, they may react and new molecules so formed may evaporate leaving the way for the fresh reactant molecules (Fig. 13.12).

In case, free valencies are responsible for the catalytic activity, it follows that with the increase of these valencies on the surface of a catalyst, the catalytic activity will be greatly enhanced. The free valencies can be increased in the following two ways:

(a) Sub-division of the catalyst,

(b) Rough surface of the catalyst.

(a) Sub-division of the catalyst: The number of free valencies increases on disintegration. Finely powdered or colloidal catalyst particles having large surface area are very rich in free valencies.

Actually, it is observed that finely divided nickel and colloidal platinum act as efficient catalysts.

(b) Rough surface of the catalyst: There are a number of active spots in the form of edges, corners, cracks and peaks on a rough surface. They give rise to an increase in number of free valencies. These active spots enhance the adsorption and thereby increase the catalytic efficiency of the catalyst.

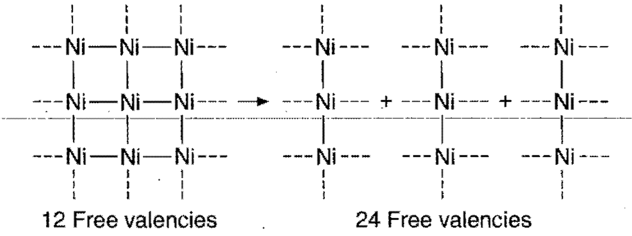

Fig. 13.13 Increase in number of free valencies

The adsorption theory explains the following facts of heterogeneous catalysis:

(i) The surface of the catalyst is used again and again due to alternate adsorption and desorption. **Thus, a small quantity of a catalyst can catalyse large amounts of reactants.**

(ii) Chemical adsorption depends on the nature of the adsorbent and adsorbate. Hence, catalysts are specific in action.

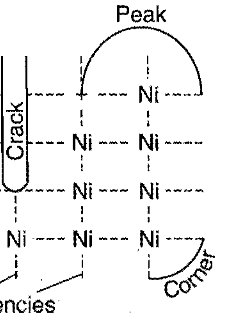

Fig. 13.14

(iii) Desorption leaves the catalytic surface unchanged. Thus, the catalyst at the end of reaction remains same in mass and composition.

(iv) The energy of adsorption compensates the activation energy of the reacting molecules to some extent. Thus, the reactions occur at faster rate.

(v) Greater efficiency of the catalyst in finely divided state and rough surface.

(vi) It adequately explains the poisoning of catalysts. The poisons are preferentially adsorbed at the active centres of the catalyst. This effect reduces the free valencies for the reacting molecules and, thus, the catalytic activity decreases.

(vii) Promoters are responsible for increasing the roughness of the surface of a catalyst. This effect increases the free valencies for the reacting molecules and, thus, the catalytic activity of the catalyst is increased.

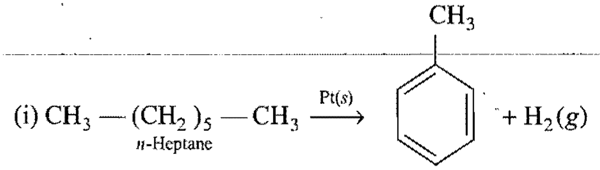
Activity and Selectivity of Heterogeneous Catalysis

Activity is the ability of a catalyst to accelerate chemical reactions. In certain cases the activity can be as high as 10^{10}, *i.e.*, the catalysed reaction is 10^{10} times faster than the uncatalysed reaction.

$$H_2(g) + O_2(g) \longrightarrow \text{No reaction}$$

$$2H_2(g) + O_2(g) \xrightarrow[\Delta]{\text{Pt}} 2H_2O(g)$$

Selectivity of a catalyst is its ability to direct the reaction in such a way as to yield particular products excluding others, *e.g.*,



n-Heptane is catalysed by Pt to toluene.

(ii) Propylene and oxygen selectively give acrolein over bismuth molybdate as catalyst.

$$CH_3-CH=CH_2+O_2 \xrightarrow[\text{BiMoO}_4]{\text{Bismuth molybdate}} \underset{\text{Acrolein}}{CH_2=CH-CHO} + H_2O$$

(iii) Acetylene on hydrogenation in presence of Pt or Ni or Pd catalyst gives ethane.

$$H-C\equiv C-H+2H_2(g) \xrightarrow{\text{Pt/Pd/Ni}} \underset{\text{Ethane}}{CH_3-CH_3}$$

Hydrogenation of acetylene in presence of Lindlar's catalyst gives ethylene.

$$H-C\equiv C-H+H_2 \xrightarrow[\text{Sulphur or quinoline}]{\text{Pd-BaSO}_4} \underset{\text{Ethylene}}{CH_2=CH_2}$$

13.14 ACID-BASE CATALYSIS

Generally, homogeneous catalysis in solution is brought about by acids and bases. On the basis of studies done by Arrhenius and Ostwald in the hydrolysis of esters and nitrites, it was established that in acid-base catalysis, it is the hydrogen ion or hydroxyl ion which acts as catalyst.

Examples of acid-base catalysis:

(i) Hydrolysis of an ester:

$$CH_3COOC_2H_5(l)+H_2O(l) \xrightarrow[\text{OH}^-]{\text{H}^+\text{ or}} CH_3COOH(l)+C_2H_5OH(l)$$

(ii) Inversion of cane sugar:

$$C_{12}H_{22}O_{11}(l)+H_2O(l) \xrightarrow{\text{H}^+} C_6H_{12}O_6(l)+C_6H_{12}O_6(l)$$

(iii) Conversion of acetone into diacetone alcohol:

$$CH_3COCH_3(l) + CH_3COCH_3(l) \xrightarrow{OH^-} CH_3COCH_2 \cdot C(CH_3)_2OH(l)$$

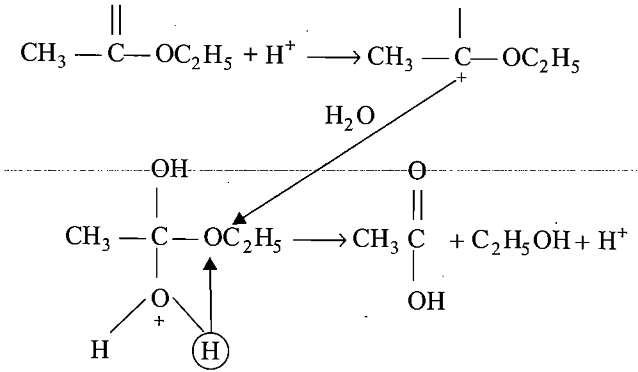
(iv) Decomposition of nitramide:

$$NH_2 \cdot NO_2(l) \xrightarrow{OH^-} N_2O(g) + H_2O(l)$$

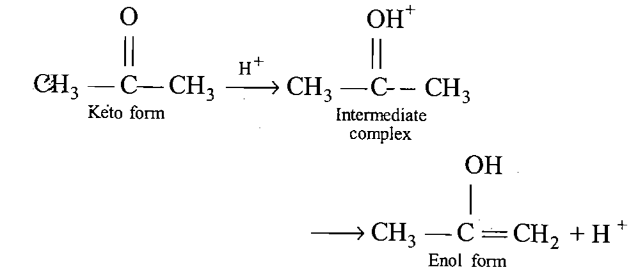
The recent work has shown that all substances which have a tendency to lose or to gain protons can show catalytic activity, *i.e.,* all Bronsted acids and bases act as acid-base catalysts.

Mechanism of Acid-Base Catalysis

(a) In acid catalysis, the proton given by Bronsted acid forms an intermediate complex with the reactant which then reacts to give back the proton (H^+). For example, the hydrolysis of ester occurs in the following manner:



The mechanism of keto-enol tautomerism of acetone is:



$$\underset{\text{Keto form}}{CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-CH_3} \xrightarrow{H^+} \underset{\substack{\text{Intermediate}\\\text{complex}}}{CH_3-\overset{\overset{\displaystyle OH^+}{\|}}{C}-CH_3} \longrightarrow \underset{\text{Enol form}}{CH_3-\overset{\overset{\displaystyle OH}{|}}{C}=CH_2} + H^+$$

(b) In base catalysed hydrolysis, the OH^- ion or any Bronsted base accepts a proton from the reactant to form an intermediate complex which then reacts or decomposes to regenerate the OH^- or Bronsted base. In presence of OH^- ions, the decomposition of nitroamine can be shown as:

$$NH_2NO_2 + OH^- \longrightarrow \begin{array}{c} NHNO_2^- \\ \downarrow \\ N_2O + OH^- \end{array} + H_2O$$

or in presence of CH_3COO^- ions,

$$NH_2NO_2 + CH_3COO^- \longrightarrow \begin{array}{c} NHNO_2^- \\ \downarrow \\ N_2O + OH^- \end{array} + CH_3COOH$$

$$OH^- + CH_3COOH \longrightarrow CH_3COO^- + H_2O$$

13.15 ENZYME CATALYSIS

Enzymes are complex nitrogenous organic compounds which are produced by living plants and animals. Enzymes are actually high molecular mass protein molecules. Enzymes form colloidal solutions in water and are very effective catalysts. They catalyse numerous reactions, especially those connected with natural processes. Numerous reactions occur in the bodies of animals and plants to maintain the life process. These reactions are catalysed by enzymes. The enzymes are thus termed as **biochemical catalysts** and the phenomenon is known as **biochemical catalysis.**

Many enzymes have been obtained in pure crystalline state from living cells. However, the first enzyme was synthesised in the laboratory in 1969. The following are some of the examples of enzyme catalysis:

(i) Inversion of cane sugar: The invertase enzyme converts cane sugar into glucose and fructose.

$$\underset{\text{Cane sugar}}{C_{12}H_{22}O_{11}(l)} + H_2O(l) \xrightarrow{\text{Invertase}} \underset{\text{Glucose}}{C_6H_{12}O_6(l)} + \underset{\text{Fructose}}{C_6H_{12}O_6(l)}$$

(ii) Conversion of glucose into ethyl alcohol: The zymase enzyme converts glucose into ethyl alcohol and carbon dioxide.

$$\underset{\text{Glucose}}{C_6H_{12}O_6(l)} \xrightarrow{\text{Zymase}} \underset{\text{Ethyl alcohol}}{2C_2H_5OH(l)} + 2CO_2(g)$$

(iii) Conversion of starch into maltose: The diastase enzyme converts starch into maltose.

$$\underset{\text{Starch}}{2(C_6H_{10}O_5)_n(l)} + nH_2O(l) \xrightarrow{\text{Diastase}} \underset{\text{Maltose}}{nC_{12}H_{22}O_{11}(l)}$$

(iv) Conversion of maltose into glucose: The maltase enzyme converts maltose into glucose.

$$\underset{\text{Maltose}}{C_{12}H_{22}O_{11}(l)} + H_2O(l) \xrightarrow{\text{Maltase}} \underset{\text{Glucose}}{2C_6H_{12}O_6(l)}$$

(v) Decomposition of urea into ammonia and carbon dioxide: The enzyme urease catalyses this decomposition.

$$NH_2CONH_2(l) + H_2O(l) \xrightarrow{\text{Urease}} 2NH_3(g) + CO_2(l)$$

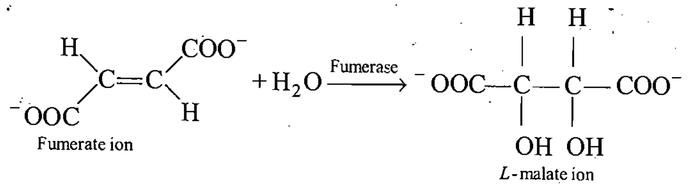
(vi) In stomach, the pepsin enzyme converts proteins into peptides while in intestine, the pancreas trypsin converts proteins into amino acids by hydrolysis.

(vii) Conversion of ethyl alcohol into acetic acid: The *Mycoderma aceti* enzyme converts dilute solutions of alcohol into acetic acid and water.

$$C_2H_5OH(l) + O_2(g) \xrightarrow{\textit{Mycoderma aceti}} CH_3COOH(l) + H_2O(l)$$

(viii) Conversion of milk into curd: It is an enzymatic reaction brought about by *lactic bacilli* enzyme present in curds.

(ix) The enzyme **fumerase** catalyses the hydration process of fumerate ion.



This reaction shows selectivity of enzymes because fumerase enzyme is unable to catalyse '*Cis*' isomer, *i.e.*, malate ion.

(x) In our body, the enzyme **carbonic anhydrase** catalyses the following reaction:

$$CO_2(aq.) + H_2O(l) \rightleftharpoons H^+(aq.) + HCO_3^-(aq.)$$

Forward process takes place when CO_2 goes to tissues from blood, whereas backward process takes place when CO_2 gas is released from the blood to the lungs.

Carbonic anhydrase has very high efficiency, one molecule of it catalyses 10^6 substrate molecules.

(xi) Lysozyme is found in the tear of our eyes. It protects our eyes from bacteria. It breaks down the cell wall of bacteria and then it ruptures due to endo-osmosis.

(xii) Nitrogenase enzyme is found in the bacteria of the root nodules of leguminous plants such as peas and beans. It catalyses the nitrogen fixation, *i.e.*, conversion of N_2 from atmosphere to the NH_3 in the soil.

Table 13.1 gives the summary of some important enzymatic reactions:

Table 13.1 Some enzymatic reactions

	Enzyme	Source	Enzymatic reaction
1.	Invertase	Yeast	Sucrose ⟶ Glucose and fructose
2.	Zymase	Yeast	Glucose ⟶ Ethyl alcohol and carbon dioxide
3.	Diastase	Malt	Starch ⟶ Maltose
4.	Maltase	Yeast	Maltose ⟶ Glucose
5.	Urease	Soyabean	Urea ⟶ Ammonia and carbon dioxide
6.	Pepsin	Stomach	Proteins ⟶ Amino acids
7.	Trypsin	Intestine	Proteins ⟶ Amino acids
8.	Amylase	Saliva	Starch ⟶ Glucose
9.	*Lactic bacilli*	Curd	Fermentation of milk
10.	*Mycoderma aceti*	Vinegar	Ethyl alcohol ⟶ Acetic acid
11.	Lipase	Castor seed	Fat ⟶ Glycerol
12.	Ptylin	Saliva	Starch ⟶ Sugar

Characteristics of Enzyme Catalysis

Enzyme catalysis is intermediate between homogeneous and heterogeneous catalysis. In general, it is similar to inorganic heterogeneous catalysis and sometimes it is called microheterogeneous catalysis. However, it is unique in its efficiency and high degree of specificity. The following characteristics are exhibited by enzyme catalysts:

(i) Most efficient catalysts: The enzyme-catalysed reactions are very fast in comparison to the reactions catalysed by inorganic substances. This is due to the fact that activation energy of a reaction in presence of an enzyme is low. One molecule of an enzyme may transform one million molecules of the reactant per minute.

(ii) High specific nature: Each enzyme is specific for a given reaction, *i.e.*, one catalyst cannot catalyse more than one reaction. For example, the enzyme urease catalyses the hydrolysis of urea only. It does not catalyse any other amide, not even methyl urea.

(iii) Temperature dependence: The rate of an enzyme reaction depends on the temperature. The enzyme activity rises rapidly with temperature and becomes maximum at a definite temperature, called the **optimum temperature.** Beyond the optimum temperature, the enzyme activity decreases and ultimately becomes zero. The enzyme activity is destroyed at about 70° C. The optimum temperature of enzyme reactions occurring in the human body is 37° C. At higher temperatures (fever), the enzyme activity becomes less. The favourable temperature range for enzymatic activity is 25–37 ° C.

(iv) pH dependence: The rate of an enzyme-catalysed reaction varies with pH of the system. The enzyme activity is maximum at a particular pH called optimum pH. The optimum pH of enzyme reactions occurring in human body is 7.4. The favourable pH range for enzymatic reactions is 5–7.

Activity of enzyme decreases above and below the optimum pH. Effect of pH on enzymatic rate may reflect denaturation.

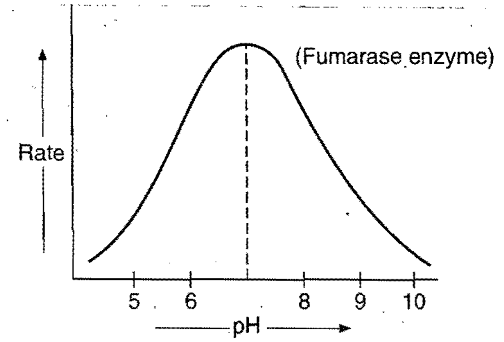


Fig. 13.15

(v) No effect on equilibrium state: Like ordinary catalysts, enzymes cannot disturb the final state of equilibrium of a reversible reaction.

(vi) Colloidal nature: Enzymes form colloidal solutions in water. Their efficiency is retarded in presence of large quantities of electrolytes. Enzymes are destroyed by ultraviolet rays.

(vii) Activators or coenzymes: The enzymatic activity is increased in the presence of certain substances, known as **coenzymes.** It has been observed that when a small non-protein

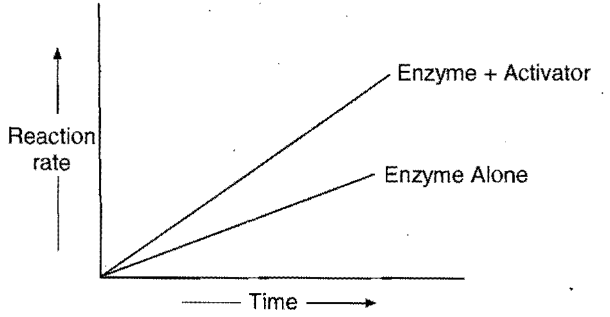

Fig. 13.16 Effect of activators on the rate of enzyme catalysis

(vitamin) is present along with an enzyme, the catalytic activity is enhanced considerably.

Activators are generally metal ions such as $Na^+, Mn^{2+}, Co^{2+}, Cu^{2+}$, etc. These metal ions, when weakly bonded to enzyme molecules, increase their catalytic activity. Amylase in presence of sodium chloride, *i.e.*, Na^+ ions are catalytically very active.

(viii) Inhibitors and poisons: Like ordinary catalysts, enzymes are also inhibited or poisoned by the presence of certain substances. The inhibitors or poisons interact with the active functional groups on the enzyme surface and often reduce or completely destroy the catalytic activity of the enzymes.

The use of many drugs is related to their action as enzyme inhibitors in the body.

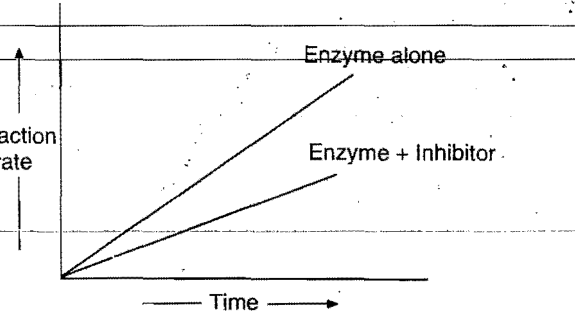

Fig. 13.17 Effect of inhibitor on the rate of enzyme catalysis

Mechanism of enzyme catalysis: There are a number of cavities present on the surface of colloidal particles of enzymes. These cavities are of characteristic shape and possess active groups such as $—NH_2$, —COOH, —SH, —OH, etc. These are actually the active centres on the surface of enzyme particles. The molecules of the reactant (substrate), which have complementary shape, fit into these cavities just like a key fits into a lock. On account of the presence of active groups, an activated complex is formed which then decomposes to yield the products.

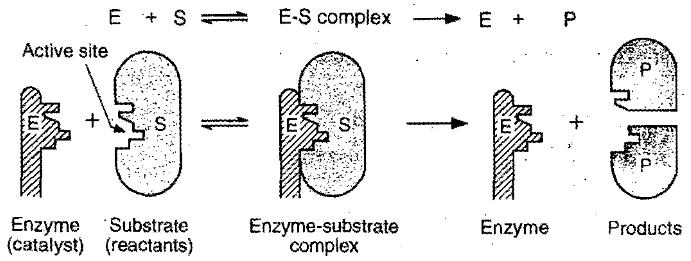

Fig. 13.18

Michaelis and Menten suggested the following mechanism for enzyme catalysis:

Step 1. Binding of enzyme to substrate to form an activated complex,

$$E + S \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} ES$$

Step 2. Product formation in the activated complex,

$$ES \xrightarrow{k_2} EP$$

Step 3. Decomposition of *EP* into products and enzyme again, $EP \longrightarrow P + E$

This mechanism accounts for the high specificity of enzymatic reactions.

The rate of enzyme catalysed reaction is given by:

$$\text{rate} = k_2[ES] = \frac{k_2[E][S]}{K_m + [S]} \text{...(i) (Michaelis-Menten equation)}$$

K_m = Michaelis- Menten constant

$[S]$ = Concentration of substrate

$[E]$ = Concentration of enzyme

Case I. When, $[S] >>> K_m$, then K_m can be neglected.

$\therefore$ Rate $= k_2[E]$ and the reaction belongs to first order. The rate law may be given as,

$$r_{\max} = k_2[E] \qquad \text{...(ii)}$$

Dividing eq. (i) by (ii)

$$\frac{r}{r_{\max}} = \frac{[S]}{[S] + K_m}$$

when, $K_m = [S], r = \frac{1}{2} r_{\max}$

Case II. When, $[S] <<< K_m$, then reaction will be of second order.

$$\text{Rate} = \frac{k_2}{K_m}[E][S] \qquad \text{(Second order rate law)}$$

Enzyme kinetics may be graphically represented as :

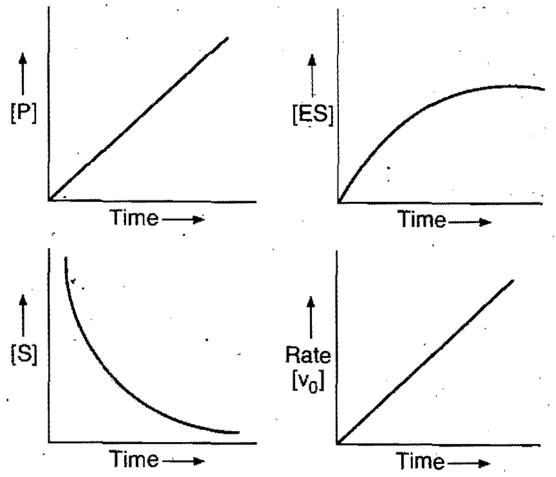

Fig. 13.19 Variation with time in enzyme catalysis

Competitive Enzyme Kinetics

Enzyme X and enzyme Y catalyse the same reaction and exhibit v_0 (rate) versus [S] curves shown ahead :

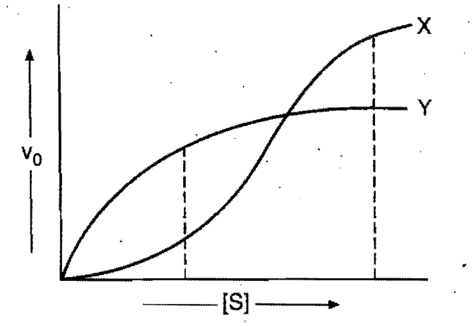

Fig. 13.20

At low substrate concentration, enzyme Y will be more efficient because activation energy will be low, in the presence of enzyme (Y). At high substrate concentration, enzyme X will be more efficient.

13.16 CATALYSTS IN INDUSTRY

Some of the important technical catalytic processes are listed in table 13.2 as to give an idea about the utility of catalysts in industries.

Table 13.2 Some Industrial Catalytic Processes

Process	Catalyst
1. Haber's process for the manufacture of ammonia. $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$	Finely divided iron. Molybdenum as promoter. Conditions: 200 atmospheric pressure and 450–500°C temperature.
2. Ostwald's process for the manufacture of nitric acid. $4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$ $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$ $4NO_2(g) + 2H_2O(l) + O_2(g) \longrightarrow 4HNO_3(l)$	Platinised asbestos Temperature 300°C.
3. Lead chamber process for the manufacture of sulphuric acid. $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ $SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(l)$	Nitric oxide.
4. Contact process for the manufacture of sulphuric acid. $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ $SO_3(g) + H_2SO_4(l) \longrightarrow \underset{\text{Oleum}}{H_2S_2O_7(l)}$ $H_2S_2O_7(l) + H_2O(l) \longrightarrow 2H_2SO_4(l)$	Platinised asbestos or vanadium pentoxide (V_2O_5). Temperature 400 – 450°C.
5. Deacon process for the manufacture of chlorine. $4HCl(g) + O_2(g) \longrightarrow 2H_2O(l) + 2Cl_2(g)$	Cupric chloride ($CuCl_2$). Temperature 500°C.
6. Bosch process for the manufacture of hydrogen. $\underbrace{CO + H_2}_{\text{Water gas}} + H_2O(l) \longrightarrow CO_2(g) + 2H_2(g)$	Ferric oxide (Fe_2O_3) + chromic oxide as a promoter. Temperature 400–600°C.
7. Synthesis of methanol. $CO(g) + 2H_2(g) \longrightarrow CH_3OH(l)$	Zinc oxide (ZnO) + chromic oxide as a promoter. Pressure 200 atmospheres and temperature 250°C
8. Hydrogenation of vegetable oils. $Oil(l) + H_2(g) \longrightarrow$ Vanaspati ghee(s)	Nickel (finely divided). Temperature 150 –200°C. High pressure
9. Manufacture of ethyl alcohol by fermentation of molasses (sugar solution). $C_{12}H_{22}O_{11}(l) + H_2O(l) \xrightarrow{\text{Invertase}} C_6H_{12}O_6(l) + C_6H_{12}O_6(l)$ $C_6H_{12}O_6(l) \xrightarrow{\text{Zymase}} 2C_2H_5OH(l) + 2CO_2(g)$	Invertase enzyme and zymase (yeast) enzyme Temperature 25–30°C. Conversion occurs in 2 or 3 days.
10. Manufacture of ethyl alcohol from starch. (a) Starch $\xrightarrow{\text{Diastase}}$ Maltose (b) Maltose $\xrightarrow{\text{Maltase}}$ Glucose $\xrightarrow{\text{Zymase}}$ Alcohol	Germinated barley (diastase enzyme) Temperature 50 – 60°C. Yeast (maltase and zymase enzymes). Temperature 25–30°C.
11. Manufacture of acetic acid from ethyl alcohol. $C_2H_5OH(l) + O_2(g) \longrightarrow CH_3COOH(l) + H_2O(l)$	*Mycoderma aceti.* Temperature 25–30°C.
12. Bergius process for the synthesis of petrol from coal. Coal + $H_2(g) \longrightarrow$ Mix. of hydrocarbons	Ferric oxide (Fe_2O_3) Temperature 475°C. Pressure 200 atmosphere.
13. Polymerisation of ethene to polythene. $\underset{\text{Ethene}}{nCH_2{=}CH_2} \longrightarrow \underset{\text{Polythene}}{\left[\!-CH_2-CH_2-\!\right]_n}$	$TiCl_4$ and Al R_3 (Ziegler Natta Catalyst)

13.17 ZEOLITES

Zeolites are naturally occurring or synthetic microporous aluminosilicates of general formula:

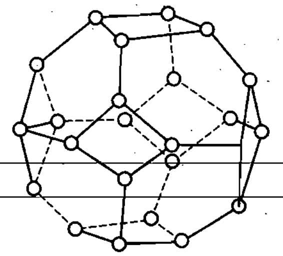
$$M_{x/n}\,[(AlO_2)_x(SiO_2)_y]m\cdot H_2O$$

where, $M = Na^+, K^+$ or Ca^{2+} like metals

n = valency of metal cation

m = molecules of water of crystallization

Zeolite may be considered as open structure of silica in which trivalent aluminium has been substituted in a fraction $x/(x+y)$ of tetravalent sites occupied by silicon atoms. Since a substitution of an atom of silicon by aluminium generates one negative charge on the aluminosilicate frame work, substitution of x atoms generates x negative charge on the aluminosilicate framework. This charge is neutralised by the exchangeable cations M of valency n. The void spaces which can be greater than 50% of the volume are occupied by 'm' molecules of water in the unit cell. Zeolite is derived from the Greek language which means 'boiling stone' because the water trapped in void spaces boils off when the naturally occurring zeolite stone is heated. Building block of zeolite is truncated octahedron (Cubo-octahedron). This structure is called β-cage or sodalite cage.



Truncated octahedron.

Stoichiometric formulae of some well known **zeolites** are:

(i) Faujasite (natural) $Na_{56}[(AlO_2)_{56}(SiO_2)_{136}]250H_2O$

(ii) Gemelinite $Na_2Ca(AlO_2)_2(SiO_2)_4\cdot 6H_2O$

(iii) Zeolite sieve of molecular porosity-5 (ZSM-5)

$$H_x[(AlO_2)_x(SiO_2)_{96-x}].16H_2O$$

(iv) Erionite $Na_2K_2CaMg(AlO_2)_2(SiO_2)_2.6H_2O$

Shape selectivity of zeolite: Zeolite is the most widely studied shape selective catalyst. Shape selectivity of zeolite depends upon pore structure of the catalyst, pore size generally varies between 260 pm to 740 pm. Such catalysts are highly specific, it is because molecules of only a particular size and shape can enter these pores and get adsorbed. Shape selectivity of ZSM-5 in the conversion of alcohols into hydrocarbons are given in following table. The table gives the percentage of different hydrocarbons in the mixtures of hydrocarbons obtained from two different alcohols, *i.e.*, CH_3OH (methyl alcohol) and $nC_7H_{15}OH$ (*n*-heptyl alcohol).

Product	**Starting with CH_3OH (%)**	**Starting with $C_7H_{15}OH$ (%)**
Methane	1.0	0.0
Ethane	0.6	0.3
Isobutane	18.7	19.3
n-butane	5.6	11.0
Iso-pentane	7.8	8.7
Benzene	1.7	3.4
Toluene	10.5	14.3
Xylene	17.2	11.6

Persorption : It is a special type of sorption, introduced by Mc Bain. Persorption is the process in which the molecules like H_2O, CH_3OH, C_2H_5OH are adsorbed in the internal cavity of zeolite or chabazite $(CaAl_2Si_4O_{12}\cdot 6H_2O)$.

Phase transfer catalyst: Substrate dissolved in organic layer and an anionic reagent dissolved in the aqueous layer are brought together by a catalyst. The catalyst transports the anion into the organic phase where reaction takes place with the substrate.

Quaternary ammonium and phosphonium salts with their unique ability to dissolve in both aqueous and organic liquids are the most suitable phase transfer catalysts.

13.18 AUTOMOBILE CATALYTIC CONVERTER

Automobile exhaust systems are being designed with built in catalytic converters. This system contains two types of heterogeneous catalyst, powdered noble metals and powdered transition metal oxides. They catalyze the oxidation of unburned hydrocarbon fuel and of partial combustion products such as carbon monoxide.

$$\underset{\text{Iso-octane}}{2C_8H_{18}} + 25O_2(g) \xrightarrow[\text{NiO}]{\text{Pt}} 16CO_2(g) + 18H_2O(g)$$

$$2CO(g) + O_2(g) \xrightarrow[\text{NiO}]{\text{Pt}} 2CO_2(g)$$

The same catalysts also catalyze another reaction, the decomposition of nitrogen oxide NO, into harmless N_2 and O_2.

$$2NO(g) \xrightarrow[\text{NiO}]{\text{Pt}} N_2(g) + O_2(g)$$

SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. Adsorption: It is a tendency of accumulation of molecular species at the surface of a solid or liquid. The molecular species which accumulates is termed **adsorbate** and the material on whose surface adsorption has taken place is called **adsorbent.** The process of removing an adsorbed substance from the surface of the adsorbent is called **desorption.**

2. Distinction between adsorption and absorption: In adsorption, the substance is concentrated only at the surface while in absorption, the substance is uniformly distributed throughout the bulk of the adsorbent. In adsorption, the concentration of the adsorbate increases on the surface only while in absorption, the concentration is uniform throughout the bulk of adsorbent. Both adsorption and absorption take place simultaneously and the process is termed **sorption.** However, adsorption is instantaneous while absorption is a slow process.

3. Physical adsorption or physisorption: If the forces of attraction existing between adsorbate and adsorbent are van der Waals' forces, the adsorption is called **physical adsorption** or **physisorption.** In general, more easily liquefiable gases are readily adsorbed near their critical temperatures. It is generally reversible. It occurs readily at low temperature and decreases with increasing temperature. The extent of adsorption increases with increase of surface area and increase of pressure. Heat of adsorption is quite low (20– 40 kJ mol^{-1} or about 5 kcal mol^{-1}).

4. Chemisorption: If the forces of attraction between adsorbate particles and adsorbent are almost of the same strength as chemical bonds, the adsorption is termed **chemisorption** or **Langmuir adsorption.** This type of adsorption is highly specific and commonly irreversible in nature. It is slow at low temperature but increases with rise of temperature on account of high energy of activation. High pressure is favourable for chemisorption. Heat of adsorption is high (40– 400 kJ mol^{-1} or 10–100 kcal mol^{-1}). It also increases with increase of surface area.

5. Adsorption isotherms: The curve showing the variation of the amount of adsorbate at a particular temperature with pressure or concentration is termed **adsorption isotherm.**

Freundlich adsorption isotherm: Freundlich, in 1909, gave an empirical relationship between the quantity of adsorbate adsorbed by unit mass of solid adsorbent and pressure at a particular temperature. The relationship is expressed by the following equation:

$$\frac{x}{m} = k \cdot P^{1/n}$$

where, x is the mass of gas adsorbed, m is the mass of adsorbent, P is the pressure of gas and k, n are constants. Another form of equation is:

$$\log \frac{x}{m} = \log k + \frac{1}{n} \log P$$

This is the equation of a straight line. The slope of the straight line gives the value of $\frac{1}{n}$ and the intercept on the y-axis gives the value of log k.

6. Adsorption from solution phase: Solids can adsorb solutes from solutions also. Litmus solution becomes colourless when shaken with charcoal. Similarly, when a solution of acetic acid in water is shaken with charcoal, a part of the acid is adsorbed by charcoal. In such cases, the following observations have been made:

(i) The extent of adsorption decreases with the rise of temperature.

(ii) The extent of adsorption increases with the surface area of the adsorbent.

(iii) The extent of adsorption depends upon the concentration of the solute in solution.

$$\frac{x}{m} = kC^{1/n}$$

or $$\log \frac{x}{m} = \log k + \frac{1}{n} \log C$$

7. Applications of adsorption: Important applications of adsorption are:

(i) Production of high vacuum.

(ii) Gas masks—It is a device which consists of activated charcoal. This is used to adsorb poisonous gases.

(iii) Humidity control—Silica gel and aluminium gel are used for this purpose.

(iv) Removal of colouring matter from solutions—Animal charcoal is used for decolorising cane sugar.

(v) Heterogeneous catalysis (vi) Separation of inert gases by coconut charcoal (vii) Softening of hard water (viii) De-ionising of water (ix) Cleaning agents (x) Froth floatation process (xi) Adsorption indicators (xii) Chromatographic analysis (xiii) In medicines.

8. Catalysis: Substances which alter the velocity of a reaction by mere presence, without undergoing any change in mass and composition, are termed catalysts and the phenomenon is known as catalysis. Catalytic reactions are broadly divided into two groups: (i) Homogeneous catalysis (ii) Heterogeneous catalysis. When the reactants and catalyst are in the same phase, the catalysis is said to be **homogeneous catalysis.**

Examples: $2SO_2(g) + O_2(g) \xrightarrow{NO(g)} 2SO_3(g)$

$$CH_3COOCH_3(l) + H_2O(l) \xrightarrow{HCl(l)} CH_3COOH(l) + CH_3OH(l)$$

$$C_{12}H_{22}O_{11}(l) + H_2O(l) \xrightarrow{H_2SO_4(l)} C_6H_{12}O_6(l) + C_6H_{12}O_6(l)$$

(ii) Those catalytic reactions in which the physical state of reactants is different from the catalysts are termed heterogeneous catalysis.

Examples: $2SO_2(g) + O_2(g) \xrightarrow{Pt(s)} 2SO_3(g)$

$$N_2(g) + 3H_2(g) \xrightarrow{Fe(s)} 2NH_3(g)$$

$$4NH_3(g) + 5O_2(g) \xrightarrow{Pt(s)} 4NO(g) + 6H_2O(g)$$

$$4HCl(g) + O_2(g) \xrightarrow{Cu_2Cl_2(s)} 2H_2O(g) + 2Cl_2(g)$$

9. Types of catalysis:

(i) Positive catalysis: When the rate of reaction is accelerated by a foreign substance, it is said to be a positive catalyst and the phenomenon is positive catalysis.

(ii) Negative catalysis: The substance which when added to the reaction mixture, retards the reaction rate is termed negative catalyst and the phenomenon is known as negative catalysis.

(iii) Autocatalysis: In certain reactions, one of the products acts as a catalyst. In the initial stages the reaction is slow but as soon as the products come into existence, the reaction rate increases.

(iv) Induced catalysis: When one reaction influences the rate of another reaction, which does not occur under ordinary conditions, the phenomenon is known as induced catalysis.

10. Characteristics of catalysis: The following are the characteristics which are common to most of the catalytic reactions:

(i) A catalyst remains unchanged in mass and chemical composition at the end of the reaction.

(ii) A small quantity of the catalyst is generally sufficient to catalyse almost an unlimited reaction.

(iii) A catalyst cannot initiate the reaction.

(iv) The catalyst is generally specific in nature.

(v) The catalyst cannot change the position of equilibrium in a reversible reaction. However, it can help to achieve the equilibrium state in lesser time.

(vi) Substances which themselves are not catalysts but when mixed in small quantities with the catalysts enhance their efficiency are called as **promoters** or **activators.**

(vii) Substances which destroy the activity of a catalyst by their presence are known as **catalytic poisons.**

(viii) A catalyst has a particular temperature at which its activity is maximum. This temperature is termed as **optimum temperature.**

(ix) A positive catalyst lowers the activation energy and provides a new pathway involving lower amount of activation energy.

11. Theories of catalysis: Two broad theories of catalytic action have been proposed:

(i) Intermediate compound formation theory: This was proposed by Clement and Desormes in 1806. According to this theory, the catalyst first forms an intermediate with one of the reactants, which being unstable combines with other reactants to form the desired product and the catalyst is regenerated.

$$A + K \text{ (catalyst)} = AK \text{ (intermediate)}$$

$$AK + B = AB + K$$

The scope of this theory is limited as the formation of intermediate is not possible in the case of many reactions.

It also fails to explain the action of promoters and poisons.

(ii) Adsorption theory: The catalytic activity is localised on the surface of a catalyst. The molecules of the reactants are adsorbed on the surface of the catalyst. The increase in concentration of the reactants on the surface increases the rate of reaction (law of mass action). There are free valencies on the surface which are responsible for loose chemical combination of the reactants with the catalyst. If different molecules are adsorbed side by side, they may react readily and new molecules are formed which evaporate leaving the way for the fresh reactant molecules. The free valencies can be increased in two ways:

(a) Sub-division of the catalyst,

(b) Rough surface of the catalyst.

Adsorption theory is a better theory as it can explain a number of characteristics of the catalyst, especially a heterogeneous catalyst.

12. Enzyme catalysis: Enzymes are complex nitrogenous organic compounds of high molecular masses produced by living plants and animals. Enzymes are protein molecules, form colloidal solutions in water and catalyse numerous reactions especially connected with natural processes. The enzymes are also termed as **biochemical catalysts** and the phenomenon is known as biochemical catalysis.

The catalytic activity of enzymes is perhaps the greatest of all the catalysts. Their activity is also due to their capacity to lower the activation energy for a reaction. Each enzyme can catalyse a specific reaction. The enzyme reactions are sensitive to temperature and pH. Generally, the optimum temperature varies between 290–300 K and the favourable pH range is 5–7.

Questions

1. **Matrix Matching Problems (For IIT Aspirants):**

[A] Match the reactions of Column-I with the catalysts in Column-II:

Column-I (Reaction)	**Column-II (Catalyst)**
(a) $2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$	(p) Al_2O_3
(b) $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$	(q) Pt
(c) $2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$	(r) V_2O_5
(d) $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$	(s) MnO_2

[B] Match the reaction in List-I with the catalysts in List-II and types of catalysis in List-III:

List-I	**List-II**	**List-III**
(a) Oxidation of SO_2 to SO_3 in lead chamber process	(p) NO	(u) Positive catalyst
(b) Synthesis of methanol from CO and H_2	(q) Pt	(v) Poisoned by CO
(c) Oxidation of CO to CO_2	(r) V_2O_5	(w) Heterogeneous
(d) Oxidation of NH_3 to NO in Ostwald's process	(s) Rh	(x) Homogeneous

[C] Match the Column-I with Column-II:

Column-I	**Column-II**
(a) ZSM-5	(p) $Na_2K_2CaMg(AlO_2)_2(SiO_2)_2 \cdot 6H_2O$
(b) Erionite	(q) Catalyst to convert alcohol to gasoline (petrol)
(c) Gemelinite	(r) $Na_2Ca(AlO_2)_2(SiO_2)_4 \cdot 6H_2O$
(d) Cavity size 550 pm	(s) $H_x[(AlO_2)_x(SiO_2)_{96-x}] \cdot 16H_2O$

[D] Match the List-I with List-II:

List-I	**List-II**
(a) Mo	(p) Promotor
(b) Cu	(q) Negative catalyst
(c) TEL	(r) Decomposition of hydrogen peroxide
(d) Glycerine	(s) Haber process

[E] Match the Column-I with Column-II:

Column-I	**Column-II**
(a) Removal of water by silica gel	(p) Absorption
(b) Removal of water by anhydrous $CaCl_2$	(q) Adsorption
(c) Surface phenomena	(r) Evaporation of liquid
(d) Bulk phenomena	(s) Boiling of liquid

[F] Match the Column-I with Column-II:

Column-I	**Column-II**
(a) $BaSO_4$	(p) Inhibitor for decomposition of H_2O_2
(b) Acetamide	(q) Catalyst
(c) Zeolite	(r) Removes hardness of water
(d) Nickel	(s) Poison for Pd in Lindlar's catalyst

[G] Match the phenomena in Column-I with example in Column-II:

Column-I	**Column-II**
(a) Persorption	(p) H_2 on Ni surface
(b) Sorption	(q) CH_3OH in chabazite
(c) Negative adsorption	(r) NH_3 in H_2O
(d) Occlusion	(s) Dil. NaCl on blood charcoal

Answers

1. [A] (a—s); (b—q, r); (c—q); (d—p).
[B] (a—p—x, u); (b—q, s—v, u); (c—p—x, u); (d—q—u, v, w).
[C] (a—q, s); (b—p); (c—r); (d—s).
[D] (a—p, s); (b—p); (c—q); (d—r).
[E] (a—q); (b—p); (c—q, r); (d—p, s).
[F] (a—s); (b—p); (c—q, r); (d—q).
[G] (a—q); (b—r); (c—s); (d—p).

• PRACTICE PROBLEMS •

1. Show that the maximum enzyme catalysed reaction rate will occur for

$$[\mathrm{H^+}]_{\text{opt}} = \sqrt{k_1 k_2}$$

The general pH control enzyme catalysed reaction is

$$E\mathrm{H}_2^{2+} \rightleftharpoons E\mathrm{H}^+ \rightleftharpoons E$$

Only $E\mathrm{H}^+$ is capable for binding substrate and catalysing the desired reaction;

$$k_1 = \frac{[E\mathrm{H}^+][\mathrm{H}^+]}{[E\mathrm{H}_2^{2+}]}; \quad k_2 = \frac{[E][\mathrm{H}^+]}{[E\mathrm{H}^+]}$$

[**Hint:** $k_1 k_2 = \dfrac{[E]\,[\mathrm{H}^+]^2}{[E\mathrm{H}_2^{2+}]}$

In pH control it may be considered that $[E] \approx [E\mathrm{H}_2^{2+}]$, *i.e.*, enzyme combines almost completely with H^+ ions.

Thus, $k_1 k_2 \approx [\mathrm{H}^+]^2; [\mathrm{H}^+] = \sqrt{k_1 k_2}$]

2. The rate of decomposition of acetaldehyde into methane and CO in the presence of I_2 at 800 K follows the rate law

$$\text{Rate} = k\,[CH_3CHO][I_2]$$

The decomposition is believed to go by a two steps mechanism:

$$CH_3CHO + I_2 \longrightarrow CH_3I + HI + CO$$

$$CH_3I + HI \longrightarrow CH_4 + I_2$$

What is the catalyst for the reaction? Which of the two steps is a slower one?

[**Ans.** I_2 is catalyst; first step is slow.]

3. A solution of palmitic acid ($M = 256$) in benzene contains 4.24 g acid per litre. When this solution is dropped on the water surface, benzene evaporates and palmitic acid forms monomolecular film of the solid type. If we wish to cover an area of 500 cm^2 with a monolayer, what volume of solution should be used? The area occupied by one palmitic acid molecule may be taken to be 2.1×10^{-20} m^2.

[**Ans.** 0.0239 cm^3]

[**Hint:** V litre volume of solution taken.

$$W = (4.24 \times V)\ \text{g}$$

$$\text{Number of atoms} = \frac{W}{\text{Atomic mass}} \times \text{Avogadro's number}$$

$$= \frac{4.24V}{256} \times 6.023 \times 10^{23}$$

$$\text{Area} = 500 \times 10^{-4}\ \text{m}^2 = \left[\frac{4.24V}{256} \times 6.023 \times 10^{23}\right] \times 21 \times 10^{-20}$$

$$V = 0.0000239\ \text{litre} = 0.0239\ \text{cm}^3]$$

4. Give the mechanism of the following reactions:

(a) In lead chamber process, NO(g) is used as catalyst in the oxidation of SO_2 to SO_3.

(b) NO(g) catalyses the decomposition ozone to oxy

(c) Ozone layer depletion by Freon or Teflon.

[**Hint:** (a) $2NO(g) + O_2(g) \longrightarrow \underset{\text{Intermediate}}{2NO_2}$

$$2NO_2(g) + 2SO_2(g) \longrightarrow 2SO_3(g) + 2NO(g)$$

OR

$$SO_2(g) + H_2O + NO_2(g) \longrightarrow \underset{\text{Intermediate}}{H_2SNO_5}$$

$$H_2SNO_5 \longrightarrow H_2SO_4 + NO(g)$$

(b) $NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g)$

$$O_3(g) \longrightarrow O_2(g) + O(g)$$

$$NO_2(g) + O(g) \longrightarrow NO(g) + O_2(g)$$

$$2O_3(g) \longrightarrow 3O_2(g) \quad \text{(Overall reaction)}$$

(c) Chlorine atoms furnished by freon and teflon act as a catalyst in the decomposition of ozone in the ozone layer.

$$O_3 \xrightarrow{\text{Sunlight}} O_2 + [O]$$

$$O_3 + Cl \longrightarrow O_2 + OCl$$

$$OCl + O \longrightarrow Cl + O_2\ ]$$

5. One gram of charcoal adsorbs 100 mL of 0.5 M CH_3COOH to form a mono-layer and thereby the molarity of acetic acid is reduced to 0.49 M. Calculate the surface area of the charcoal adsorbed by each molecule of acetic acid. Surface area of charcoal = 3.01×10^2 m^2/gm. **(IIT 2003)**

[**Hint:** Number of moles of acetic acid initially present

$$= \frac{MV}{1000} = \frac{0.5 \times 100}{1000} = 0.05$$

Number of moles of acetic acid left

$$= \frac{MV}{1000} = \frac{0.49 \times 100}{1000} = 0.049$$

Number of moles of acetic acid adsorbed

$$= 0.05 - 0.049 = 0.001\ \text{mol}$$

Number of molecules of acid adsorbed

$$= 0.001 \times 6.023 \times 10^{23} = 6.023 \times 10^{20}$$

Area occupied by single molecule of acetic acid

$$= \frac{\text{Total area}}{\text{Number of molecules adsorbed}}$$

$$= \frac{3.01 \times 10^2}{6.023 \times 10^{20}}$$

$$= 5 \times 10^{-19}\ \text{m}^2]$$

OBJECTIVE QUESTIONS

[illegible]: Questions with single correct answer

1. Adsorption is the phenomenon in which a substance:
   (a) accumulates on the surface of the other substance
   (b) goes into the body of the other substance
   (c) remains close to the other substance
   (d) oxidises or reduces the other substance
2. Physical adsorption is appreciable at:
   (a) higher temperature (b) lower temperature
   (c) room temperature (d) 100° C
3. The rate of chemisorption:
   (a) decreases with increase of pressure
   (b) is independent of pressure
   (c) is maximum at one atmospheric pressure
   (d) increases with increase of pressure
4. A poisonous gas is adsorbed at activated charcoal. The activated charcoal is:
   (a) absorber (b) adsorbate
   (c) adsorbent (d) absorbate
5. Chromatography is a technique based on:
   (a) solubilities of solute
   (b) adsorption of solute
   (c) chemical adsorption followed by dispersion
   (d) differential adsorption of different constituents of a mixture
6. Which of the following is not a characteristic of chemisorption?
   (a) Adsorption is irreversible
   (b) ΔH is of the order of 400 kJ
   (c) Adsorption is specific
   (d) Adsorption increases with increase of surface area
7. In the Freundlich adsorption isotherm equation :
   $\log\left(\frac{x}{m}\right) = \log k + \frac{1}{n}\log P$, the value of '$n$' is: **[CET (J&K) 2009]**
   (a) any value from 0 to 1
   (b) a negative integer
   (c) a positive integer
   (d) a positive or negative fractional number
8. Which of the following is not the application of adsorption?
   (a) De-ionisation of water
   (b) Gas masks
   (c) Hygroscopic nature of $CaCl_2$
   (d) Heterogeneous catalysis
9. Which one of the following is not a correct statement?
   (a) Physical adsorption is reversible in nature
   (b) Physical adsorption involves van der Waals' forces
   (c) Rate of physical adsorption increases with increase of pressure on the adsorbate
   (d) High activation energy is involved
10. Which one of the following is the correct statement?
    (a) Chemisorption is reversible in nature
    (b) Chemisorption is high at low temperature
    (c) Chemisorption depends on the nature of gas
    (d) Chemisorption does not involve activation energy
11. A catalyst is a substance which:
    (a) increases the equilibrium concentration of the product
    (b) changes the equilibrium constant of the reaction
    (c) shortens the time to reach equilibrium
    (d) supplies energy to the reaction
12. A catalyst:
    (a) increases the free energy change in the reaction
    (b) decreases the free energy change in the reaction
    (c) does not increase or decrease the free energy change in the reaction
    (d) can either decrease or increase the free energy change depending on what catalyst we use
13. Which of the following statements is more correct?
    (a) A catalyst only accelerates the rate of a chemical reaction
    (b) A catalyst can retard the rate of a chemical reaction
    (c) A catalyst can control the speed of a reaction
    (d) A catalyst alters the speed of a reaction
14. A catalyst is a substance which: **[JEE (WB) 2008]**
    (a) increases the equilibrium constant of the reaction
    (b) increases the equilibrium concentration of products
    (c) does not alter the reaction mechanism
    (d) changes the activation energy of the reaction
15. Which of the following reactions is an example for homogeneous catalysis? **[CET (J&K) 2006]**
    (a) $2H_2O_2(l) \xrightarrow{MnO_2(s)} 2H_2O(l) + O_2(g)$
    (b) $2SO_2(g) + O_2(g) \xrightarrow{V_2O_5(s)} 2SO_3(g)$
    (c) $2CO(g) + O_2(g) \xrightarrow{NO(g)} 2CO_2(g)$
    (d) $H_2(g) + C_2H_4(g) \xrightarrow{Ni(s)} C_2H_6(g)$
16. The substance which decreases the rate of a chemical reaction is called:
    (a) inhibitor (b) poison (c) moderator (d) promoter
17. The decomposition of hydrogen peroxide can be slowed down by the addition of a small amount of acetamide. The latter acts as:
    (a) inhibitor (b) promoter (c) moderator (d) poison
18. The temperature at which the catalytic activity of the catalyst is maximum, is called:
    (a) critical temperature (b) room temperature
    (c) absolute temperature (d) optimum temperature
19. Efficiency of the catalyst depends on its:
    (a) molecular weight (b) number of free valencies
    (c) physical state (d) amount used
20. Which of the following types of metals make the most efficient catalysts?

(a) Transition metals (b) Alkali metals
(c) Alkaline earth metals (d) Radioactive metals

21. Enzymes are made up of: **[CG (PET & PMT) 2007]**
(a) edible proteins
(b) proteins with specific structure
(c) nitrogen containing carbohydrate
(d) carbohydrates

22. In lead chamber process, which one of the following oxides is used as a catalyst?
(a) NO (b) NO_2 (c) N_2O_3 (d) N_2O_5

23. Enzymes are:
(a) substances made by chemists to activate washing powders
(b) catalysts found in organisms
(c) synthetic catalysts
(d) very active vegetative catalysts

24. Alcoholic fermentation is brought about by the action of:
(a) yeast (b) CO_2 (c) O_2 (d) CO

25. Glucose or fructose is converted into C_2H_5OH in the presence of:
(a) invertase (b) diastase (c) maltase (d) zymase

26. The name catalysis was given by:
(a) Rutherford (b) Langmuir
(c) Graham (d) Berzelius

27. In the reaction, $KMnO_4 + H_2SO_4 + H_2C_2O_4 \longrightarrow$ Products, Mn^{2+} ions act as:
(a) positive catalyst (b) negative catalyst
(c) autocatalyst (d) enzyme catalyst

28. In the Haber process of synthesis of NH_3:
(a) Mo acts as a catalyst and Fe as a promoter
(b) Fe acts as a catalyst and Mo as a promoter
(c) Fe acts as inhibitor and Mo as a catalyst
(d) Fe acts as promoter and Mo as autocatalyst

29. TEL minimises the knocking effect when mixed with petrol. It acts as:
(a) positive catalyst (b) negative catalyst
(c) autocatalyst (d) induced catalyst

30. Edges and peaks are more effective in a catalyst because:
(a) they have more free valencies
(b) they have limited number of atoms
(c) they have limited number of molecules
(d) none of the above

31. Hydrolysis of starch involves the use of the enzyme:
(a) maltase (b) zymase
(c) invertase (d) diastase

32. Which of the following statements is incorrect?
(a) Enzymes exist in colloidal state
(b) Enzymes are catalysts
(c) Enzymes can catalyse any reaction
(d) Urease is an enzyme

33. Which of the following catalysts is used in Friedel-Crafts reaction for preparation of toluene from benzene?
(a) Anhydrous aluminium chloride
(b) Nickel
(c) Platinum (d) Palladium

34. Platinised asbestos is used as a catalyst in the manufacture of H_2SO_4. It is an example of:
(a) homogeneous catalyst (b) heterogeneous catalyst
(c) autocatalyst (d) induced catalyst

35. The catalyst used in the manufacture of sulphuric acid by contact process is:
(a) Al_2O_3 (b) Cr_2O_3 (c) V_2O_5 (d) MnO_2

36. The formation of diethyl ether from ethanol is catalysed by:
(a) H_2SO_4 (b) Al_2O_3 (c) Cu (d) Ni

37. Which of the following catalysts is sensitive to temperature changes?
(a) Fe (b) Pt (c) Ni (d) Enzyme

38. The catalyst used in the Deacon's process for the manufacture of chlorine is:
(a) Pt (b) $CuCl_2$ (c) V_2O_5 (d) Fe

39. A catalytic poison renders the catalyst ineffective because: **(IIT 1991)**
(a) it is preferentially adsorbed on the catalyst
(b) it adsorbs the molecules of the reactants
(c) it combines chemically with the catalyst
(d) it combines with one of the reactants

40. A finely divided state of the catalyst is more efficient because in this state:
(a) more surface area is available
(b) more energy is stored in the catalyst
(c) positive charge is acquired
(d) negative charge is acquired

41. The catalyst used in the hydrogenation of oils is:
(a) V_2O_5 (b) Fe (c) Ni (d) Pt

42. Which of the following statements is not true? **(MLNR 1993)**
(a) The action of a catalyst is specific
(b) The catalyst does not alter the equilibrium
(c) A small amount of catalyst is sufficient to catalyse large amounts of reactants
(d) The catalyst initiates the reaction

43. The catalyst used in the manufacture of hydrogen by Bosch's process is:
(a) Fe_2O_3 (b) Cr_2O_3
(c) $Fe_2O_3 + Cr_2O_3$ (d) Cu

44. The catalyst used for olefin polymerisation is: **[JEE (WB) 2009]**
(a) Ziegler-Natta catalyst (b) Wilkinson catalyst
(c) Raney nickel catalyst (d) Merifield resin

45. The modern theory of catalysis is based on:
(a) active masses (b) atomic or molecular weights
(c) size of the particles (d) number of free valencies

46. According to adsorption theory of catalysis, the reaction rate increases, because:
(a) adsorption produces heat which increases the rate of reaction
(b) in the process of adsorption, the kinetic energy of the molecules increases
(c) the concentration of reactants at the active centres becomes high due to adsorption
(d) the activation energy of the reaction becomes high due to adsorption

47. Which one of the following statements is false?
(a) Enzymes are highly specific
(b) Enzymes increase activation energy
(c) Enzymes require optimum temperature
(d) Enzymes require optimum pH

48. An example of an autocatalytic reaction is:
(a) hydrogenation of oils
(b) decomposition of nitroglycerine
(c) oxidation of Na_3AsO_3 in presence of Na_2SO_3
(d) thermal decomposition of $KClO_3$ in presence of MnO_2

49. Enzyme catalysis is an example of:
(a) autocatalysis (b) heterogeneous catalysis
(c) homogeneous catalysis (d) induced catalysis

50. The biocatalysts are:
(a) enzymes (b) minerals
(c) plants (d) all proteins

51. Which one of the following statements is incorrect in the case of heterogeneous catalyst? **(CPMT 1990)**
(a) The catalyst lowers the energy of activation
(b) The catalyst actually forms a compound with the reactant
(c) The surface of the catalyst plays a very important role
(d) There is no change in the energy of activation

52. Regarding criteria of catalysis which one of the following statements is not true? **(CPMT 1990)**
(a) The catalyst is unchanged chemically during the reaction
(b) A small quantity of catalyst is often sufficient to bring about a considerable amount of the reaction
(c) In reversible reaction, the catalyst alters the equilibrium position
(d) The catalyst accelerates the rate of reaction

53. In which of the following processes, a catalyst is not used?
(a) Haber's process (b) Deacon's process
(c) Solvay process (d) Lead chamber process

54. The effect of a catalyst in a chemical reaction is to change the:
(a) activation energy (b) equilibrium concentration
(c) heat of reaction (d) final products

55. Protons accelerate the hydrolysis of esters. This is an example of:
(a) a promoter (b) a heterogeneous catalyst
(c) an acid-base catalyst (d) an autocatalyst

56. In the Ostwald's process for the manufacture of HNO_3, the catalyst used is:
(a) Fe (b) Pt
(c) V_2O_5 (d) Mo

57. The efficiency of an enzyme in catalysing a reaction is due to its capacity:
(a) to form a strong enzyme substrate complex
(b) to decrease the bond energies in the substrate molecule
(c) to change the shape of the substrate molecule
(d) to lower the activation energy of the reaction

58. The enzymes are killed:
(a) at a very high temperature
(b) during the chemical reaction
(c) at low temperature
(d) under atmospheric pressure

59. The enzyme ptyalin used for digestion of food is present in:
(a) saliva (b) blood
(c) intestine (d) adrenal glands

60. Which of the following acts as a negative catalyst?
(a) Lead tetraethyl as antiknock compound
(b) Glycerol in decomposition of H_2O_2
(c) Ethanol in the oxidation of chloroform
(d) All of the above

61. Which of the following types of materials act as effective catalysts?
(a) Alkali metals (b) Transition metals
(c) Alkaline earth metals (d) Radioactive metals

62. In which of the following reactions is a catalyst required?
(a) $S + O_2 \longrightarrow SO_2$ (b) $C + O_2 \longrightarrow CO_2$
(c) $2SO_2 + O_2 \longrightarrow 2SO_3$ (d) All of these

63. Which is not the characteristic of a catalyst? **(AFMC 1992)**
(a) It changes the equilibrium point
(b) It initiates the reaction
(c) It alters the rate of reaction
(d) It increases the average KE of molecules

64. In chemical reaction, the catalyst: **(AFMC 1993)**
(a) alters the amount of products
(b) lowers the activation energy
(c) decreases ΔH of forward reaction
(d) increases ΔH of forward reaction

65. Which statement is not correct? **[PMT (MP) 1993]**
(a) Physical adsorption is due to van der Waals' forces
(b) Physical adsorption decreases at high temperature and low pressure
(c) Physical adsorption is reversible
(d) Adsorption energy for chemical adsorption is generally lesser than that for physical adsorption

66. In the adsorption of oxalic acid by activated charcoal, the activated charcoal is known as:
(a) adsorbent (b) adsorbate
(c) absorber (d) none of these

67. Which can adsorb larger volume of hydrogen gas?
(a) Colloidal solution of palladium
(b) Finely divided nickel
(c) Finely divided platinum
(d) Colloidal $Fe(OH)_3$

68. Platinum is used as a catalyst in:
(a) oxidation of ammonia to form nitric acid
(b) hardening of oils
(c) production of synthetic rubber
(d) synthesis of methanol

69. Hydrolysis of cane sugar is catalysed by:
(a) H^+ (b) mineral acids
(c) enzymes (d) all of these

70. $KClO_3$ on heating decomposes into KCl and O_2. If some MnO_2 is added the reaction goes much faster because:
(a) MnO_2 decomposes to give oxygen
(b) MnO_2 provides heat by reacting
(c) better contact is provided by MnO_2
(d) MnO_2 acts as catalyst

71. Which acts as poison for Pd-charcoal in Lindlar's catalyst?
(a) $BaSO_4$ (b) Quinoline
(c) Both (a) and (b) (d) None of these

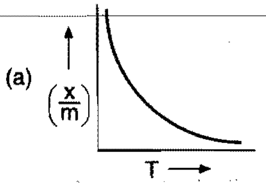
72. The inhibitors:
(a) retard the rate of a chemical reaction
(b) stop a chemical reaction immediately
(c) are reducing agents
(d) do not allow the reaction to proceed

73. The catalyst used in the manufacture of nitric acid by Ostwald's process is:
(a) Mo (b) Pt (c) V_2O_5 (d) Fe

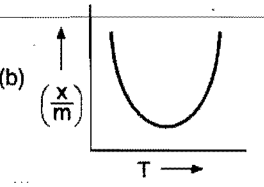
74. Which is an example of autocatalysis?
(a) Hydrolysis of methyl acetate
(b) Decomposition of TNG
(c) Oxidation of oxalic acid by $KMnO_4$
(d) All of the above

75. Which plot is the adsorption isobar for chemisorption?

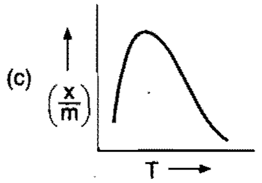
(a)



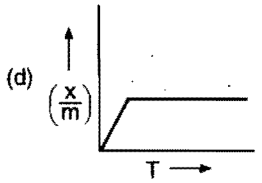
(b)



(c)



(d)



76. In the titration between oxalic acid and acidified potassium permanganate, the manganous salt formed during the reaction catalyses the reaction. The manganous salt acts as:
(a) promoter (b) positive catalyst
(c) autocatalyst (d) none of these

77. Adsorption is accompanied by:
(a) decrease in entropy of the system
(b) decrease in enthalpy of the system
(c) $T\Delta S$ for the process is negative
(d) all of the above

78. Consider the following statements:
1. Zeolites are aluminosilicates.
2. Aluminium can occupy two adjacent sites in zeolites.
Which of the following statements is correct? **(SCRA 2009)**
(a) 1 only (b) 2 only
(c) both 1 and 2 (d) neither 1 nor 2

79. Zeolites are used as catalyst in:
(a) petrochemical industries during cracking
(b) the preparation of H_2SO_4
(c) the hydrolysis of ester
(d) all of the above

80. Choose the correct statement for chemical adsorption: **[CET (Gujarat) 2006]**
(a) Value of adsorption enthalpy is above -20 kJ mol^{-1}
(b) van der Waals' forces exist between adsorbent and adsorbate
(c) Usually monomolecular layer is formed on adsorbent
(d) Multimolecular layer may be formed on adsorbent

81. The function of zymase is to: **(AIIMS 1992)**
(a) change starch into sugar
(b) ferment glucose to alcohol and carbon dioxide
(c) change malt sugar into glucose
(d) change starch into malt sugar and dextrin

82. Which of the following relations is/are correct? **(AIIMS 1995)**
(i) x/m = constant (at high pressure)
(ii) x/m = constant × $P^{1/n}$ (at intermediate pressure)
(iii) x/m = constant × P^n (at low pressure)
(a) All are correct (b) All are wrong
(c) (i) and (ii) are correct (d) (iii) is correct

83. The principle(s) involved in chromatographic operation is/are: **(AIIMS 1996)**
(a) adsorption (b) absorption
(c) partition (d) none of these

84. The function of enzymes in the living system is to: **(CBSE 1997)**
(a) transport oxygen
(b) provide immunity
(c) catalyse biochemical reaction
(d) provide energy

85. Which one of the following is a shape selective catalyst?
(a) V_2O_5 (b) Cr_2O_3
(c) Hydrated zeolites (d) ZSM-5

86. The process which is catalysed by one of the products is called: **(DPMT 1999)**
(a) acid-based catalyst (b) autocatalyst
(c) negative catalyst (d) positive catalyst

87. The heats of adsorption in physisorption lie in the range (kJ/mol):
(a) 40–400 (b) 40–100 (c) 10–400 (d) 1–10

88. In physical adsorption, the forces associated are: **[CET (Haryana) 2000]**
(a) ionic (b) covalent
(c) van der Waals' (d) H-bonding

89. In Ziegler-Natta polymerisation of ethylene, the active species are:
(a) $AlCl_3$ (b) EtA
(c) CH_2CH_2 (d) Ti^{3+}
(e) $TiCl_4$

90. ZSM-5 converts:
(a) alcohol to petrol (b) benzene to toluene
(c) toluene to benzene (d) heptane to toluene

91. A catalyst increases the rate of reaction by: **(CPMT 1999)**
(a) decreasing enthalpy
(b) decreasing internal energy

(c) decreasing activation energy
(d) increasing activation energy

92. The role of a catalyst in a reversible reaction is to: **(EAMCET 1999)**
(a) increase the rate of forward reaction
(b) decrease the rate of backward reaction
(c) alter the equilibrium constant of a reaction
(d) allow the equilibrium to be achieved quickly

93. A catalyst in finely divided state is more efficient because in this state:
(a) it has got large activation energy
(b) it can react with one reactant more effectively
(c) it has large surface area
(d) all of the above

94. In case of autocatalysis: **(KCET 2002)**
(a) reactant catalyses
(b) heat produced in the reaction catalyses
(c) product catalyses
(d) solvent catalyses

95. Which of the following statements is false? **(KCET 2002)**
(a) Increase of pressure increases the amount of adsorption
(b) Increase of temperature may decrease the amount of adsorption
(c) The adsorption may be monolayered or multilayered
(d) Particle size of the adsorbent will not affect the amount of adsorption

96. Rate of physi-sorption increases with: **(IIT 2003)**
(a) decrease in temperature (b) increase in temperature
(c) decrease in pressure (d) decrease in surface area

97. Which of the following characteristics is not correct for physical adsorption? **(AIEEE 2003)**
(a) Adsorption increases with increase in temperature
(b) Adsorption is spontaneous
(c) Both enthalpy and entropy of adsorption are negative
(d) Adsorption on solid is reversible

98. According to adsorption theory of catalysis, the speed of reaction increases because: **(CBSE 2003)**
(a) the concentration of the reactant molecules at the active centres of catalyst becomes high due to adsorption
(b) in the process of adsorption, the activation energy of the molecules becomes large
(c) adsorption produces heat which increases the speed of the reaction
(d) adsorption lowers the activation energy of the reaction

99. The chemical equilibrium of a reversible reaction is not influenced by: **(KCET 2004)**
(a) catalyst (b) pressure
(c) temperature (d) concentration

100. Identify the gas which is readily adsorbed by activated charcoal: **(KCET 2004)**
(a) N_2 (b) H_2 (c) O_2 (d) SO_2

101. Pick out the one which does not belong to the family of enzymes: **(KCET 2004)**
(a) lipase (b) pepsin (c) ptylin (d) cellulose

102. Which one of the following statements about zeolite is false? **[CBSE (PMT) 2004]**
(a) They are used as cation exchanger
(b) They have open structure which enables them to take up small molecules
(c) Zeolites are aluminosilicates having a three dimensional network
(d) Some of the SiO_4^{4-} units are replaced by AlO_4^{5-} and AlO_6^{9-} ions in zeolites

103. Adsorption of gases on solid surface is generally exothermic because: **[IIT (S) 2004]**
(a) enthalpy is positive (b) entropy decreases
(c) entropy increases (d) free energy increases

104. Identify the correct statement regarding enzymes. **(AIEEE 2004)**
(a) Enzymes are specific biological catalysts that can normally function at very high temperature ($T \approx 1000$ K)
(b) Enzymes are normally heterogeneous catalysts that are very specific in action
(c) Enzymes are specific biological catalysts that cannot be poisoned
(d) Enzymes are specific biological catalysts that possess well defined active site

105. The extent of adsorption of a gas on a solid depends on: **(KCET 2005)**
(a) nature of the gas (b) pressure of the gas
(c) temperature of the gas (d) all are correct

106. The conversion of maltose to glucose is possible by the enzyme: **(AFMC 2005)**
(a) zymase (b) lactase
(c) maltase (d) diastase

107. Which of the following is true in respect of adsorption? **[PET (Kerala) 2006]**
(a) $\Delta G < 0; \Delta S > 0; \Delta H < 0$ (b) $\Delta G < 0; \Delta S < 0; \Delta H < 0$
(c) $\Delta G > 0; \Delta S > 0; \Delta H < 0$ (d) $\Delta G < 0; \Delta S < 0; \Delta H > 0$
(e) $\Delta G > 0; \Delta S > 0; \Delta H > 0$

108. If x/m is the mass of adsorbate adsorbed per unit mass of adsorbent, P is the pressure of the adsorbate gas, a and b are constants, which of the following represents **"Langmuir adsorption isotherm"?** **[PET (Kerala) 2006]**
(a) $\log\left(\frac{x}{m}\right) = \log\left(\frac{a}{b}\right) + \frac{1}{a}\log P$
(b) $\frac{x}{m} = \frac{b}{a} + \frac{1}{aP}$ (c) $\frac{x}{m} = \frac{1+bP}{aP}$
(d) $\frac{1}{(x/m)} = \frac{a}{b} + \frac{P}{a}$ (e) $\frac{1}{(x/m)} = \frac{b}{a} + \frac{1}{aP}$

109. The efficiency of an enzyme to catalyse a reaction is due to its capacity to: **[PMT (Kerala) 2006]**
(a) reduce the activation energy of the reaction
(b) form strong enzyme-substrate complex
(c) decrease the bond energy of all substrate molecules
(d) increase the free energy of the catalyst-substrate reaction
(e) alter the substrate geometry to fit into the shape of the enzyme molecule

110. Although, nitrogen does not adsorb on a surface at room temperature, it adsorbs on the surface at 83 K. Which one of the following statements is correct? **[PMT (HP) 2006]**

(a) At 83 K, there is formation of monomolecular layer
(b) At 83 K, there is formation of multimolecular layers
(c) At 83 K, nitrogen molecules are held by chemical bonds
(d) At 83 K, nitrogen is adsorbed as atoms

111. What is the equation form of Langmuir adsorption isotherm under high pressure? **[CET (Gujarat) 2006]**

(a) $\frac{x}{m}=\frac{a}{b}$ (b) $\frac{x}{m}=aP$ (c) $\frac{x}{m}=\frac{1}{aP}$ (d) $\frac{x}{m}=\frac{b}{a}$

[**Hint:** Langmuir adsorption isotherm may be given as:

$$\frac{x}{m}=\frac{aP}{a+bP}$$

~~At high pressure, $a+bP \approx bP$~~

$$\therefore \quad \frac{x}{m}=\frac{aP}{bP}$$

$$\frac{x}{m}=\frac{a}{b}\ ]$$

112. Freundlich adsorption isotherm is: **[MHT-CET 2007; DCE 2009]**

(a) $\frac{x}{m}=KP^{1/n}$ (b) $x=mKP^{1/n}$
(c) $\frac{x}{m}=KP^{-n}$ (d) all of these

113. Which of the following statements is incorrect regarding physisorption? **(AIEEE 2009)**

(a) It occurs because of van der Waals' forces
(b) More easily liquefiable gases are adsorbed readily
(c) Under high pressure it results into multimolecular layer on adsorbent surface
(d) Enthalpy of adsorption ($\Delta H_{\text{adsorption}}$) is low and positive

114. Active charcoal is a good catalyst because: **[Jamia Millia Islamia (Engg.) 2006]**

(a) it is made of carbon atoms
(b) it is very reactive
(c) it has more adsorption power
(d) it has inert nature towards reagent

115. According to the adsorption theory of catalysis, the speed of reaction increases because: **(AIIMS 2007)**

(a) adsorption produces heat which increases the speed of the reaction
(b) adsorption lowers the activation energy of the reaction
(c) the concentration of reactant molecules at the active centres of the catalyst becomes high due to adsorption
(d) in the process of adsorption, the activation energy of the molecules becomes large

116. The Langmuir adsorption isotherm is deduced using the assumption: **[CBSE (Med.) 2007]**

(a) the adsorption sites are equivalent in their ability to adsorb the particles
~~(b) the heat of adsorption varies with coverage~~
~~(c) the adsorbed molecules interact with each other~~
(d) the adsorption takes place in multilayers

117. The efficiency of enzyme catalysis is due to its capacity to: **[PET (Kerala) 2007]**

(a) form a strong enzyme-substrate complex
(b) change the shape of the substrate
~~(c) lower the activation energy of the reaction~~
(d) form a colloidal solution in water
(e) decrease the bond energies in substrate molecules

118. Which type of phenomenon is used when coloured dye is removed from solution of sugar by charcoal ? **[CET (Gujarat) 2008]**

(a) Absorption
(b) Adsorption
(c) Absorption and adsorption both
(d) None of the above

119. Shape selective catalysis is a reaction catalysed by : **[PMT (Kerala) 2008]**

(a) zeolites (b) enzymes
(c) platinum (d) Ziegler-Natta catalyst
(e) acids or bases

Assertion-Reason TYPE QUESTIONS

The questions given below consist of two statements each printed as '**Assertion**' **(A)** and '**Reason**' **(R).** While answering these questions you are required to choose any one of the following four responses:

(a) If both (A) and (R) are true and (R) is the correct explanation of (A).
(b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
(c) If (A) is correct but (R) is incorrect.
(d) If (A) and (R) are both incorrect.

1. (A) A catalyst does not alter the equilibrium constant of the reaction.
(R) The catalyst forms a complex with the reactants and provides an alternate path with the lower energy of activation for the reaction; the forward and backward reactions are affected to the same extent. **(AIIMS 2010)**

2. (A) Hydrolysis of ethyl acetate in presence of acid is a reaction of first order whereas in presence of alkali, it is a reaction of second order.
(R) Acid only acts as a catalyst whereas alkali acts as one of the reactants.

3. (A) In chemisorption, adsorption keeps on increasing with temperature.
(R) Heat keeps on providing more and more activation energy.

4. (A) A reaction cannot become fast by itself unless a catalyst is added.
(R) A catalyst always increases the speed of a reaction.

5. (A) A catalyst speeds up a reaction but doesn't participate in its mechanism.
(R) A catalyst provides an alternative path of lower activation energy to the reactants.

6. (A) Fruit formation process shows increase in rate with passage of time.
   (R) Hydrolysis of ester is a homogeneous autocatalytic reaction.
7. (A) A catalyst speeds up the process without participating in its mechanism.
   (R) A catalyst provides an alternative path of lower activation energy to the reactants.
8. (A) Catalysts are always transition metals.
   (R) Transition metals have a variable oxidation state.
9. (A) The mass of nickel catalyst recovered after being used in the hydrogenation of an oil is less than the mass of nickel added to the reaction.
   (R) Catalyst take part in the reaction but are recovered in the end.
10. (A) All enzymes are proteins, but all proteins are not enzymes.
   (R) Enzymes are biocatalysts and posses a stable configuration having active sites.
11. (A) The reaction of oxalic acid with acidified $KMnO_4$ is first slow and then proceeds with faster speed.
   (R) Acidified $KMnO_4$ is a strong oxidising agent.
12. (A) For adsorption ΔG, ΔS and ΔH all have negative values.
   (R) Adsorption is a spontaneous process accompanied by decrease in randomness.
13. (A) A gas with higher critical temperature is adsorbed more than a gas with lower critical temperature.
   (R) Higher critical temperature implies that the gas is more easily liquefiable.
14. (A) Physical adsorption of molecules on the surface requires activation energy.
   (R) Because the bonds of adsorbed molecules are broken. **(AIIMS 1994)**
15. (A) Activity of an enzyme is pH dependent.
   (R) Changes in pH affect the solubility of the enzyme in water. **(AIIMS 2003)**
16. (A) Alcohols are dehydrated to hydrocarbons in presence of acidic zeolite.
   (R) Zeolites are porous catalyst. **(AIIMS 2004)**
17. (A) ZSM-5 is used as a catalyst in petrochemical industries.
   (R) Zeolites are three-dimensional network silicates in which some silicon atoms are replaced by aluminium atoms.
18. (A) A catalyst increases the rate of a reaction.
   (R) In presence of a catalyst, the activation energy of the reaction increases. **[EAMCET (Engg.) 2007]**

   [**Hint:** A negative catalyst may increase the activation energy of reaction.]
19. (A) NO is used as a homogeneous catalyst for oxidation of CO.

$$2CO + O_2 \longrightarrow 2CO_2$$

   (R) NO increases the rate of oxidation.

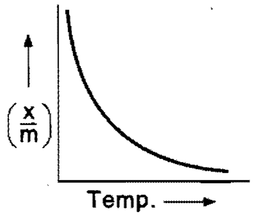
BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS *for* IIT ASPIRANTS

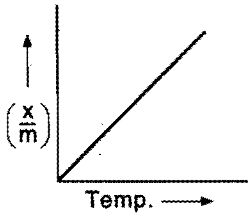
1. In presence of a catalyst, the activation energy is lowered by 3 kcal at 27°C. Hence, the rate of reaction will increase by:
   (a) 32 times (b) 243 times (c) 2 times (d) 148 times
   [**Hint:** $$\frac{\text{Rate in presence of catalyst}}{\text{Rate in absence of catalyst}} = \text{Antilog}\left[\frac{\Delta E}{2.303RT}\right]$$
   $$= \text{Antilog}\left[\frac{3000}{2.303 \times 2 \times 300}\right]$$]
2. According to the adsorption theory of catalysis, the rate of reaction increases because:
   (a) adsorption lowers the activation energy of the reaction
   (b) concentration of reactant molecules at the active centres of the catalyst becomes high due to adsorption
   (c) adsorption produces heat which increases the rate of reaction
   (d) adsorption increases the activation energy of the reaction
3. Which of the following characteristics is not correct for physical adsorption?
   (a) Adsorption is spontaneous
   (b) ΔH and ΔS are negative
   (c) It is reversible in nature
   (d) Degree of adsorption increases with temperature
4. Freundlich adsorption isotherm gives a straight line on plotting:
   (a) $\frac{x}{m}$ vs. P (b) $\log\left(\frac{x}{m}\right)$ vs. P
   (c) $\log\left(\frac{x}{m}\right)$ vs. $\log P$ (d) $\frac{x}{m}$ vs. $\frac{1}{P}$
5. Adsorption is an exothermic process. The amount of substance adsorbed should: **(DPMT 2009)**
   (a) increase with decrease in temperature
   (b) increase with increase in temperature
   (c) decrease with decrease in temperature
   (d) decrease with increase in temperature
6. In homogeneous catalytic reactions, there are three alternative paths A, B and C (shown in the figure). Which one of the following indicates the relative ease with which the reaction can take place?

   (a) $A > B > C$ (b) $C > B > A$ (c) $B > C > A$ (d) $A = B = C$
   [**Hint:** Activation energy in the different paths lies in the following sequence: $C < B < A$.
   Lesser is the activation energy, greater is the ease with which the reaction can take place.
   $\therefore C > B > A$ (Decreasing ease with which the reaction can take place.)]
7. For the reaction ($A \longrightarrow B + C$); the energy profile diagram is given in the figure.

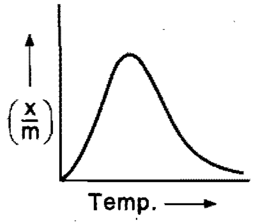
   The decrease in energy of activation in presence of catalyst is:
   (a) z (b) $z - p$ (c) $y - z$ (d) $z - x$
8. Which of the following represents physical adsorption?



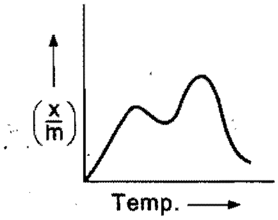
(a)



(b)



(c)



(d)

9. The colloidal system consisting of a liquid adsorbate in a solid adsorbent is termed as:
   (a) aerosol (b) foam
   (c) emulsion (d) gel

10. Which can adsorb a larger volume of hydrogen gas?
(a) Colloidal solution of palladium
(b) Finely divided nickel
(c) Finely divided platinum
(d) Colloidal $Fe(OH)_3$

11. Which is false for a catalyst?
(a) A catalyst can initiate a reaction
(b) It does not alter the position of equilibrium in a reversible reaction
(c) A catalyst remains unchanged in quality and composition at the end of reaction
(d) Catalysts are sometimes very specific in reaction

12. The curve showing the variation of pressure with temperature for a given amount of adsorption is called:
(a) adsorption isobar (b) adsorption isotherm
(c) adsorption isostere (d) adsorption isochore

13. Which of the following statements is incorrect?
(a) Adsorption always leads to a decrease in enthalpy and entropy of the system
(b) Adsorption arises due to unsaturation of valence forces of atoms or molecules on the surface
(c) Adsorption increases with rise in temperature
(d) Adsorption decreases the surface energy

14. Which of the following gas molecules have maximum value of enthalpy of physisorption?
(a) C_2H_6 (b) Ne (c) H_2O (d) H_2
[**Hint:** Since, H_2O can be liquefied easily, hence it will have the maximum enthalpy of physisorption.]

15. Which of the following gases is adsorbed most by activated charcoal? **[AMU (Med.) 2010]**
(a) CO_2 (b) N_2 (c) CH_4 (d) H_2
[**Hint:** CO_2 is an easily liquefiable gas, hence it is adsorbed most by charcoal.]

16. Which of the following factors are responsible for the increase in the rate of a surface catalysed reaction? **[PMT (Kerala) 2006]**
I. A catalyst provides proper orientation for the reactant molecules to react
II. Heat of adsorption of reactants on a catalyst helps reactant molecules to overcome activation energy
III. The catalyst increases the activation energy of the reaction
IV. Adsorption increases the local concentration of reactant molecules on the surface of the catalyst
Select the correct answer using the codes given below:
(a) I and II (b) I and III (c) II and IV (d) I, II and III
(e) I, II and IV

17. In Langmuir's model of adsorption of a gas on a solid surface: **(AIEEE 2006)**
(a) the rate of dissociation of adsorbed molecules from the surface does not depend on the surface covered
(b) the adsorption at a single site on the surface may involve multiple molecules at the same time
(c) the mass of gas striking a given area of surface is proportional to the pressure of the gas
(d) the mass of gas striking a given area of surface is independent of the pressure of the gas

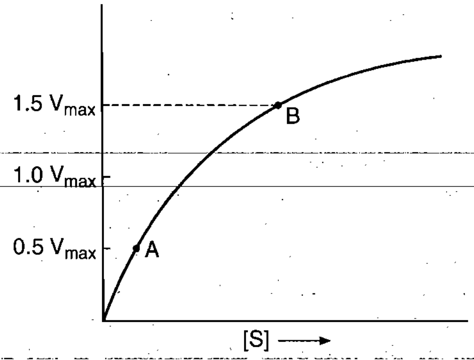
18. An enzyme $[E]$ is combined with the substrate $[S]$ as follows:

$$E + S \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} ES$$

$$ES \xrightarrow{k_2} P + E$$

The overall reaction rate is given by:

$$\text{Rate} = \frac{V_{\max}[S]}{K_m + [S]}$$ and the rate of reaction varies with substrate concentration as:



The order of reaction at point A is:
(a) one (b) two (c) three (d) zero

19. Which type of graph gives straight line in Langmuir adsorption isotherm ? **[CET (Gujarat) 2008]**
(a) $\frac{x}{m} \rightarrow \frac{1}{P}$ (b) $\frac{m}{x} \rightarrow \frac{1}{P}$
(c) $\log\left(\frac{x}{m}\right) \rightarrow \frac{1}{P}$ (d) $\log\left(\frac{x}{m}\right) \rightarrow P$

20. Plot of $\log\left(\frac{x}{m}\right)$ against $\log P$ is a straight line inclined at an angle of 45°. When the pressure is 0.5 atm and Freundlich parameter, k is 10, the amount of solute adsorbed per gram of adsorbent will be : ($\log 5 = 0.6990$) **[PET (Kerala) 2008]**
(a) 1 g (b) 2 g (c) 3 g (d) 5 g
(e) 2.5 g
[**Hint :** According to Freundlich Adsorption Isotherm :

$$\log\left(\frac{x}{m}\right) = \log k + \frac{1}{n}\log P$$

When $\log\left(\frac{x}{m}\right)$ is plotted against $\log P$, we get straight line of slope $(1/n)$ and intercept $(\log k)$.

$$\frac{1}{n} = \tan 45° = 1$$

$$\log k = \log 10 = 1$$

$$\frac{x}{m} = k\,(P)^{1/n} = 10\,(0.5)^1 = 5$$

When $m = 1\,\text{g}$, $x = 5\,\text{g}$]

21. Following graphs will be true when :
(a) $P = 0$ (b) $P = 1$
(c) $\frac{1}{n} = 0$ (d) $\frac{1}{n} = \infty$

LINKED COMPREHENSION TYPE QUESTIONS

Passage 1

Only the surface atoms in an adsorbent, play an active role in adsorption. These atoms possess some residual forces like van der Waals' forces and chemical forces.

In the process of adsorption, weak adsorbate is substituted by strong adsorbate. Activated charcoal used in gas mask is already exposed to the atmospheric air, so the gases and water vapours in air are adsorbed on its surface. When the mask is exposed to chlorine atmosphere, the gases are displaced by chlorine. Porous and finely powdered solids, e.g., charcoal and Fuller's earth adsorb more as compared to the hard non-porous material. It is due to this property that the powdered charcoal is used in gas masks. In general, easily liquefiable gases like CO_2, NH_3, Cl_2 and SO_2, etc., are adsorbed to a greater extent than the elemental gases, e.g., H_2, N_2, O_2, He, etc.

Answer the following questions:

1. Gas masks work on the principle of:
   (a) physical adsorption
   (b) chemical adsorption
   (c) both physical and chemical adsorptions
   (d) absorption
2. Which of the following gases will be most easily adsorbed by the charcoal in the gas mask?
   (a) H_2 (b) O_2 (c) N_2 (d) SO_2
3. Gas mask contains:
   (a) charcoal granules (b) powdered charcoal
   (c) calcium carbonate (d) Fuller's earth
4. Which of the following gas molecules has maximum value of enthalpy of physisorption in a gas mask?
   (a) C_2H_6 (b) Ne (c) H_2O (d) H_2
5. Which of the following gases will substitute O_2 from adsorbed charcoal?
   (a) H_2 (b) N_2 (c) Ar (d) Cl_2

Passage 2

Freundlich adsorption isotherm is obeyed by the adsorptions where the adsorbate forms a multimolecular layer on the surface of adsorbent. In such cases, the degree of adsorption varies linearly with pressure but at high pressure, it becomes independent of pressure.

The relation of Freundlich adsorption isotherm is:

$$\frac{x}{m} = kP^{1/n}$$

where, k and n are constants.

Langmuir adsorption isotherm is obeyed by the adsorption where the adsorbate forms only a unimolecular adsorbed layer. The mathematical relation of Langmuir adsorption isotherm is:

$$\frac{x}{m} = \frac{aP}{1+bP}$$

Select whether the following statements are true or false:

1. When $\log\left(\frac{x}{m}\right)$ is plotted against $\log P$, we get a straight line with slope $(1/n)$.
   (a) True (b) False
2. The degree of adsorption (x/m) at low pressure will be:
   $$\frac{x}{m} = a$$
   (a) True (b) False
3. When $\left(\frac{m}{x}\right)$ is plotted against $\frac{1}{P}$, we get a straight line with slope $(1/a)$ and intercept (b/a).
   (a) True (b) False
4. In the mathematical relation of Freundlich adsorption isotherm, the value of $(1/n)$ is $0 \le \frac{1}{n} \le 1$.
   (a) True (b) False
5. Freundlich adsorption isotherm is valid for chemisorption.
   (a) True (b) False

SELF ASSESSMENT

ASSIGNMENT NO. 13

SECTION-I

Straight Objective Type Questions

This section contains 8 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. At high pressure, Langmuir adsorption isotherm takes the form:

(a) $\frac{x}{m} = \frac{aP}{1+bP}$ (b) $\frac{x}{m} = \frac{a}{b}$

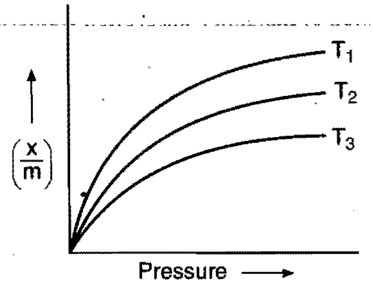
(c) $\frac{x}{m} = aP$ (d) $\frac{m}{x} = \frac{b}{a} + \frac{1}{aP}$

2. Which of the following is used to adsorb water?

(a) Silica gel (b) Anhydrous $CaCl_2$

(c) Coal (d) Coke

3. Select the correct option for the following graph:



(a) $T_1 > T_2 > T_3$ (b) $T_1 = T_2 = T_3$

(c) $T_1 < T_2 < T_3$ (d) $T_1 > T_2 < T_3$

4. Which of the following substances adsorbs H_2 gas most strongly?

(a) Platinum black (b) Nickel powder

(c) Activated charcoal (d) Silica gel

5. The order of volume of gases NH_3, CO_2 and CH_4 adsorbed by one gram of charcoal at 298 K is:

(a) $CH_4 > CO_2 > NH_3$ (b) $NH_3 > CH_4 > CO_2$

(c) $NH_3 > CO_2 > CH_4$ (d) $CO_2 > NH_3 > CH_4$

6. Activated charcoal is prepared by:

(a) adding $Ba_3(PO_4)_2$ to charcoal

(b) treatment with conc. HNO_3

(c) heating charcoal with steam to make it more porous

(d) adding silica to charcoal

7. In the manufacture of H_2SO_4 by contact process the presence of AS_2O_3 acts as:

(a) catalytic promoter (b) induced catalyst

(c) catalytic poison (d) autocatalyst

8. In Rosenmund reactions, presence of $BaSO_4$ acts as .... for Pd.

(a) promoter (b) moderator

(c) inhibitor (d) poison

SECTION-II

Multiple Answers Type Objective Questions

9. Which of the following are correct about a catalyst?

(a) It participates in the reaction but is recovered at last

(b) It does not affect ΔG

(c) It does not affect ΔH

(d) It alters the mechanism of reaction

10. Which of the following statements are correct?

(a) Physical adsorption is of multimolecular layer

(b) Degree of chemical adsorption increases with increase in temperature

(c) Adsorption increases the surface energy

(d) Sometimes solvent is adsorbed in preference to solute

11. Which of the following are zeolites?

(a) Granite (b) Faujasite

(c) Natrolite (d) Thomisite

12. Which of the following act as negative catalysts?

(a) Ethanol in oxidation of chloroform

(b) Tetra ethyl lead used as antiknocking agent

(c) Glycerol in the decomposition of H_2O_2

(d) Fe in the formation of ammonia by Haber's process

13. Select the correct statements about enzymes:

(a) Enzymes are biological catalysts found in organisms

(b) All enzymes are proteins

(c) Enzymes can catalyse any reaction

(d) Enzymes' activity is optimum at 27° C

SECTION-III

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbled as illustrated in the following examples:

If the correct matches are (a-p,s) (b-q,r), (c-p,q) and (d-s), then the correctly bubbled 4 × 4 matrix should be as follows:

	p	q	r	s
a	●	○	○	●
b	○	●	●	○
c	●	●	○	○
d	○	○	○	●

14. Match the Column-I with Column-II:

Column-I (Process)	**Column-II (Catalyst)**
(a) Cracking of hydrocarbons	(p) Ni
(b) Ostwald's process	(q) NO
(c) Sulphuric acid manufacture	(r) Pt
(d) Catalytic converter	(s) NiO

15. Match the Column-I with Column-II:

Column-I (Catalyst)	**Column-II (Process)**
(a) Ni	(p) Cracking of hydrocarbons
(b) $AlCl_3$	(q) Fischer-Tropsch process
(c) Co/Al_2O_3	(r) Hydrogenation of oil
(d) Zeolite	(s) Friedel-Crafts reaction

16. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) Chemisorption	(p) Exothermic
(b) Physisorption	(q) Endothermic
(c) Desorption	(r) Removal of adsorbed substance
(d) Activation of adsorbent	(s) Specific

Answers

1. (b) **2.** (a) **3.** (c) **4.** (a) **5.** (c) **6.** (c) **7.** (c) **8.** (d)
9. (a, b, c, d) **10.** (a, b, d) **11.** (b, c, d) **12.** (a, b, c) **13.** (a, b, d) **14.** (a-r) (b-r) (c-q, r) (d-p, s)
15. (a-r) (b-s) (c-q) (d-p) **16.** (a-p, s) (b-p), (c-q, r) (d-q)

CHAPTER 14

VOLUMETRIC ANALYSIS

Volumetric analysis is a method of quantitative analysis. It involves the measurement of the volume of a known solution required to bring about the completion of the reaction with a measured volume of the unknown solution whose concentration or strength is to be determined. By knowing the volume of the known solution, the concentration of the solution under investigation can be calculated. Volumetric analysis is also termed as **titrimetric analysis.**

14.1 IMPORTANT TERMED USED IN VOLUMETRIC ANALYSIS

(i) Titration: The process of addition of the known solution from the burette to the measured volume of solution of the substance to be estimated until the reaction between the two is just complete, is termed as **titration.** Thus, a titration involves two solutions:

(a) Unknown solution and (b) Known solution or standard solution.

(ii) Titrant: The reagent or substance whose solution is employed to estimate the concentration of unknown solution is termed **titrant.** There are two types of reagents or titrants:

(a) Primary titrants: These reagents can be accurately weighed and their solutions are not to be standardised before use. Oxalic acid, potassium dichromate, silver nitrate, copper sulphate, ferrous ammonium sulphate, sodium thiosulphates, etc., are the examples of primary titrants.

(b) Secondary titrants: These reagents cannot accurately weighed and their solutions are to be standardised before use. Sodium hydroxide, potassium hydroxide, hydrochloric acid, sulphuric acid, iodine, potassium permanganate, etc., are the examples of secondary titrants.

(iii) Standard solution: The solution of exactly known concentration of the titrant is called the standard solution.

(iv) Titrate: The solution consisting the substance to be estimated is termed unknown solution. The substance is termed **titrate.**

(v) Equivalence point: The point at which the reagent (titrant) and the substance (titrate) under investigation are chemically equivalent is termed **equivalence point or stoichiometric end point** or **simply end point.**

(vi) Indicator: It is the auxiliary substance used for physical (visual) detection of the completion of titration or detection of end point is termed as indicator. Indicators show change in colour or turbidity at the stage of completion of titration.

14.2 CONCENTRATION REPRESENTATION OF SOLUTION

1. Concentration Representation in Physical Units

(a) Strength of solution: Number of grams of solute dissolved per litre of solution is called strength of solution.

(b) Parts Per Million (ppm): Number of grams of solute dissolved per 10^6 grams of solvent is called concentration of solution in the unit of Parts Per Million (ppm). This unit is used to represent hardness of water and concentration of very dilute solutions.

(c) Percentage by mass: Number of grams of solute dissolved per 100 grams of solution is called percentage by mass.

(d) Percentage by volume: Number of millilitres of solute per 100 mL of solution is called percentage by volume.

For example, if 25 mL ethyl alcohol is diluted with water to make 100 mL solution then the solution thus obtained is 25% ethyl alcohol by volume.

(e) Percentage mass by volume: Number of grams of solute present per 100 mL of solution is called percentage mass by volume.

For example, let 25 g glucose is dissolved in water to make 100 mL solution then the solution is 25% glucose mass by volume.

2. Concentration Representation in Chemical Units

(a) Normality: Number of gram equivalents of solute dissolved per litre of solution is called the normality of the solution. It is denoted by N and it can be calculated as,

$$N = \frac{w_B \times 1000}{E_B \times V} \qquad \text{... (i)}$$

where, w_B = mass of solute in grams

E_B = gram equivalent mass of solute

V = volume of solution in mL

Another relation for calculation of normality is

$$N = \frac{x \times d \times 10}{E_B} \quad \text{... (ii)}$$

where, d = density of solution is g/mL

x = percentage by mass of solute

Symbol	Normality	Physical significance
(i) N	Normal solution, *i.e.*, Normality = 1	1 g equivalent of solute per litre of solution
(ii) $0.1\ N$ or $\frac{N}{10}$	Decinormal solution, *i.e.*, Normality = 0.1	0.1 g equivalent of solute per litre of solution
(iii) $0.01\ N$ or $\frac{N}{100}$	Centinormal solution, *i.e.*, Normality = 0.01	0.01 g equivalent of solute per litre of solution
(iv) $0.001\ N$ or $\frac{N}{1000}$	Millinormal solution, *i.e.*, Normality = 0.001	0.001 g equivalent of solute per litre of solution
(v) $0.5\ N$ or $\frac{N}{2}$	Seminormal solution, *i.e.*, Normality = 0.5	0.5 g equivalent of solute per litre of solution

Note: If normality of a solution is given then number of equivalents of solute in a definite volume of solution may be calculated easily.

$$\text{Number of equivalents of solute} = \frac{N \times V}{1000}$$

where, V = volume of solution in mL.

(b) Molarity: Number of moles of solute dissolved per litre of solution is called molarity. It is denoted by 'M'. It may be calculated using the following relations:

$$M = \frac{w_B \times 1000}{m_B \times V} \quad \text{... (i)}$$

or

$$M = \frac{x \times d \times 10}{m_B} \quad \text{... (ii)}$$

where, w_B = mass of solute in grams

m_B = gram molecular mass of solute

x = percentage by mass of solute

d = density of solution in g mL^{-1}

In the problems of volumetric analysis, concept of molarity is very useful. Let us consider an equation of the following type :

$$n_1 A + n_2 B \longrightarrow m_1 C + m_2 D$$

Let molar of A and B are M_1 and M_2 respectively, then

$$\frac{M_1 V_1}{n_1}(A) = \frac{M_2 V_2}{n_2}(B)$$

(c) Molality: Number of moles of solute dissolved per 1000 g (per kg) of solvent is called molality of solution. It is denoted by 'm'. It can be calculated as,

$$m = \frac{w_B \times 1000}{m_B \times w_A}$$

where, w_B = mass of solute in grams

m_B = gram molecular mass of solute

[illegible] = mass of solvent in grams

Principle of Volumetric Analysis

Volumetric analysis is based on the **principle of equivalence.** According to this principle, substances combine together in the ratio of their equivalent masses.

Let x g of a compound 'A' completely react with y g of another compound 'B'.

Then, $$\frac{\text{Equivalent mass of '}A\text{'}}{\text{Equivalent mass of '}B\text{'}} = \frac{x}{y}$$

$$\frac{x}{\text{Equivalent mass of '}A\text{'}} = \frac{y}{\text{Equivalent mass of '}B\text{'}}$$

Number of gram equivalents of 'A' = Number of gram equivalents of 'B'

Thus, **one gram equivalent of a substance 'A' completely reacts with one gram equivalent of another substance 'B'.**

According to the principle of equivalence,

Number of gram equivalents of A

= No. of gram equivalents of B

$$\text{Number of gram equivalents of } A = \frac{N_A \times V_A}{1000};$$

where, V_A = volume of A in mL

$$\text{Number of gram equivalents of } B = \frac{N_B \times V_B}{1000};$$

where, V_B = volume of B in mL

$$\therefore \quad \frac{N_A \times V_A}{1000} = \frac{N_B \times V_B}{1000}$$

$$N_A \times V_A = N_B \times V_B$$

The above equation is called normality equation and it is very useful in numerical calculations of volumetric analysis.

14.3 CLASSIFICATION OF REACTIONS INVOLVED IN VOLUMETRIC ANALYSIS

1. Neutralisation Reactions

The reaction in which acids and bases react to form salt is called neutralisation.

e.g., $$HCl + NaOH \longrightarrow NaCl + H_2O$$

$$H^+_{(acid)} + OH^-_{(base)} \longrightarrow H_2O\text{(feebly ionised)}$$

The titration based on neutralisation is called acidimetry or alkalimetry.

2. Oxidation-Reduction Reactions

The reactions involving simultaneous loss and gain of electrons among the reacting species are called oxidation-reduction or redox reactions, *e.g.*, let us consider oxidation of ferrous sulphate (Fe^{2+} ion) by potassium permanganate (MnO_4^- ion) in acidic medium.

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O \quad \text{(Gain of electrons or reduction)}$$

$$5 \times [Fe^{2+} \longrightarrow Fe^{3+} + e^-] \quad \text{(Loss of electrons or oxidation)}$$

$$\overline{MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O}$$

In the given reaction, MnO_4^- acts as oxidising agent and Fe^{2+} acts as reducing agent.

The titrations involving redox reactions are called redox titrations. These titrations are also called according to the reagent used in the titration, *e.g.*, iodometric, iodimetric, cerimetric, permanganometric and dichromometric titrations.

3. Precipitation Reaction

A chemical reaction in which cations and anions combine to form a compound of very low solubility (in the form of residue or precipitate), is called precipitation.

e.g., $BaCl_2 + Na_2SO_4 \longrightarrow \underset{\text{(White precipitate)}}{BaSO_4} + 2NaCl$

$$AgNO_3 + NaCl \longrightarrow \underset{\text{(White precipitate)}}{AgCl} + NaNO_3$$

The titrations involving precipitation reactions are called **precipitation titrations.**

4. Complex Formation Reactions

These are ion combination reactions in which a soluble slightly dissociated complex ion or compound is formed. Complex compounds retain their identity in the solution and have the properties of the constituent ions and molecules.

e.g., $CuSO_4 + 4NH_3 \longrightarrow \underset{\text{(Complex compound)}}{[Cu(NH_3)_4]SO_4}$

$$AgNO_3 + 2KCN \longrightarrow \underset{\text{(Complex compound)}}{K[Ag(CN)_2]} + KNO_3$$

$$2CuSO_4 + K_4[Fe(CN)_6] \longrightarrow \underset{\text{(Complex compound)}}{Cu_2[Fe(CN)_6]} + 2K_2SO_4$$

The titrations involving complex formation reactions are called **complexometric titrations.**

14.4 CALCULATION OF EQUIVALENT MASS OF DIFFERENT SUBSTANCES

The equivalent mass of a substance is defined as the number of parts by mass of it which combine with or displace 1.0078 parts by mass of hydrogen, 8 parts by mass of oxygen and 35.5 parts by mass of chlorine.

The equivalent mass of a substance expressed in grams is called **gram equivalent mass.**

The equivalent mass of a substance is not constant. It depends upon the reaction in which the substance is participating. A compound may have different equivalent mass in different chemical reactions and under different experimental conditions.

(A) Equivalent Mass of an Acid

It is the mass of an acid in grams which contains 1.0078 g of replaceable H^+ ions or it is the mass of acid which contains one mole of replaceable H^+ ions. It may be calculated as:

$$\text{Equivalent mass of acid} = \frac{\text{Molecular mass of acid}}{\text{Basicity of acid}}$$

Basicity of acid = number of replaceable hydrogen atoms present in one molecule of acid

Acid	Basicity	Molecular mass	Equivalent mass
HNO_3	1	63	$\frac{63}{1} = 63$
HCl	1	36.5	$\frac{36.5}{1} = 36.5$
CH_3COOH	1	60	$\frac{60}{1} = 60$
H_3PO_2	1	66	$\frac{66}{1} = 66$
H_2SO_4	2	98	$\frac{98}{2} = 49$
$\underset{\text{COOH}}{\overset{\text{COOH}}{\vert}} \cdot 2H_2O$	2	126	$\frac{126}{2} = 63$
H_3PO_3	2	82	$\frac{82}{2} = 41$

Note: Phosphoric acid may act as monobasic or dibasic or tribasic acid, *e.g.*,

(i) $H_3PO_4 + NaOH \longrightarrow NaH_2PO_4 + H_2O$

Here, phosphoric acid acts as monobasic acid.

$$\therefore \text{ Equivalent mass of } H_3PO_4 = \frac{\text{Molecular mass}}{\text{Basicity}} = \frac{98}{1} = 98$$

(ii) $H_3PO_4 + 2NaOH \longrightarrow Na_2HPO_4 + 2H_2O$

Here, Basicity of $H_3PO_4 = 2$

$$\text{Equivalent mass of } H_3PO_4 = \frac{\text{Molecular mass}}{\text{Basicity}} = \frac{98}{2} = 49$$

(iii) $H_3PO_4 + 3NaOH \longrightarrow Na_3PO_4 + 3H_2O$

Here, Basicity of $H_3PO_4 = 3$

$$\text{Equivalent mass of } H_3PO_4 = \frac{\text{Molecular mass}}{\text{Basicity}} = \frac{98}{3} = 32.66$$

(B) Equivalent Mass of a Base

It is the mass of the base which contains one mole of replaceable OH^- ions in a molecule.

$$\text{Equivalent mass of base} = \frac{\text{Molecular mass of base}}{\text{Acidity of the base}}$$

Acidity of base = Number of replaceable OH^- ions present in one molecule of the base

or

It is the mass of a base which completely reacts with one gram equivalent mass of an acid, *e.g.*, $$\underset{74\,g}{Ca(OH)_2} + \underset{73\,g}{2HCl} \longrightarrow CaCl_2 + 2H_2O$$

$$= 2\text{ g equivalent of HCl}$$

2 gram equivalent of HCl reacts with 74 g $Ca(OH)_2$

$\therefore$ 1 gram equivalent of HCl will react with 37 g $Ca(OH)_2$

Thus, equivalent mass of $Ca(OH)_2 = 37$

Base	Acidity	Molecular mass	Equivalent mass
NaOH	1	40	40/1 = 40
KOH	1	56	56/1 = 56
$Ca(OH)_2$	2	74	74/2 = 37
NH_4OH	1	35	35/1 = 35

(C) Equivalent Mass of Salt

Let us consider a salt of weak acid (H_2CO_3) and strong base (NaOH). This salt undergoes hydrolysis in water to form basic solution.

$$Na_2CO_3 + 2H_2O \rightleftharpoons H_2CO_3 + 2Na^+ + 2OH^-$$

Such salts react with mineral acids like HCl

$$Na_2CO_3 + 2HCl \longrightarrow 2NaCl + H_2O + CO_2$$

In the above reaction one mole of Na_2CO_3 reacts with 2 equivalents of HCl

$$\therefore \text{ Equivalent mass of } Na_2CO_3 = \frac{\text{Molecular mass of } Na_2CO_3}{2}$$

$$= \frac{106}{2} = 53$$

Thus, *mass of the salt which reacts with one gram equivalent of acid or base is called its equivalent mass, e.g.*,

(i) $$\underset{1\text{ mol}}{NH_4Cl} + \underset{1\text{ g equivalent}}{NaOH} \longrightarrow NH_3 + NaCl + H_2O$$

$$\text{Equivalent mass of } NH_4Cl = \frac{\text{Molecular mass of } NH_4Cl}{1}$$

(ii) $$\underset{1\text{ mol}}{AgNO_3} + \underset{1\text{ g equivalent}}{HCl} \longrightarrow AgCl + HNO_3$$

$$\text{Equivalent mass of } AgNO_3 = \frac{\text{Molecular mass of } AgNO_3}{1}$$

Alternatively,

$$\text{Equivalent mass of salt} = \frac{\text{Molecular mass of salt}}{\text{Total positive or negative valency}}$$

Salt	Valency	Equivalent mass
NaCl	1	molecular mass/1
$CaCl_2$	2	molecular mass/2
$Ca_3(PO_4)_2$	6	molecular mass/6
$AlCl_3$	3	molecular mass/3

(D) Equivalent Mass of an Oxidising Agent

(a) Available oxygen concept: The mass of oxidising agent which contains 8 g of available oxygen (*i.e.*, the oxygen which can be used for oxidation) is called the equivalent mass of oxidising agent.

Examples:

(i) $$\underset{294.2\,g}{K_2Cr_2O_7} + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + \underset{\substack{3\times 16\,g\\ = 48\,g}}{3[O]}$$

$$\text{Equivalent mass of } K_2Cr_2O_7 = \frac{294.2}{48} \times 8 = 49.03$$

(ii) Equivalent mass of $KMnO_4$: Potassium permanganate is a powerful oxidising agent in acid, base and in neutral medium.

(1) Acid medium:

$$\underset{2\times 158\,g}{2KMnO_4} + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + \underset{5\times 16\,g}{5[O]}$$

~~80 g oxygen is furnished by 316 g $KMnO_4$~~

~~$\therefore$ 8 g oxygen is furnished by 31.6 g $KMnO_4$~~

i.e., equivalent mass of $KMnO_4$ in acidic medium is 31.6.

(2) Neutral medium:

$$\underset{2\times 158\,g}{2KMnO_4} + H_2O \longrightarrow 2MnO_2 + 2KOH + \underset{3\times 16\,g}{3[O]}$$

$$\text{Equivalent mass of } KMnO_4 = \frac{316}{48} \times 8 = 52.66$$

(3) Alkaline medium:

$$2KMnO_4 + 2KOH \longrightarrow 2K_2MnO_4 + H_2O + [O]$$

$$2 \times 158\text{ g } KMnO_4 \equiv 16\text{ g 'O'}$$

$$\text{Equivalent mass of } KMnO_4 = \frac{316}{16} \times 8 = 158$$

(b) Electron concept:

Equivalent mass of oxidising agent

$$= \frac{\text{Molecular mass of oxidising agent}}{\text{Number of electrons gained by one molecule}}$$

Examples: (i) Equivalent mass of potassium dichromate:

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$

$$\text{Equivalent mass of } K_2Cr_2O_7 = \frac{\text{Molecular mass}}{6} = \frac{294}{6} = 49$$

(ii) Equivalent mass of $KMnO_4$ in acid medium:

$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$$

$$\text{Equivalent mass of } KMnO_4 = \frac{\text{Molecular mass}}{5} = \frac{158}{5} = 31.6$$

Similarly, equivalent mass of $KMnO_4$ in neutral and alkaline medium can be calculated.

$$MnO_4^- + e^- \longrightarrow MnO_4^{2-} \qquad \text{(Neutral medium)}$$

$$MnO_4^- + 2H_2O + 3e^- \longrightarrow MnO_2 + 4OH^- \text{ (Alkaline medium)}$$

(c) Oxidation number concept:

Equivalent mass of oxidising agent

$$= \frac{\text{Molecular mass of oxidising agent}}{\text{Total change in oxidation number per molecule of oxidising agent}}$$

Examples:

(i) Equivalent mass of $K_2Cr_2O_7$:

$$\overset{+2}{K_2}\,\underline{\overset{+12}{Cr_2}}\,\overset{-14}{O_7} + 4H_2SO_4 \rightarrow K_2SO_4 + \underline{\overset{+6}{Cr}}_2\overset{-6}{(SO_4)_3} + 4H_2O + 3[O]$$

Change in oxidation number of chromium = 12 − 6 = 6

$$\text{Equivalent mass of } K_2Cr_2O_7 = \frac{\text{Molecular mass}}{6} = \frac{294}{6} = 49$$

(ii) Equivalent mass of $KMnO_4$ in acid medium:

$$2\overset{+1}{K}\,\underline{\overset{+7}{Mn}}\,\overset{-8}{O_4} + 3H_2SO_4 \longrightarrow K_2SO_4 + 2\underline{\overset{+2}{Mn}}\,\overset{-2}{SO_4} + 3H_2O + 5[O]$$

Change in oxidation number of manganese = 7 − 2 = 5

Equivalent mass of $KMnO_4$

$$= \frac{\text{Molecular mass}}{5} = \frac{158}{5} = 31.6$$

(E) Equivalent Mass of a Reducing Agent

(a) Available oxygen concept: The amount of reducing agent in gram which reacts with 8 g of available oxygen is called gram equivalent mass of reducing agent.

Examples:

(i) Oxalic acid:

$$\underset{1\ \text{mol}\ (126\ \text{g})}{\begin{array}{c}\text{COOH}\\ |\\ \text{COOH}\end{array}} \cdot 2H_2O + \underset{16\ \text{g}}{[O]} \longrightarrow 2CO_2 + 3H_2O$$

$$\text{Equivalent mass of oxalic acid} = \frac{126}{16} \times 8 = 63$$

(ii) Ferrous sulphate:

$$\underset{2\ \text{mol}\ (2\times 152\ \text{g})}{2FeSO_4} + H_2SO_4 + \underset{16\ \text{g}}{[O]} \longrightarrow Fe_2(SO_4)_3 + H_2O$$

$$\text{Equivalent mass of ferrous sulphate} = \frac{2\times 152}{16} \times 8 = 152$$

Similarly, equivalent mass of Mohr salt can be determined.

$$2\ \text{mol}\ FeSO_4(NH_4)_2SO_4 \cdot 6H_2O \equiv 1 \text{ gram atom of oxygen}$$

$$\therefore \text{Equivalent mass of Mohr salt} = \frac{392 \times 2 \times 8}{16} = 392$$

(b) Electron loss concept:

Equivalent mass of a reducing agent

$$= \frac{\text{Molecular mass}}{\text{Number of electrons lost by one molecule}}$$

Example: Ferrous ammonium sulphate (Mohr salt). Oxidation of Mohr salt involves the following ionic reaction:

$$Fe^{2+} \longrightarrow Fe^{3+} + e^-$$

Equivalent mass = Molecular mass

(c) Oxidation number concept:

$$\text{Equivalent mass} = \frac{\text{Molecular mass}}{\text{Total change in oxidation number of the oxidised element per molecule}}$$

The oxidation number of iron in ferrous salt is +2 while the oxidation number of iron in ferric salt is +3. The change in oxidation number per atom of iron is 1, *i.e.*, one unit.

∴ Equivalent mass of ferrous ammonium sulphate

$$= \frac{\text{Molecular mass}}{1} = \frac{392}{1} = 392$$

SOME SOLVED EXAMPLES

Example 1. *When hydrogen gas was passed over 8.08 g of heated metal oxide, it was completely reduced and 1.8 g of water was formed:*

(a) What is weight of oxygen in the metal oxide?

(b) What is the equivalent mass of the metal?

Solution: (a) When hot metal oxide is treated with hydrogen, 1.8 g water is formed.

18 g H_2O contains 16 g oxygen.

Thus, 1.8 g H_2O will contain 1.6 g oxygen.

(b) Equivalent mass may be defined as weight of the metal that combines with 8 parts of oxygen to form its oxide.

Mass of metal in its oxide = 8.08 − 1.6
= 6.48 g

∵ 1.6 g oxygen combines with 6.48 g of metal

$$\therefore 8 \text{ g oxygen will combine with} = \frac{6.48}{1.6} \times 8 \text{ g of metal} = 32.4 \text{ g}$$

Thus, equivalent mass of metal = 32.4

Example 2. *SO_2 is oxidised to SO_4^{2-} in acid medium. Calculate equivalent mass of SO_2.*

Solution: $\overset{+4}{S}O_2(g) + 2H_2O \longrightarrow \overset{+2}{H_2}\overset{+6}{S}\overset{-8}{O_4} + 2H^+ + 2e^-$

Change in oxidation number of sulphur = 6 − 4 = 2

$$\text{Equivalent mass of } SO_2 = \frac{\text{Molecular mass}}{2} = \frac{64}{2} = 32$$

Example 3. *What is the equivalent mass of:*

(a) H_3PO_4 when neutralised to HPO_4^{2-}

(b) $HClO_4$

(c) $NaIO_3$ when reduced to I^-

(d) $NaIO_3$ when reduced to I_2

(e) $Al(OH)_3$.

Solution: (a) Molecular mass of $H_3PO_4 = (3 + 31 + 64) = 98$ g. H_3PO_4 when neutralised to HPO_4^{2-}, two H^+ ions have been replaced.

$$\text{Thus, eq. mass} = \frac{\text{Mol. mass}}{\text{No. of replaceable hydrogen atoms}} = \frac{98}{2} = 49.0 \text{ g}$$

(b) $HClO_4$ molecule contains one replaceable hydrogen atom.

$$\text{Thus, eq. mass} = \frac{\text{Mol. mass}}{1} = \frac{100.5}{1} = 100.5$$

(c) $NaIO_3 \longrightarrow I^-$

Oxidation no. $+5$ $\quad -1$

Change in oxidation number = 6

Mol. mass of $NaIO_3 = (23 + 127 + 48) = 198$ g

$$\text{Eq. mass of } NaIO_3 = \frac{\text{Mol. mass}}{\text{Change in O.N.}} = \frac{198}{6} = 33.0$$

(d) $NaIO_3 \longrightarrow I_2$

Oxidation no. $+5$ $\quad 0$

Change in oxidation number = 5

$$\text{Eq. mass of } NaIO_3 = \frac{198}{5} = 39.6$$

(e) The acidity of $Al(OH)_3$ is 3.

$$\text{Eq. mass of } Al(OH)_3 = \frac{\text{Mol. mass}}{\text{Acidity}} = \frac{78}{3} = 26.0 \text{ g}$$

Example 4. *Calculate the number of millimoles and milliequivalents of $Cr_2O_7^{2-}$ ions in acid medium when 100 mL of 0.01 M $Cr_2O_7^{2-}$ is reduced to Cr^{3+} by Fe^{2+}.*

Solution: $\underset{1\text{ mol}}{Cr_2O_7^{2-}} + 14H^+ + \underset{6\text{ mol}}{6e^-} \longrightarrow 2Cr^{3+} + 7H_2O$

$$\therefore \quad 0.01\,M\ Cr_2O_7^{2-} \equiv 0.06\,N\ Cr_2O_7^{2-}$$

Number of millimoles $= M \times V = 0.01 \times 100 = 1$

Number of milliequivalents $= N \times V = 0.06 \times 100 = 6$

Example 5. *Give the relation between molecular mass (M) and equivalent mass (E) of the underlined species in the following reactions:*

(*a*) $\underline{H_3PO_4} + Ca(OH)_2 \longrightarrow CaHPO_4 + 2H_2O$

(*b*) $\underline{H_2O_2} + MnO_4^- \longrightarrow Mn^{2+} + O_2 + H_2O$

(*c*) $\underline{4H_3PO_3} \longrightarrow 3H_3PO_4 + PH_3$

(*d*) $\underline{HC{\equiv}CH} + 2Na \longrightarrow NaC{\equiv}CNa + H_2$

Solution: (a) $\underline{H_3PO_4} + Ca(OH)_2 \longrightarrow CaHPO_4 + 2H_2O$

Basicity of $H_3PO_4 = 2$

$$\therefore \text{ Equivalent mass of } H_3PO_4(E) = \frac{\text{Molecular mass }(M)}{2}$$

(b) $\underline{\overset{+2}{H_2}\,\overset{-2}{O_2}} \longrightarrow \overset{0}{O_2}$

Change in oxidation number of $H_2O_2 = 2$

$$\therefore \text{ Equivalent mass of } H_2O_2\ (E) = \frac{\text{Molecular mass }(M)}{2}$$

(c) $\underline{\overset{+3}{H_3}\ \overset{+3}{P}\,\overset{-6}{O_3}} \longrightarrow \overset{+3}{H_3}\ \overset{+5}{P}\,\overset{-8}{O_4}$

Change in oxidation number of 'P' = 2

$$\therefore \text{ Equivalent mass } (E_1) = \frac{\text{Molecular mass }(M)}{2}$$

$$\overset{+3}{H_3}\ \overset{+3}{P}\,\overset{-6}{O_3} \longrightarrow \overset{-3}{P}\,\overset{+3}{H_3}$$

Change in oxidation number of 'P' $= +3 - (-3) = +6$

$$\text{Equivalent mass } (E_2) = \frac{\text{Molecular mass }(M)}{6}$$

Overall equivalent mass $= E_1 + E_2$

$$= \frac{M}{2} + \frac{M}{6} = \frac{4M}{6} = \frac{2M}{3}$$

(d) $\underline{H{-}C{\equiv}C{-}H} + 2Na \longrightarrow NaC{\equiv}CNa + H_2$

Basicity of acetylene = 2

$$\therefore \quad \text{Equivalent mass } (E) = \frac{\text{Molecular mass }(M)}{2}$$

Example 6. *Determine the number of g equivalents of solute in (a) 100 mL of 5 N HCl (b) 250 mL of 0.1 N Na_2CO_3.*

Solution : We know that

Number of g equivalents = Normality × Vol. of solution (litres)

(a) Number of g equivalents of HCl $= 5 \times \dfrac{100}{1000} = 0.5$

(b) Number of g equivalents of $Na_2CO_3 = 0.1 \times \dfrac{250}{1000}$

$= 0.025$

Example 7. *What volumes of 12 N HCl and 3 N HCl must be mixed to form one litre 6 N HCl?*

Solution: Let x mL of 12 N HCl and y mL of 3 N HCl be mixed to form one litre 6 N HCl.

So, $\quad x + y = 1000 \quad$ ... (i)

Applying the formula $N_1V_1 + N_2V_2 = N_3V_3$,

$N_1 = 12\,N, V_1 = x, N_2 = 3\,N, V_2 = y, N_3 = 6\,N, V_3 = 1000$

So, $\quad 12x + 3y = 6 \times 1000 \quad$ ... (ii)

Putting the value of $y = (1000 - x)$ from eq. (i) in eq. (ii),

$$12x + 3(1000 - x) = 6000$$

or $\quad 12x - 3x + 3000 = 6000$

or $\quad 9x = 3000$

$$x = \frac{3000}{9} = 333.3 \text{ mL}$$

So, $\quad y = (1000 - x) = (1000 - 333.3) = 666.7$ mL

i.e., 333.3 mL 12 N HCl and 666.7 mL 3 N HCl are mixed.

Example 8. (*a*) *What is the normality of a 96 per cent solution of H_2SO_4 of specific gravity 1.84?*

(*b*) *How many mL of 96 per cent sulphuric acid solution is necessary to prepare one litre 0.1 N H_2SO_4?*

(*c*) *To what volume should 10 mL of 96 per cent H_2SO_4 be diluted to prepare 2 N solution?*

Solution: Mass of 1 litre of H_2SO_4 solution

= Vol. × Density

$= 1000 \times 1.84 = 1840$ g

Mass of H_2SO_4 present in one litre 96% H_2SO_4 solution

$$= \frac{96}{100} \times 1840 = 1766.4 \text{ g}$$

Strength of H_2SO_4 solution $= 1766.4$ g/L

(a) $\text{Normality} = \frac{\text{Strength}}{\text{Eq. mass}} = \frac{1766.4}{49} = 36.05\ N$

(b) Let the volume taken be V_1 mL

Applying $N_1V_1 = N_2V_2$

$N_1 = 36.05N, \quad V_1 = ?, \quad N_2 = \frac{N}{10}, \quad V_2 = 1000 \text{ mL}$

$$36.05 \times V_1 = \frac{1}{10} \times 1000$$

So, $V_1 = \frac{1000}{36.05 \times 10} = 2.77 \text{ mL}$

i.e., 2.77 mL of H_2SO_4 is diluted to one litre.

(c) $\underset{\text{Before dilution}}{N_BV_B} = \underset{\text{After dilution}}{N_AV_A}$

$$10 \times 36.05 = V_A \times 2$$

$$V_A = 180.25 \text{ mL}$$

i.e., 10 mL of given H_2SO_4 is diluted to 180.25 mL.

Example 9. *250 mL of x M solution and 500 mL of y M solution of a solute A are mixed and diluted to 2 litre to produce a final concentration of 1.6 M.*

If $x : y = 5 : 4$, calculate x and y.

Solution: We know that,

$$M_1V_1 + M_2V_2 = M_R(V_1 + V_2)$$

$$x \times 250 + y \times 500 = 1.6(2000)$$

$$x + 2y = 1.6 \times 8$$

$$x + 2y = 12.8$$

$$\frac{x}{y} + 2 = \frac{12.8}{y}$$

$$\frac{5}{4} + 2 = \frac{12.8}{y}$$

$$\frac{13}{4} = \frac{12.8}{y}$$

$$y = \frac{12.8 \times 4}{13} = 3.94$$

Similarly, $x = 4.92$

Example 10. *2.68×10^{-3} mol of a solution containing an ion A^{n+} required 1.6×10^{-3} mol of MnO_4^- for oxidation of A^{n+} to AO_3^- ion in acid medium. What is the value of n?*

Solution: A^{n+} is oxidised to AO_3^-

Change in oxidation number $= 5(\text{in } AO_3^-) - n(\text{in } A^{n+})$

$= 5 - n$ ... (i)

2.68×10^{-3} mol of A^{n+} ion react with 1.6×10^{-3} mol of MnO_4^- ions

$\therefore$ 1 mol of A^{n+} ion will react with $\frac{1.6 \times 10^{-3}}{2.68 \times 10^{-3}}$ mol of MnO_4^- ions

$= 0.579$ mol of MnO_4^- ions

$$2K\overset{+7}{Mn}O_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2\overset{+2}{Mn}SO_4 + 3H_2O + 5[O]$$

Number of equivalents of MnO_4^- used in oxidation of A^{n+} to $AO_3^- = 0.597 \times 5 = 2.985 \approx 3$

Thus, from equation (i), $5 - n = 3$

$n = 2$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. An element X having equivalent mass E forms a general oxide X_mO_n, its atomic mass should be:

(a) $\frac{2En}{m}$ (b) $2mEn$ (c) $\frac{E}{n}$ (d) $\frac{ME}{2n}$

[**Ans.** (a)]

[**Hint:** Amount of X that combines with 8 g of oxygen,

i.e., $E = \frac{m \times \text{Atomic mass}}{n \times 2}$

$\therefore$ $\text{Atomic mass} = \frac{2En}{m}$]

2. In the reaction,

$$FeS_2 + KMnO_4 + H^+ \longrightarrow Fe^{3+} + SO_2 + Mn^{2+} + H_2O$$

the equivalent mass of FeS_2 would be equal to:

(a) molar mass (b) $\frac{\text{molar mass}}{10}$

(c) $\frac{\text{molar mass}}{11}$ (d) $\frac{\text{molar mass}}{13}$

[**Ans.** (c)]

[**Hint:** $Fe^{2+} \longrightarrow Fe^{3+} + e^-$; $S_2^{2-} \longrightarrow 2S^{4+} + 10e^-$

$\therefore$ $FeS_2 \longrightarrow 2S^{4+} + Fe^{3+} + 11e^-$

Equivalent mass of $FeS_2 = \frac{\text{Molar mass}}{11}$]

3. The equivalent mass of H_3BO_3 in its reaction with NaOH to form $Na_2B_4O_7$ is equal to:

(a) molar mass/4 (b) molar mass/3

(c) molar mass/2 (d) molar mass

[**Ans.** (d)]

[**Hint:** Boric acid is a monobasic acid.

Hence, Equivalent mass = Molar mass]

4. For the reaction, $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$, if molecular masses of NH_3 and N_2 are M_1 and M_2, their equivalent masses are E_1 and E_2, then $(E_1 - E_2)$ is:

(a) $\frac{2M_1 - M_2}{6}$ (b) $M_1 - M_2$

(c) $3M_1 - M_2$ (d) $M_1 - 3M_2$

[**Ans.** (a)]

[**Hint:** Equivalent mass of N_2, *i.e.*, $E_2 = \frac{M_2}{6}$

Equivalent mass of NH_3, *i.e.*, $E_1 = \frac{M_1}{3}$

Then, $E_1 - E_2 = \frac{M_1}{3} - \frac{M_2}{6} = \frac{2M_1 - M_2}{6}$]

5. X g metal gave Y g of its oxide. Hence, equivalent mass of the metal is:

(a) $\left(\frac{X}{Y-X}\right)\times 8$ (b) $\left(\frac{Y-X}{X}\right)\times 8$

(c) $\left(\frac{Y+X}{X}\right)\times 8$ (d) $\frac{X}{Y}\times 8$

[**Ans.** (a)]

[**Hint:** Mass of oxygen in the oxide = $(Y-X)$

$\therefore$ 8 g oxygen will combine with $\frac{X}{Y-X}\times 8$ g metal.

$$\therefore \qquad E=\left(\frac{X}{Y-X}\right)\times 8]$$

6. $KMnO_4$ (m.w. = 158) oxidises oxalic acid in acid medium to CO_2 and water as follows:

$$5C_2O_4^{2-}+2MnO_4^-+16H^+\rightarrow 10CO_2+2Mn^{2+}+8H_2O$$

What is the equivalent weight of $KMnO_4$? **[CET (J&K) 2006]**

(a) 158 (b) 31.6 (c) 39.5 (d) 79

[**Ans.** (b)]

[**Hint:** MnO_4^- $\longrightarrow$ Mn^{2+}

(Oxidation number of Mn = + 7) (Oxidation number of Mn = + 2)

$$\text{Equivalent mass of } KMnO_4=\frac{\text{Molecular mass}}{\text{Change in oxidation number}}$$

$$=\frac{158}{5}=31.6]$$

7. The formula mass of Mohr's salt is 392. The iron present in it is oxidised by $KMnO_4$ in acid medium. The equivalent mass of Mohr's salt is:

(a) 392 (b) 31.6 (c) 278 (d) 156

[**Ans.** (a)]

[**Hint:** Formula of Mohr's salt: $FeSO_4\cdot(NH_4)_2SO_4\cdot 6H_2O$

Oxidation of Fe^{2+} ions take place as:

$$5Fe^{2+}+MnO_4^-+8H^+\longrightarrow 5Fe^{3+}+Mn^{2+}+4H_2O$$

Change in oxidation number of Fe = + 3 − (+2) = + 1

$$\text{Equivalent mass of Mohr's salt}=\frac{\text{Molecular mass}}{\text{Change in oxidation number}}$$

$$=\frac{392}{1}=392]$$

8. In a redox reaction, dichromate ion ($Cr_2O_7^{2-}$) is reduced to Cr^{3+} ion, the equivalent mass of $K_2Cr_2O_7$ in this reaction is: **(EAMCET 2007)**

(a) $\frac{\text{molecular mass}}{3}$ (b) $\frac{\text{molecular mass}}{6}$

(c) $\frac{\text{molecular mass}}{1}$ (d) $\frac{\text{molecular mass}}{2}$

[**Ans.** (b)]

[**Hint:** $Cr_2O_7^{2-}+14H^++6e^-\longrightarrow 2Cr^{3+}+7H_2O$

Change in oxidation number = 6

$$\therefore \text{Equivalent mass}=\frac{\text{Molecular mass}}{6}]$$

14.5 ACID-BASE TITRATIONS

The determination of concentration of bases by titration with a standard acid is called **acidimetry** and the determination of concentration of acids by titration with a standard base is called **alkalimetry.**

The substances which give different colours with acids and bases are called acid-base indicators. These indicators are used in the visual detection of the equivalence point in acid-base titrations. The acid-base indicators are also called pH indicators because their colour change according to pH of the solution.

pH Range of Indicators

Indicators	pH range	Colour of indicator	
		Acid medium	Basic medium
Methyl orange	3.1 – 4.4	Red	Orange
Bromo phenol blue	3 – 4.6	Yellow	Blue
Methyl red	4.2 – 6.3	Red	Yellow
Litmus	5 – 8	Red	Blue
Bromo-thymol blue	6 – 7.6	Yellow	Blue
Phenol red	8.3 – 10	Colourless	Pink
Thymol phthalein	8.3 – 10.5	Colourless	Blue

In the selection of indicator for a titration, following two informations are taken into consideration:

(i) pH range of indicator.

(ii) pH change near the equivalence point in the titration.

The indicator whose pH range is included in the pH change of the solution near the equivalence point, is taken as suitable indicator for the titration.

(i) Strong acid-strong base titration: In the titration of HCl with NaOH, the equivalence point lies in the pH change of 4 –10. Thus, methyl orange, methyl red and phenolphthalein will be suitable indicators.

(ii) Weak acid-strong base titration: In the titration of CH_3COOH with NaOH the equivalence point lies between 7.5 and 10. Hence, phenolphthalein (8.3–10) will be the suitable indicator.

(iii) Weak base-strong acid titration: In the titration of NH_4OH (weak base) against HCl (strong acid), the pH at equivalence point is about 6.5 and 4. Thus, methyl orange (3.1–4.4) or methyl red (4.2–6.3) will be suitable indicators.

(iv) Weak acid-weak base titration: In the titration of a weak acid (CH_3COOH) with weak base (NH_4OH) the pH at the equivalence point is about 7, *i. e.*, lies between 6.5 and 7.5 but no sharp change in pH is observed in these titrations. Thus, no simple indicator can be employed for the detection of the equivalence point.

(v) Titration of a salt of a weak acid and a strong base with strong acid:

$$\underset{\text{Weak acid}}{H_2CO_3}+\underset{\text{Strong base}}{2NaOH}\longrightarrow Na_2CO_3+2H_2O$$

Na_2CO_3 when titrated with HCl, the following two stages are involved:

$$Na_2CO_3+HCl\longrightarrow NaHCO_3+NaCl \qquad \text{(First stage)}$$

pH = 8.3, near equivalence point

$NaHCO_3 + HCl \longrightarrow NaCl + H_2CO_3$ (Second stage)
pH = 4, near equivalence point

For first stage, phenolphthalein and for second stage, methyl orange will be the suitable indicator.

14.6 TITRATION OF MIXTURE OF NaOH, Na_2CO_3 AND $NaHCO_3$ BY STRONG ACID LIKE HCl

In this titration the following indicators are mainly used:

(i) Phenolphthalein (weak organic acid): It shows colour change in the pH range (8–10).

(ii) Methyl orange (weak organic base): It shows colour change in the pH range (3.1–4.4). Due to lower pH range, it indicates complete neutralisation of whole of the base.

S.No.	Base	Phenolphthalein	Methyl orange
1.	NaOH	Shows complete neutralisation, $NaOH + HCl \rightarrow NaCl + H_2O$	Shows complete neutralisation, $NaOH + HCl \rightarrow NaCl + H_2O$
2.	Na_2CO_3	Shows half neutralisation due to following reaction: $Na_2CO_3 + HCl \rightarrow NaHCO_3 + NaCl$	Shows complete neutralisation, $Na_2CO_3 + 2HCl \rightarrow 2NaCl + H_2O + CO_2$
3.	$NaHCO_3$	Shows no reaction	Show complete reaction, $NaHCO_3 + HCl \rightarrow NaCl + H_2O + CO_2$

Let for complete neutralisation of Na_2CO_3, $NaHCO_3$ and NaOH, x, y and z mL of standard HCl are required. The titration of the mixture may be carried by two methods as summarised below:

Mixture	Volume of HCl used with		Volume of HCl used	
	Phenolphthalein from beginning	Methyl orange from beginning	Phenolphthalein from beginning	Methyl orange after first end point
1. NaOH + Na_2CO_3	$z + (x/2)$	$(x + z)$	$z + \frac{x}{2}$	$x/2$ (for remaining 50% Na_2CO_3)
2. NaOH + $NaHCO_3$	$z + 0$	$(z + y)$	$(z + 0)$	y (for 100% remaining $NaHCO_3$)
3. Na_2CO_3 + $NaHCO_3$	$(x/2) + 0$	$(x + y)$	$(x/2) + 0$	$(x/2) + y$ (for remaining 50% of Na_2CO_3 and 100% $NaHCO_3$ are indicated)

SOME SOLVED EXAMPLES

Example 11. *What is the strength in g per litre of a solution of sulphuric acid, 12 mL of which neutralise 15 mL of N/10 sodium hydroxide solution?*

Solution: Applying $\underset{\text{(NaOH)}}{N_1V_1} = \underset{(H_2SO_4)}{N_2V_2}$

$$\frac{1}{10} \times 15 = N_2 \times 12$$

$$N_2 = \frac{15}{10 \times 12} = 0.125$$

Normality × Eq. mass = Strength (g/L)

Strength = 0.125 × 49 = 6.125 g/L

Example 12. *4.9 g of H_2SO_4 is present in 100 mL of the solution. What is the molarity of the solution? Calculate its normality also.*

Solution: Strength (g/L) of $H_2SO_4 = \frac{4.9}{100} \times 1000 = 49$

$$\text{Molarity} = \frac{\text{Strength}}{\text{Mol. mass}} = \frac{49}{98} = 0.5\,M$$

Normality = n × Molarity

$$n = \frac{\text{Mol. mass}}{\text{Eq. mass}} = \frac{98}{49} = 2$$

Normality = 2 × 0.5 = 1.0

Hence, the H_2SO_4 solution is 1 N.

Example 13. *25 mL of N/10 caustic soda solution exactly neutralises 20 mL of an acid solution containing 7.875 g of acid per litre. Calculate the equivalent mass of the acid.*

Solution: $\underset{\text{(NaOH)}}{N_1V_1} = \underset{\text{(Acid)}}{N_2V_2}$

$$\frac{1}{10} \times 25 = N_2 \times 20$$

$$N_2 = \frac{25}{10 \times 20} = 0.125$$

Strength = Normality × Eq. mass

$$\text{Eq. mass of the acid} = \frac{7.875}{0.125} = 63.00$$

Example 14. *150 mL of N/10 HCl is required to react completely with 1.0 g of a sample of limestone. Calculate the percentage purity of calcium carbonate.*

Solution: $150\text{ mL}\,\frac{N}{10}\text{ HCl} \equiv 150\text{ mL}\,\frac{N}{10}\,CaCO_3$

$$\underset{\text{Mol. mass}}{CaCO_3} + \underset{\text{2g eq.}}{2HCl} \longrightarrow CaCl_2 + H_2O + CO_2$$

$$\text{Eq. mass of } CaCO_3 = \frac{40 + 12 + 48}{2} = \frac{100}{2} = 50$$

Mass of $CaCO_3$ present in 150 mL $N/10$ solution,

$$\left[N \times E \times \frac{V}{1000}\right] = 50 \times \frac{1}{10} \times \frac{150}{1000} = 0.75\text{ g}$$

$$\text{Purity} = \frac{0.75}{1} \times 100 = 75\%$$

Example 15. *0.63 g of dibasic acid was dissolved in water. The volume of the solution was made 100 mL. 20 mL of this acid solution required 10 mL $\frac{N}{5}$ NaOH solution. What is the equivalent mass and molecular mass of the acid?*

Solution: $$\underset{\text{(Acid)}}{N_1V_1} \equiv \underset{\text{(NaOH)}}{N_2V_2}$$

$$N_1 \times 20 = \frac{1}{5} \times 10$$

$$N_1 = \frac{1}{5} \times \frac{10}{20} = \frac{1}{10}$$

Strength of the acid solution = Eq. mass of the acid × Normality

$$= E \times \frac{1}{10} = \frac{E}{10}\ \text{g/L}$$

Mass of acid in 100 mL of the solution $= \frac{E}{10} \times \frac{100}{1000} = \frac{E}{100}$

Mass of acid in 100 mL of the solution = 0.63 g (given)

So, $\frac{E}{100} = 0.63$ or $E = 63$

Mol. mass = Basicity × Eq. mass

$= 2 \times 63 = 126$

Example 16. *10.875 g of a mixture of NaCl and Na_2CO_3 was dissolved in water and the volume made up to 250 mL, 20 mL of this solution required 75.5 mL of $\frac{N}{10}$ H_2SO_4. Find out the percentage composition of the mixture.*

Solution: Only Na_2CO_3 will react with H_2SO_4.

Applying $$\underset{(Na_2CO_3)}{N_1V_1} \equiv \underset{(H_2SO_4)}{N_2V_2}$$

$$N_1 \times 20 = 75.5 \times \frac{1}{10}$$

$$N_1 = \frac{75.5}{20 \times 10} = 0.3775$$

$$\underset{\text{1 mol. mass}}{Na_2CO_3} + \underset{\text{2g eq.}}{H_2SO_4} \longrightarrow Na_2SO_4 + H_2O + CO_2$$

Eq. mass of $Na_2CO_3 = \frac{106}{2} = 53$

Mass of Na_2CO_3 present in 250 mL 0.3775 *N* solution

$$= \frac{N \times E \times V}{1000} = \frac{0.3775 \times 53 \times 250}{1000}$$

$$= 5.0018\ \text{g}$$

Mass of NaCl = (10.875 − 5.0018) = 5.8732 g

$$Na_2CO_3 = \frac{5.0018}{10.875} \times 100 = 45.99\%$$

$$NaCl = \frac{5.8732}{10.875} \times 100 = 54.0\%$$

Example 17. *A quantity of ammonium chloride was heated with 100 mL of 0.8 N NaOH solution till the reaction was complete. The excess of NaOH was neutralised with 12.5 mL of 0.75 N H_2SO_4. Calculate the quantity of ammonium chloride.*

Solution:

12.5 mL of 0.75 *N* H_2SO_4 ≡ 12.5 mL of 0.75 *N* NaOH

12.5 mL of 0.75 *N* NaOH ≡ 11.72 mL of 0.8 *N* NaOH

NaOH solution used by NH_4Cl

= (100 − 11.72) mL of 0.8 N NaOH

= 88.28 mL of 0.8 *N* NaOH

≡ 88.28 mL of 0.8 *N* NH_4Cl

Mass of NH_4Cl present in 88.28 mL of 0.8 *N* NH_4Cl solution

$$= \frac{N \times E \times V}{1000} = \frac{0.8 \times 53.5 \times 88.28}{1000} = 3.7783\ \text{g}$$

[Eq. mass of NH_4Cl = 53.5]

Example 18. *A sample of $Na_2CO_3 \cdot H_2O$ weighing 0.62 g is added to 100 mL of 0.1 N sulphuric acid. Will the resulting solution be acidic, basic or neutral? (At. mass H = 1, C = 12, O = 16, Na = 23, S = 32)*

Solution: Mass of $Na_2CO_3 \cdot H_2O$ = 0.62 g

$$\text{No. of g equivalents} = \frac{\text{Mass}}{\text{Eq. mass}} = \frac{0.62}{62} = 0.01$$

[Eq. mass of $Na_2CO_3 \cdot H_2O = \frac{124}{2} = 62$]

No. of g equivalents of H_2SO_4 in 100 mL $= \frac{0.1}{1000} \times 100$

$$= \frac{0.1}{10} = 0.01$$

Both the substances are present in same equivalent; they will completely neutralise each other and hence, the resulting solution will be neutral.

Example 19. *A solution containing 4.2 g of KOH and $Ca(OH)_2$ is neutralised by an acid. If it consumes 0.1 g equivalents of the acid, calculate the composition of the sample.*

Solution: Let mass of KOH be present in mixture = *a* g

and Mass of $Ca(OH)_2$ = (4.2 − *a*) g

Eq. mass of KOH = 56; Eq. mass of $Ca(OH)_2 = \frac{74}{2} = 37$

g equivalent of KOH + g equivalent of $Ca(OH)_2$

= g equivalent of the acid

$$\frac{a}{56} + \frac{(4.2 - a)}{37} = 0.1$$

or $37a - 56a = 0.1 \times 56 \times 37 - 4.2 \times 56$

or $19a = 28$

$$a = \frac{28}{19} = 1.47$$

Mass of KOH in the sample = 1.47 g

Percentage of KOH = 35

and Percentage of $Ca(OH)_2$ = 100 − 35 = 65

Example 20. *40 mL of HCl is exactly neutralised by 20 mL of NaOH solution. The resulting neutral solution is evaporated to dryness and the residue is found to have a mass of 0.117 g. Calculate the normality of the HCl and NaOH.*

Solution: $$\underset{\substack{36.5\\ \text{1g eq.}}}{HCl} + \underset{\substack{40\\ \text{1g eq.}}}{NaOH} \longrightarrow \underset{\substack{58.5\\ \text{1g eq.}}}{NaCl} + H_2O$$

$$\text{Mass of NaCl obtained} = 0.117\text{ g}$$

$$\text{Eq. mass of NaCl} = 58.5$$

$$\text{No. of g equivalents of NaCl} = \frac{0.117}{58.5} = 0.002$$

Thus, 0.002 g eq. of HCl will react with 0.002 g eq. of NaOH to form 0.002 g eq. NaCl.

$$\text{Normality of HCl} = \frac{0.002}{40} \times 1000 = 0.05\,N$$

$$\text{Normality of NaOH} = \frac{0.002}{20} \times 1000 = 0.10\,N$$

Example 21. *1.03 g mixture of sodium carbonate and calcium carbonate require 20 mL N HCl for complete neutralisation. Calculate the percentage of sodium carbonate and calcium carbonate in the given mixture.*

Solution: $\underset{106}{Na_2CO_3} + \underset{2\times 36.5}{2HCl} \longrightarrow 2NaCl + H_2O + CO_2$

$$\begin{array}{lll} \text{Eq. mass} & 53 & 36.5 \\ & 1\text{ g eq.} & 1\text{ g eq.} \end{array}$$

$$\underset{100}{CaCO_3} + \underset{2\times 36.5}{2HCl} \longrightarrow CaCl_2 + H_2O + CO_2$$

$$\begin{array}{lll} \text{Eq. mass} & 50 & 36.5 \\ & 1\text{ g eq.} & 1\text{ g eq.} \end{array}$$

Let x g $CaCO_3$ be present in the mixture.

$$\text{Mass of } Na_2CO_3 \text{ in the mixture} = (1.03 - x)\text{ g}$$

$$\text{No. of g equivalents of } CaCO_3 = \frac{x}{50}$$

$$\text{No. of g equivalents of } Na_2CO_3 = \frac{(1.03 - x)}{53}$$

$$\text{No. of g equivalents in 20 mL } N \text{ HCl} = \frac{\text{Normality} \times \text{Vol.}}{1000} = \frac{1 \times 20}{1000} = \frac{1}{50}$$

At equivalence point,

No. of g equivalents of $CaCO_3$ + No. of g equivalents of Na_2CO_3 = No. of gram equivalents of HCl

$$\frac{x}{50} + \frac{1.03 - x}{53} = \frac{1}{50}$$

or

$$x = 0.50$$

$$CaCO_3 = 0.50\text{ g}, \quad \%\,CaCO_3 = \frac{0.50}{1.03} \times 100 = 48.54$$

$$Na_2CO_3 = 0.53\text{ g}, \%\,Na_2CO_3 = \frac{0.53}{1.03} \times 100 = 51.46$$

Example 22. *1.325 g of anhydrous sodium carbonate are dissolved in water and the solution made up to 250 mL. On titration 25 mL of this solution neutralise 20 mL of a solution of sulphuric acid. How much water should be added to 450 mL of this acid solution to make it exactly N/12?*

Solution: $\text{Eq. mass of } Na_2CO_3 = \frac{\text{Mol. mass}}{2} = \frac{106}{2} = 53$

250 mL of the sodium carbonate solution contains = 1.325 g

1000 mL of the sodium carbonate solution contains

$$= \frac{1.325\text{ g}}{250} \times 1000 = 5.300\text{ g}$$

$$\text{Normality of } Na_2CO_3 \text{ solution} = \frac{\text{Strength (g/L)}}{\text{Eq. mass}} = \frac{5.30}{53} = \frac{1}{10}\,N$$

Applying $\underset{(Na_2CO_3)}{N_1V_1} \equiv \underset{(H_2SO_4)}{N_2V_2}$

$$\frac{1}{10} \times 25 = N_2 \times 20$$

$$N_2 = \frac{25}{10 \times 20} = \frac{1}{8}$$

Applying $\underset{\text{(Before dilution)}}{N_BV_B} \equiv \underset{\text{(After dilution)}}{N_AV_A}$

$$\frac{1}{8} \times 450 = \frac{1}{12} \times V_A$$

$$V_A = \frac{450 \times 12}{8} = 675\text{ mL}$$

Water to be added for dilution = (675 − 450) = 225 mL

Example 23. *A sample of sodium carbonate contains sodium sulphate also. 1.5 g of the sample is dissolved in water and volume raised to 250 mL. 25 mL of this solution requires 20 mL of $\frac{N}{10}$ H_2SO_4 solution for neutralisation. Calculate the percentage of sodium carbonate in the sample.*

Solution: Only Na_2CO_3 will react with H_2SO_4.

Applying $\underset{(Na_2CO_3)}{N_1V_1} = \underset{(H_2SO_4)}{N_2V_2}$

$$N_1 \times 25 = 20 \times \frac{1}{10}$$

$$N_1 = \frac{20}{25 \times 10} = 0.08$$

$$\text{Eq. mass of } Na_2CO_3 = \frac{\text{Mol. mass}}{2} = \frac{106}{2} = 53$$

Mass of Na_2CO_3 present in 250 mL 0.08 N solution

$$= \frac{N \times E \times V}{1000} = \frac{0.08 \times 53 \times 250}{1000} = 1.06\text{ g}$$

$$\text{Percentage of } Na_2CO_3 \text{ in the mixture} = \frac{1.06}{1.50} \times 100 = 70.67$$

Example 24. *In a sample of sodium carbonate some sodium sulphate is also mixed. 1.25 g of this sample is dissolved and the volume made up to 250 mL. 25 mL of this solution neutralises 20 mL of $\frac{N}{10}$ sulphuric acid. Calculate the percentage of sodium carbonate in the sample.*

Solution: 25 mL of sample solution neutralises

$$= 20 \text{ mL } \frac{N}{10} H_2SO_4$$

250 mL of sample solution will neutralise

$$= 200 \text{ mL } \frac{N}{10} H_2SO_4$$

$$200 \text{ mL } \frac{N}{10} H_2SO_4 \equiv 200 \text{ mL } \frac{N}{10} Na_2CO_3 \text{ solution}$$

$$\text{Amount of } Na_2CO_3 \text{ present} = \frac{E \times N \times V}{1000}$$

$$= \frac{53 \times 200}{10 \times 1000} = 1.06$$

$$\% \text{ of } Na_2CO_3 \text{ in the sample} = \frac{1.06}{1.25} \times 100 = 84.8$$

Example 25. *1.725 g of a metal carbonate is mixed with 300 mL of $\frac{N}{10}$ HCl. 10 mL of $\frac{N}{2}$ sodium hydroxide were required to neutralise excess of the acid. Calculate the equivalent mass of the metal carbonate.*

Solution: 10 mL of $\frac{N}{2}$ NaOH solution

$$= 10 \text{ mL of } \frac{N}{2} \text{ HCl solution}$$

$$\equiv 50 \text{ mL of } \frac{N}{10} \text{ HCl solution}$$

$$\text{Volume of } \frac{N}{10} \text{ HCl used for neutralisation} = 300 - 50 = 250 \text{ mL}$$

$$250 \text{ mL of } \frac{N}{10} \text{ HCl} \equiv 250 \text{ mL of } \frac{N}{10} \text{ metal carbonate solution}$$

Let the equivalent mass of metal carbonate be E.
Mass of metal carbonate present in solution

$$= \frac{N \times E \times V}{1000} = 1.725$$

$$= \frac{1 \times E \times 250}{10 \times 1000} = 1.725$$

$$= \frac{E}{40} = 1.725$$

$$E = 40 \times 1.725 = 69$$

Example 26. *1.575 g of oxalic acid $(COOH)_2 \cdot xH_2O$ are dissolved in water and the volume made up to 250 mL. On titration 16.68 mL of this solution requires 25 mL of $\frac{N}{15}$ NaOH solution for complete neutralisation. Calculate x.*

Solution:

$$25 \text{ mL of } \frac{N}{15} \text{ NaOH solution} \equiv 25 \text{ mL of } \frac{N}{15} \text{ oxalic acid solution}$$

$$\text{Mass of oxalic acid present in 25 mL of } \frac{N}{15} \text{ oxalic acid solution}$$

$$= \frac{N \times E \times V}{1000} = \frac{1 \times (90 + 18x) \times 25}{15 \times 2 \times 1000}$$

$$= \frac{(90 + 18x)}{1200} \text{ g}$$

Actually $\frac{(90+18x)}{1200}$ g oxalic acid is present in 16.68 mL solution.

250 mL of the solution contains oxalic acid

$$= \frac{(90 + 18x) \times 250}{1200 \times 16.68} = 1.575 \text{ (given)}$$

$$\text{or} \quad 90 + 18x = \frac{1.575 \times 1200 \times 16.68}{250} = 126$$

$$\text{or} \quad 18x = 126 - 90 = 36$$

$$x = 2$$

Example 27. *25 mL of a mixture of NaOH and Na_2CO_3 when titrated with N/10 HCl using phenolphthalein indicator required 25 mL HCl. The same volume of mixture when titrated with N/10 HCl using methyl orange indicator required 30 mL of HCl. Calculate the amount of Na_2CO_3 and NaOH in one litre of this mixture.*

Solution: When phenolphthalein is the indicator, whole of NaOH has been neutralised and carbonate converted into bicarbonate, *i.e.*,

$$NaOH + HCl \longrightarrow NaCl + H_2O$$

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$

So, 25 mL $\frac{N}{10}$ HCl ≡ NaOH + 1/2 Na_2CO_3 present in 25 mL of mixture

In another titration when methyl orange is the indicator, whole of NaOH has been neutralised and carbonate converted into carbonic acid, *i.e.*,

$$Na_2CO_3 + 2HCl \longrightarrow 2NaCl + H_2CO_3$$

$$30 \text{ mL } \frac{N}{10} \text{ HCl} \equiv NaOH + Na_2CO_3 \text{ present in 25 mL of mixture}$$

Hence,

$$(30 - 25) \text{ mL } \frac{N}{10} \text{ HCl} \equiv \frac{1}{2} Na_2CO_3 \text{ present in 25 mL of mixture}$$

Hence,

$$10 \text{ mL } \frac{N}{10} \text{ HCl} \equiv Na_2CO_3 \text{ present in 25 mL of mixture}$$

$$\equiv 10 \text{ mL } \frac{N}{10} Na_2CO_3 \text{ solution}$$

$$\text{Amount of } Na_2CO_3 = \frac{53 \times 10}{10 \times 1000} = 0.053 \text{ g}$$

This amount of Na_2CO_3 is present in 25 mL of mixture.

The amount present in one litre of mixture

$$= \frac{0.053}{25} \times 1000 = 2.12 \text{ g}$$

$$(30-10)\,\text{mL}\,\frac{N}{10}\,\text{HCl} \equiv \text{NaOH present in 25 mL mixture}$$

$$\equiv 20\ \text{mL}\ \frac{N}{10}\ \text{NaOH}$$

$$\text{Amount of NaOH in 25 mL of mixture} = \frac{40 \times 20}{10 \times 1000} = 0.08\ \text{g}$$

$$\text{The amount present in one litre of mixture} = \frac{0.08}{25} \times 1000 = 3.20\ \text{g}$$

Example 28. *25 mL of a mixture of* $NaOH + Na_2CO_3$, *when titrated with* $\frac{N}{10}$ *HCl using phenolphthalein indicator required 25 mL HCl to decolourise phenolphthalein. At this stage methyl orange was added and addition of acid was continued. The second end point was reached after further addition of 5 mL of the acid. Calculate the amount of* Na_2CO_3 *and NaOH in one litre of the solution.*

Solution: Between first and second end points,

$$NaHCO_3 + HCl \longrightarrow NaCl + H_2CO_3$$

$$5\ \text{mL}\ \frac{N}{10}\ \text{HCl} \equiv \frac{1}{2}\ Na_2CO_3 \text{ present in 25 mL of a mixture}$$

$$\text{or } 10\ \text{mL}\ \frac{N}{10}\ \text{HCl} \equiv Na_2CO_3 \text{ present in 25 mL of a mixture}$$

$$\equiv 10\ \text{mL}\ \frac{N}{10}\ Na_2CO_3 = 0.053\ \text{g}\ Na_2CO_3$$

$$\text{Amount of } Na_2CO_3 \text{ in one litre of mixture} = \frac{0.053}{25} \times 1000$$

$$= 2.12\ \text{g}$$

$$(25-5)\,\text{mL}\,\frac{N}{10}\,\text{HCl} \equiv \text{NaOH present in 25 mL of mixture}$$

$$\equiv 25\ \text{mL}\ \frac{N}{10}\ \text{NaOH}$$

$$\equiv 0.08\ \text{g NaOH}$$

$$\text{Amount of NaOH in one litre of mixture} = \frac{0.08}{25} \times 1000$$

$$= 3.2\ \text{g}$$

Example 29. *A solution contains* Na_2CO_3 *and* $NaHCO_3$. *10 mL of the solution required 2.5 mL of 0.1 M* H_2SO_4 *for neutralisation using phenolphthalein as indicator. Methyl orange is then added when a further 2.5 mL of 0.2 M* H_2SO_4 *was required. Calculate the amount of* Na_2CO_3 *and* $NaHCO_3$ *in one litre of the solution.*

Solution: 2.5 mL of 0.1 M H_2SO_4 = 2.5 mL of 0.2 N H_2SO_4

$$= \frac{1}{2}\ Na_2CO_3 \text{ present in 10 mL of mixture}$$

So,

5 mL of 0.2 N H_2SO_4 = Na_2CO_3 present in 10 mL of mixture

$$\equiv 5\ \text{mL of } 0.2\ N\ Na_2CO_3$$

$$\equiv \frac{0.2 \times 53}{1000} \times 5 = 0.053\ \text{g}$$

$$\text{Amount of } Na_2CO_3 = \frac{0.053}{10} \times 1000 = 5.3\ \text{g/L of mixture}$$

Between first and second end points,

= 2.5 mL of 0.2 M H_2SO_4 used

= 2.5 mL of 0.4 N H_2SO_4 used

= 5 mL of 0.2 N H_2SO_4 used

$$\equiv \frac{1}{2}\ Na_2CO_3 + NaHCO_3 \text{ present in 10 mL of mixture}$$

$$(5-2.5)\,\text{mL}\ 0.2\ N\ H_2SO_4$$

$$\equiv NaHCO_3 \text{ present in 10 mL of mixture}$$

$$\equiv 2.5\ \text{mL}\ 0.2\ N\ NaHCO_3$$

$$\equiv \frac{0.2 \times 84}{1000} \times 2.5 = 0.042\ \text{g}$$

$$\text{Amount of } NaHCO_3 = \frac{0.042}{10} \times 1000 = 4.20\ \text{g/L of mixture.}$$

Example 30. *Calculate the normality of a solution obtained by mixing 100 mL* $\frac{N}{10}$ H_2SO_4, *50 mL* $\frac{N}{2}$ HNO_3 *and 25 mL* $\frac{N}{5}$ *HCl solutions.*

Solution: Let the final normality be N.

Total volume = (100 + 50 + 25) = 175 mL

So,
$$175 \times N = \underset{(H_2SO_4)}{N_1V_1} + \underset{(HNO_3)}{N_2V_2} + \underset{(HCl)}{N_3V_3}$$

$$= \left(100 \times \frac{1}{10}\right) + \left(50 \times \frac{1}{2}\right) + \left(25 \times \frac{1}{5}\right)$$

$$= (10 + 25 + 5) = 40$$

$$N = \frac{40}{175} = 0.2286$$

Hence, normality of solution = 0.2286 N

Example 31. *0.5 g of fuming* H_2SO_4 *(oleum) is diluted with water. This solution is completely neutralised by 26.7 mL of 0.4 N NaOH. Find the percentage of free* SO_3 *in the sample solution.*

Solution: Oleum consists of SO_3 and H_2SO_4.

Let the mass of SO_3 in the given sample of oleum be = x g

Mass of H_2SO_4 in the given sample of oleum = $(0.5 - x)$ g

$$\text{Eq. mass of } SO_3 = \frac{80}{2} = 40$$

$$\text{No. of g equivalents of } SO_3 = \frac{x}{40}$$

$$[2NaOH + SO_3 \longrightarrow Na_2SO_4 + H_2O$$
$$2NaOH + H_2SO_4 \longrightarrow Na_2SO_4 + 2H_2O]$$

$$\text{Eq. mass of } H_2SO_4 = \frac{98}{2} = 49$$

$$\text{No. of g equivalents of } H_2SO_4 = \frac{(0.5 - x)}{49}$$

$$\text{Total no. of g equivalents} = \frac{x}{40} + \frac{(0.5-x)}{49}$$

26.7 mL of 0.4 N NaOH contain no. of equivalents of NaOH

$$= \frac{0.4}{1000} \times 26.7$$

At equivalence point,

$$\text{No. of g equivalents of NaOH} = \frac{x}{40} + \frac{(0.5-x)}{49}$$

So, $$\frac{0.4 \times 26.7}{1000} = \frac{49x + (40 \times 0.5 - 40x)}{40 \times 49}$$

$$x = \frac{0.9328}{9} = 0.1036$$

$$\text{Hence, \% of free } SO_3 = \frac{0.1036}{0.5} \times 100$$

$$= 20.72$$

Example 32. *0.789 g of crystalline barium hydroxide is dissolved in water. For the neutralisation of this solution, 20 mL of* $\frac{N}{4}$ *HNO_3 is required. How many molecules of water are present in one g mole of this base? ($Ba = 137.4$, $O = 16$, $N = 14$, $H = 1$)*

Solution: Let the molecular formula be $Ba(OH)_2 \cdot xH_2O$

$$\text{Mol. mass of } Ba(OH)_2 \cdot xH_2O = 137.4 + (2 \times 16) + 2 \times 1 + 18x$$

$$= 171.4 + 18x$$

$$\text{Eq. mass of } Ba(OH)_2 \cdot xH_2O = \frac{171.4 + 18x}{2}$$

$$20 \text{ mL } \frac{N}{4} HNO_3 \equiv 20 \text{ mL } \frac{N}{4} Ba(OH)_2 \cdot xH_2O$$

$$\text{Amount of } Ba(OH)_2 \cdot xH_2O = \frac{(171.4 + 18x)}{2 \times 4} \times \frac{20}{1000}$$

$$= \frac{171.4 + 18x}{400} \text{ g}$$

$$\text{Amount of } Ba(OH)_2 \cdot xH_2O = 0.789 \text{ g}$$

Hence, $$\frac{171.4 + 18x}{400} = 0.789$$

or $$171.4 + 18x = 0.789 \times 400$$

$$x = \frac{144.2}{18} = 8.01 \approx 8$$

Thus, 8 g moles of water molecules are present in one g mole of the base.

Example 33. *A piece of aluminium weighing 2.7 g is heated with 75 mL of H_2SO_4 (sp. gr. 1.18, containing 24.7% H_2SO_4 by mass). After the metal is carefully dissolved, the solution is diluted to 400 mL. Calculate the molarity of the free H_2SO_4 in the resulting solution.*

Solution: $$\text{Mass of } H_2SO_4 = \frac{24.7}{100} \times 75 \times 1.18$$

$$= 21.8595 \text{ g}$$

$$\text{Reaction}: \quad \underset{2 \times 27}{2Al} + \underset{3 \times 98}{3H_2SO_4} \longrightarrow Al_2(SO_4)_3 + 3H_2$$

H_2SO_4 required for dissolving 2.7 g Al

$$= \frac{3 \times 98}{2 \times 27} \times 2.7 = 14.7 \text{ g}$$

H_2SO_4 left unreacted = (21.895 − 14.7) g = 7.1595 g

7.1595 g H_2SO_4 is present in 400 mL

$$\text{Amt. of } H_2SO_4 \text{ present in one litre} = \frac{7.1595}{400} \times 1000 \text{ g}$$

$$= 17.898 \text{ g}$$

$$\text{No. of g moles of } H_2SO_4 = \frac{17.898}{98} = 0.1826$$

Hence, molarity of $H_2SO_4 = 0.1826\ M$

Example 34. *0.50 g of a mixture of K_2CO_3 and Li_2CO_3 requires 30 mL of a 0.25 N HCl solution for neutralisation. What is the percentage composition of the mixture?*

Solution: $$\begin{array}{lcccl} & K_2CO_3 & + & 2HCl & \longrightarrow 2KCl + H_2O + CO_2 \\ & 138 & & 2 \times 36.5 & \\ \text{Eq. mass} & 69 & & 36.5 & \end{array}$$

$$\begin{array}{lcccl} & Li_2CO_3 & + & 2HCl & \longrightarrow 2LiCl + H_2O + CO_2 \\ & 74 & & 2 \times 36.5 & \\ \text{Eq. mass} & 37 & & 36.5 & \end{array}$$

Let x g of K_2CO_3 be present in the mixture.

$$\text{Mass of } Li_2CO_3 = (0.50 - x)$$

$$\text{No. of g equivalents of } K_2CO_3 = \frac{x}{69}$$

$$\text{No. of g equivalents of } Li_2CO_3 = \frac{(0.50 - x)}{37}$$

No. of g equivalents in 30 mL of 0.25 N HCl

$$= \frac{\text{Normality} \times \text{Volume}}{1000} = \frac{0.25 \times 30}{1000}$$

$$= \frac{3}{400}$$

At equivalence point,

$$\frac{x}{69} + \frac{(0.50 - x)}{37} = \frac{3}{400}$$

So, $$x = 0.48$$

$$K_2CO_3 = 0.48 \text{ g; or } 96\%$$

$$Li_2CO_3 = 0.02 \text{ g; or } 4\%$$

Example 35. *5 mL of 8 N nitric acid, 4.8 mL of 5 N hydrochloric acid and a certain volume of 17 M sulphuric acid are mixed together and made up to 2 litres. Thirty mL of this acid mixture exactly neutralise 42.9 mL of sodium carbonate solution containing one gram of $Na_2CO_3 \cdot 10H_2O$ in 100 mL of water. Calculate the amount in grams of the sulphate ions in solution.*

Solution: Molecular mass of $Na_2CO_3 \cdot 10H_2O = 286$

$$\text{Equivalent mass of } Na_2CO_3 \cdot 10H_2O = \frac{286}{2} = 143$$

100 mL solution of sodium carbonate contains = 1 g
1000 mL solution of sodium carbonate contains = 10 g

$$\text{Normality of the solution} = \frac{10}{143}$$

Applying the formula,
Normality of acid solution × its volume
= Normality of sodium carbonate solution × its volume,

$$\text{Normality of the acid solution} = \frac{10 \times 42.9}{143 \times 30} = 0.1$$

Let V mL be the volume of H_2SO_4 taken.

$$8 \times 5 + 4.8 \times 5 + 34 \times V = 0.1 \times 2000$$

$$V = 4 \text{ mL}$$

$$\text{Amount of } SO_4^{2-} = \frac{\text{Normality} \times \text{Eq. mass} \times \text{Volume}}{1000}$$

$$= \frac{34 \times 48 \times 4}{1000} = 6.528 \text{ g}$$

Example 36. *2.26 g of an ammonium salt were treated with 100 mL of normal NaOH solution and boiled till no more of ammonia gas was given off. The excess of NaOH solution left over required 60 mL normal sulphuric acid. Calculate the percentage of ammonia in the salt.*

Solution: 60 mL normal $H_2SO_4 \equiv$ 60 mL normal NaOH

Thus, (100 − 60) mL normal NaOH were consumed by ammonium salt.

So, 40 mL normal NaOH ≡ 40 mL normal NH_3

Amount of NH_3 in 40 mL normal NH_3

$$= \frac{\text{Eq. mass of } NH_3 \times 40}{1000}$$

$$= \frac{17 \times 40}{1000} = 0.68$$

$$\text{So, \% of ammonia in the ammonium salt} = \frac{0.68}{2.26} \times 100$$

$$= 30.09$$

Example 37. *10 mL of a solution containing sulphuric acid and hydrochloric acid required 16 mL $\frac{N}{8}$ caustic soda solution for neutralisation. On adding excess of barium chloride to 20 mL of the same solution of the mixture of the two acids it gives 0.3501 g barium sulphate. What is the amount of hydrochloric acid per litre in the mixture of acids? (Ba = 137.4, S = 32, O = 16, Cl = 35.5)*

Solution: Mol. mass of $BaSO_4$ = (137.4 + 32 + 64) = 233.4

$$\underset{98\text{ g}}{H_2SO_4} + BaCl_2 \longrightarrow \underset{233.4\text{ g}}{BaSO_4} + 2HCl$$

233.4 g of $BaSO_4$ is obtained from = 98 g of H_2SO_4

$$0.3501 \text{ g of } BaSO_4 \text{ is obtained from} = \frac{98}{233.4} \times 0.3501$$

$$= 0.147 \text{ g of } H_2SO_4$$

20 mL of acid mixture contains 0.147 g of H_2SO_4

So, 10 mL of acid mixture contains 0.0735 g of H_2SO_4

Amount of NaOH in 16 mL $\frac{N}{8}$ NaOH solution

$$= \frac{E \times N \times V}{1000}$$

$$= \frac{40 \times 16}{8 \times 1000} = 0.08 \text{ g}$$

$$\underset{98\text{ g}}{H_2SO_4} + \underset{2 \times 40 = 80\text{ g}}{2NaOH} \longrightarrow Na_2SO_4 + 2H_2O$$

Thus, 98 g of H_2SO_4 require = 80 g of NaOH

$$0.0735 \text{ g of } H_2SO_4 \text{ will require} = \frac{80}{98} \times 0.0735 \text{ g of NaOH}$$

$$= 0.06 \text{ g of NaOH}$$

Let the amount of HCl in 10 mL acid mixture be = x g

$$\underset{36.5\text{ g}}{HCl} + \underset{40\text{ g}}{NaOH} \longrightarrow NaCl + H_2O$$

36.5 g HCl require = 40 g of NaOH

$$x \text{ g HCl will require} = \frac{40}{36.5} x \text{ g of NaOH}$$

$$= 1.0958x \text{ g of NaOH}$$

$$1.0958x + 0.06 = 0.08$$

$$x = \frac{(0.08 - 0.06)}{1.0958} = 0.01825 \text{ g}$$

Amount of HCl present in one litre of the acid solution

$$= \frac{0.01825 \times 1000}{10} = 1.825$$

Example 38. *A small amount of $CaCO_3$ completely neutralises 525 mL of 0.1 N HCl and no acid is left in the end. After converting all calcium chloride to $CaSO_4$, how much plaster of Paris can be obtained?* **(Dhanbad 1991)**

Solution:

525 mL of 0.1 N HCl = 525 mL of 0.1 N $CaCl_2$
= 525 mL of 0.1 N plaster of Paris

$$\text{Molecular mass of plaster of Paris} = CaSO_4 \cdot \tfrac{1}{2} H_2O = 145$$

$$\text{Equivalent mass of plaster of Paris} = \frac{145}{2} = 72.5$$

Mass of plaster of Paris in 525 mL of 0.1 N solution

$$= \frac{N \times E \times V}{1000} = \frac{0.1 \times 72.5 \times 525}{1000}$$

$$= 3.806 \text{ g}$$

Example 39. *25 mL of 0.107 M H_3PO_4 was titrated with 0.115 M solution of NaOH to the end point identified by indicator bromocresol green. This required 23.1 mL. The titration was repeated using phenolphthalein as indicator. This time 25 mL of 0.107 M H_3PO_4 required 46.2 mL of the 0.115 M NaOH. What is the coefficient 'n' in the following reaction?*

$$H_3PO_4 + nOH^- \longrightarrow [H_{3-n}PO_4]^{n-} + nH_2O$$

Solution: Number of milliequivalents of H_3PO_4

$$= 25 \times 0.107 \times n$$
$$= 2.675 \times n$$

In first titration: Number of milliequivalents of OH^- used

$$= 23.1 \times 0.115 \times 1 = 2.66$$

(Acidity of NaOH = 1)

In second titration: Number of milliequivalents of OH^- used

$$= 46.2 \times 0.115 \times 1 = 5.313$$

$\therefore$ In first titration: $2.675 \times n = 2.66$

i.e., $n = 1$

$\therefore$ In second titration: $2.675 \times n = 5.313$

$$n = 2$$

Example 40. *11.2 g carbon reacts completely with 19.63 litre O_2 at NTP. The cooled gases are passed through 2 litre of 2.5 N NaOH solution. Calculate concentration of remaining NaOH and Na_2CO_3 in solution. (CO does not react with NaOH under these conditions.)*

Solution: Let x moles of carbon be converted into CO and y moles of carbon be converted into CO_2.

$$\underset{x}{C} + \underset{x/2}{\tfrac{1}{2}O_2} \longrightarrow CO$$

$$\underset{y}{C} + \underset{y}{O_2} \longrightarrow CO_2$$

Total volume of oxygen used $= \frac{x}{2} \times 22.4 + y \times 22.4$

$$= 19.63$$

$$11.2x + 22.4y = 19.63 \qquad \text{... (i)}$$

$$x + y = \frac{11.2}{12};\ i.e., 12x + 12y = 11.2 \qquad \text{... (ii)}$$

Solving eqs. (i) and (ii), we get

$$x = 0.11,\ y = 0.82$$

Number of moles of CO_2 formed = 0.82

Number of milliequivalents of NaOH solution through which CO_2 is massed $= N \times V = 2.5 \times 2000 = 5000$

Number of milliequivalents of CO_2 passed $= 0.82 \times 2 \times 1000$

$$= 1640$$

$$2NaOH + CO_2 \longrightarrow Na_2CO_3 + H_2O$$

Number of milliequivalents of $Na_2CO_3 = 1640$

$$N_{Na_2CO_3} = \frac{1640}{2000} = 0.82$$

Number of milliequivalents of remaining NaOH

$$= 5000 - 1640 = 3360$$

Normality of remaining NaOH $= \frac{3360}{2000} = 1.68$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

9. How many grams of $NaHCO_3$ are required to neutralise 1 mL of 0.0902 N vinegar?

(a) 8.4×10^{-3} g (b) 1.5×10^{-3} g

(c) 0.758×10^{-3} g (d) 1.07×10^{-3} g

[Ans. (c)]

[Hint: Number of equivalents of $NaHCO_3$

$$= \text{Number of equivalents of acid}$$
$$= \frac{NV}{1000} = \frac{0.0902 \times 1}{1000}$$

Mass of $NaHCO_3 = \frac{0.0902 \times 1 \times 84}{1000}$

$$= 0.758 \times 10^{-3}\ \text{g}]$$

10. 0.7 g of $Na_2CO_3 \cdot xH_2O$ was dissolved in water and the volume made up to 100 mL, 20 mL of it required 19.8 mL of $\frac{N}{10}$ HCl for complete neutralisation. The value of x is:

(a) 7 (b) 3

(c) 2 (d) 5

[Ans. (c)]

[Hint: Number of milliequivalents of $Na_2CO_3 \cdot xH_2O$ in 20 mL

$$= 19.8 \times \frac{1}{10}$$
$$= 1.98$$

$\therefore$ Number of milliequivalents in 100 mL $= 1.98 \times 5 = 9.9$

$$\frac{\text{Mass}}{\text{Equivalent mass}} \times 1000 = 9.9$$

$$\frac{0.7}{M/2} \times 1000 = 9.9$$

$$M = 141.40$$

(Molar mass of $Na_2CO_3 \cdot xH_2O$)

$$106 + 18x = 141.40$$
$$x = 2]$$

11. Calculate the equivalent mass of Na_2CO_3 when it is titrated against HCl in presence of phenolphthalein.

(a) 106 (b) 53

(c) 26.5 (d) 212

[Ans. (a)]

[Hint: The reaction involved is,

$$Na_2CO_3 + HCl \longrightarrow NaCl + NaHCO_3$$

Equivalent mass of $Na_2CO_3 = \frac{106}{1} = 106]$

12. 1 mol H_2SO_4 will exactly neutralise:

(a) 2 mol of ammonia (b) 1 mol of $Ba(OH)_2$

(c) 0.5 mol of $Ba(OH)_2$ (d) 2 mol of KOH

[Ans. (a, b, d)]

[Hint: $2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4$

$$Ba(OH)_2 + H_2SO_4 \longrightarrow BaSO_4 + 2H_2O$$
$$2KOH + H_2SO_4 \longrightarrow K_2SO_4 + 2H_2O]$$

13. Which of the following gives equivalent mass of Na_2CO_3 when titrated against HCl in the presence of methyl orange?

(a) 5.3 (b) 53
(c) 10.6 (d) 106
[**Ans.** (b)]

[**Hint:** $Na_2CO_3 + 2HCl \xrightarrow{\text{Methyl orange}} 2NaCl + H_2O + CO_2$
Equivalent mass = molecular mass/2 = 106/2 = 53]

14.7 REDOX TITRATIONS

Oxidimetry: The determination of the strength of a solution of a reducing agent by titration with a standard solution of an oxidising agent is called oxidimetry.

Reductimetry: The determination of the strength of a solution of an oxidising agent by titration with standard solution of reducing agent is called reductimetry.

(Species) Oxidising Agent (OA) Or Reducing Agent (RA)	Reaction involved	Change in oxidation number Or Number of electrons involved	Equivalent mass
MnO_4^- (Acidic medium OA)	$MnO_4^- + 8H^+ + 5e^- \rightarrow Mn^{2+} + 4H_2O$	5	M.w./5
MnO_4^- (Neutral medium OA)	$MnO_4^- + 2H_2O + 3e^- \rightarrow MnO_2 + 4OH^-$	3	M.w./3
MnO_4^- (Basic medium OA)	$MnO_4^- + e^- \rightarrow MnO_4^{2-}$	1	M.w./1
H_2O_2 (OA)	$H_2O_2 + 2H^+ + 2e^- \rightarrow 2H_2O$	2	M.w./2
H_2O_2 (RA)	$H_2O_2 \rightarrow O_2 + 2H^+ + 2e^-$	2	M.w./2
$S_2O_3^{2-}$ (RA)	$2S_2O_3^{2-} \rightarrow S_4O_6^{2-} + 2e^-$	1 (per molecule)	M.w./1
Cl_2 (OA) (Obtained from bleaching powder)	$Cl_2 + 2e^- \rightarrow 2Cl^-$	2	M.w./2
$Cr_2O_7^{2-}$ (OA)	$Cr_2O_7^{2-} + 14H^+ + 6e^- \rightarrow 2Cr^{3+} + 7H_2O$	6	M.w./6
MnO_2 (OA)	$MnO_2 + 4H^+ + 2e^- \rightarrow Mn^{2+}$	2	M.w./2
Fe^{2+} (RA)	$Fe^{2+} \rightarrow Fe^{3+} + e^-$	1	M.w./1

Equivalent Mass of Substance Undergoing Disproportionation

Let us consider, disproportionation of H_3PO_2.

$$3H_3\overset{+1}{P}O_2 \longrightarrow 2H_3\overset{+3}{P}O_3 + \overset{-3}{P}H_3$$

−2*e* oxidation

$+4e^-$

Reduction

$$n\text{-factor} = \frac{n_1 \times n_2}{n_1 + n_2} = \frac{4 \times 2}{4+2} = \frac{4}{3}$$

$$\text{Equivalent mass of } H_3PO_2 = \frac{\text{Molecular mass}}{n\text{-factor}} = \frac{m}{4/3} = \frac{3m}{4}$$

14.8 IODOMETRIC AND IODIMETRIC TITRATIONS

(Titrating solution is $Na_2S_2O_3 \cdot 5H_2O$ called hypo.)

(i) *Estimation of* I_2:

$$I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$$

Eq. mass of $Na_2S_2O_3 \cdot 5H_2O$ = M. w./1

(ii) *Estimation of* $CuSO_4$:

$$2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2$$

$$2Cu^{2+} + 4I^- \longrightarrow Cu_2I_2 + I_2$$

Eq. mass of $CuSO_4$ = M. w./1

(iii) *Estimation of* MnO_2 *present in pyrolusite:*

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$$

$$Cl_2 + 2KI \longrightarrow 2KCl + I_2$$

or $$MnO_2 + 4H^+ + 2Cl^- \longrightarrow Mn^{2+} + 2H_2O + Cl_2$$

$$Cl_2 + 2I^- \longrightarrow 2Cl^- + I_2$$

Eq. mass of MnO_2 = M. w./2

(iv) *Estimation of available chlorine in bleaching powder:*

$$CaOCl_2 + H_2O \longrightarrow Ca(OH)_2 + Cl_2$$

$$Cl_2 + 2KI \longrightarrow 2KCl + I_2$$

Eq. mass of $CaOCl_2$ = M. w./2

(v) *Estimation of* H_2O_2:

$$H_2O_2 + 2I^- + 2H^+ \longrightarrow I_2 + 2H_2O$$

Eq. mass of H_2O_2 = M. w./2

(vi) *Estimation of ozone:*

$$O_3 + 6I^- + 6H^+ \longrightarrow 3I_2 + 3H_2O$$

Eq. mass of O_3 = M. w./6

(vii) *Estimation of* $Cr_2O_7^{2-}$:

$$Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 3I_2 + 2Cr^{3+} + 7H_2O$$

Eq. mass of $Cr_2O_7^{2-}$ = M. w./6

(viii) *Estimation of* ClO^-:

$$ClO^- + 2I^- + 2H^+ \longrightarrow H_2O + Cl^- + I_2$$

Eq. mass of ClO^- = M. w./2

(ix) *Estimation of* IO_3^-:

$$IO_3^- + 5I^- + 6H^+ \longrightarrow 3I_2 + 3H_2O$$

Eq. mass of IO_3^- = M. w./5

SOME SOLVED EXAMPLES

Example 41. *0.5 g of an oxalate was dissolved in water and the solution made to 100 mL. On titration 10 mL of this solution required 15 mL of* $\frac{N}{20}$ *$KMnO_4$. Calculate the percentage of oxalate in the sample.*

Solution:

$$15 \text{ mL } \frac{N}{20} KMnO_4 = 10 \times \text{Normality of oxalate solution.}$$

$$\text{Normality of oxalate solution} = \frac{15}{10} \times \frac{1}{20} = \frac{3}{40}$$

Strength of oxalate solution = Normality × Eq. mass of oxalate

$$= \frac{3}{40} \times 44 = 3.3 \text{ g/L} \quad \left[\text{Eq. mass of } C_2O_4^{2-} = \frac{88}{2} = 44\right]$$

$$\text{Amount of oxalate in 100 mL solution} = \frac{3.3}{1000} \times 100 = 0.33 \text{ g}$$

$$\% \text{ of oxalate} = \frac{0.33}{0.5} \times 100 = 66.0$$

Example 42. *How many mL of a 0.05 M $KMnO_4$ solution are required to oxidise 2.0 g of $FeSO_4$ in a dilute solution (acidic)?*

Solution:

$$\underset{10 \times 151.8}{10FeSO_4} + \underset{2 \times 158}{2KMnO_4} + 8H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 5Fe_2(SO_4)_3 + 8H_2O$$

10×151.8 g of $FeSO_4$ require $KMnO_4 = 2 \times 158$ g

$$2 \text{ g of } FeSO_4 \text{ will require } KMnO_4 = \frac{2 \times 158 \times 2}{10 \times 151.8} \text{ g}$$

Suppose, V mL of $KMnO_4$ solution (0.05 M) is required.

$$\text{Amount of } KMnO_4 \text{ in this solution} = \frac{158 \times 0.05}{1000} \times V$$

Thus,

$$\frac{158 \times 0.05 \times V}{1000} = \frac{2 \times 158 \times 2}{10 \times 151.8}$$

$$V = 52.7 \text{ mL}$$

Example 43. *5.5 g of a mixture of $FeSO_4 \cdot 7H_2O$ and $Fe_2(SO_4)_3 \cdot 9H_2O$ required 5.4 mL of 0.1 N $KMnO_4$ solution for complete oxidation. Calculate the gram mole of hydrated ferric sulphate in the mixture.*

(At. mass $H = 1, O = 16, S = 32, Fe = 56$)

Solution: Only $FeSO_4 \cdot 7H_2O$ will be oxidised by $KMnO_4$.

$$\text{Mol. mass of } FeSO_4 \cdot 7H_2O = 278$$

As the conversion involves one electron,

$$Fe^{2+} \longrightarrow Fe^{3+} + e^-,$$

$$\text{The eq. mass of } FeSO_4 \cdot 7H_2O = \frac{278}{1} = 278$$

5.4 mL of 0.1 N $KMnO_4$

$\equiv$ 5.4 mL of 0.1 N $FeSO_4 \cdot 7H_2O$ solution

$$\text{Amount of } FeSO_4 \cdot 7H_2O = \frac{0.1 \times 278}{1000} \times 5.4 = 0.15 \text{ g}$$

Amount of $Fe_2(SO_4)_3 \cdot 9H_2O = (5.5 - 0.15) = 5.35$ g

Mol. mass of $Fe_2(SO_4)_3 \cdot 9H_2O = 562$

$$\text{No. of g moles of } Fe_2(SO_4)_3 \cdot 9H_2O = \frac{\text{Mass}}{\text{Mol. mass}}$$

$$= \frac{5.35}{562} = 0.00952$$

$$= 9.52 \times 10^{-3}$$

Example 44. *0.5 g mixture of $K_2Cr_2O_7$ and $KMnO_4$ was treated with excess of KI in acidic medium. Iodine liberated required 100 cm³ of 0.15 N sodium thiosulphate solution for titration. Find the per cent amount of each in the mixture.* (IIT 1995)

Solution: Let 'a' g of $K_2Cr_2O_7$ be present in the mixture.

$$\text{Mass of } KMnO_4 = (0.5 - a) \text{ g}$$

$$\text{Eq. mass of } K_2Cr_2O_7 = \frac{\text{Mol. mass}}{6} = \frac{294}{6} = 49.0$$

$$\text{Eq. mass of } KMnO_4 = \frac{\text{Mol. mass}}{5} = \frac{158}{5} = 31.6$$

$$\text{No. of equivalents of } K_2Cr_2O_7 = \frac{a}{49.0}$$

$$\text{No. of equivalents of } KMnO_4 = \frac{(0.5 - a)}{31.6}$$

No. of equivalents of $Na_2S_2O_3$ in 100 cm³ of 0.15 N solution

$$= \frac{100 \times 0.15}{1000} = 0.015$$

Equivalents of $K_2Cr_2O_7$ + Equivalents of $KMnO_4$

$\equiv$ Equivalents of iodine

$\equiv$ Equivalents of $Na_2S_2O_3$

$$\frac{a}{49.0} + \frac{(0.5 - a)}{31.6} = 0.015$$

$$17.4a = 1.274$$

$$a = 0.0732$$

$$\% \text{ of } K_2Cr_2O_7 = \frac{0.0732 \times 100}{0.5} = 14.64$$

$$\% \text{ of } KMnO_4 = 85.36$$

Example 45. *Calculate the percentage of available chlorine in a given sample of bleaching powder from the following data:*

3.55 g of bleaching powder when treated with acetic acid and xcess of KI liberated iodine which required 60 mL of 0.5 N odium thiosulphate solution.

Solution: $60 \text{ mL } 0.5\,N\ Na_2S_2O_3 \equiv 60 \text{ mL } 0.5\,N\ I_2$

$$\equiv 60 \text{ mL } 0.5\,N\ Cl_2$$

$$\text{Amount of chlorine} = \frac{35.5 \times 0.5}{1000} \times 60 = 1.065 \text{ g}$$

$$\% \text{ available chlorine} = \frac{1.065}{3.55} \times 100 = 30.0$$

Example 46. *0.261 g of a sample of pyrolusite was heated with excess of HCl and the chlorine evolved was passed in a solution of KI. The liberated iodine required 90 mL $\frac{N}{30}$ $Na_2S_2O_3$. Calculate the percentage of MnO_2 in the sample.*

Solution: $MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$

$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$

$$2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI$$

$$90 \text{ mL } \frac{N}{30}\, Na_2S_2O_3 \equiv 90 \text{ mL } \frac{N}{30}\, I_2$$

$$\equiv 90 \text{ mL } \frac{N}{30}\, Cl_2$$

$$\equiv 90 \text{ mL } \frac{N}{30}\, MnO_2$$

$$\text{Eq. mass of } MnO_2 = \frac{\text{Mol. mass}}{2} = \frac{87}{2}$$

[Since, change in O.N. is from 4 to 2]

$$\text{Amount of } MnO_2 = \frac{87}{2 \times 30} \times \frac{90}{1000} = 0.1305 \text{ g}$$

$$\% \text{ of } MnO_2 = \frac{0.1305}{0.261} \times 100 = 50$$

Example 47. (*i*) *What is the mass of sodium bromate and molarity of the solution necessary to prepare 85.4 mL of 0.672 N solution when the half reaction is,*

$$BrO_3^- + 6H^+ + 6e \longrightarrow Br^- + 3H_2O$$

(*ii*) *What would be the mass as well as molarity if the half cell reaction is,*

$$2BrO_3^- + 12H^+ + 10e \longrightarrow Br_2 + 6H_2O$$

Solution:

(i) Molecular mass of $NaBrO_3 = 23 + 80 + (3 \times 16) = 151$

Each bromate ion takes-up 6 electrons; therefore,

$$\text{Eq. mass of } NaBrO_3 = \frac{\text{Mol. mass}}{6} = \frac{151}{6}$$

Amount of $NaBrO_3$ in 85.5 mL 0.672 N solution

$$= \frac{0.672}{1000} \times \frac{151}{6} \times 85.5 = 1.446 \text{ g}$$

$$\text{Molarity} = \frac{\text{Normality}}{n} = \frac{0.672}{6} = 0.112\,M$$

(ii) Each bromate ion takes-up 5 electrons; therefore,

$$\text{Eq. mass of } NaBrO_3 = \frac{\text{Mol. mass}}{5} = \frac{151}{5}$$

Amount of $NaBrO_3$ in 85.5 mL 0.672 N solution

$$= \frac{151}{5} \times \frac{0.672}{1000} \times 85.5$$

$$= 1.7352 \text{ g}$$

$$\text{Molarity} = \frac{\text{Normality}}{n} = \frac{0.672}{5} = 0.1344\,M$$

Example 48. *50 mL of an aqueous solution of H_2O_2 was treated with an excess of KI solution and dilute H_2SO_4. The liberated iodine required 20 mL 0.1 N $Na_2S_2O_3$ solution for complete interaction. Calculate the concentration of H_2O_2 in g/L.*

Solution: $H_2O_2 + 2KI + H_2SO_4 \longrightarrow K_2SO_4 + 2H_2O + I_2$

$$2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI$$

$$\text{Eq. mass } H_2O_2 = \frac{34}{2} = 17$$

$$20 \text{ mL } 0.1\,N\ Na_2S_2O_3 = 20 \text{ mL } 0.1\,N\ I_2 \text{ solution}$$

$$\equiv 20 \text{ mL } 0.1\,N\ H_2O_2 \text{ solution}$$

Amount of H_2O_2 in 50 mL *aq.* solution

$$= \frac{0.1 \times 17}{1000} \times 20 = 0.034 \text{ g}$$

$$\text{Concentration in g/L} = \frac{0.034}{50} \times 1000 = 0.68$$

Example 49. *0.124 g of iron wire was dissolved in dilute H_2SO_4 in oxygen free atmosphere and the resultant solution was titrated against 0.09672 N solution of $KMnO_4$. The titre value was 22.90 mL. Calculate the percentage purity of iron wire.*

Solution:

$$22.90 \text{ mL } 0.09672\,N\ KMnO_4 \equiv 22.90 \text{ mL } 0.09672\,N\ FeSO_4$$

$$\text{Amount of } FeSO_4 \text{ in the solution} = \frac{0.09672 \times 152 \times 22.90}{1000}$$

$$= 0.3366 \text{ g}$$

$$\text{Amount of iron in 0.3366 g of } FeSO_4 = \frac{56}{152} \times 0.3366$$

$$= 0.124 \text{ g}$$

Thus, $\text{percentage} = \frac{0.124}{0.124} \times 100 = 100$

The iron wire is 100% pure.

Example 50. *A sample of hydrazine sulphate ($N_2H_6SO_4$) was dissolved in 100 mL of water. 10 mL of this solution was* *reacted with excess of $FeCl_3$ solution and warmed to complete the reaction. Ferrous ion formed was estimated and it required 20 mL of $\frac{M}{50}$ $KMnO_4$. Estimate the amount of hydrazine sulphate in one litre of solution.*

Reactions: $4Fe^{3+} + N_2H_4 \longrightarrow N_2 + 4Fe^{2+} + 4H^+$

$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

Solution: $20\text{ mL}\ \frac{M}{50}\ \text{KMnO}_4 = 20\text{ mL}\ \frac{N}{10}\ \text{KMnO}_4$

$$\left[\text{Equivalent mass of KMnO}_4 = \frac{\text{Molecular mass}}{5}\right]$$

$$20\text{ mL}\ \frac{N}{10}\ \text{KMnO}_4 \equiv 20\text{ mL}\ \frac{N}{10}\ \text{Ferrous ion}$$

$$\equiv 20\text{ mL}\ \frac{N}{10}\ \text{FeCl}_3$$

$$\equiv 20\text{ mL}\ \frac{N}{10}\ \text{N}_2\text{H}_6\text{SO}_4$$

$$\text{Eq. mass N}_2\text{H}_6\text{SO}_4 = \frac{\text{Mol. mass}}{4} = \frac{130}{4} = 32.5$$

[Since, change in O.N. ($\text{N}_2\text{H}_4 \rightarrow \text{N}_2$) per molecule = 4]

Amount of hydrazine sulphate in 10 mL of solution

$$= \frac{1}{10} \times \frac{32.5}{1000} \times 20 = 0.065\text{ g}$$

Amount of hydrazine sulphate in one litre of solution

$$= \frac{0.065}{10} \times 1000 = 6.50\text{ g}$$

Example 51. *0.1 M $KMnO_4$ is used for the following titration. What volume of the solution in mL will be required to react with 0.158 g of $Na_2S_2O_3$?*

$$S_2O_3^{2-} + MnO_4^- + H_2O \longrightarrow MnO_2(s) + SO_4^{2-} + OH^-$$

(not balanced) (MLNR 1992)

Solution: $\text{S}_2\text{O}_3^{2-} \longrightarrow 2\text{SO}_4^{2-}$

Change in oxidation number of sulphur per molecule of $\text{S}_2\text{O}_3^{2-} = 2 \times (6 - 2) = 8$

Change in oxidation number of Mn per molecule of MnO_4^- $= 7 - 4 = 3$

$$\text{No. of moles in 0.158 g of Na}_2\text{S}_2\text{O}_3 = \frac{0.158}{158} = 1 \times 10^{-3}$$

$$\text{No. of equivalents} = 8 \times 10^{-3}$$

Normality of 0.1 M KMnO_4 solution $= 0.1 \times 3 = 0.3$

Let V mL of volume of KMnO_4 be required; then

$$\frac{V}{1000} \times 0.3 = 8 \times 10^{-3}$$

or $$V = \frac{8}{0.3} \times 10^{-3} \times 10^3$$

$$= 26.7\text{ mL}$$

Example 52. *25 mL of H_2O_2 solution were added to excess of acidified solution of KI. The iodine so liberated required 20 mL of 0.1 N $Na_2S_2O_3$ for titration. Calculate the strength of H_2O_2 in terms of normality, percentage and volume.* (MLNR 1996)

Solution: 20 mL of 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$

$$= 20\text{ mL of 0.1 } N\ \text{I}_2 \text{ solution}$$

$$= 20\text{ mL of 0.1 } N\ \text{H}_2\text{O}_2 \text{ solution}$$

$$\equiv 25\text{ mL of 0.08 } N\ \text{H}_2\text{O}_2 \text{ solution}$$

$$\text{Mass of H}_2\text{O}_2 \text{ in 100 mL solution} = \frac{0.08 \times 17 \times 100}{1000} = 0.136\text{ g}$$

$$\% = 0.136$$

68 g H_2O_2 evolve oxygen at NTP = 22400 mL

0.00136 g H_2O_2 evolve oxygen at NTP

$$= \frac{22400}{68} \times 0.00136 = 0.448$$

The solution is of 0.448 volume.

Example 53. *0.804 g sample of iron ore was dissolved in acid. Iron was reduced to +2 state and it required 47.2 mL of 0.112 N $KMnO_4$ solution for titration. Calculate the percentage of iron and Fe_3O_4 in the ore.*

Solution: The titration involves the conversion of ferrous into ferric.

$$5\text{Fe}^{2+} + \text{MnO}_4^- + 8\text{H}^+ \longrightarrow 5\text{Fe}^{3+} + \text{Mn}^{2+} + 4\text{H}_2\text{O}$$

47.2 mL of 0.112 N KMnO_4 ≡ 47.2 mL of 0.112 N Fe^{2+} ions

$$= \frac{47.2 \times 0.112 \times 55.5}{1000} = 0.2934$$

Mass of iron = 0.2934 g

$$\text{\% of iron in the ore} = \frac{0.2934}{0.804} \times 100 = 36.49$$

$$\underset{(3\times 55.5)}{3\text{Fe}} \longrightarrow \underset{(3\times 55.5 + 64)}{\text{Fe}_3\text{O}_4}$$

3×55.5 g of iron form 230.5 g of Fe_3O_4.

$$\text{0.2934 g of iron will form} = \frac{230.5}{166.5} \times 0.2934 = 0.406\text{ g}$$

$$\text{\% of Fe}_3\text{O}_4 \text{ in the ore} = \frac{0.406}{0.804} \times 100 = 50.5$$

Example 54. *An equal volume of a reducing agent is treated separately with 1 M $KMnO_4$ in acid, neutral and alkaline media. The volume of $KMnO_4$ required are 20 mL in acid, 33.4 mL in neutral and 100 mL in alkaline media. Find out the oxidation state of manganese in each reaction product. Give the balanced equations for all the three half reactions. Find out the volume of 1 M $K_2Cr_2O_7$ consumed, if the same volume of the reducing agent is treated in acid medium.*

Solution: Let N_1, N_2 and N_3 be the normalities of $1\,M$ $KMnO_4$ solution in acid, neutral and alkaline mediums, respectively.

$$20\,\text{mL}\ N_1 \equiv 33.4\,\text{mL}\ N_2 \equiv 100\,\text{mL}\ N_3$$

In acidic medium, the half reaction is:

$$MnO_4^- + 8H^+ + 5e^- = Mn^{2+} + 4H_2O$$

$$1\,M\ KMnO_4 = 5\,N\ KMnO_4$$

Thus, from above relation,

$$N_2 = \frac{20}{33.4} \times N_1 = \frac{20}{33.4} \times 5\,N = 3\,N$$

and $$N_3 = \frac{20}{100} \times N_1 = \frac{20}{100} \times 5\,N = 1\,N$$

The equations in the three media are:

$$MnO_4^- + 5e^- \xrightarrow{\text{Acid}} Mn^{2+}$$

$$MnO_4^- + 3e^- \xrightarrow{\text{Neutral}} Mn^{4+}$$

$$MnO_4^- + e^- \xrightarrow{\text{Alkaline}} Mn^{6+}$$

The balanced equations are:

$$MnO_4^- + 8H^+ + 5e^- \xrightarrow{\text{Acid}} Mn^{2+} + 4H_2O$$

$$MnO_4^- + 2H_2O + 3e^- \xrightarrow{\text{Neutral}} MnO_2 + 4OH^-$$

$$MnO_4^- + e^- \xrightarrow{\text{Alkaline}} MnO_4^{2-}$$

The balanced equation in the case of acidified $K_2Cr_2O_7$ solution can be written as:

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 3Cr^{3+} + 7H_2O$$

$$1\,M\ K_2Cr_2O_7 = 6\,N\ K_2Cr_2O_7$$

The volume required for the titration of the same volume of reducing agent with acidified $K_2Cr_2O_7$ solution as follows:

$$20\ \text{mL}\ 5\,N\ KMnO_4 \equiv V\ 6\,N\ K_2Cr_2O_7$$

$$V = \frac{20 \times 5}{6} = 16.66\,\text{mL}$$

Example 55. *1.6 g of pyrolusite ore was treated with $50\,cm^3$ of $1.0\,N$ oxalic acid and some sulphuric acid. The oxalic acid left undecomposed was raised to $250\,cm^3$ in a flask. $25\,cm^3$ of this solution when titrated with $0.1\,N$ $KMnO_4$ required $32\,cm^3$ of the solution. Find the percentage of pure MnO_2 in the sample and also the percentage of available oxygen.* (IIT 1996)

Solution: $25\ cm^3$ of undecomposed oxalic acid required

$$= 32\ cm^3\ 0.1\,N\ KMnO_4\ \text{solution}$$

Thus, $250\,cm^3$ of undecomposed oxalic acid required

$$= 320\ cm^3\ 0.1\,N\ KMnO_4\ \text{solution}$$

$$\equiv 32\ cm^3\ 1\,N\ KMnO_4\ \text{solution}$$

$$= 32\ cm^3\ 1\,N\ \text{oxalic acid solution}$$

Oxalic acid used by pyrolusite

$$= (50 - 32)\ cm^3\ 1\,N\ \text{solution}$$

$$= 18\ cm^3\ 1\,N\ \text{solution}$$

$$\equiv 18\ cm^3\ 1\,N\ MnO_2\ \text{solution}$$

$$\text{Mass of } MnO_2 = \frac{N \times E \times V}{1000} = \frac{1 \times 18 \times 87}{1000 \times 2} = 0.783\ \text{g}$$

$$\text{Percentage of } MnO_2 = \frac{0.783}{1.6} \times 100 = 48.9$$

$$\underset{87\,\text{g}}{MnO_2} \longrightarrow MnO + \overset{16\,\text{g}}{O}$$

$$\text{Oxygen given by } 0.783\ \text{g}\ MnO_2 = \frac{16}{87} \times 0.783 = 0.144\ \text{g}$$

$$\%\ \text{of available oxygen} = \frac{0.144}{1.6} \times 100 = 9.0$$

Example 56. *A mixture of $H_2C_2O_4$ and $NaHC_2O_4$ weighing 2.02 g was dissolved in water and the solution made up to one litre. 10 mL of this solution required 3.0 mL of $0.1\,N$ NaOH solution for complete neutralisation. In another experiment 10 mL of same solution in hot dilute H_2SO_4 medium required 4 mL of $0.1\,N$ $KMnO_4$ for complete neutralisation. Calculate the amount of $H_2C_2O_4$ and $NaHC_2O_4$ in the mixture.* (IIT 1990)

Solution: Let mass of $H_2C_2O_4$ present in the mixture be $= a$ g in 1 litre

and mass of $NaHC_2O_4$ present in the mixture be $= b$ g in 1 litre

For acid-base reaction

$$H_2C_2O_4 + 2NaOH \longrightarrow Na_2C_2O_4 + 2H_2O$$

$$\text{Eq. mass of } H_2C_2O_4 = \frac{\text{Mol. mass}}{2} = \frac{90}{2} = 45$$

$$NaHC_2O_4 + NaOH \longrightarrow Na_2C_2O_4 + H_2O$$

$$\text{Eq. mass of } NaHC_2O_4 = \frac{\text{Mol. mass}}{1} = 112$$

Now,

$$\underset{\text{in 10 mL solution}}{\text{Equivalents of } H_2C_2O_4} + \underset{\text{in 10 mL solution}}{\text{Equivalents of } NaHC_2O_4} = \frac{3 \times 0.1}{1000}$$

$$\frac{a \times 10}{45 \times 1000} + \frac{b \times 10}{112 \times 1000} = \frac{3 \times 0.1}{1000}$$

or $$112a + 45b = \frac{3 \times 0.1 \times 45 \times 112}{10} = 151.2 \qquad \text{... (i)}$$

For redox reaction

$$\text{Eq. mass of } H_2C_2O_4 = \frac{90}{2} = 45;$$

$$\text{Eq. mass of } NaHC_2O_4 = \frac{112}{2} = 56$$

(Change in oxidation number of carbon per molecule = 2; $C_2^{3+} \longrightarrow 2C^{4+}$)

Now,

$$\underset{\text{in 10 mL solution}}{\text{Equivalents of } H_2C_2O_4} + \underset{\text{in 10 mL solution}}{\text{Equivalents of } NaHC_2O_4} = \frac{4 \times 0.1}{1000}$$

$$\frac{a \times 10}{45 \times 1000} + \frac{b \times 10}{56 \times 1000} = \frac{4 \times 0.1}{1000}$$

or $$56a + 45b = 100.8 \qquad \text{... (ii)}$$

Solving equations (i) and (ii),

$$a = 0.9 \text{ g} \quad \text{and} \quad b = 1.12 \text{ g}$$

Example 57. *A 3.0 g sample containing Fe_3O_4, Fe_2O_3 and an inert impure substance is treated with excess of KI solution in presence of dilute H_2SO_4. The entire iron is converted to Fe^{2+} along with the liberation of iodine. The resulting solution is diluted to 100 mL. A 20 mL of the dilute solution requires 11.0 mL of 0.5 M $Na_2S_2O_3$ solution to reduce the iodine present. A 50 mL of the diluted solution after complete extraction of iodine requires 12.8 mL of 0.25 M $KMnO_4$ solution in dilute H_2SO_4 medium for oxidation of Fe^{2+}. Calculate the percentage of Fe_2O_3 and Fe_3O_4 in the original sample.* **(IIT 1996)**

Solution: Fe_3O_4 is an equimolar mixture of Fe_2O_3 and FeO. Thus, the sample contains Fe_2O_3, FeO and impurities. The amount of iodine liberated depends on the amount of Fe_2O_3 and the entire iron is converted into Fe^{2+}.

$$Fe_3O_4 + 2KI + H_2SO_4 \longrightarrow 3FeO + H_2O + K_2SO_4 + I_2$$

$$Fe_2O_3 + KI + H_2SO_4 \longrightarrow 2FeO + H_2O + K_2SO_4 + I_2$$

$$\begin{aligned} 5 \times 11.0 \text{ mL of } 0.5\,M\,Na_2S_2O_3 &\equiv 55.0 \text{ mL of } 0.5\,N\,Na_2S_2O_3 \text{ soln.} \\ &\equiv 55.0 \text{ mL of } 0.5\,N\,I_2 \text{ soln.} \\ &\equiv 55.0 \text{ mL of } 0.5\,N\,Fe_2O_3 \text{ soln.} \\ &= 27.5 \times 10^{-3} \text{ equivalent } Fe_2O_3 \text{ soln.} \\ &= 13.75 \times 10^{-3} \text{ moles } Fe_2O_3 \end{aligned}$$

$$\begin{aligned} 2 \times 12.8 \text{ mL of } 0.25\,M\,KMnO_4 \text{ soln.} & \\ &\equiv 25.6 \text{ mL of } 1.25\,N\,KMnO_4 \text{ soln.} \\ &\equiv 25.6 \text{ mL of } 1.25\,N \text{ FeO soln.} \\ &= 32.0 \times 10^{-3} \text{ equivalent FeO} \\ &= 32.0 \times 10^{-3} \text{ moles FeO} \end{aligned}$$

$$\text{Moles of FeO in } Fe_3O_4 = 0.032 - 0.0275 = 0.0045$$

$$\text{Mass of } Fe_3O_4 = 0.0045 \times 232 = 1.044 \text{ g}$$

Moles of Fe_2O_3 existing separately

$$= 0.01375 - 0.0045 = 0.00925$$

$$\text{Mass of } Fe_2O_3 = 0.00925 \times 160 = 1.48 \text{ g}$$

$$\%\ Fe_3O_4 = \frac{1.044}{3} \times 100 = 34.8$$

$$\%\ Fe_2O_3 = \frac{1.48}{3} \times 100 = 49.33$$

Example 58. *Hydroxylamine reduces iron (III) according to the equation,*

$$2NH_2OH + 4Fe^{3+} \longrightarrow N_2O(g)\uparrow + H_2O + 4Fe^{2+} + 4H^+$$

Iron (II) thus produced is estimated by titration with a standard permanganate solution. The reaction is:

$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

A 10 mL sample of hydroxylamine solution was diluted to one litre. 50 mL of this diluted solution was boiled with excess of iron (III) solution. The resulting solution required 12 mL of 0.02 M $KMnO_4$ solution for complete oxidation of iron (II). Calculate the mass of hydroxylamine in one litre of the original solution.

Solution:

$$\begin{aligned} 12 \text{ mL of } 0.02\,M\,KMnO_4 &\equiv 12 \text{ mL of } 0.1\,N\,KMnO_4 \\ &\equiv 12 \text{ mL of } 0.1\,N\,Fe^{2+} \\ &\equiv 12 \text{ mL of } 0.1\,N\,NH_2OH \end{aligned}$$

$$\text{Eq. mass of } NH_2OH = \frac{\text{Mol. mass}}{2} = \frac{33}{2} = 16.5$$

Mass of NH_2OH in 12 mL of 0.1 N NH_2OH soln.

$$= \frac{N \times E \times V}{1000} = \frac{0.1 \times 16.5 \times 12}{1000} = 0.0198 \text{ g}$$

50 mL of diluted solution contains NH_2OH = 0.0198 g

1000 mL of diluted solution contains NH_2OH

$$= \frac{0.0198}{50} \times 1000 = 0.396 \text{ g}$$

10 mL of original solution contains NH_2OH = 0.396 g

1000 mL of original solution contains NH_2OH

$$= 100 \times 0.396 = 39.6 \text{ g}$$

Example 59. *0.56 g of limestone was treated with oxalic acid to give CaC_2O_4. The precipitate decolourised 45 mL of 0.2 N $KMnO_4$ in acid solution. Calculate the % of CaO in limestone.*

Solution:

$$\begin{aligned} 45 \text{ mL of } 0.2\,N\,KMnO_4 &= 45 \text{ mL of } 0.2\,N\,CaC_2O_4 \\ &= 45 \text{ mL of } 0.2\,N\,CaCO_3 \\ &= 45 \text{ mL of } 0.2\,N \text{ CaO} \end{aligned}$$

$$\text{Mass of CaO} = \frac{N \times E \times V}{1000} = \frac{0.2 \times 28 \times 45}{1000} = 0.252 \text{ g}$$

$$\%\text{ of CaO in limestone} = \frac{0.252}{0.56} \times 100 = 45$$

Example 60. *A solution of 0.2 g of a compound containing Cu^{2+} and $C_2O_4^{2-}$ ions on titration with 0.02 M $KMnO_4$ in presence of H_2SO_4 consumes 22.6 mL oxidant. The resulting solution is neutralised by Na_2CO_3, acidified with dilute acetic acid and titrated with excess of KI. The liberated iodine required 11.3 mL of 0.05 M $Na_2S_2O_3$ for complete reduction. Find out the mole ratio of Cu^{2+} and $C_2O_4^{2-}$ in the compound.* **(IIT 1991)**

Solution: **1st case:** Only $C_2O_4^{2-}$ ions are oxidised by $KMnO_4$ solution.

$$\text{Normality of } KMnO_4 \text{ solution} = 0.02 \times 5 = 0.1\,N$$

$$22.6 \text{ mL of } 0.1\,N\,KMnO_4 = 22.6 \text{ mL of } 0.1\,N\,C_2O_4^{2-} \text{ soln.}$$

Mass of $C_2O_4^{2-}$ ions in the solution $= \dfrac{N\times E\times V}{1000} = \dfrac{N\times M\times V}{1000\times 2}$

No. of moles of $C_2O_4^{2-}$ ions in the solution $= \dfrac{N\times M\times V}{1000\times 2\times M}$

$$= \frac{N\times V}{2000}$$

$$= \frac{0.1\times 22.6}{2000}$$

$$= 11.3\times 10^{-4}$$

2nd case: Only Cu^{2+} ions are reduced by KI and iodine liberated is neutralised by $Na_2S_2O_3$ solution.

$$11.3 \text{ mL of } 0.05\,M\ Na_2S_2O_3 \equiv 11.3 \text{ mL of } 0.05\,N\ Na_2S_2O_3$$

$$= 11.3 \text{ mL of } 0.05\,N\ I_2$$

$$= 11.3 \text{ mL of } 0.05\,N\ Cu^{2+}$$

Mass of Cu^{2+} ions in the solution $= \dfrac{N\times E\times V}{1000} = \dfrac{N\times M\times V}{1000}$

No. of moles of Cu^{2+} ions in the solution $= \dfrac{N\times M\times V}{1000\times M}$

$$= \frac{N\times V}{1000}$$

$$= \frac{0.05\times 11.3}{1000}$$

$$= 5.65\times 10^{-4}$$

Molar ratio of $\dfrac{Cu^{2+}}{C_2O_4^{2-}} = \dfrac{5.65\times 10^{-4}}{11.3\times 10^{-4}} = \dfrac{1}{2}$

Example 61. *12 g of an impure sample of arsenious oxide was dissolved in water containing 7.5 g of sodium bicarbonate and the resulting solution was diluted to 250 mL. 25 mL of this solution was completely oxidised by 22.4 mL of a solution of iodine. 25 mL of this iodine solution reacted with same volume of a solution containing 24.8 g of sodium thiosulphate solution ($Na_2S_2O_3\cdot 5H_2O$) in one litre. Calculate the percentage of arsenious oxide in the sample. (Atomic mass of As = 75)* (IIT 1999)

Solution: Normality of $Na_2S_2O_3$ soln. $= \dfrac{24.8}{248} = 0.1\,N$

Applying $N_1V_1 = N_2V_2$

Volume of As_2O_3 soln. in $NaHCO_3$ × Normality of this soln.

= Volume of iodine soln. × Normality of iodine soln.

$$25\times N_1 = 22.4\times 0.1$$

$$\therefore \quad N_1 = \frac{22.4\times 0.1}{25}$$

Amt. of As_2O_3 present in 250 mL of the solution

$$= N_1 \times \frac{\text{Equivalent mass of } As_2O_3}{1000}\times 250$$

$$= \frac{22.4\times 0.1}{25}\times\frac{198}{4}\times\frac{250}{1000} = 1.1088 \text{ g}$$

Percentage of $As_2O_3 = \dfrac{1.1088}{12}\times 100 = 9.24$

Example 62. *Hydrogen peroxide solution (20 mL) reacts quantitatively with a solution of $KMnO_4$ (20 mL) acidified with dilute H_2SO_4. The same volume of the $KMnO_4$ solution is just decolourised by 10 mL of $MnSO_4$ in neutral medium simultaneously forming a dark brown precipitate of hydrated MnO_2. The brown precipitate is dissolved in 10 mL of 0.2 M sodium oxalate under boiling condition in the presence of dilute H_2SO_4. Write the balanced equations involved in the reactions and calculate the molarity of H_2O_2.* (IIT 2001)

Solution:

$$\text{(i)}\ \underset{\substack{\text{ppt.}\\ \text{1 mole}}}{MnO_2} + \underset{\text{1 mole}}{Na_2C_2O_4} + 2H_2SO_4 \longrightarrow MnSO_4 + Na_2SO_4 + 2CO_2 + 2H_2O$$

$$\text{mM of } MnO_2 = \text{mM of } Na_2C_2O_4 = 10\times 0.2 = 2$$

$$\text{(ii)}\ \underset{\text{2 mole}}{2\,KMnO_4} + 3MnSO_4 + 2H_2O \longrightarrow \underset{\substack{\text{ppt.}\\ \text{5 mole}}}{5MnO_2} + K_2SO_4 + 2H_2O$$

$$\text{mM of } KMnO_4 = \text{mM of } MnO_2 \times \frac{2}{5} = 2\times\frac{2}{5} = \frac{4}{5}$$

$$\text{(iii)}\ \underset{\text{2 mole}}{2KMnO_4} + 3H_2SO_4 + \underset{\text{5 mole}}{5H_2O_2} \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2$$

$$\therefore \quad \text{mM of } H_2O_2 = \text{mM of } KMnO_4 \times \frac{5}{2} = \frac{4}{5}\times\frac{5}{2} = 2$$

$$\therefore \quad M\times 20 = 2$$

$$\text{or} \quad M_{H_2O_2} = \frac{2}{20} = 0.1\,M$$

Example 63. *The Mn_3O_4 formed on strong heating of a sample of $MnSO_4\cdot 4H_2O$ was dissolved in 100 cm^3 of 0.1 N $FeSO_4$ containing dilute H_2SO_4. The resulting solution reacted completely with 50 cm^3 of $KMnO_4$ solution. 25 cm^3 of this $KMnO_4$ solution requires 30 cm^3 of 0.1 N $FeSO_4$ solution for complete reaction. Calculate the amount of $MnSO_4\cdot 4H_2O$ in the sample.* (IIT 2001)

Solution: $MnSO_4\cdot 4H_2O \xrightarrow{\text{Heat}} Mn_3O_4$

Mn_3O_4 is dissolved in ferrous sulphate solution and is reduced from $Mn^{(8/3)+}$ to Mn^{2+}. The excess of $FeSO_4$ is estimated by doing titration with $KMnO_4$ solution. The normality of $KMnO_4$ solution is determined by another ferrous sulphate solution.

For normality of $KMnO_4$ solution:

$$25\times N = 30\times 0.1$$

$$N = \frac{30\times 0.1}{25} = \frac{3}{25}$$

Let the volume of unreacted $FeSO_4$ solution be V mL

$$V \text{ mL of } 0.1\,N\ \mathrm{FeSO_4} = 50 \text{ mL of } \frac{3}{25}\,N\ \mathrm{KMnO_4}$$

or
$$V = \frac{50\times 3}{0.1\times 25} = 60 \text{ mL}$$

$$\therefore \text{Volume of } \mathrm{FeSO_4} \text{ used for } \mathrm{Mn_3O_4} = (100-60)\text{ mL} = 40 \text{ mL}$$

$$40 \text{ mL of } 0.1\,N\ \mathrm{FeSO_4} \equiv 40 \text{ mL of } 0.1\,N\ \mathrm{Mn_3O_4} \equiv 40 \text{ mL of } 0.1\,N\ \mathrm{MnSO_4\cdot 4H_2O}$$

$$\text{Mass of } \mathrm{MnSO_4\cdot 4H_2O} = \frac{E\times 0.1\times 40}{1000} = \frac{E}{250}\text{ g}$$

Equivalent mass of

$$\mathrm{MnSO_4\cdot 4H_2O} = \frac{M}{\left(\frac{8}{3}-2\right)} = \frac{3M}{2} = \frac{3\times 223}{2}$$

$$\therefore \text{Mass of } \mathrm{MnSO_4\cdot 4H_2O} = \frac{3\times 223}{2\times 250} = 1.338 \text{ g}$$

Example 64. *0.96 g of hydrogen iodide was heated to 450°C till the equilibrium was reached. It was then quickly cooled and the amount of iodine liberated required 15.7 cc of N/10 sodium thiosulphate. Calculate the percentage of hydrogen iodide dissociated at 450°C.*

Solution: Reactions involved

$$2\mathrm{HI} \rightleftharpoons \mathrm{H_2} + \mathrm{I_2}$$

$$\mathrm{I_2} + 2\mathrm{Na_2S_2O_3} \rightarrow 2\mathrm{NaI} + \mathrm{Na_2S_4O_6}$$

$$1 \text{ mole } \mathrm{I_2} \equiv 2 \text{ mole hypo}$$

$$\text{No. of moles of hypo} = \frac{\text{Mass}}{\text{Molecular mass (158)}} = \frac{E\times N\times V}{1000\times 158}$$

where, E, N and V are equivalent weight, normality and volume of hypo used.

$$E = 158, N = 1/10, V = 15.7$$

$$\because \quad \text{No. of moles of } \mathrm{Na_2S_2O_3} = \frac{158\times 1/10\times 15.7}{1000\times 158} = 1.57\times 10^{-3} \text{ mole}$$

Moles of $\mathrm{I_2}$ produced by decomposition of HI

$$= \frac{1}{2} \text{ mole of } \mathrm{Na_2S_2O_3}$$

$$= \frac{1}{2}\times 1.57\times 10^{-3} = 0.785\times 10^{-3} \text{ mole} \quad \text{... (i)}$$

$$\text{Moles of HI} = \frac{\text{Mass}}{\text{M.w.}} = \frac{0.96}{128} = 7.5\times 10^{-3}$$

$$\begin{array}{llll} & \mathrm{HI} \rightleftharpoons & \frac{1}{2}\mathrm{H_2} & + \frac{1}{2}\mathrm{I_2} \\ \text{At } t = 0 & C & 0 & 0 \\ \text{At equilibrium} & C(1-\alpha) & \frac{C\alpha}{2} & \frac{C\alpha}{2} \end{array}$$

where, $C = 7.5\times 10^{-3}$, α = degree of dissociation

$$\text{Moles of } \mathrm{I_2} = \frac{C\alpha}{2} = \frac{7.5\times 10^{-3}\alpha}{2} \quad \text{... (ii)}$$

Equating eqs. (i) and (ii), we get

$$\frac{7.5\times 10^{-3}\alpha}{2} = 0.785\times 10^{-3}$$

$$\alpha = 0.209$$

$$\%\text{ dissociation of HI} = \text{Degree of dissociation}\times 100 = 0.209\times 100 = 20.9\%$$

Example 65. *50 mL sample of ozonised oxygen at NTP was passed through a solution of potassium iodide. The liberated iodine required 15 mL of 0.08 N $Na_2S_2O_3$ solution for complete titration. Calculate the volume of ozone at NTP in the given sample.*

Solution: Reactions involved may be given as:

$$2\mathrm{KI} + \mathrm{H_2O} + \mathrm{O_3} \longrightarrow 2\mathrm{KOH} + \mathrm{I_2} + \mathrm{O_2}\uparrow$$

$$\mathrm{I_2} + 2\mathrm{Na_2S_2O_3} \longrightarrow 2\mathrm{NaI} + \mathrm{Na_2S_4O_6}$$

$$1 \text{ mole } \mathrm{O_3} = 2 \text{ mole } \mathrm{Na_2S_2O_3} \quad \text{... (i)}$$

$$\text{No. of moles of hypo} = \frac{\text{Mass}}{\text{Molecular mass (158)}} = \frac{E\times N\times V}{1000\times 158}$$

where, $E_{\mathrm{Na_2S_2O_3}} = 158, N = 0.08, V = 15$

$$\therefore \quad \text{No. of moles of hypo} = \frac{158\times 0.08\times 15}{1000\times 158} = 1.2\times 10^{-3}$$

$$\text{No. of moles of } \mathrm{O_3} = \frac{1}{2} \text{ mole of hypo} \quad \text{[from eq. (i)]}$$

$$= \frac{1}{2}\times 1.2\times 10^{-3}$$

$$= 6\times 10^{-4} \text{ mole}$$

$$\text{Volume of } \mathrm{O_3} \text{ at NTP} = \text{No. of moles}\times 22400 = 6\times 10^{-4}\times 22400 = 13.44 \text{ mL at NTP}$$

Example 66. *10 mL of a potassium dichromate solution liberates iodine from potassium iodide solution. When the iodine was titrated with hypo solution (N/20), the titre value was 15 mL. Find the concentration of dichromate solution in g per litre.*

Solution: The reactions involved may be given as

$$\mathrm{Cr_2O_7^{2-}} + 6\mathrm{I^-} + 14\mathrm{H^+} \longrightarrow 2\mathrm{Cr^{3+}} + 3\mathrm{I_2} + 7\mathrm{H_2O}$$

$$3[\mathrm{I_2} + 2\mathrm{Na_2S_2O_3}] \longrightarrow 3[2\mathrm{NaI} + \mathrm{Na_2S_4O_6}]$$

$$1 \text{ mole } \mathrm{K_2Cr_2O_7} \equiv 6 \text{ moles of } \mathrm{Na_2S_2O_3} \quad \text{... (i)}$$

$$\text{No. of moles of hypo} = \frac{\text{Mass}}{\text{M.w. (158)}} = \frac{E\times N\times V}{1000\times 158}$$

$$= \frac{158 \times 1/20 \times 15}{1000 \times 158}$$

$$= 7.5 \times 10^{-4} \text{ mole}$$

$$\text{No. of moles of } K_2Cr_2O_7 = \frac{1}{6}[\text{No. of moles of } Na_2S_2O_3]$$

$$= 1.25 \times 10^{-4} \text{ mole}$$

$$\text{Mass of } K_2Cr_2O_7 \text{ in 10 mL solution} = 1.25 \times 10^{-4} \times 294$$

$$= 0.03675 \text{ g}$$

$$\text{Weight of } K_2Cr_2O_7 \text{ in 10 mL solution} = 3.675 \text{ g/L}$$

Example 67. *1.5 g of sample of impure potassium dichromate was dissolved in water and made up to 500 mL solution. 25 mL of this solution required iodometrically 24 mL of a sodium thiosulphate solution. 26 mL of this sodium thiosulphate solution required 25 mL of N/20 solution of pure potassium dichromate. Find the percentage purity of impure sample of potassium dichromate.*

Solution: Normality of sodium thiosulphate solution may be determined as:

$$N_1V_1(Na_2S_2O_3) = N_2V_2 \text{ (pure } K_2Cr_2O_7)$$

$$N_1 \times 26 = 25 \times \frac{1}{20}$$

$$N_1 = 0.048 \text{ (hypo)}$$

The reaction involved may be given as:

$$Cr_2O_7^{2-} + 6I^- + 4H^+ \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$$

$$3[I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6]$$

$$1 \text{ mole } K_2Cr_2O_7 \equiv 6 \text{ mole } Na_2S_2O_3 \qquad \text{... (i)}$$

25 mL of solution of $K_2Cr_2O_7$ is treated by 24 mL of 0.048 *N* hypo

$\therefore$ 500 mL of solution will be titrated by 480 mL of 0.048 *N* hypo

$$\text{No. of moles of hypo} = \frac{\text{Mass}}{\text{M.w. (158)}} = \frac{E \times N \times V}{1000 \times 158}$$

$$= \frac{158 \times 0.048 \times 480}{1000 \times 158}$$

$$= 0.02304 \text{ mole}$$

$$\text{No. of moles of } K_2Cr_2O_7 = \frac{1}{6}[\text{No. of moles of hypo}]$$

$$= \frac{1}{6}[0.02304] = 3.84 \times 10^{-3}$$

$$\text{Mass of } K_2Cr_2O_7 = 3.84 \times 10^{-3} \times 294$$

$$= 1.12896$$

$$\% \text{ purity} = \frac{1.12896}{1.5} \times 100 = 75.26\%$$

Example 68. *5 g of a sample of brass were dissolved in 1 litre dil. H_2SO_4. 20 mL of this solution were mixed with KI and liberated iodine required 20 mL of 0.0327 N hypo solution for titration. Calculate the amount of copper in the alloy.*

Solution: When brass is extracted with concentrated H_2SO_4, it gives copper sulphate.

$$2[Cu + 2H_2SO_4 \longrightarrow CuSO_4 + SO_2 + 2H_2O]$$

$$2CuSO_4 + 4KI \longrightarrow 2K_2SO_4 + 2CuI_2$$

$$2CuI_2 \longrightarrow Cu_2I_2 + I_2$$

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$

$$2 \text{ mole Cu} \equiv 1 \text{ mole } I_2 \equiv 2 \text{ mole hypo}$$

20 mL of solution reacts with 20 mL of 0.0327 *N* hypo

$\therefore$ 1000 mL of solution will react with 1000 mL of 0.0327 *N* hypo

$$\text{No. of moles of hypo used} = \frac{\text{Mass}}{\text{Molecular mass (158)}}$$

$$= \frac{E \times N \times V}{1000 \times 158}$$

where, $E = 158$, $N = 0.0327$ given, $V = 1000$ mL

$$\therefore \text{ No. of moles of hypo used} = \frac{158 \times 0.0327 \times 1000}{1000 \times 158}$$

$$= 0.0327$$

$$\text{No. of moles of Cu} = \text{No. of moles of hypo}$$

$$= 0.0327 \text{ mole}$$

$$\text{Mass of copper in brass} = 0.0327 \times 63.5 = 2.07645$$

$$\% \text{ of copper in brass} = \frac{2.07645}{5} \times 100$$

$$= 41.529\%$$

Example 69. *An excess KI solution is mixed in a solution of $K_2Cr_2O_7$ and liberated iodine required 72 mL of 0.05 N $Na_2S_2O_3$ for complete reaction. How many grams of $K_2Cr_2O_7$ were present in the solution of $K_2Cr_2O_7$? The reaction occurs as:*

$$Cr_2O_7^{2-} + 6I^- + 14H^+ \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$$

Solution: The reaction involved may be given as:

$$Cr_2O_7^{2-} + 6I^- + 14H^+ \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$$

$$3[I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6]$$

$$1 \text{ mole } K_2Cr_2O_7 = 6 \text{ mole } Na_2S_2O_3 \qquad \text{... (i)}$$

$$\text{No. of moles of hypo} = \frac{\text{Mass}}{\text{M.w. (158)}} = \frac{E \times N \times V}{1000 \times 158}$$

$$N_{Na_2S_2O_3} = \frac{158 \times 0.05 \times 72}{1000 \times 58} = 3.6 \times 10^{-3}$$

$$\text{No. of moles of } K_2Cr_2O_7 = \frac{1}{6}[\text{No. of moles of } Na_2S_2O_3]$$

$$= \frac{1}{6}[3.6\times 10^{-3}] = 6\times 10^{-4} \text{ mole}$$

Mass of $K_2Cr_2O_7$ in the given solution

$$= \text{No. of moles} \times \text{Molecular weight}$$

$$= 6\times 10^{-4}\times 294 = 0.1764$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

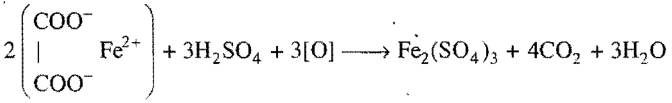
14. How many moles of MnO_4^- ions will react with 1 mole of ferrous oxalate in acid medium?

(a) 1/5 (b) 2/5 (c) 3/5 (d) 5/3

[Ans. (c)]

[Hint:

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$



$$2\left(\begin{array}{l}COO^-\\ |\qquad Fe^{2+}\\ COO^-\end{array}\right) + 3H_2SO_4 + 3[O] \longrightarrow Fe_2(SO_4)_3 + 4CO_2 + 3H_2O$$

$$\therefore \quad 6 \text{ mole } KMnO_4 \equiv 10 \text{ mole } FeC_2O_4$$

$\therefore$ 1 mole FeC_2O_4 will react with $\frac{3}{5}$ mole of $KMnO_4$]

15. The molecular mass of $K_2Cr_2O_7$ is 294 amu. It acts as oxidising agent in a redox titration. Its equivalent mass in acid medium will be:

(a) 294 (b) 49 (c) 147 (d) 74

[Ans. (b)]

[Hint: $\overset{+12}{K_2Cr_2O_7} + 4H_2SO_4 \rightarrow K_2SO_4 + \overset{+6}{Cr_2(SO_4)_3} + 4H_2O + 3[O]$

Change in oxidation number = 6

$$\text{Equivalent mass} = \frac{\text{Molecular mass}}{6} = \frac{294}{6} = 49]$$

16. In acid medium, both $KMnO_4$ and $K_2Cr_2O_7$ act as oxidising agents. Which among the following is correct about the oxidising behaviour?

(a) $KMnO_4 > K_2Cr_2O_7$ (b) $KMnO_4 < K_2Cr_2O_7$

(c) $KMnO_4 = K_2Cr_2O_7$ (d) Cannot be predicted

[Ans. (a)]

[Hint:

$$2\overset{+7}{KMnO_4} + 3H_2SO_4 \rightarrow K_2SO_4 + 2\overset{+2}{MnSO_4} + 3H_2O + 5[O]$$

Change in oxidation number = 10

$$\overset{+12}{K_2Cr_2O_7} + 4H_2SO_4 \rightarrow K_2SO_4 + \overset{+6}{Cr_2(SO_4)_3} + 4H_2O + 3[O]$$

Change in oxidation number = 6]

17. $KMnO_4$ reacts with oxalic acid according to the equation,

$$2MnO_4^- + 5C_2O_4^{2-} + 16H^+ \rightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

Here, 20 mL of 0.1 *M* $KMnO_4$ is equivalent to:

(a) 120 mL of 0.25 *M* $H_2C_2O_4$

(b) 150 mL of 0.1 *M* $H_2C_2O_4$

(c) 50 mL of 0.1 *M* $H_2C_2O_4$

(d) 50 mL of 0.2 *M* $H_2C_2O_4$

[Ans. (c)]

[Hint: $\frac{M_1V_1}{n_1}(KMnO_4) = \frac{M_2V_2}{n_2}(H_2C_2O_4)$

$$\frac{0.1\times 20}{2} = \frac{M_2V_2}{5}$$

$$M_2V_2 = 5$$

It is possible in the option (c).]

18. A solution of H_2O_2 is titrated against a solution of $KMnO_4$. The reaction is:

$$2MnO_4^- + 5H_2O_2 + 6H^+ \longrightarrow 2Mn^{2+} + 5O_2 + 8H_2O$$

If it requires 46.9 mL of 0.145 *M* $KMnO_4$ to oxidise 20 g of H_2O_2, the mass percentage of H_2O_2 in this solution is:

(a) 2.9 (b) 29 (c) 21 (d) 4.9

[Ans. (a)]

[Hint: Number of moles of $KMnO_4 = \frac{MV}{1000} = \frac{0.145\times 46.9}{1000}$

$$= 6.8\times 10^{-3}$$

Number of moles of $H_2O_2 = 6.8\times 10^{-3}\times 2.5 = 0.017$

$$\text{Mass of } H_2O_2 = 0.017\times 34 = 0.578$$

$$\text{Mass \% of } H_2O_2 = \frac{0.578}{20}\times 100 \approx 2.9]$$

19. In an oxidation-reduction, MnO_4^- ion is converted to Mn^{2+}, what is the number of equivalents of $KMnO_4$ (mol. wt. = 158) present in 250 mL of 0.04 *M* $KMnO_4$ solution ?

(CPMT 2008)

(a) 0.02 (b) 0.05 (c) 0.04 (d) 0.07

[Ans. (b)]

[Hint : In redox-reaction :

$$8H^+ + MnO_4^- + 5e^- \longrightarrow Mn^{2+} + 4H_2O$$

Change in oxidation state of $MnO_4^- = (+7) - (+2) = +5$

$$\therefore \quad N_{KMnO_4} = M_{KMnO_4}\times 5$$

$$= 0.04\times 5 = 0.20$$

$$\text{Number of equivalents} = \frac{NV}{1000} = \frac{0.2\times 250}{1000} = 0.05\,]$$

20. The strength of 10 volume of H_2O_2 solution is :

(AMU Engg. 2009)

(a) 10 (b) 68 (c) 60.70 (d) 30.36

[Ans. (d)]

[Hint : 10 volume H_2O_2 means, 1 litre of H_2O_2 will give 10 litre oxygen at STP.

$$\underset{68\text{ g}}{2H_2O_2} \longrightarrow 2H_2O + \underset{22.4\text{ L at STP}}{O_2}$$

$\because$ 22.4 L O_2 is obtained at STP from 68 g H_2O_2

$\therefore$ 10 L O_2 is obtained at STP from $\frac{68}{22.4}\times 10$ g H_2O_2

$$= 30.36\text{ g}$$

Thus, strength of H_2O_2 = 30.36 g/L.]

Questions

1. Calculate the equivalent mass of underlined species:
   (i) $Na_2SO_3 + \underline{Na_2CrO_4} \rightarrow Na_2SO_4 + Cr(OH)_3$
   (ii) $Fe_3O_4 + \underline{KMnO_4} \rightarrow Fe_2O_3 + MnO_2$
   (iii) $\underline{2Na_2S_2O_3} + I_2 \rightarrow Na_2S_4O_6 + 2NaI$
   (iv) $\underline{As_2S_3} + 10NO_3^- + 4H^+ \rightarrow 10NO_2 + 2AsO_4^{3-} + 3S + 2H_2O$
   (v) $\underline{H_3PO_3} \rightarrow H_3PO_4 + PH_3$
   (vi) $\underline{5SO_2} + 2KMnO_4 + 2H_2O \rightarrow K_2SO_4 + 2MnSO_4 + 2H_2SO_4$
2. 12 mL of 0.25 *N* sulphuric acid is neutralised with 15 mL of sodium hydroxide solution on titration. Calculate the normality of sodium hydroxide solution.
3. What will be the volume of *N*/10 solution of oxalic acid obtained by dissolving 63 g of oxalic acid?
4. If 1.26 g of oxalic acid is dissolved in 250 mL of solution, find its normality. The equivalent mass of oxalic acid is 63.
5. (a) 50 mL of 0.2 *N* $KMnO_4$ is required for complete oxidation of 0.45 g of anhydrous oxalic acid. Calculate the normality of oxalic acid solution.
   (b) In the titration of Fe^{2+} ions with $KMnO_4$ in acid medium, why is dilute H_2SO_4 used and not dilute HCl? [CBSE (Mains) 2005]

   [**Hint:** The reaction involved in the titration is:
   $$10FeSO_4 + 2KMnO_4 + 3H_2SO_4 \longrightarrow 5Fe_2(SO_4)_3 + K_2SO_4 + 2MnSO_4 + 3H_2O$$
   If HCl is taken in place of H_2SO_4, then HCl will be oxidised to Cl_2.]
6. 30 mL of sodium carbonate solution is mixed with 20 mL of 0.8 *N* sulphuric acid. The resultant solution needed 20 mL of 0.7 *N* hydrochloric acid solution for complete neutralisation. Determine the strength of the sodium carbonate in gram per litre. (Take sodium carbonate to be anhydrous.)
7. 0.25 g of an oxalate salt was dissolved in 100 mL of water. 10 mL of this solution required 8 mL of *N*/20 $KMnO_4$ for its oxidation. Calculate the percentage of oxalate in the salt.
8. 1.13 g of an ammonium sulphate were treated with 50 mL of normal NaOH solution and boiled till no more ammonia was given off. The excess of the alkali solution left over was titrated with normal H_2SO_4. The volume required was 30 mL. Find out the percentage of NH_3 in the salt.
9. The normality of the mixture of HCl and H_2SO_4 solution is *N*/5. 0.287 g of AgCl is obtained when 20 mL of this solution is treated with excess of $AgNO_3$. Calculate the percentage of both the acids in the mixture.
10. 1.17 g of an impure sample of oxalic acid was dissolved and made up to 200 mL with water. 10 mL of this solution in acid medium required 8.5 mL of a solution of potassium permanganate containing 3.16 g per litre of oxidation. Calculate the percentage purity of oxalic acid.
11. What amount of silver chloride will be obtained when 20 mL *N*/20 HCl is made to react with excess of $AgNO_3$?
12. 1.0 g carbonate of a metal was dissolved in 50 mL *N*/2 HCl solution. The resulting liquid required 25 mL of *N*/5 NaOH solution to neutralise it completely. Calculate the equivalent mass of the metal carbonate.
13. 0.35 g of a metal was dissolved in 50 mL *N*-acid. The whole solution then required 20.85 mL of normal alkaline solution to neutralise the excess of the acid. Calculate the equivalent mass of the metal.
14. 2.650 g of anhydrous sodium carbonate are dissolved in water and the solution made up to 500 mL. On titration 50 mL of this solution neutralises 50 mL of a solution of sulphuric acid. How much water should be added to 450 mL of this acid as to make it exactly *N*/12 ?
15. Two acids *A* and *B* are titrated separately each time with 25 mL of *N* Na_2CO_3 solution and require 10 mL and 40 mL respectively for complete neutralisation. What volume of *A* and *B* would you mix to produce one litre of normal acid solution?
16. 1.64 g of a mixture of calcium carbonate and magnesium carbonate were dissolved in 50 mL of 0.8 *N* hydrochloric acid. The excess of the acid required 16 mL *N*/4 sodium hydroxide solution for neutralisation. Find out the percentage composition of the mixture of two carbonates.
17. 30 mL of *N*/10 HCl are required to neutralise 50 mL of a sodium carbonate solution. How many mL of water must be added to 30 mL of this solution so that the solution obtained may have a concentration equal to *N*/50?
18. 2.65 g of diacidic base was dissolved in water and made up to 500 mL. 20 mL of this solution completely neutralised 12 mL of *N*/6 HCl. Find out the equivalent mass and molecular mass of the base.
19. In a sample of sodium carbonate, some sodium sulphate is mixed. 2.50 g of this sample is dissolved and the volume made up to 500 mL. 25 mL of this solution neutralises 20 mL of *N*/10 sulphuric acid. Calculate the percentage of sodium carbonate in the sample.
20. Some amount of NH_4Cl was boiled with 50 mL of 0.75 *N* NaOH solution till the reaction was complete. After the completion of the reaction, 10 mL of 0.75 *N* H_2SO_4 were required for the neutralisation of the remaining NaOH. Calculate the amount of NH_4Cl taken.
21. 25 mL of a mixed solution of sodium carbonate and sodium bicarbonate required 10 mL of *N*/20 HCl when titrated in the presence of phenolphthalein but 25 mL of the same when titrated separately in presence of methyl orange required 25 mL of *N*/10 HCl. Calculate the amount of anhydrous sodium carbonate and bicarbonate in grams per litre of the solution.
22. 4 g of a mixture of NaCl and Na_2CO_3 were dissolved in water and volume made up to 250 mL. 15 mL of this solution required 50 mL of *N*/10 HCl for complete neutralisation. Calculate the percentage composition of the original mixture.
23. 40 mL of a mixture of Na_2CO_3 and NaOH when titrated against *N*/10 HCl, the end point with phenolphthalein was reached at 25 mL of HCl and at this stage methyl orange was added, the quantity of acid further required for second end point was 5 mL. Calculate the amount of Na_2CO_3 and NaOH in g/L of the solution.

24. Find out the percentage of oxalate in a given sample of an oxalate salt of which when 0.3 g were dissolved in 100 mL of water required 90 mL of *N*/20 $KMnO_4$ solution for complete oxidation.

25. A 1.0 g sample of H_2O_2 solution containing '*x*' per cent by weight requires *x* mL of a $KMnO_4$ solution for complete oxidation under acidic conditions. Calculate the normality of the $KMnO_4$ solution.

26. 25 g of a sample of ferrous sulphate was dissolved in water containing dilute H_2SO_4 and the volume made up to one litre. 25 mL of this solution required 20 mL of *N*/10 $KMnO_4$ solution for complete oxidation. Calculate the percentage of $FeSO_4 \cdot 7H_2O$ in the sample.

27. A sample of KCl is contaminated with NaCl. 4.176 g of the sample is dissolved in distilled water and the solution is made to 500 mL. 25 mL of the above solution required 27.50 mL of a solution of silver nitrate (normality factor 0.115) to react completely with it. Calculate the percentage contamination of the sample.

28. The saponification number of fat or oil is defined as the number of mg of KOH required to saponify 1 g oil or fat. A sample of peanut oil weighing 1.5763 g is added to 25 mL of 0.421 *M* KOH. After saponification is complete, 8.46 mL of 0.2732 *M* H_2SO_4 is needed to neutralise excess of KOH. What is the saponification number of peanut oil?

29. 500 mL of 2 *M* HCl, 100 mL of 2 *M* H_2SO_4 and one gram equivalent of monoacidic alkali are mixed together. 30 mL of this solution required 20 mL of $Na_2CO_3 \cdot xH_2O$ solution obtained by dissolving 143 g $Na_2CO_3 \cdot xH_2O$ in one litre solution. Calculate the water of crystallisation of $Na_2CO_3 \cdot xH_2O$.

30. 1 g of the complex $[Cr(H_2O)_5Cl]Cl_2 \cdot H_2O$ was passed through a cation exchanger to produce HCl. The acid liberated was diluted to 1 litre. What is the normality of this acid solution?

31. 5.0 g of bleaching powder was suspended in water and volume made up to half a litre. 20 mL of this suspension when acidified with acetic acid and treated with excess of KI solution liberated iodine which required 20 mL of a decinormal hypo solution for titration. Calculate percentage of available chlorine in bleaching powder. (IIT 1990)

32. To a solution of excess of KI in dilute H_2SO_4, 25 mL of an unknown solution of $KMnO_4$ were added. The liberated iodine was exactly reduced by 42.5 mL of *N*/10 $Na_2S_2O_3$ solution. Calculate the concentration of $KMnO_4$ solution.

33. In 20 mL of a solution of HCl, 3 g of $CaCO_3$ were dissolved, 0.5 g of $CaCO_3$ being left undissolved. Find out the strength of this solution in terms of (i) normality and (ii) g/L. Find the volume of this acid which would be required to make 1 litre of normal solution of this acid.

34. 1.0 litre of a solution contains 5.3 g of Na_2CO_3 and 8 g of NaOH. 20 mL of this solution are taken and titrated against *N*/10 HCl using separately (a) methyl orange as an indicator and (b) phenolphthalein as an indicator. What will be the titre values in these two cases?

35. To 20 mL of a copper solution after necessary treatment were added excess of KI and the liberated iodine required 11.2 mL decinormal solution of hypo. Express the strength of the original solution in grams of copper per litre of the solution.

36. 0.28 g of a commercial sample of $K_2Cr_2O_7$ was dissolved in water. Excess of KI was added to it along with dilute H_2SO_4. Iodine liberated was then titrated against sodium thiosulphate solution containing 24.82 g of $Na_2S_2O_3 \cdot 5H_2O$ per litre. The thiosulphate solution required was 50 mL. Find the percentage purity of the sample of $K_2Cr_2O_7$.

37. A mixture containing KCl and NaCl was dissolved and total halide was determined by titration with silver nitrate. A sample weighing 0.3250 g required 51 mL of 0.1 *N* solution. Calculate the percentage of each salt in the sample.

38. 1.355 g of pyrolusite sample are added to 50 mL of 1 *N* oxalic acid solution containing sulphuric acid. After the reaction is completed, the contents are transferred to a measuring flask and the volume made up to 200 mL. 20 mL of this solution is titrated against $KMnO_4$ solution whose strength is 2 g/L and 31.6 mL of $KMnO_4$ solution are required. Calculate the percentage purity in the given sample of pyrolusite.

39. 0.5 g of bleaching powder was suspended in water an excess of KI added. On acidifying with dilute H_2SO_4 iodine was liberated which required 50 mL of *N*/10 hyposolution. Calculate the percentage of available chlorine in bleaching powder.

40. Calculate the number of oxalic acid molecules in 100 mL of 0.02 *N* oxalic acid solution. (IIT 1991)

[**Hint :** Molarity $= \frac{0.02}{2} = 0.01\,M$

No. of molecules in one molar solution $= 6.02 \times 10^{23}$

No. of molecules in 100 mL of 0.01 *M* oxalic acid solution

$$= \frac{0.01 \times 6.02 \times 10^{23}}{1000} \times 100 = 6.02 \times 10^{20}]$$

41. 1.26 g of a dibasic acid were dissolved in water and made up to 200 mL. 20 mL of this solution were completely neutralised by 10 mL of *N*/5 caustic soda solution. Calculate the equivalent mass and molecular mass of the acid.

42. 3.0 g of a sample of impure ammonium chloride were boiled with excess of caustic soda solution. Ammonia gas so evolved was passed into 120 mL of *N*/2 H_2SO_4. 28 mL of *N*/2 NaOH were required to neutralise residual acid. Calculate the percentage of purity of the given sample of ammonium chloride.

[**Hint :** $(120 - 28)$ mL *N*/2 $H_2SO_4 \equiv 92$ mL *N*/2 NH_4Cl]

43. 2.20 g of an ammonium salt were boiled with 75 mL of *N* NaOH till the emission of ammonia gas ceased. The excess of unused NaOH solution required 70 mL of *N*/2 sulphuric acid for neutralisation. Calculate the percentage of ammonia in the salt.

44. 3.45 g of a metallic carbonate were mixed with 240 mL of *N*/4 HCl. The excess acid was neutralised by 50 mL of *N*/5 KOH solution. Calculate the equivalent mass of the metal.

Hint : Equivalent mass of metal carbonate

$$= \frac{3.45 \times 4 \times 1000}{200} = 69$$

Equivalent mass of metal = 69 − Eq. mass of carbonate

$$= (69 - 30) = 39]$$

45. (a) 2 g of a metal carbonate were dissolved in 50 mL of *N* HCl. 100 mL of 0.1 *N* NaOH were required to neutralise the resultant solution. Calculate the equivalent mass of the metal carbonate.

(b) How much water should be added to 75 mL of 3 *N* HCl to make it a normal solution?

46. Upon mixing 45.0 mL of 0.25 *M* lead nitrate solution with 25 mL of 0.1 *M* chromic sulphate solution, precipitation of lead sulphate takes place. How many moles of lead sulphate are formed? Also calculate the molar concentrations of the species left behind in the final solution. Assume that lead sulphate is completely insoluble. **(IIT 1993)**

[**Hint :** The reaction is:

$$\underset{3\text{ mole}}{3Pb(NO_3)_2} + \underset{1\text{ mole}}{Cr_2(SO_4)_3} \longrightarrow \underset{3\text{ mole}}{3PbSO_4} + \underset{2\text{ mole}}{2Cr(NO_3)_3}$$

$$\text{No. of moles of } Pb(NO_3)_2 = 45 \times 10^{-3} \times 0.25$$
$$= 11.25 \times 10^{-3} \text{ mole}$$

$$\text{No. of moles of } Cr_2(SO_4)_3 = 25 \times 10^{-3} \times 0.1 = 2.5 \times 10^{-3} \text{ mole}$$

Thus, $Cr_2(SO_4)_3$ has limiting concentration. It shall be consumed fully and the number of moles of lead sulphate produced will be

$$= 3 \times 2.5 \times 10^{-3} = 7.5 \times 10^{-3} \text{ mole}$$

$$\text{No. of moles of lead nitrate left} = 11.25 \times 10^{-3} - 7.5 \times 10^{-3}$$
$$= 3.75 \times 10^{-3} \text{ mole}$$

$$\text{Total volume} = (45.0 + 25.0) = 70 \text{ mL or } 70 \times 10^{-3} \text{ litre}$$

$$\text{Molarity} = \frac{3.75 \times 10^{-3}}{70 \times 10^{-3}} = 0.0536\,M$$

$$\text{No. of moles of } Cr(NO_3)_3 \text{ formed} = 2 \times 2.5 \times 10^{-3} = 5 \times 10^{-3} \text{ mole}$$

$$\text{Molarity} = \frac{5 \times 10^{-3}}{70 \times 10^{-3}} = 0.0714\,M$$

$Pb(NO_3)_2$ and $Cr(NO_3)_3$ will be present in solution in ionic form.

Thus, $[Pb^{2+}] = 0.0536\,M$

$[Cr^{3+}] = 0.0714\,M$

$[NO_3^-] = (2 \times 0.0536) + (3 \times 0.0714)$

$= 0.3214\,M$]

47. A sample of hydrazine sulphate ($N_2H_6SO_4$) were dissolved in 250 mL of water. 10 mL of this solution was reacted with excess of ferric chloride solution and warmed to complete the reaction. Ferrous ions formed were estimated and it required 10 mL of 0.04 *M* potassium permanganate solution. Estimate the amount of hydrazine sulphate dissolved in 250 mL of the solution. Reactions:

$$4Fe^{3+} + N_2H_4 \longrightarrow N_2 + 4Fe^{2+} + 4H^+$$
$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

(MLNR 1993)

[**Hint :** See example 50]

48. In an ore the only oxidisable material is Sn^{2+}. This ore is titrated with a dichromate solution containing 2.5 g $K_2Cr_2O_7$ in 0.50 litre. A 0.40 g of sample of the ore required 10.0 cm^3 of the titrant to reach equivalent point. Calculate the percentage of tin in ore. (K = 39.1, Cr = 52, Sn = 118.7) **(IIT 1993)**

[**Hint :** Mol. mass of $K_2Cr_2O_7 = 2 \times 39.1 + 2 \times 52 + 7 \times 16$

$$= 78.2 + 104.0 + 112.0$$
$$= 294.2$$

$$\text{Eq. mass of } K_2Cr_2O_7 = \frac{294.2}{6} = 49.03$$

$$\text{Normality of } K_2Cr_2O_7 \text{ solution} = \frac{2.5}{49.03} \times \frac{1000}{500} = \frac{5}{49.03}\,N$$

$$10 \text{ mL } \frac{5}{49.03}\,N\ K_2Cr_2O_7 \equiv 10 \text{ mL } \frac{5}{49.03}\,N \text{ stannous ion}$$

$$\text{Eq. mass of } Sn^{2+} = \frac{118.7}{2} = 59.35$$

$$\text{Amount of Sn in the sample} = \frac{5}{49.03} \times \frac{59.35}{1000} \times 10$$
$$= 0.0605 \text{ g}$$

$$\text{Percentage of Sn in the ore} = \frac{0.0605}{0.40} \times 100 = 51]$$

49. 2.26 g of impure ammonium chloride were boiled with 100 mL of *N* NaOH solution till no more ammonia was given off. The excess of NaOH solution left over required 30 mL 2 *N* H_2SO_4 for neutralisation. Calculate the percentage purity of the salt.

(H = 1; N = 14; O = 16; Na = 23; S = 32; Cl = 35.5)

50. Metallic tin in the presence of HCl is oxidised by $K_2Cr_2O_7$ solution to stannic chloride. What volume of decinormal dichromate solution would be reduced by 1 g of Sn? **(MLNR 1994)**

[**Hint :**

$$\underset{3\times118.7\text{ g}}{3Sn} + \underset{2\times294\text{ g}}{2K_2Cr_2O_7} + 28HCl \longrightarrow 3SnCl_4 + 4KCl + 4CrCl_3 + 14H_2O$$

$$K_2Cr_2O_7 \text{ required for 1 g of Sn} = \frac{2 \times 294}{3 \times 118.7} = 1.65 \text{ g}]$$

51. A 0.5 g sample containing MnO_2 is treated with HCl liberating Cl_2. The Cl_2 is passed into a solution of KI and 30.0 cm^3 of 0.1 *M* $Na_2S_2O_3$ are required to titrate the liberated iodine. Calculate the percentage of MnO_2 in the sample. **(IIT 1994)**

[**Hint:** $30.0 \text{ mL } 0.1\,M\,Na_2S_2O_3 \equiv 30.0 \text{ mL } 0.1\,N\ Na_2S_2O_3$

$$\equiv 30.0 \text{ mL } 0.1\,N\ I_2$$
$$\equiv 30.0 \text{ mL } 0.1\,N\ Cl_2$$
$$\equiv 30.0 \text{ mL } 0.1\,N\ MnO_2$$

$$\text{Amount of } MnO_2 \text{ present} = \frac{N \times E \times V}{1000}$$
$$= \frac{1}{10} \times \frac{87}{2} \times \frac{30}{1000}$$

$$\%\ MnO_2 = \frac{87 \times 30 \times 100}{10 \times 2 \times 1000 \times 0.5} = 26.1]$$

52. 3.2 g of a mixture of calcium carbonate and sodium chloride was dissolved in 100 mL of 1.02 *N* HCl. After the reaction the solution was filtered and after separating the precipitate the volume was raised to 200 mL. 20 mL of this solution required 25 mL *N*/5 caustic soda solution for neutralisation. Find out the percentage of calcium carbonate in the mixture.

53. 4 g of a mixture of Na_2SO_4 and anhydrous Na_2CO_3 were dissolved in pure water and volume made up to 250 mL. 20 mL of this solution required 25 mL of *N*/5 H_2SO_4 for complete neutralisation. Calculate the percentage composition of the mixture.

54. A 1.2 g mixture of Na_2CO_3 and K_2CO_3 was dissolved in water to form 100 cm^3 of a solution. 20 cm^3 of this solution required 40 cm^3 of 0.1 *N* HCl for neutralisation. Calculate the mass of Na_2CO_3 and K_2CO_3 in the mixture. **(IIT 1997)**

55. One litre of a mixture of O_2 and O_3 at NTP was allowed to react with an excess of acidified solution of KI. The iodine liberated required 40 mL of $M/10$ sodium thiosulphate solution for titration. What is the weight per cent of ozone in the mixture? Ultraviolet radiation of wavelength 300 nm can decompose ozone. Assuming that one photon can decompose one ozone molecule, how many photons would have been required for the complete decomposition of ozone in the original mixture?

[Hint: Let the total moles of O_2 and O_3 in the mixture be n.

Applying $PV = nRT$

$$1 \times 1 = n \times 0.0821 \times 273$$

$$n = 0.044 \text{ mole.}$$

$$\text{Moles of } O_3 = \text{moles of } I_2 = 1/2 \text{ moles of } Na_2S_2O_3$$

$$= \frac{1}{2} \times \frac{1}{10} \times \frac{40}{1000} = 0.002 \text{ moles}$$

Moles of O_2 in the mixture = 0.044 − 0.002 = 0.042 moles

Mass of $O_2 = 0.042 \times 32 = 1.344$ g

Mass of $O_3 = 0.002 \times 48 = 0.096$ g

$$\% \ O_3 = \frac{0.096}{1.44} \times 100 = 6.67$$

No. of photons required to decompose 0.002 moles of ozone

$$= 0.002 \times 6.02 \times 10^{23} = 1.204 \times 10^{21}]$$

56. 20 mL of a solution containing 0.2 g of impure sample of H_2O_2 reacts with 0.316 g of $KMnO_4$ (acidic). Calculate:
   (a) Purity of H_2O_2
   (b) Volume of dry O_2 evolved at 27° C and 750 mm pressure.

57. Five gram of copper alloy was dissolved in one litre of dilute H_2SO_4. 20 mL of this solution was titrated iodometrically and it required 20 mL of a hypo solution. 20 mL of $K_2Cr_2O_7$ which contained 2.4 g per litre, in presence of H_2SO_4 and excess of KI, required 30 mL of the same hypo solution. Calculate the % purity of copper in the alloy.

58. How many millilitres of 0.5 M H_2SO_4 are needed to dissolve 0.5 g of copper (II) carbonate?

[Hint : $N_1V_1 = N_2V_2$

N_1 = Normality of $H_2SO_4 = 0.5 \times 2 = 1 \ N$

V_1 = Vol. of H_2SO_4

N_2 = Normality of copper (II) carbonate $= \dfrac{0.5 \times 2}{123.5} \ N$

V_2 = Volume of copper (II) carbonate = 1000 mL

Thus, $$1.0 \times V_1 = \frac{0.5 \times 2}{123.5} \times 1000$$

or $$V_1 = 8.09 \text{ mL}]$$

59. An aqueous solution containing 0.10 g KIO_3 (formula weight = 214.0) was treated with an excess of KI solution. The solution was acidified with HCl. The liberated iodine consumed 45.0 mL of thiosulphate solution to decolourise the blue starch-iodine complex. Calculate the molarity of the sodium thiosulphate solution.

[Hint : $2KIO_3 + 10KI + 12HCl \longrightarrow 12KCl + 6I_2 + 6H_2O$

$$[2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6] \times 6$$

$$\underset{\text{2 moles}}{2KIO_3} + 10KI + \underset{\text{12 moles}}{12Na_2S_2O_3} + 12HCl \longrightarrow 12KCl + 12NaI + 6Na_2S_4O_6 + 6H_2O$$

No. of moles of $KIO_3 = \dfrac{0.10}{214}$

No. of moles of $Na_2S_2O_3$ required for $\dfrac{0.10}{214}$ moles of KIO_3

$$= \frac{12}{2} \times \frac{0.10}{214} = \frac{0.60}{214}$$

$$\text{Molarity of } Na_2S_2O_3 = \frac{0.6}{214} \times \frac{1000}{45} = 0.0623 \ M]$$

60. Gastric juice contains 3 g of HCl per litre. If a person produces 2.5 litre of gastric juice per day, how many antacid tablets each containing 400 mL of $Al(OH)_3$ are needed to neutralise all the HCl produced in one day?

61. Zinc can be determined volumetrically by the precipitation reactions,

$$3Zn^{2+} + 2K_4[Fe(CN)_6] \longrightarrow K_2Zn_3[Fe(CN)_6] + 6K^+$$

A sample of Zn ore weighing 1.5432 g was prepared for reaction and required 34.68 mL of 0.1043 M $K_4[Fe(CN)_6]$ for titration. What is percentage of zinc in the ore?

62. A mixture of KOH and Na_2CO_3 solution required 15 mL of $N/20$ HCl using phenolphthalein as indicator. The same amount of alkali mixture when titrated using methyl orange as indicator required 25 mL of same acid. Calculate amount of KOH and Na_2CO_3 present in solution.

63. 1000 mL O_2 at NTP was passed through Siemen's ozonizer so that the volume is reduced to 888 mL at same condition. Ozonized oxygen is passed through KI solution. Liberated I_2 was titrated with 0.05 N hypo. Calculate volume of hypo used.

64. 30 mL of $K_2Cr_2O_7$ liberated iodine from KI solution when the iodine was titrated with hypo solution ($N/20$), the titre value was 45 mL. Find the concentration of $K_2Cr_2O_7$ in g per litre.

65. Excess of KI and dil. H_2SO_4 were mixed in 50 mL H_2O_2. The liberated I_2 required 20 mL of 0.1 N $Na_2S_2O_3$. Find out the strength of H_2O_2 in g per litre.

66. 25 mL H_2O_2 were added to excess of acidified solution of KI. The iodine so liberated required 20 mL of 0.1 N sodium thiosulphate for titration. Calculate the strength in terms of normality, percentage and volume.

67. Cl_2 gas can be produced in the lab by the reaction,

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$$

If a 6.13 g sample that is 96% $K_2Cr_2O_7$ is allowed to react with 320 mL of HCl solution having density 1.15 g/mL and containing 30% by mass of HCl, what mass of Cl_2 is generated?

68. What is the weight in gram of available O_2 per litre from a solution of H_2O_2, 10 mL of which when titrated with $N/20$ $KMnO_4$ solution required 25 mL for the reaction?

$$2KMnO_4 + 5H_2O_2 + 4H_2SO_4 \longrightarrow 5O_2 + 8H_2O + 2KHSO_4 + 2MnSO_4$$

69. A quantity of $KMnO_4$ was boiled with HCl and the gas evolved was led into a solution of KI. When the reaction was complete, the I_2 liberated was titrated with a solution of hypo containing 124 g of $Na_2S_2O_3 \cdot 5H_2O$ per litre. It was found that exactly 60 mL were required to decolourise the solution of I_2. What weight of $KMnO_4$ was used?

70. 0.5 g of a sample of bleaching powder was suspended in water and excess KI is added. On acidifying with dil. H_2SO_4, I_2 was liberated which required 50 mL of $N/10$ hypo ($Na_2S_2O_3 \cdot 5H_2O$). Calculate the percentage of available Cl_2 in bleaching powder.

71. 1.2 g of a sample of $CaOCl_2$ were suspended in water made up to 100 mL. 25 mL of this solution was treated with KI and the I_2 liberated corresponded to 10 mL of $N/25$ hypo. Calculate the percentage of Cl_2 available in $CaOCl_2$.

72. 1.6 g of pyrolusite was treated with 60 mL of normal oxalic acid and some H_2SO_4. The oxalic acid left undecomposed was made up to 250 mL, 25 mL of this solution required 32 mL of 0.1 N potassium permanganate ($KMnO_4$). Calculate the percentage of pure MnO_2 in pyrolusite.

73. A sample of pyrolusite weighing 0.5 g is distilled with conc. HCl. The evolved Cl_2 when passed through a solution of KI liberates sufficient I_2 to react with 125 mL of $N/12.5$ hypo ($Na_2S_2O_3 \cdot 5H_2O$). Calculate the percentage of MnO_2 in pyrolusite.

74. The iodide content of a solution was determined by titration with sodium thiosulphate crystalline containing 11.2% impurity. Calculate the normality of iodide ion solution in 250 mL of the iodide solution required 20 mL hypo (42 g hypo is dissolved in 1 litre).

75. The formula weight of an acid is 82. In a titration, 100 cm^3 of a solution of this acid containing 39.0 g of the acid per litre were completely neutralised by 95.0 cm^3 of aqueous NaOH containing 40.0 g of NaOH per litre. What is the basicity of the acid? (IIT 2000)

[**Hint :** Normality of NaOH = 1

$$\text{Normality of acid} = \frac{1 \times 95}{100} = 0.95$$

Let the eq. mass of the acid be E.

$$\therefore \quad \frac{39}{E} = 0.95 \text{ or } E = 41\ ; \qquad \text{Basicity} = \frac{82}{41} = 2]$$

76. 20 mL of a solution containing ferrous sulphate and ferric sulphate acidified with H_2SO_4 is reduced by metallic zinc. The solution required 27.4 mL of 0.1 N solution of $K_2Cr_2O_7$ for oxidation. However before reduction with zinc, 20 mL of same solution required 17.96 mL of same $K_2Cr_2O_7$. Calculate the mass of $FeSO_4$ and $Fe_2(SO_4)_3$ per litre of the solution.

[**Hint :** After reduction $Fe_2(SO_4)_3$ is also reduced to $FeSO_4$ and titration gives total concentration of $FeSO_4$ and $Fe_2(SO_4)_3$. Titration before reduction gives only $FeSO_4$.

Milli equiv. of $K_2Cr_2O_7$ after reduction $= 27.4 \times 0.1 = 2.740$
Milli equiv. of $K_2Cr_2O_7$ before reduction $= 17.96 \times 0.1 = 1.796$
Milli equiv. of $Fe_2(SO_4)_3$ in 20 mL = 0.944
Milli equiv. of $FeSO_4$ in 20 mL = 1.796

$$\therefore \quad FeSO_4\ (gL^{-1}) = \frac{1.796}{1000} \times \text{Eq. mass} \times 40$$
$$= \frac{1.796}{1000} \times 152 \times 40 = 10.92$$
$$Fe_2(SO_4)_3\ (gL^{-1}) = \frac{0.944}{1000} \times \text{Eq. mass} \times 40$$
$$= \frac{0.944}{1000} \times 200 \times 40 = 7.55]$$

77. 3.0 g of pyrolusite ore were treated with 20 g of pure ferrous ammonium sulphate (Mol. mass = 392 g mol^{-1}) and dilute H_2SO_4. After the reaction, the solution was diluted to 500 mL. 50 mL of diluted solution required 10 mL of 0.1 N $K_2Cr_2O_7$ solution. Calculate the % of pure MnO_2 in pyrolusite.

[**Hint:** MnO_2 present in pyrolusite oxidises ferrous ammonium sulphate into ferric ammonium sulphate, *i.e.*, $Fe^{2+} \longrightarrow Fe^{3+}$. Unreacted ferrous ammonium sulphate is estimated by potassium dichromate solution.

$$MnO_2 + 2Fe^{2+} + 4H^+ \longrightarrow Mn^{2+} + 2H_2O + 2Fe^{3+}$$
$$Cr_2O_7^{2-} + 6Fe^{2+} + 14H^+ \longrightarrow 2Cr^{3+} + 7H_2O + 6Fe^{3+}$$

50 mL diluted ferrous ammonium sulphate solution

$$= 10 \text{ mL of } 0.1\ N\ K_2Cr_2O_7$$

500 mL diluted ferrous ammonium sulphate solution

$$= 10 \times 10 \text{ mL of } 0.1\ N\ K_2Cr_2O_7$$
$$= 100 \text{ mL of } 0.1\ N \text{ FeAS}$$
$$= \frac{0.1 \times 392}{1000} \times 100 = 3.92 \text{ g}$$

$$\text{Used FeAS} = (20 - 3.92) = 16.08 \text{ g}$$

$$MnO_2 \text{ present in pyrolusite} = \frac{87}{392 \times 2} \times 16.08 = 1.784 \text{ g}$$

$$\text{Percentage of pure } MnO_2 = \frac{1.784}{3.0} \times 100 = 59.4\%]$$

OBJECTIVE QUESTIONS

Set–1 : Questions with single correct answer

1. A normal solution:
(a) contains one gram equivalent mass of the substance in one litre solution
(b) contains one gram molecular mass of the substance in one litre solution
(c) contains one gram equivalent mass of the substance in 100 mL of the solution
(d) is that whose concentration is known

2. Which one of the following is a standard solution?
(a) It contains one gram equivalent mass of the substance in one litre solution
(b) Its strength is accurately known
(c) Its strength is to be determined
(d) A solution which has been prepared from pure substance

3. The molecular mass of H_3PO_3 is 82. Its equivalent mass, if it is completely neutralised, is:
(a) 82 (b) 27.3 (c) 41 (d) 246

4. The molecular mass of Mohr's salt, $FeSO_4(NH_4)_2SO_4 \cdot 6H_2O$, is 392. Its equivalent mass is:
(a) 196 (b) 39.2 (c) 98.0 (d) 392

5. According to the following equation,
$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$
the equivalent mass of $K_2Cr_2O_7$ is:
(a) mol. mass/3 (b) mol. mass/6
(c) mol. mass (d) mol. mass/12

6. Amount of oxalic acid required to prepare 250 mL of $N/10$ solution (Mol. mass of oxalic acid = 126) is:
(a) 1.5759 g (b) 3.15 g (c) 15.75 g (d) 63.0 g

7. Normality of 2% H_2SO_4 solution by volume is nearly:
(a) 2 (b) 4 (c) 0.2 (d) 0.4

8. The molecular mass of $KMnO_4$ is M. Its equivalent mass in acidic medium will be:
(a) M (b) $M/2$ (c) $M/5$ (d) $M/4$

9. When $KMnO_4$ is reduced with oxalic acid in acidic medium, the oxidation number of Mn changes from:
(a) 7 to 4 (b) 6 to 4 (c) 7 to 2 (d) 4 to 2

10. For the half cell reaction,

$$2BrO_3^- + 12H^+ + 10e \longrightarrow Br_2 + 6H_2O$$

the equivalent mass of sodium bromate is:
(a) equal to its mol. mass (b) 1/3 of its mol. mass
(c) 1/6 of its mol. mass (d) 1/5 of its mol. mass

11. In the reaction,

$$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$$

equivalent mass of iodine is:
(a) equal to its molecular mass
(b) 1/2 the molecular mass
(c) 1/4 the molecular mass
(d) twice the molecular mass

12. A molal solution is one that contains one mole of the solute in:
(a) 1000 g of the solvent (b) one litre of the solvent
(c) one litre of the solution (d) 22.4 litre of the solvent

13. In alkaline conditions, $KMnO_4$ reacts as follows,

$$2KMnO_4 + 2KOH \longrightarrow 2K_2MnO_4 + H_2O + [O]$$

Therefore, its equivalent mass will be:
(a) 31.6 (b) 52.7 (c) 72.0 (d) 158.0

14. 0.1 N solution of Na_2CO_3 is being titrated with 0.1 N HCl, the best indicator to be used is:
(a) potassium ferricyanide (b) phenolphthalein
(c) methyl orange (d) litmus

15. For the preparation of a litre of $N/10$ solution of H_2SO_4, we need:
(a) 9.8 g (b) 4.9 g (c) 10 g (d) 98 g

16. Molecular mass of a tribasic acid is M. Its equivalent mass will be:
(a) $M/3$ (b) $3\,M$ (c) $M/2$ (d) $2\,M$

17. A solution containing Fe^{2+} ions is titrated with $KMnO_4$ solution. Indicator used will be:
(a) phenolphthalein (b) methyl orange
(c) litmus (d) none of these

18. If 200 mL of $N/10$ HCl were added to 1 g calcium carbonate, what would remain after the reaction?
(a) $CaCO_3$ (b) HCl
(c) Neither of the two (d) Part of both

19. How many mL of 1 M H_2SO_4 acid solution is required to neutralise 10 mL of 1 M NaOH?
(a) 5 mL (b) 2.5 mL
(c) 10 mL (d) 20 mL

20. 200 mL of 3 N HCl were mixed with 200 mL of 6 N H_2SO_4 solution. The final normality of H_2SO_4 in the resultant solution will be:
(a) 9 N (b) 3 N (c) 6 N (d) 2 N

21. The volume of water to be added to 400 mL of $N/8$ HCl to make it exactly $N/12$, is:
(a) 400 mL (b) 300 mL
(c) 200 mL (d) 100 mL

22. 100 mL of 0.3 N HCl were mixed with 200 mL of 0.6 N H_2SO_4 solution. The final normality of acid was:
(a) 0.4 N (b) 0.5 N (c) 0.6 N (d) 0.9 N

23. The M mass of NaOH is 40.50 mL of a solution containing 2 g of NaOH in 500 mL will require for complete neutralisation:
(a) 10 mL decinormal HCl (b) 20 mL decinormal HCl
(c) 50 mL decinormal HCl (d) 25 mL decinormal HCl

24. 50 g of a sample of NaOH required for complete neutralisation, 1 litre N HCl. What is the percentage purity of NaOH?
(a) 80 (b) 70 (c) 60 (d) 50

25. Weight of iodine required to oxidise 500 mL N $Na_2S_2O_3$ solution, is:
(a) 6.35 g (b) 63.5 g (c) 127 g (d) 254 g

26. 25 mL N $K_2Cr_2O_7$ acidified solution will liberate . . . iodine from KI solution.
(a) 0.3175 g (b) 3.175 g (c) 31.75 g (d) 317.5 g

27. The indicator used in iodometric titrations is:
(a) phenolphthalein (b) litmus
(c) potassium iodide (d) starch

28. Which of the following acids is added in the titration of oxalic acid and potassium permanganate?
(a) HNO_3 (b) HCl
(c) CH_3COOH (d) H_2SO_4

29. In the titration of $K_2Cr_2O_7$ iodometrically, near the end point the colour of the solution becomes:
(a) green (b) red (c) yellow (d) blue

30. In the titration of ferrous ammonium sulphate and potassium dichromate, the external indicator used is:
(a) KCNS (b) NH_4CNS
(c) $K_3Fe(CN)_6$ (d) $K_4Fe(CN)_6$

31. 0.1 N solution of a dibasic acid can be prepared by dissolving 0.45 g of the acid in water and diluting to 100 mL. The molecular mass of the acid is:
(a) 45 (b) 90 (c) 135 (d) 180

32. 100 mL of 0.2 N HCl solution is added to 100 mL of 0.2 N $AgNO_3$ solution. The molarity of nitrate ions in the resulting mixture will be:
(a) 0.05 M (b) 0.5 M (c) 0.1 M (d) 0.2 M

33. In an experiment, 20 mL of a decinormal HCl solution was added to 15 mL of a decinormal $AgNO_3$ solution. AgCl was precipitated out and excess of acid was titrated with N/20 NaOH solution. The volume of NaOH required was:
(a) 10 mL (b) 20 mL (c) 30 mL (d) 5 mL

34. Iodine solution is prepared by dissolving iodine in:
(a) NaOH (b) Na_2CO_3 (c) H_2O (d) KI

35. Which one of the following is not a primary standard?
(a) Oxalic acid (b) Sodium thiosulphate
(c) Sodium hydroxide (d) Potassium dichromate

36. Which one of the following is a primary standard?
(a) $KMnO_4$ (b) $CuSO_4 \cdot 5H_2O$
(c) I_2 (d) H_2SO_4

37. When 10 mL of 10 M solution of H_2SO_4 and 100 mL of 1 M solution of NaOH are mixed, the resulting solution will be:
(a) acidic (b) neutral
(c) alkaline (d) cannot be predicted

38. 1.0 g of a metal carbonate neutralises 200 mL of 0.1 N HCl. The equivalent mass of the metal will be:
(a) 50 (b) 40 (c) 20 (d) 100

39. The normality of a 26% mass/volume solution of ammonia (density 0.885 g/mL) is approximately:
(a) 1.5 (b) 4.0 (c) 0.4 (d) 15.3

40. The molarity of pure water is:
(a) 18 M (b) 50.0 M (c) 55.6 M (d) 100 M

41. 5.0 g of H_2O_2 is present in 100 mL of the solution. The molecular mass of H_2O_2 is 34. The molarity of the solution is:
(a) 1.5 M (b) 0.15 M (c) 3.0 M (d) 50 M

42. 2 N solution of sodium carbonate is equivalent to a solution of strength:
(a) 106 g per 100 mL (b) 53 g per 100 mL
(c) 10.6 g per 100 mL (d) 5.3 g per 100 mL

43. Which one of these solutions has the highest normality?
(a) 8 g KOH per 100 mL (b) 0.5 M H_2SO_4
(c) 6 g of NaOH per 100 mL (d) N H_3PO_4

44. 1 g of a metal required 50 mL of 0.5 N HCl to dissolve it. The equivalent mass of the metal is:
(a) 25 (b) 50 (c) 20 (d) 40

45. What volume of CO_2 at NTP will be liberated by the action of 100 mL of 0.2 N HCl on $CaCO_3$?
(a) 112 mL (b) 224 mL (c) 448 mL (d) 120 mL

46. The equivalent mass of phosphoric acid (H_3PO_4) is 49. It behaves as . . . acid.
(a) monobasic (b) dibasic
(c) tribasic (d) tetrabasic

47. The normality of 10% (mass/volume) acetic acid is:
(a) 1 N (b) 10 N (c) 1.7 N (d) 0.83 N

48. Equivalent mass of $KMnO_4$, when it is converted to $MnSO_4$, is: [illegible]
(a) M/5 (b) M/3 (c) M/6 (d) M/2

49. How many grams of CH_3OH would have to be added to water to prepare 150 mL of a solution that is 2.0 M CH_3OH? [illegible]
(a) 9.6 (b) 2.4 (c) 9.6×10^3 (d) 4.3×10^2

50. On dissolving 1 mole of each of the following acids in one litre water, the acid which does not give a solution of strength 1 N is: [illegible]
(a) HCl (b) $HClO_4$ (c) HNO_3 (d) H_3PO_4

51. 0.16 g a dibasic acid required 25 mL of decinormal NaOH solution for complete neutralisation. The molecular mass of the acid is: [illegible]
(a) 32 (b) 64 (c) 128 (d) 256

52. 5 mL of N HCl, 20 mL of N/2 H_2SO_4 and 30 mL of N/3 HNO_3 are mixed together and volume made to one litre. The normality of the resulting solution is: [illegible]
(a) N/5 (b) N/10
(c) N/20 (d) N/40

53. The equivalent mass of $MnSO_4$ is half its molecular mass when it is converted to:
(a) Mn_2O_3 (b) MnO_2
(c) MnO_4^- (d) MnO_4^{2-}

54. For the redox reaction,

$$MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O$$

the correct coefficients of the reactants for the balanced reaction are: [illegible]

	MnO_4^-	$C_2O_4^{2-}$	H^+
(a)	2	5	16
(b)	16	5	2
(c)	5	16	2
(d)	2	16	5

55. 100 mL solution consists 4 g caustic soda. The normality of the solution is: [illegible]
(a) 1.0 (b) 0.1 (c) 0.5 (d) 4.0

56. The amount of a caustic soda required for complete neutralisation of 100 mL 0.1 N HCl is: [PMT (MP) 1994]
(a) 4.0 g (b) 0.04 g (c) 0.4 g (d) 2.0 g

57. What volume of $N/2$ and $N/10$ HCl should be taken in order to make a 2 litre solution of $N/5$ strength?
(a) 0.5 litre $N/2$ HCl and 1.5 litre of $N/10$ HCl
(b) 1 litre $N/2$ HCl and 1 litre $N/10$ HCl
(c) 1.5 litre $N/2$ HCl and 0.5 litre $N/10$ HCl
(d) 0.7 litre $N/2$ HCl and 1.3 litre $N/10$ HCl

58. The molar concentration of the chloride ion in the solution obtained by mixing 300 mL of 3.0 M NaCl and 200 mL of 4.0 M solution of $BaCl_2$ is:
(a) 1.6 M (b) 1.8 M (c) 5.0 M (d) 0.5 M

59. The normality of 0.3 M phosphorous acid (H_3PO_3) is: [illegible]
(a) 0.1 (b) 0.9 (c) 0.3 (d) 0.6

60. A 100 mL solution of 0.1 N HCl was titrated with 0.2 N NaOH solution. The titration was discontinued after adding 30 mL of NaOH solution. The titration was completed by adding 0.25 N KOH solution. The volume of KOH required for completing the titration is: [illegible]
(a) 70 mL (b) 32 mL (c) 35 mL (d) 16 mL

61. An aqueous solution of 6.3 g of oxalic acid dihydrate is made up to 250 mL. The volume of 0.1 N NaOH required to completely neutralise 10 mL of this solution is: [illegible]
(a) 40 mL (b) 20 mL (c) 10 mL (d) 4 mL

62. In order to prepare one litre normal solution of $KMnO_4$, how many grams of $KMnO_4$ are required if the solution is to be used in acid medium for oxidation? [illegible]
(a) 158 g (b) 31.6 g (c) 62 g (d) 790 g

63. 3 g of an oxide of a metal is converted to chloride completely and it yielded 5 g of chloride. Equivalent weight of the metal is: [illegible]
(a) 33.25 (b) 3.325 (c) 12 (d) 20

64. Phosphoric acid H_3PO_4 can be neutralised to:
(a) HPO_4^{2-} (b) PO_4^{3-} (c) $H_2PO_4^-$ (d) HPO_3^{2-}

65. 'a' g KHC_2O_4 required to reduce 100 mL of 0.02 M $KMnO_4$ in acid medium and 'b' g KHC_2O_4 neutralises 100 mL of 0.05 M $Ca(OH)_2$ then :
(a) $a = b$ (b) $2a = b$
(c) $a = 2b$ (d) none of these

66. Which of the following statements is /are true about H_3PO_2?
(a) It is a tribasic acid
(b) One mole of it is neutralised by 0.5 mole of $Ca(OH)_2$
(c) NaH_2PO_2 is acidic salt
(d) It disproportionates to H_3PO_3 and PH_3 on heating

67. Mixture of 1 mole BaF_2 and 2 mole H_2SO_4 can be neutralised by:
(a) 1 mole KOH (b) 2 mole $Ca(OH)_2$
(c) 4 mole NaOH (d) 2 mole KOH

68. $28\,NO_3^- + 3As_2S_3 + 4H_2O \rightarrow 6AsO_4^{3-} + 28NO + 9SO_4^{2-} + 8H^+$.
What will be the equivalent mass of As_2S_3 in above reaction?
(a) $\frac{\text{M. wt.}}{2}$ (b) $\frac{\text{M. wt.}}{4}$ (c) $\frac{\text{M. wt.}}{24}$ (d) $\frac{\text{M. wt.}}{28}$

69. The number of moles of $KMnO_4$ that will need to react completely with one mole of ferrous oxalate in acidic solution is: [IIT (July) 1997]
(a) 2/5 (b) 3/5 (c) 4/5 (d) 1

70. The number of moles of $KMnO_4$ that will be needed to react with one mole of sulphite ion in acidic solution is: [IIT (July) 1997]
(a) 2/5 (b) 3/5 (c) 4/5 (d) 1

71. The equivalent weight of KIO_3 in the reaction,

$$2Cr(OH)_3 + OH^- + KIO_3 \longrightarrow 2CrO_4^{2-} + 5H_2O + KI \text{ is:}$$

[PET (MP) 2003]
(a) molecular weight (b) $\frac{\text{molecular weight}}{3}$
(c) $\frac{\text{molecular weight}}{6}$ (d) $\frac{\text{molecular weight}}{2}$

72. In the reaction,

$$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$$

equivalent weight of iodine will be equal to: [PMT (MP) 2004]
(a) 4/6 of molecular weight
(b) molecular weight
(c) 2/9 of molecular weight
(d) twice the molecular weight

73. The volume of a concentrated H_2SO_4, mixed with 0.5 N KOH to prepare 150 cm^3 of 0.2 N KOH. Solution is: (KCET 2004)
(a) 50 cm^3 (b) 60 cm^3 (c) 70 cm^3 (d) 80 cm^3

74. For the decolorisation of 1 mole of $KMnO_4$, the number of moles of H_2O_2 required is: (AIIMS 2004)
(a) 1/2 (b) 3/2 (c) 5/2 (d) 7/2

75. The product of oxidation of I^- with MnO_4^- in alkaline medium is: [IIT (S) 2004]
(a) IO_3^- (b) I_2 (c) IO^- (d) IO_4^-

76. Volume of 0.1 M $K_2Cr_2O_7$ required to oxidise 35 mL of 0.5 M $FeSO_4$ solution is: [illegible]
(a) 29.2 mL (b) 17.5 mL
(c) 175 mL (d) 145 mL

77. A commercial sample of H_2O_2 is labelled 10 volume. Its percentage strength is nearly: [illegible]
(a) 1% (b) 3% (c) 10% (d) 90%

78. 50 mL of 10 N H_2SO_4, 25 mL of 12 N HCl and 40 mL of 5 N HNO_3 are mixed and the volume of the mixture is made 1000 mL by adding water. The normality of the resulting solution will be: [illegible]
(a) 1 N (b) 2 N (c) 3 N (d) 4 N
(e) 9 N

[**Hint:** $N_1V_1 + N_2V_2 + N_3V_3 = N_R \times V_R$
$10 \times 50 + 12 \times 25 + 5 \times 40 = N_R \times 1000$
$500 + 300 + 200 = N_R \times 1000$
$N_R = 1$ (Resultant normality)]

79. Acidified $KMnO_4$ oxidizes oxalic acid to CO_2. What is the volume (in litre) of 10^{-4} M $KMnO_4$ required to completely oxidize 0.5 litre of 10^{-2} M oxalic acid in acid medium? [illegible]
(a) 125 (b) 1250 (c) 200 (d) 20

[**Hint:** $2KMnO_4 + 3H_2SO_4 + 5\begin{matrix}COOH\\ |\\ COOH\end{matrix} \longrightarrow K_2SO_4$
$+ 2MnSO_4 + 10CO_2 + 8H_2O$

$$\frac{M_1V_1}{n_1}(KMnO_4) = \frac{M_2V_2}{n_2}\begin{pmatrix}COOH\\ |\\ COOH\end{pmatrix}$$

$$\frac{10^{-4} \times V_1}{2} = \frac{10^{-2} \times 0.5}{5}$$

$$V_1 = 20 \text{ L}]$$

80. The concentration of oxalic acid is 'x' mol litre^{-1}. 40 mL of this solution reacts with 16 mL of 0.05 M acidified $KMnO_4$. What is the pH of 'x' M oxalic acid solution?
(Assume that oxalic acid dissociates completely.)
[EAMCET (Engg.) 2006]

(a) 1.3 (b) 1.699 (c) 1 (d) 2

[**Hint:** $2KMnO_4 + 3H_2SO_4 + 5\begin{matrix}COOH\\ |\\ COOH\end{matrix} \longrightarrow K_2SO_4 + 2MnSO_4$
$+ 8H_2O + 10CO_2$

$$\frac{M_1V_1}{n_1}(KMnO_4) = \frac{M_2V_2}{n_2}\begin{pmatrix}COOH\\ |\\ COOH\end{pmatrix}$$

$$\frac{0.05 \times 16}{2} = \frac{x \times 40}{5}$$

$$x = 0.05\ M$$

$$[H^+] = 2 \times 0.05 = 0.1\ M$$

$$pH = -\log(H^+) = -\log(0.1) = 1]$$

81. Consider the titration of potassium dichromate solution with acidified Mohr's salt solution using diphenylamine as indicator. The number of moles of Mohr's salt required per mole of dichromate is: (IIT 2007)

(a) 3 (b) 4 (c) 5 (d) 6

[**Hint:** $Cr_2O_7^{2-} + 6Fe^{2+} + 14H^+ \longrightarrow 2Cr^{3+} + 6Fe^{3+} + 7H_2O$
1 mole of dichromate oxidises six moles of ferrous ion present in Mohr's salt]

82. The number of moles of $KMnO_4$ that will be needed to react with one mole of sulphite ion in acidic solution is:
[CBSE (Med.) 2007]

(a) $\frac{4}{5}$ (b) $\frac{2}{5}$ (c) 1 (d) $\frac{3}{5}$

[**Hint:** The redox reaction is:
$$2MnO_4^- + 5SO_3^{2-} + 6H^+ \longrightarrow 2Mn^{2+} + 5SO_4^{2-} + 3H_2O$$
1 mole SO_3^{2-} will be oxidised by $\frac{2}{5}$ mol of MnO_4^-]

83. For the reaction between $KMnO_4$ and H_2O_2, the number of electrons transferred per mole of H_2O_2 is:
[PMT (Haryana) 2007]

(a) one (b) two (c) three (d) four

84. Number of moles of $K_2Cr_2O_7$ reduced by one mole of Sn^{2+} is:
[PMT (Raj.) 2007]

(a) 1/3 (b) 3 (c) 1/6 (d) 6

85. The formula mass of Mohr's salt is 392. The iron present in it is oxidised by $KMnO_4$ in acid medium. The equivalent mass of Mohr's salt is: [Indraprasth (Engg.) 2007]

(a) 392 (b) 31.6 (c) 278 (d) 156

86. To neutralise completely 20 mL of 0.1 M aqueous solution of phosphorus acid (H_3PO_3), the volume of 0.1 M aqueous KOH solution required is: [Jamia Millia Islamia (Engg.) 200

(a) 10 mL (b) 20 mL (c) 40 mL (d) 60 mL

[**Hint:** $H_3PO_3 + 2KOH \longrightarrow K_2HPO_3 + 2H_2O$

$$\frac{M_1V_1}{n_1} = \frac{M_2V_2}{n_2}$$

$$\frac{0.1 \times 20}{1} = \frac{0.1 \times V_2}{2}$$

$$V_2 = 40 \text{ mL}]$$

87. 10 cm^3 of 0.1 N monobasic acid requires 15 cm^3 of sodium hydroxide solution whose normality is :

(a) 0.066 N (b) 0.66 N (c) 1.5 N (d) 0.15 N
(KCET 2008)

[**Hint :** $N_1V_1 = N_2V_2$

$$0.1 \times 10 = N_2 \times 15$$

$$N_2 = 0.066]$$

88. Amount of oxalic acid present in solution can be oxidised by its titration with $KMnO_4$ solution in the presence of H_2SO_4. The titration gives unsatisfactory result when carried out in the presence of HCl, because HCl: (AIEEE 2008)

(a) oxidises oxalic acid to carbon dioxide and water
(b) gets oxidised by oxalic acid to chlorine
(c) Furnishes H^+ ions in addition to those from oxalic acid
(d) reduces permanganate to Mn^{2+}

89. How many moles of acidified $FeSO_4$ can be completely oxidised by one mole of $KMnO_4$? [BHU (Mains) 2008]

(a) 10 (b) 5 (c) 6 (d) 2

[**Hint:** $2KMnO_4 + 3H_2SO_4 \rightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$

$[2FeSO_4 + H_2SO_4 + [O] \rightarrow Fe_2(SO_4)_3 + H_2O] \times 5$

$2KMnO_4 + 10FeSO_4 + 8H_2SO_4 \rightarrow K_2SO_4 + 2MnSO_4$
$+ 5Fe_2(SO_4)_3 + 8H_2O$

---

2 mole $KMnO_4 \equiv 10$ mole $FeSO_4$
1 mole $KMnO_4 \equiv 5$ mole $FeSO_4$]

90. In the titration of nitric acid against potassium carbonate, the indicator used is : [Comed (Karnataka) 20

(a) methyl orange (b) self indicator
(c) phenolphthalein (d) diphenylamine

91. In transforming 0.01 mole of PbS to $PbSO_4$, the volume of 10 volume H_2O_2 required will be : [JEE (WB) 20

(a) 11.2 mL (b) 22.4 mL (c) 33.6 mL (d) 44.8 mL

[**Hint :** $PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$

0.04 mole of H_2O_2 is required to react with 0.01 mole PbS.
Molarity of H_2O_2 may be calculated as,

Volume strength = Molarity × 11.2

$$10 = M \times 11.2$$

$$M = 0.892$$

$$\text{Number of moles} = \frac{MV}{1000}$$

$$0.04 = \frac{0.892 \times V}{1000}$$

$$V = 44.8 \text{ mL}]$$

92. A solution containing Na_2CO_3 and NaOH requires 300 mL of 0.1 *N* HCl using phenolphthalein as an indicator. Methyl orange is then added to above titrated solution when a further 25 mL of 0.2 *N* HCl is required. The amount of NaOH present in the original solution is:

(a) 0.5 g (b) 1 g (c) 2 g (d) 4 g

[**Hint** : 300 mL HCl of 0.1 *N* neutralises entire amount of NaOH and 1/2 of Na_2CO_3. Remaining 1/2 of Na_2CO_3 is neutralised by 25 mL of 0.2 *N* HCl, *i.e.*, 50 mL of 0.1 *N* HCl.

Thus, 250 mL of 0.1 *N* HCl is required to neutralise NaOH completely.

$$\begin{aligned} N_1V_1(\text{NaOH}) &= N_2V_2(\text{HCl}) \\ &= 0.1 \times 250 \\ &= 25 \\ W_{\text{NaOH}} &= \frac{ENV}{1000} = \frac{40 \times 25}{1000} = 1\text{ g}\,] \end{aligned}$$

93. Ceric ammonium sulphate and potassium permanganate are used as oxidising agents in acidic medium for oxidation of ferrous ammonium sulphate to ferric sulphate. The ratio of number of moles of ceric ammonium sulphate required per mole of ferrous ammonium sulphate to the number of moles of $KMnO_4$ required per mole of ferrous ammonium sulphate is:

(a) 5.0 (b) 0.2 (c) 0.6 (d) 2.0

[**Hint** : Oxidation of ferrous ammonium sulphate by $KMnO_4$ is :

$$2KMnO_4 + 8H_2SO_4 + 10FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O \longrightarrow$$
$$K_2SO_4 + 2MnSO_4 + 5Fe_2(SO_4)_3 + 10(NH_4)_2SO_4 + 68H_2O$$

$\therefore$ 1 mole of $FeSO_4(NH_4)_2SO_4 \cdot 6H_2O$ consumes 1/5 mole of $KMnO_4$.

$$Fe^{2+} + Ce^{4+} \longrightarrow Fe^{3+} + Ce^{3+}$$

$$\text{Required ratio} = \frac{1}{1/5} = 5.0\,]$$

94. One kilogram of sea water sample contains 6 mg of dissolved O_2. The concentration of O_2 in the sample in ppm is:

(a) 0.6 (b) 6.0 (c) 60.0 (d) 16.0
(e) 32.0

[**Hint** : 1 kg water $\equiv 10^6$ mg:
10^6 mg water contains 6 mg O_2
$\therefore$ Concentration of O_2 is 6 ppm.]

95. The estimation of available chlorine in bleaching powder is done by:

(a) Acid-base titration (b) Permanganometric titration
(c) Iodimetric titration (d) Iodometric titration

96. What volume of 0.1 M H_2SO_4 is required in litres to neutralize completely 1 litre of a solution containing 20 g of NaOH?

(a) 5.0 (b) 0.5 (c) 2.5 (d) 10.0

[**Hint** : $M_{\text{NaOH}} = \dfrac{w_B \times 1000}{m_B \times V} = \dfrac{20 \times 1000}{40 \times 1000} = 0.5$

Reaction : $H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$

$$\frac{M_1V_1}{1} = \frac{M_2V_2}{2}$$
$$0.1 \times V_1 = \frac{0.5 \times 1}{2}$$
$$V_1 = 2.5\text{ L}]$$

Assertion-Reason TYPE QUESTIONS

The questions given below consist of an **'Assertion' (A)** and **'Reason' (R).** Use the following keys to choose the appropriate answer:

(a) If both (A) and (R) are correct, and (R) is the correct explanation of (A).
(b) If both (A) and (R) are correct, but (R) is not the correct explanation of (A).
(c) If (A) is correct, but (R) is incorrect.
(d) If (A) is incorrect, but (R) is correct.

1. (A) H_3PO_3 is a dibasic acid.
(R) Two H-atoms are directly attached to phosphorus '*P*'.

2. (A) Equivalent mass of $KMnO_4$ is equal to one-fifth of its molecular mass when it acts as an oxidising agent in acidic medium.
(R) Oxidation number of Mn in $KMnO_4$ is +7.

3. (A) 5 *M* HCl solution is diluted 10 times, its molarity becomes 50.
(R) On dilution, molarity of the solution decreases.

4. (A) In the reaction, $2S_2O_3^{2-} + I_2 \rightarrow S_4O_6^{2-} + 2I^-$; I_2 is oxidised.
(R) During oxidation, loss of electron takes place.

5. (A) In the titration of HCl against NaOH, phenolphthalein is used as suitable indicator.
(R) Phenolphthalein is pink coloured in basic medium.

6. (A) Concentration of H_2O_2 is expressed in volume.
(R) Volume strength of H_2O_2 = Normality × 5.6.

7. (A) Iodimetric titrations are redox titrations.
(R) The iodine solution acts as an oxidising agent.

8. (A) Starch is used as absorption indicator in iodometric and iodimetric titrations.
(R) Starch forms iodostarch complex with iodine, which is blue coloured.

9. (A) H_3BO_3 is monobasic Lewis acid but its salt Na_3BO_3 exists.
(R) H_3BO_3 reacts with NaOH to give Na_3BO_3.
[Hint $H_3BO_3 + NaOH \longrightarrow NaB(OH)_4$
$3C_2H_5OH + H_3BO_3 \longrightarrow (C_2H_5)_3BO_3 + 3H_2O$
$(C_2H_5)_3BO_3 + 3NaOH \longrightarrow Na_3BO_3 + 3C_2H_5OH$]

10. (A) Equivalent weight of a base = $\dfrac{\text{Molecular weight}}{\text{Acidity}}$
(R) Acidity is the number of replaceable hydrogen atoms in one molecule of the base.

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS for IIT ASPIRANTS

1. The value of n in the equation,

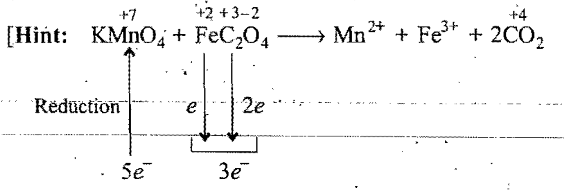
$$Cr_2O_7^{2-} + 14H^+ + ne^- \longrightarrow 2Cr^{3+} + 7H_2O$$

is:

(a) 2 (b) 3 (c) 4 (d) 6

2. The number of moles of acidified $KMnO_4$ required to oxidise one mole of ferrous oxalate (FeC_2O_4) is:

(a) 5 (b) 3 (c) 0.6 (d) 1.5



[**Hint:** $\overset{+7}{KMnO_4} + \overset{+2\ +3-2}{FeC_2O_4} \longrightarrow Mn^{2+} + Fe^{3+} + 2\overset{+4}{CO_2}$

∴ 5 mole $FeC_2O_4 \equiv 3$ mole $KMnO_4$

1 mole $FeC_2O_4 \equiv 0.6$ mole $KMnO_4$]

3. A solution contains Na_2CO_3 and $NaHCO_3$. 10 mL of the solution required 2.5 mL of 0.1 M H_2SO_4 for neutralisation using phenolphthalein as indicator. Methyl orange is then added when a further 2.5 mL of 0.2 M H_2SO_4 was required. Then the amount of Na_2CO_3 and $NaHCO_3$ in 1 litre of the solution is:

(a) 5.3 g and 4.2 g (b) 3.3 g and 6.2 g

(c) 4.2 g and 5.3 g (d) 6.2 g and 3.3 g

4. V_1 mL of NaOH of normality x and V_2 mL of $Ba(OH)_2$ of normality y are together sufficient to neutralize exactly 100 mL of 0.1 N HCl. If $V_1 : V_2 = 1 : 4$ and if $x : y = 4 : 1$, what fraction of the acid is neutralised by $Ba(OH)_2$?

(a) 0.5 (b) 0.33 (c) 0.67 (d) 0.25

5. A 0.518 g sample of limestone is dissolved in HCl and then the calcium is precipitated as CaC_2O_4. After filtering and washing the precipitate, it requires 40 mL of 0.25 N $KMnO_4$ solution acidified with H_2SO_4 to titrate it as,

$$MnO_4^- + H^+ + C_2O_4^{2-} \longrightarrow CO_2 + Mn^{2+} + 2H_2O$$

The percentage of CaO in the sample is:

(a) 54% (b) 27.1% (c) 42% (d) 84%

[**Hint:** Number of milliequivalents of CaC_2O_4, $KMnO_4$ and CaO will be same.

$$40 \times 0.25 = W / \frac{56}{2} \times 1000$$

$$W = 0.28 \text{ g (Mass of CaO)}$$

$$\% \text{ CaO} = \frac{0.28}{0.518} \times 100 = 54\%]$$

6. When 40 mL of 0.1 N HCl and 20 mL of 0.1 M H_2SO_4 are mixed together, the normality of the mixture will be:

(a) $\frac{1}{5}N$ (b) $\frac{2}{15}N$ (c) $\frac{15}{2}N$ (d) $\frac{5}{1}N$

[**Hint:** $N_1V_1 + N_2V_2 = N_R(V_1 + V_2)$

$$0.1 \times 40 + 0.2 \times 20 = N_R(60)$$

$$N_R = \frac{8}{60} = \frac{2}{15}\ ]$$

7. What is the normality of 0.3 M H_3PO_4 when it undergoes the reaction as?

$$H_3PO_4 + 2OH^- \longrightarrow HPO_3^{2-} + 2H_2O$$

(a) 0.3 N (b) 0.15 N (c) 0.60 N (d) 0.90 N

8. In the mixture of ($NaHCO_3 + Na_2CO_3$), volume of HCl required is x mL with phenolphthalein indicator and y mL with methyl orange indicator in same titration. Hence, volume of HCl for complete reaction of Na_2CO_3 is:

(a) $2x$ (b) y (c) $x/2$ (d) $(y - x)$

[**Hint:** In presence of phenolphthalein, 50% Na_2CO_3 is neutralised whereas $NaHCO_3$ remains unaffected. In presence of methyl orange, both Na_2CO_3 and $NaHCO_3$ will be 100% neutralised.

Let volume of HCl for complete reaction of $Na_2CO_3 = V_1$ mL and volume of HCl for complete reaction of $NaHCO_3 = V_2$ mL. With phenolphthalein, 50% Na_2CO_3 will be neutralized.

∴ $$\frac{V_1}{2} = x,\ V_1 = 2x]$$

9. 40 mL of 0.05 M $Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$ (sesquicarbonate) is titrated against 0.05 M HCl. x mL of HCl is used when phenolphthalein is the indicator and y mL HCl is used when methyl orange is the indicator in two separate titrations; hence $(y - x)$ is:

(a) 80 mL (b) 30 mL

(c) 120 mL (d) none of these

10. Equivalent mass of H_3PO_2 when it disproportionates into PH_3 and H_3PO_3 is (Molecular mass = M):

(a) M (b) $\frac{M}{2}$ (c) $\frac{M}{4}$ (d) $\frac{3M}{4}$

[**Hint:** $H_3\overset{+1}{P}O_2 \longrightarrow H_3\overset{+3}{P}O_3$; Eq. wt. $= \frac{M}{2}$

(Change in oxidation number = 2)

$$H_3\overset{+1}{P}O_2 \longrightarrow \overset{-3}{P}H_3;\ \text{Eq. wt.} = \frac{M}{4}$$

(Change in oxidation number = 4)

The equivalent mass of H_3PO_2 in the process of disproportionation $= \frac{M}{2} + \frac{M}{4} = \frac{3M}{4}$]

11. The reagent commonly used to determine hardness of water titrimetrically is:

(a) oxalic acid (b) disodium salt of EDTA

(c) sodium citrate (d) sodium thiosulphate

12. The equivalent mass of sodium thiosulphate ($Na_2S_2O_3 \cdot 5H_2O$) in the reaction,

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$

is:

(a) 248 (b) 124 (c) 596 (d) 62

13. If 100 mL of the acid is neutralised by 100 mL of 4 M NaOH, the purity of concentrated HCl (sp. gravity = 1.2) is:

(a) 12% (b) 98% (c) 73% (d) 43%

14. 2 moles of $FeSO_4$ are oxidised by x moles of $KMnO_4$ in acid medium into ferric sulphate. 3 moles of ferric oxalate are oxidised by y moles of $K_2Cr_2O_7$ in acid medium. The value of (x/y) is:

(a) 6/5 (b) 2/15 (c) 18/5 (d) 3/5

15. What volume of 0.05 M $Cr_2O_7^{2-}$ in acid medium is needed for complete oxidation of 200 mL of 0.6 M FeC_2O_4 solution?

(a) 0.6 L (b) 1.2 L (c) 2.4 L (d) 3.6 L

16. $KMnO_4$ reacts with oxalic acid according to the reaction:

$$2KMnO_4 + 5C_2O_4^{2-} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

Then, 20 mL of 0.1 M $KMnO_4$ is equivalent to:

(a) 30 mL of 0.5 M $C_2H_2O_4$ (oxalic acid)
(b) 50 mL of 0.1 M $C_2H_2O_4$ (oxalic acid)
(c) 20 mL of 0.5 M $C_2H_2O_4$ (oxalic acid)
(d) 10 mL of 0.1 M $C_2H_2O_4$ (oxalic acid)

[**Hint:** $\frac{M_1V_1}{n_1}(KMnO_4) = \frac{M_2V_2}{n_2}(H_2C_2O_4)$

$$\frac{0.1 \times 20}{2} = \frac{M_2V_2}{5}$$

$$M_2V_2 = 5$$

(It is possible in case of b.)]

17. Potassium permanganate is titrated against ferrous ammonium sulphate in acidic medium; the equivalent mass of potassium permanganate is:

(a) $\frac{\text{molecular mass}}{3}$ (b) $\frac{\text{molecular mass}}{5}$
(c) $\frac{\text{molecular mass}}{2}$ (d) $\frac{\text{molecular mass}}{10}$

[**Hint:** The ionic reaction involved in titration is:

$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 4H_2O + 5Fe^{3+}$$

Since, a molecule of $KMnO_4$ accepts 5 electrons in acid medium, its equivalent mass will be $\left(\frac{\text{molecular mass}}{5}\right)$.]

18. Number of moles of $K_2Cr_2O_7$ that can be reduced by 1 mole of Sn^{2+} ions is:

(a) 1/3 (b) 3/2 (c) 5/6 (d) 6/5

[**Hint:** The redox reaction is:

$$Cr_2O_7^{2-} + 14H^+ + 3Sn^{2+} \longrightarrow 2Cr^{3+} + 7H_2O + 3Sn^{4+}$$

$\therefore$ 1 mole of Sn^{2+} will reduce 1/3 mole of $K_2Cr_2O_7$]

19. Potassium permanganate acts as an oxidising agent in acidic, alkaline as well as neutral media. Which among the following statements is incorrect?

(a) $N = M/5$ (in acid medium)
(b) $N = M/3$ (in alkaline medium)
(c) $N = M/3$ (in neutral medium)
(d) $N = M$ (in alkaline medium)

20. The number of equivalents of $Na_2S_2O_3$ required for the volumetric estimation of one equivalent of Cu^{2+} is:

(a) 1/3 (b) 1 (c) 3/2 (d) 2/3

[**Hint:** Number of equivalents of reacting species in a chemical reaction are same.]

21. The equivalent mass of $MnSO_4$ becomes half of its molecular mass when it is converted into:

(a) MnO_4^- (b) MnO_2 or Mn_3O_4
(c) MnO_4^{2-} (d) $Mn_2O_4^{2-}$

[**Hint:** When $\overset{(+2)}{Mn}SO_4$ is converted to $\overset{(+4)}{Mn}O_2$, the oxidation number changes by 2, thus

$$\text{Equivalent mass of } MnSO_4 = \frac{\text{Molecular mass}}{2}]$$

22. A solution of 10 mL of $\frac{M}{10}$ $FeSO_4$ was titrated with $KMnO_4$ solution in acidic medium; the amount of $KMnO_4$ used will be:

(a) 10 mL of 0.5 M (b) 10 mL of 0.1 M
(c) 10 mL of 0.02 M (d) 5 mL of 0.1 M

[**Hint:** The involved reaction is:

$$2KMnO_4 + 8H_2SO_4 + 10FeSO_4 \longrightarrow 5Fe_2(SO_4)_3 + 2MnSO_4 + K_2SO_4 + 8H_2O$$

$$\frac{M_1V_1}{n_1}(KMnO_4) = \frac{M_2V_2}{n_2}(FeSO_4)$$

$$\frac{M_1V_1}{2} = \frac{0.1 \times 10}{10}$$

$M_1V_1 = 0.2$ which is possible in (c)]

23. Among the following reactions, used in titrations, select the reaction(s) in which the chlorine is oxidised:

1. $MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$
2. $2KI + Cl_2 \longrightarrow 2KCl + I_2$
3. $CaOCl_2 + H_2O \longrightarrow Ca(OH)_2 + Cl_2$
4. $CrO_2Cl_2 + 2NaOH \longrightarrow Na_2CrO_4 + 2HCl$

(a) reactions 2, 3 and 4 (b) reaction 1 only
(c) reactions 1 and 3 (d) reaction 4 only
(e) reactions 2 and 4

24. Oxalic acid dihydrate, $H_2C_2O_4 \cdot 2H_2O(s)$ is often used as a primary reagent to standardise sodium hydroxide solution. Which of these facts are reasons to choose this substance as a primary standard?

I. It is diprotic.
II. It is a stable compound that can be weighed directly in air.
III. It is available in pure form.

(a) III only (b) I and II only
(c) II and III only (d) I, II and III

25. A 20 mL sample of a $Ba(OH)_2$ solution is titrated with 0.245 M HCl. If 27.15 mL of HCl is required, what is the molarity of the $Ba(OH)_2$ solution?

(a) 0.166 M (b) 0.180 M (c) 0.333 M (d) 0.666 M

26. A solution of which substance can best be used as both titrant and its own indicator in an oxidation-reduction titration?

(a) I_2 (b) NaOCl (c) $K_2Cr_2O_7$ (d) $KMnO_4$

27. A 0.2 g sample of benzoic acid, C_6H_5COOH, is titrated with a 0.120 M $Ba(OH)_2$ solution. What volume of the $Ba(OH)_2$ solution is required to reach the equivalence point?

Substance	Molar mass
C_6H_5COOH	122.1 g mol^{-1}

(a) 6.82 mL (b) 13.6 mL (c) 17.6 mL (d) 35.2 mL

28. What mass of magnesium hydroxide is required to neutralise 125 mL of 0.136 M HCl solution?

Substance	Molar mass
$Mg(OH)_2$	58.33 g mol^{-1}

(a) 0.248 g (b) 0.496 g (c) 0.992 g (d) 1.98 g

29. In the titration of $K_2Cr_2O_7$ and $FeSO_4$, the following data is obtained: V_1 mL of $1M_1$ $K_2Cr_2O_7$ requires V_2 mL of $1M_2$ $FeSO_4$. Which of the following relations is true for the above titration?

(a) $6M_1V_1 = M_2V_2$ (b) $M_1V_1 = 6M_2V_2$
(c) $M_1V_1 = M_2V_2$ (d) $3M_1V_1 = 4M_2V_2$

[Hint:

$$K_2Cr_2O_7 + 7H_2SO_4 + 6FeSO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 3Fe_2(SO_4)_3 + 7H_2O$$

$$\frac{M_1V_1}{n_1}(K_2Cr_2O_7) = \frac{M_2V_2}{n_2}(FeSO_4)$$

$$\frac{M_1V_1}{1} = \frac{M_2V_2}{6}$$

$$6M_1V_1 = M_2V_2\,]$$

30. When 20 mL of $\frac{M}{10}$ NaOH are added to 10 mL of $\frac{M}{10}$ HCl, the resulting solution will:

(a) turn blue litmus red
(b) turn phenolphthalein solution pink
(c) turn methyl orange red
(d) have no effect on either red or blue litmus

31. A sample of coconut oil weighing 1.5763 g is mixed with 25 mL of 0.4210 M KOH. Some KOH is used in saponification of coconut oil. After the saponification is complete, 8.46 mL of 0.2732 M H_2SO_4 is required to neutralize excess KOH. The saponification number of peanut oil is:

(a) 209.6 (b) 98.9 (c) 108.9 (d) 218.9

[Hint: Number of milliequivalent of KOH added

$$= 25 \times 0.421 = 10.525$$

Number of milliequivalents left unreacted

= Number of milliequivalents of H_2SO_4 used

$= 8.46 \times 0.2732 \times 2 = 4.623$ (Here, basicity of $H_2SO_4 = 2$)

Number of milliequivalents of KOH used by oil

$$= 10.525 - 4.623 = 5.902$$

$$\text{Mass of KOH used} = \frac{5.902 \times 56}{1000} = 0.3305 \text{ g} = 330.5 \text{ mg}$$

Saponification number = Mass of KOH in mg used by 1 g oil or fat

$$= \frac{0.3305 \times 1000}{1.5763} = 209.6\,]$$

32. 12.5 mL of a solution containing 6 g of a dibasic acid in one litre was found to be neutralized by 10 mL of a decinormal solution of NaOH. The molecular mass of the acid is:

(a) 110 (b) 75 (c) 120 (d) 150

[Hint: N_1V_1 (acid) $= N_2V_2$ (base)

$$N_1 \times 12.5 = \frac{1}{10} \times 10$$

$$N_1 = \frac{1}{12.5}$$

$$\text{Strength} = N \times Ew$$

$$6 = \frac{1}{12.5} \times Ew$$

$$Ew = 75$$

Molar mass = Equivalent mass × Basicity

$$= 75 \times 2 = 150\,]$$

33. 20 mL of 0.1 M H_3BO_3 solution on complete neutralisation requires x mL of 0.05 M NaOH solution. The value of x will be:

(a) 20 mL (b) 40 mL (c) 120 mL (d) 80 mL

[Hint: Boric acid is monobasic acid.

$$H_3BO_3 + NaOH \longrightarrow Na[B(OH)_4]$$

$$\frac{M_1V_1}{n_1} = \frac{M_2V_2}{n_2}$$

$$\frac{0.1 \times 20}{1} = \frac{0.05 \times x}{1}$$

$$x = 40 \text{ mL}\,]$$

34. The ammonia evolved from the treatment of 0.30 g of an organic compound for the estimation of nitrogen was passed in 100 mL of 0.1 M sulphuric acid. The excess of acid required 20 mL of 0.5 M sodium hydroxide solution for complete neutralization. The organic compound is:

(a) acetamide (b) benzamide (c) urea (d) thiourea

[Hint: $H_2SO_4 + 2KOH \longrightarrow K_2SO_4 + 2H_2O$

$$\frac{M_1V_1}{1}(\text{excess } H_2SO_4) = \frac{M_2V_2}{2}(KOH)$$

$$\frac{0.1 \times V_1}{1} = \frac{0.5 \times 20}{2}$$

$$V_1 = 50 \text{ mL}$$

Volume of sulphuric acid used up to absorb $NH_3 = 50$ mL

$$\%N = \frac{2.8 \times MV}{W} = \frac{2.8 \times 0.1 \times 50}{0.3} = 46.6$$

Thus, the organic compound will be urea, which has 46.6% nitrogen.]

35. A solution contains Na_2CO_3 and $NaHCO_3$; 10 mL of this solution required 2.5 mL of 0.1 M H_2SO_4 for neutralisation using phenolphthalein indicator. Methyl orange is added after first end point, further titration required 2.5 mL of 0.2 M H_2SO_4. The amount of Na_2CO_3 and $NaHCO_3$ in 1 litre of the solution is:

(a) 5.3 g and 4.2 g (b) 3.3 g and 6.2 g
(c) 4.2 g and 5.3 g (d) 6.2 g and 3.3 g

36. MnO_4^- ions are reduced in acidic condition to Mn^{2+} ions whereas they are reduced in neutral condition to MnO_2. The oxidation of 25 mL of a solution X containing Fe^{2+} ions required in acidic condition, 20 mL of a solution Y containing MnO_4^- ions. What volume of solution Y would be required to oxidise 25 mL of solution X containing Fe^{2+} ions in neutral condition ?

(a) 11.4 mL (b) 12 mL
(c) 33.3 mL (d) 35 mL
(e) 25 mL

[**Hint :**

Acid medium

$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

$$\frac{M_1V_1}{1} = \frac{M_2V_2}{5}$$

$$\frac{M_1 \times 20}{1} = \frac{M_2 \times 25}{5}$$

$$M_1 = \frac{M_2}{4} \qquad \text{...(i)}$$

Neutral medium

$$MnO_4^- + 3Fe^{2+} + 4H^+ \longrightarrow MnO_2 + 3Fe^{3+} + 2H_2O$$

$$\frac{M_1V_1}{1} = \frac{M_2V_2}{3}$$

$$\left(\frac{M_2}{4}\right) \times V_1 = \frac{M_2 \times 25}{3}$$

$$V_1 = 33.3 \text{ mL}]$$

LINKED COMPREHENSION TYPE QUESTIONS

Passage 1

Pyrolusite, MnO_2, is the main ore from which manganese is produced. The manganese content of the ore may be determined by reducing the MnO_2 under acetic conditions to Mn^{2+} with the oxalate ion, $C_2O_4^{2-}$, the oxalate ion being oxidised to carbon dioxide during the reaction. The analytical determination is carried out by adding a known excess volume of oxalate solution to a suspension of the pyrolusite and digesting the mixture on a hot water bath until all the MnO_2 has been reduced. The excess, unreacted oxalate solution is then titrated with standardised potassium permanganate, $KMnO_4$ solution after which the manganese content of the ore can be calculated.

A student prepared a standard solution of sodium oxalate by weighing 3.2 g of the dry anhydrous salt, dissolving it in distilled water and making the solution up to 500 mL. 25 mL of the oxalate solution required 24.76 mL of $KMnO_4$ solution.

Answer the following questions:

1. What is the equivalent mass of MnO_2 in the present titration?
   (a) $\frac{M.w.}{1}$ (b) $\frac{M.w.}{2}$ (c) $\frac{M.w.}{3}$ (d) $\frac{2M.w.}{3}$
2. How many moles of $C_2O_4^{2-}$ ions will be oxidised by 1 mole MnO_4^-?
   (a) 1/2 (b) 3/2 (c) 5/2 (d) 7/2
3. Molarity of the sodium oxalate solution is ....
   (a) 0.04776 (b) 0.07446 (c) 0.06447 (d) 0.07644
4. What is the molarity of $KMnO_4$ solution?
   (a) 0.04776 (b) 0.01929 (c) 0.038 (d) 0.028
5. Role of $KMnO_4$ in the given titration can be described as:
   (a) oxidising agent
   (b) reducing agent
   (c) indicator
   (d) oxidising agent and indicator

Passage 2

For a series of indicators the following colours and pH range over which colour change takes place are as follows:

Indicator	**Colour change over pH range**	
U	*yellow to blue*	(*pH* 0 *to* 1.6)
V	*red to yellow*	(*pH* 2.8 *to* 4.1)
W	*red to yellow*	(*pH* 4.2 *to* 5.8)
X	*yellow to blue*	(*pH* 6.0 *to* 7.7)
Y	*colourless to red*	(*pH* 8.2 *to* 10)

Answer the following questions:

1. Indicator *V* could be used to find the equivalence point for 0.1 *M* acetic acid and 0.1 *M* ammonium hydroxide solution:
   (a) True (b) False
2. Indicator *Y* could be used to distinguish between the solutions of ammonium chloride and sodium acetate solution:
   (a) True (b) False
3. Indicator *X* could be used to distinguish between the solutions of ammonium chloride and sodium acetate solution:
   (a) True (b) False
4. Indicator *W* would be suitable for use in the determination of the concentration of acetic acid in white vinegar by base titration:
   (a) True (b) False
5. Indicator *U* could be used to distinguish between 0.1 *M* and 0.01 *M* solution of sulphuric acid:
   (a) True (b) False

Passage 3

Chemists work with standardised solution, a solution whose concentration is known. The requirements to standardise the solution are:

1. *the volume of the solution.*
2. *the number of moles of solute in that volume.*

A primary standard solution is used in determining the molarity of a solution. To find the molarity of HCl, 0.317 g of Na_2CO_3, the primary standard dissolved in water, is used in titrating the solution of HCl. 22.9 mL of acid are required to neutralise the sodium carbonate. This is the needed volume (first requirement). The stoichiometric equation is used to know the second requirement.

$$2HCl(aq.) + Na_2CO_3(aq.) \longrightarrow 2NaCl + H_2O + CO_2 \uparrow$$

Answer the following questions:

1. What is the molarity of HCl in the above case?
   (a) 0.261 *M* (b) 0.522 *M* (c) 0.1 *M* (d) 1 *M*
2. Equivalent mass of Na_2CO_3 in the above equation will be:
   (a) 106 (b) 53 (c) 26.5 (d) 13.25
3. The suitable indicator in the above titration will be:
   (a) phenolphthalein (b) methyl orange
   (c) litmus (d) bromothymol blue
4. Solution of Na_2CO_3 in water will be:
   (a) acidic (b) neutral
   (c) basic (d) cannot be predicted
5. What fraction of Na_2CO_3 will be neutralised by HCl in presence of phenolphthalein indicator?
   (a) 1/3 (b) 2/3 (c) 1/2 (d) 1/4

Passage 4

0.5 g bleaching powder was suspended in water and excess KI is added. On acidifying with dil. H_2SO_4, I_2 was liberated which required 50 mL of N/10 hypo ($Na_2S_2O_3 \cdot 5H_2O$) in presence of starch. The reactions involved are:

I. $CaOCl_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + Cl_2$
II. $2KI + Cl_2 \longrightarrow 2KCl + I_2$
III. $2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI$

Answer the following questions:

1. In the reaction (I), which one is reduced?
   (a) $CaOCl_2$ (b) H_2SO_4
   (c) Both (d) None of these

2. In the given titration, starch acts as:
   (a) oxidising agent (b) indicator
   (c) reducing agent (d) catalyst
3. In reaction (II), Cl_2 acts as:
   (a) reducing agent
   (b) oxidising agent
   (c) indicator
   (d) both oxidising agent and indicator
4. Percentage of available chlorine in bleaching powder is:
   (a) 35.5% (b) 71%
   (c) 17.25% (d) 50%
5. Starch forms iodo-starch complex in the given titration. The colour of the complex will be:
   (a) green (b) blue
   (c) pale yellow (d) milky white

• Passage 5

Hypo is the common name of sodium thiosulphate, with molecular formula $Na_2S_2O_3$. It is used as intermediate in iodometric as well as in iodimetric titrations.

Iodine and chlorine react with hypo in different ways as follows:

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$

$$Cl_2(g) + S_2O_3^{2-} \longrightarrow SO_4^{2-} + Cl^- + S$$

Suppose, 50 mL of 0.01 M $Na_2S_2O_3$ solution and 5×10^{-4} mol of Cl_2 are allowed to react according to the above equation. Hypo is also used in photography to dissolve AgBr, forming a complex compound.

$$2Na_2S_2O_3 + AgBr \longrightarrow Na_3[Ag(S_2O_3)_2] + NaBr$$

Answer the following questions:

1. The balanced chemical reaction with Cl_2 is:
   (a) $Cl_2 + 2Na_2S_2O_3 \longrightarrow 2NaCl + Na_2S_4O_6$
   (b) $Cl_2 + H_2O + Na_2S_2O_3 \longrightarrow Na_2SO_4 + 2HCl + S$
   (c) $Cl_2(g) + S_2O_3^{2-} \longrightarrow SO_4^{2-} + S + Cl^-$
   (d) none of the above
2. Number of moles of $S_2O_3^{2-}$ present in the sample is:
   (a) 0.0005 (b) 0.01
   (c) 0.0025 (d) 0.02
3. What is the molarity of Na_2SO_4 formed in the reaction between $Na_2S_2O_3$ and Cl_2?
   (a) 0.08 *M* (b) 0.04 *M*
   (c) 0.02 *M* (d) 0.01 *M*
4. The process of photography, in which $Na_2S_2O_3$ is used, is called:
   (a) developing (b) image fixing
   (c) tonning (d) all of these
5. Oxidation state of silver in $Na_3[Ag(S_2O_3)_2]$ is:
   (a) 0 (b) +1
   (c) +2 (d) −1

• Passage 6

Equivalent mass of a substance may be calculated as,

$$\textit{Equivalent mass} = \frac{\textit{Molecular mass}}{\textit{n-factor}} = \frac{\textit{Atomic mass}}{\textit{n-factor}}$$

n-factor = Basicity of acid or acidity of base
n-factor = Number of moles of electrons gained or lost per mole of oxidising or reducing agents
n-factor = Total positive or negative valency of a salt
n-factor = Valency of an ion.

Concept of n-factor is very important for redox as well as for non-redox reactions :

Answer the following questions:

1. When $KMnO_4$ is titrated against ferrous ammonium sulphate in acid medium then equivalent mass of $KMnO_4$ will be:
   (a) $\frac{\text{Molecular mass}}{10}$ (b) $\frac{\text{Molecular mass}}{5}$
   (c) $\frac{\text{Molecular mass}}{3}$ (d) $\frac{\text{Molecular mass}}{2}$

   [Hint:
   $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$ n-factor = 5]
2. Equivalent mass of ferrous oxalate FeC_2O_4 in the following reaction is:
   $$FeC_2O_4 \longrightarrow Fe^{3+} + 2CO_2$$
   (a) $\frac{\text{Molecular mass}}{1}$ (b) $\frac{\text{Molecular mass}}{2}$
   (c) $\frac{\text{Molecular mass}}{3}$ (d) $\frac{\text{Molecular mass}}{4}$

   [Hint : $Fe^{2+} \longrightarrow Fe^{3+} + e^-$
   $C_2O_4^{2-} \longrightarrow 2CO_2 + 2e^-$
   $FeC_2O_4 \longrightarrow Fe^{3+} + 2CO_2 + 3e^-$ n-factor = 3]
3. Equivalent mass of H_3PO_2 when it undergoes disproportionation to PH_3 and H_3PO_3 will be:
   (a) M.w./2 (b) M.w./4 (c) M.w./24 (d) 3M.w./4

   [Hint: $H_3PO_2 + 4H^+ + 4e^- \longrightarrow PH_3 + 2H_2O$ $n_1 = 4$
   $H_3PO_2 + H_2O \longrightarrow H_3PO_3 + 2H^+ + 2e^-$ $n_2 = 2$
   $$n\text{-factor} = \frac{n_1 \times n_2}{n_1 + n_2} = \frac{2 \times 4}{2 + 4} = \frac{8}{6} = \frac{4}{3}$$
   $$\text{E.w.} = \text{M.w.}/\frac{4}{3} = \frac{3\,\text{M.w.}}{4}\;]$$
4. BrO_3^- ion reacts with Br^- to form Br_2, in acid medium. The equivalent mass of Br_2 in this reaction is:
   (a) $\frac{4\text{M.w.}}{6}$ (b) $\frac{3\text{M.w.}}{5}$ (c) $\frac{5\text{M.w.}}{3}$ (d) $\frac{5\text{M.w.}}{8}$

   [Hint : $2BrO_3^- + 12H^+ + 10e^- \longrightarrow Br_2 + 6H_2O$ $n_1 = 10$
   $2Br^- \longrightarrow Br_2 + 6e^-$ $n_2 = 2$
   $$n\text{-factor} = \frac{n_1 \times n_2}{n_1 + n_2} = \frac{10 \times 2}{10 + 2} = \frac{20}{12} = \frac{5}{3}$$
   $$\text{E.w.} = \frac{\text{M.w.}}{5/3} = \frac{3\text{M.w.}}{5}\;]$$

SELF ASSESSMENT

ASSIGNMENT NO. 14

SECTION-I

Straight Objective Type Questions

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. For decolorisation of 1 mole of $KMnO_4$, the moles of H_2O_2 required is: (AIEEE 2007)

(a) $\frac{1}{2}$ (b) $\frac{3}{2}$ (c) $\frac{5}{2}$ (d) $\frac{7}{2}$

2. If equal volume of 1 M $KMnO_4$ and 1 M $K_2Cr_2O_7$ solutions are allowed to oxidise Fe^{2+} to Fe^{3+} in acidic medium, then Fe^{2+} will be oxidised: [illegible]

(a) more by $KMnO_4$ (b) more by $K_2Cr_2O_7$
(c) equal in both cases (d) cannot be determined

3. MnO_2 on reaction with conc. HCl liberates chlorine; the liberated chlorine on treatment with aqueous KI gives iodine. The iodine is neutralized by 40 mL of 0.1 N hypo solution. The reaction is:

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$

The amount of MnO_2 used in the reaction is:

(a) 10 g (b) 0.174 g (c) 1.74 g (d) 0.0174 g

4. 1.520 g of hydroxide of a metal on ignition gave 0.995 g of oxide. The equivalent mass of metal is:

(a) 1.52 (b) 0.995 (c) 190 (d) 9

5. Identify the incorrect statement regarding the volumetric estimation of $FeSO_4$:

(a) $KMnO_4$ can be used in aqueous HCl
(b) $K_2Cr_2O_7$ can be used in aqueous HCl
(c) $KMnO_4$ can be used in aqueous H_2SO_4
(d) $K_2Cr_2O_7$ can be used in aqueous H_2SO_4

6. When one gram mole of $KMnO_4$ is mixed with hydrochloric acid then, the volume of chlorine gas liberated at NTP will be:

(a) 11.2 litre (b) 22.4 litre (c) 56 litre (d) 44.8 litre

[**Hint:** The reaction between $KMnO_4$ and HCl may be given as:
$$2MnO_4^- + 10Cl^- + 16H^+ \longrightarrow 2Mn^{2+} + 5Cl_2 + 8H_2O]$$

7. 0.7 g of $Na_2CO_3.xH_2O$ was dissolved in water to make 100 mL solution, 20 mL of this solution required 19.8 mL of 0.1 N HCl for complete neutralisation. The value of x is:

(a) 5 (b) 2
(c) 3 (d) 4

8. 0.5 g of impure ammonium chloride was heated with caustic soda solution to evolve ammonia gas, the gas is absorbed in 150 mL of $N/5$ H_2SO_4 solution. Excess sulphuric acid required 20 mL of 1 N NaOH for complete neutralization. The percentage of NH_3 in the ammonium chloride is:

(a) 68% (b) 34% (c) 48% (d) 17%

9. One mole of a mixture of CO and CO_2 requires exactly 20 g of NaOH to convert all the CO_2 into Na_2CO_3. How many more grams of NaOH would it require for conversion into Na_2CO_3 if the mixture (one mole) is completely oxidised to CO_2?

(a) 60 g (b) 80 g (c) 40 g (d) 20 g

10. 0.1 litre of 0.01 M $KMnO_4$ is used by 100 mL of H_2O_2 in acidic medium. Volume of same $KMnO_4$ required in alkaline medium to oxidise 0.1 litre of some H_2O_2 will be:

(a) $\frac{100}{3}$ mL (b) $\frac{500}{3}$ mL (c) $\frac{300}{5}$ mL (d) $\frac{400}{3}$ mL

SECTION-II

Multiple Answers Type Objective Questions

11. One mole of acidic $KMnO_4$ reacts with:

(a) $\frac{5}{3}$ mol of FeC_2O_4 (b) $\frac{5}{2}$ mol of SO_2
(c) 4 mol of FeS (d) 1 mol of H_2SO_4

12. Boric acid (H_3BO_3) is:

(a) tribasic (b) dibasic (c) monobasic (d) aprotic

13. 0.6 mol $K_2Cr_2O_7$, in acid medium can oxidise:

(a) 3.6 mol $FeSO_4$ to $Fe_2(SO_4)_3$
(b) 0.1 mol $FeSO_4$ to $Fe_2(SO_4)_3$
(c) 0.05 mol of Sn^{2+} to Sn^{4+}
(d) 1.8 mol of Sn^{2+} to Sn^{4+}

14. Which of the following statement(s) is/are correct?

(a) H_2SO_4 and H_3PO_3 both are dibasic
(b) H_3BO_3 and H_3PO_4 both are tribasic
(c) H_3BO_3 and H_3PO_2 both are monobasic
(d) HNO_3 and HCl both are monobasic

15. In the titration of CH_3COOH against NaOH, we cannot use the:

(a) methyl orange (b) methyl red
(c) phenolphthalein (d) bromothymol blue

SECTION-III

Assertion-Reason Type Questions

This section contains 3 questions. Each question contains **Statement-1** (Assertion) and **Statement-2** (Reason). Each question has following 4 choices (a), (b), (c) and (d), out of which only one is correct.

(a) Statement-1 is true; statement-2 is true; statement-2 is a correct explanation for statement-1.
(b) Statement-1 is true; statement-2 is true; statement-2 is not a correct explanation for statement-1.
(c) Statement-1 is true; statement-2 is false.
(d) Statement-1 is false; statement-2 is true.

16. **Statement-1:** Equivalent mass of H_3PO_2 is equal to its molecular mass.

Because

Statement-2: H_3PO_2 is a monobasic acid.

17. **Statement-1:** When Na_2CO_3 is titrated against HCl in presence of phenolphthalein indicator, it is converted to NaCl.

Because

Statement-2: Phenolphthalein shows colour change in the pH range of (3.5 — 4.6).

18. **Statement-1:** 1 mol of H_2SO_4 is neutralised by 2 mol of NaOH; however, 1 equivalent of H_2SO_4 is neutralised by 1 equivalent of NaOH.

Because

Statement-2: Equivalent mass of H_2SO_4 is half of its molecular mass, however, the equivalent mass of NaOH is equal to its molecular mass.

SECTION-IV

Matrix-Matching Type Questions

This section contains 3 questions. Each question contains statement given in two columns which have to be matched. Statements (a, b, c and d) in Column-I have to be matched with statements (p, q, r and s) in Column-II. The answers to these questions have to be appropriately bubbles as illustrated in the following examples:

If the correct matches are (a-p,s); (b-q,r); (c-p,q) and (d-s); then correctly bubbled 4 × 4 matrix should be as follows:

	p	q	r	s
a	●	○	○	●
b	○	●	●	○
c	●	●	○	○
d	○	○	○	●

Match the Column-I with Column-II:

[EAMCET (Med.) 2007]

Column-I	Column-II
(a) 10 volume H_2O_2	(p) Perhydrol
(b) 20 volume H_2O_2	(q) 5.358 N
(c) 30 volume H_2O_2	(r) 1.785 M
(d) 100 volume H_2O_2	(s) 3.03%

20. Match the Column-I with Column-II:

Column-I (Acid)	Column-II (Information)
(a) CH_3COOH	(p) Tribasic (E_w = M.w./3)
(b) H_3PO_4	(q) Dibasic reducing
(c) H_2SO_4	(r) Dibasic (E_w = M.w./2)
(d) H_3PO_3	(s) Monobasic (E_w = M.w.)

21. Match the Column-I with Column-II:

Column-I (Reaction)	Column-II (Equivalent mass of reactant)
(a) $NH_3 \longrightarrow NO_3^-$	(p) M.w./20
(b) $Fe_2S_3 \longrightarrow FeSO_4 + SO_2$	(q) M.w./2
(c) $CaCO_3 + 2HCl \longrightarrow CaCl_2 + H_2O + CO_2$	(r) M.w./8
(d) $CuS \longrightarrow CuSO_4$	(s) 50

Answers

1. (c)	**2.** (a)	**3.** (b)	**4.** (d)	**5.** (a)	**6.** (c)	**7.** (b)	**8.** (b)
9. (a)	**10.** (b)	**11.** (a, b)	**12.** (c, d)	**13.** (a, d)	**14.** (a, c, d)	**15.** (a, b, d)	
16. (a)	**17.** (c)	**18.** (b)	**19.** (a-s) (b-r) (c-q) (d-p)		**20.** (a-s) (b-p) (c-r) (d-q,r)		
21. (a-r) (b-p) (c-q,s) (d-r)							

CHAPTER 15

STOICHIOMETRY

(Chemical Formulae and Equations)

In the discovery of a new chemical compound, the first question to answer is, what is the formula of the compound? The answer begins with stoichiometric calculation and analysis of the compound.

The percentage composition of a compound leads directly to its empirical formula. An **empirical formula** or simplest formula for a compound is the formula of a substance written with the smallest integer (whole number) subscripts.

The molecular formula of a compound is a multiple of its empirical formula.

$$\text{Molecular mass} = n \times \text{empirical formula mass.}$$

The calculations of empirical and molecular formulae are dealt in the very first chapter of this book.

Stoichiometry: Quantitative Relations in Chemical Reactions

Stoichiometry is the calculation of the quantities of reactants and products involved in a chemical reaction.

It is based on the chemical equation and on the relationship between mass and moles.

A chemical equation can be interpreted as follows:

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

$$\text{1 molecule } N_2 + \text{3 molecules } H_2 \longrightarrow \text{2 molecules } NH_3$$

(Molecular interpretation)

$1 \text{ mol } N_2 + 3 \text{ mol } H_2 \longrightarrow 2 \text{ mol } NH_3$ (Molar interpretation)

$28 \text{ g } N_2 + 6 \text{ g } H_2 \longrightarrow 34 \text{ g } NH_3$ (Mass interpretation)

$1 \text{ vol. } N_2 + 3 \text{ vol. } H_2 \longrightarrow 2 \text{ vol. } NH_3$ (Volume interpretation)

Thus, calculations based on chemical equations are divided into four types:

(i) Calculations based on mole-mole relationship.
(ii) Calculations based on mass-mass relationship.
(iii) Calculations based on mass-volume relationship.
(iv) Calculations based on volume-volume relationship.

(i) Calculations based on mole-mole relationship

In such calculations, number of moles of reactants are given and those of products required. Conversely, if number of moles of products are given, then number of moles of reactants are required.

SOME SOLVED EXAMPLES

Example 1. *Oxygen is prepared by catalytic decomposition of potassium chlorate ($KClO_3$). Decomposition of potassium chlorate gives potassium chloride (KCl) and oxygen (O_2). How many moles and how many grams of $KClO_3$ are required to produce 2.4 mole O_2?*

Solution: Decomposition of $KClO_3$ takes place as,

$$2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$$

$$2 \text{ mole of } KClO_3 \equiv 3 \text{ mole of } O_2$$

$\because$ 3 mole O_2 formed by 2 mole $KClO_3$

$\therefore$ 2.4 mole O_2 will be formed by $\left(\frac{2}{3} \times 2.4\right)$ mole $KClO_3$

$$= 1.6 \text{ mole of } KClO_3$$

$$\text{Mass of } KClO_3 = \text{Number of moles} \times \text{Molar mass}$$

$$= 1.6 \times 122.5 = 196 \text{ g}$$

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. One mole of calcium phosphide on reaction with excess of water gives:
(a) three moles of phosphine
(b) one mole of phosphoric acid
(c) two moles of phosphine
(d) one mole of P_2O_5
[**Ans.** (c)]
[**Hint:** $Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$
$1 \text{ mole of } Ca_3P_2 \equiv 2 \text{ mole of } PH_3$]

2. $Mg(OH)_2$ in the form of milk of magnesia is used to neutralize excess stomach acid. How many moles of stomach acid can be neutralized by 1 g of $Mg(OH)_2$? (Molar mass of $Mg(OH)_2$ = 58.33)

(a) 0.0171 (b) 0.0343 (c) 0.686 (d) 1.25

[Ans. (b)]

[Hint: $Mg(OH)_2 + 2HCl \longrightarrow MgCl_2 + 2H_2O$

Number of moles of stomach acid neutralized

$$= 2 \times \text{number of moles of } Mg(OH)_2$$

$$= 2 \times \frac{1}{58.33} = 0.0343]$$

3. When a mixture of 10 moles of SO_2 and 16 moles of O_2 were passed over a catalyst, 8 moles of SO_3 were formed at equilibrium. The number of moles of SO_2 and O_2 remaining unreacted were:

(a) 2, 12 (b) 12, 2 (c) 3, 10 (d) 10, 3

[Ans. (a)]

[Hint:

$$\begin{array}{lccccc} & 2SO_2(g) & + & O_2(g) & \rightleftharpoons & 2SO_3(g) \\ t = 0 & 10 & & 16 & & 0 \\ t_{eq.} & (10-2x) & & (16-x) & & 2x \end{array}$$

$$2x = 8, \quad i.e., \quad x = 4$$

$\therefore$ Remaining $SO_2 = 10 - 8 = 2$ mol

Remaining $O_2 = 16 - 4 = 12$ mol]

4. Calcium carbonate decomposes on heating according to the following equation:

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

How many moles of CO_2 will be obtained by decomposition of 50 g $CaCO_3$?

(a) $\frac{3}{2}$ (b) $\frac{5}{2}$ (c) $\frac{1}{2}$ (d) 1

[Ans. (c)]

[Hint:

Number of moles of CO_2 = Number of moles of $CaCO_3$

$$= \frac{\text{Mass}}{\text{Molar mass}} = \frac{50}{100} = \frac{1}{2}\ ]$$

5. Sulphur trioxide is prepared by the following two reactions:

$$S_8(s) + 8O_2(g) \longrightarrow 8SO_2(g)$$

$$2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$$

How many grams of SO_3 are produced from 1 mole of S_8?

(a) 1280 (b) 640 (c) 960 (d) 320

[Ans. (b)]

[Hint: From the given reaction, it is clear that 1 mole of S_8 will give 8 moles of SO_3.

Mass of SO_3 formed = Number of moles × Molar mass

$$= 8 \times 80 = 640 \text{ g}]$$

(ii) Calculations based on mass-mass relationship

In making necessary calculations, following steps are followed:

(a) Write down the balanced chemical equation.

(b) Write down the theoretical amount of reactants and products involved in the reaction.

(c) Calculate the unknown amount of substance using unitary method.

SOME SOLVED EXAMPLES

Example 2. *Calculate the mass of (CaO) that can be prepared by heating 200 kg of limestone $CaCO_3$ which is 95% pure.*

Solution: Amount of pure $CaCO_3 = \frac{95}{100} \times 200 = 190$ kg

$$= 190000 \text{ g}$$

$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

$$1 \text{ mole } CaCO_3 \equiv 1 \text{ mole } CaO$$

$$100 \text{ g } CaCO_3 \equiv 56 \text{ g } CaO$$

$\because$ 100 g $CaCO_3$ give 56 g CaO

$\therefore$ 190000 g $CaCO_3$ will give $\frac{56}{100} \times 190000$ g CaO

$$= 106400 \text{ g} = 106.4 \text{ kg}$$

Example 3. *Chlorine is prepared in the laboratory by treating manganese dioxide (MnO_2) with aqueous hydrochloric acid according to the reaction,*

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$$

How many grams of HCl will react with 5 g MnO_2?

Solution: 1 mole of MnO_2 reacts with 4 mole of HCl

or 87 g MnO_2 reacts with 146 g HCl

$\therefore$ 5 g MnO_2 will react with $\frac{146}{87} \times 5$ g HCl = 8.39 g HCl

Example 4. *How many grams of oxygen are required to burn completely 570 g of octane?*

Solution: Balanced equation,

$$\underset{\substack{2 \text{ mol} \\ 2 \times 114}}{2C_8H_{18}} + \underset{\substack{25 \text{ mol} \\ 25 \times 32}}{25O_2} \longrightarrow 16CO_2 + 18H_2O$$

First method: For burning 2 × 114 g of octane, oxygen required

$$= 25 \times 32 \text{ g}$$

For burning 1 g of octane, oxygen required $= \frac{25 \times 32}{2 \times 114}$ g

Thus, for burning 570 g of octane, oxygen required

$$= \frac{25 \times 32}{2 \times 114} \times 570 \text{ g} = 2000 \text{ g}$$

Mole method: Number of moles of octane in 570 grams

$$= \frac{570}{114} = 5.0$$

For burning 2.0 moles of octane, oxygen required

$$= 25 \text{ mol} = 25 \times 32 \text{ g}$$

For burning 5 moles of octane, oxygen required

$$= \frac{25 \times 32}{2.0} \times 5.0 \text{ g} = 2000 \text{ g}$$

Proportion method: Let x g of oxygen be required for burning 570.0 g of octane. It is known that 2 × 114 g of the octane require 25 × 32 g of oxygen; then, the proportion,

$$\frac{25\times 32\text{ g oxygen}}{2\times 114\text{ g octane}}=\frac{x}{570.0\text{ g octane}}$$

$$\therefore \qquad x=\frac{25\times 32\times 570}{2\times 114}=2000\text{ g}$$

Example 5. *Calculate the number of grams of magnesium chloride that could be obtained from 17.0 g of HCl when HCl is reacted with an excess of magnesium oxide.*

Solution: Balanced equation,

$$\underset{1\text{ mol}}{\text{MgO}}+\underset{\substack{2\text{ mol}\\(2\times 36.5)\text{g}\\=73\text{ g}}}{2\text{HCl}}\longrightarrow\underset{\substack{1\text{ mol}\\(24+71)\text{g}\\=95\text{ g}}}{\text{MgCl}_2}+\underset{1\text{ mol}}{\text{H}_2\text{O}}$$

$$73\text{ g of HCl produce MgCl}_2=95\text{ g}$$

$$1\text{ g of HCl produce MgCl}_2=\frac{95}{73}\text{ g}$$

$$17\text{ g of HCl will produce MgCl}_2=\frac{95}{73}\times 17\text{ g}=22.12\text{ g}$$

Example 6. *How many kilograms of pure H_2SO_4 could be obtained from 1 kg of iron pyrites (FeS_2) according to the following reactions?*

$$4FeS_2+11O_2\longrightarrow 2Fe_2O_3+8SO_2$$

$$2SO_2+O_2\longrightarrow 2SO_3$$

$$SO_3+H_2O\longrightarrow H_2SO_4$$

Solution: Final balanced equation,

$$\underset{\substack{4\text{ mol}\\4\times 120\text{g}}}{4\text{FeS}_2}+15\text{O}_2+8\text{H}_2\text{O}\longrightarrow 2\text{Fe}_2\text{O}_3+\underset{\substack{8\text{ mol}\\8\times 98\text{g}}}{8\text{H}_2\text{SO}_4}$$

$$4\times 120\text{ g of FeS}_2\text{ yield H}_2\text{SO}_4=8\times 98\text{ g}$$

$$1000\text{ g of FeS}_2\text{ will yield H}_2\text{SO}_4=\frac{8\times 98}{4\times 120}\times 1000$$

$$=1.63\text{ kg}$$

Limiting reagent: *Limiting reactant or reagent is the reactant that is entirely consumed when a reaction goes to completion.* Other reactants which are not completely consumed in the reaction are called excess reactants.

OR

The reactant which gives least amount of product on being completely consumed is called limiting reactant.

Example 7. *If 20 g of $CaCO_3$ is treated with 20 g of HCl, how many grams of CO_2 can be generated according to the following equation?*

$$CaCO_3(s)+2HCl(aq.)\longrightarrow CaCl_2(aq.)+H_2O(l)+CO_2(g)$$

Solution:

$$\underset{\substack{1\text{ mol}\\100\text{ g}}}{\text{CaCO}_3(s)}+\underset{\substack{2\text{ mol}\\73\text{g}}}{2\text{HCl}(aq.)}\longrightarrow\text{CaCl}_2(aq.)+\text{H}_2\text{O}(l)+\underset{\substack{1\text{ mol}\\44\text{g}}}{\text{CO}_2(g)}$$

Let $\text{CaCO}_3(s)$ be completely consumed in the reaction.

$$\because\ 100\text{ g CaCO}_3\text{ give }44\text{ g CO}_2$$

$$\therefore\ 20\text{ g CaCO}_3\text{ will give }\frac{44}{100}\times 20\text{ g CO}_2=8.8\text{ g CO}_2$$

Let HCl be completely consumed.

$$\because\ 73\text{ g HCl give }44\text{ g CO}_2$$

$$\therefore\ 20\text{ g HCl will give }\frac{44}{73}\times 20\text{ g CO}_2=12.054\text{ g CO}_2$$

Since, CaCO_3 gives least amount of product CO_2, hence, CaCO_3 is limiting reactant. Amount of CO_2 formed will be 8.8 g.

Example 8. *100 g sample of calcium carbonate is reacted with 70 g of orthophosphoric acid. Calculate:*

(*a*) *the number of grams of calcium phosphate that could be produced.*

(*b*) *the number of grams of excess reagent that will remain unreacted.*

Solution: (a) The balanced equation is:

$$\underset{\substack{3\text{ mol}\\3(40+12+48)\\=300\text{ g}}}{3\text{CaCO}_3}+\underset{\substack{2\text{ mol}\\2(3+31+64)\\=196\text{ g}}}{2\text{H}_3\text{PO}_4}\longrightarrow\underset{\substack{1\text{ mol}\\(3\times 40+2\times 95)\\=310\text{ g}}}{\text{Ca}_3(\text{PO}_4)_2}+3\text{CO}_2+3\text{H}_2\text{O}$$

$$300\text{ g of CaCO}_3\text{ produce Ca}_3(\text{PO}_4)_2=310\text{ g or 1 mol}$$

100 g of CaCO_3 would produce

$$\text{Ca}_3(\text{PO}_4)_2=\frac{310}{300}\times 100$$

$$=103\text{ g}$$

$$=0.33\text{ mol}$$

$$196\text{ g of H}_3\text{PO}_4\text{ produce Ca}_3(\text{PO}_4)_2=310\text{ g or 1 mol}$$

$$70\text{ g of H}_3\text{PO}_4\text{ would produce Ca}_3(\text{PO}_4)_2=\frac{310}{196}\times 70$$

$$=110.7\text{ g or 0.356 mol}$$

The above values suggest that CaCO_3 is the limiting reagent. Hence, calcium phosphate formed is 103 g or 0.33 mole.

(b) For producing 103 g of $\text{Ca}_3(\text{PO}_4)_2$, H_3PO_4 required will be

$$=\frac{196}{310}\times 103=65.12\text{ g}$$

$$\text{Mass of remaining H}_3\text{PO}_4=(70-65.12)=4.88\text{ g}$$

Example 9. *1 g of Mg is burnt in a closed vessel which contains 0.5 g of O_2:*

(*i*) *Which reactant is left in excess?*

(*ii*) *Find the mass of the excess reactant.*

Solution: (i) The balanced equation is:

$$\underset{\substack{2\times 24\\=48\text{ g}}}{2\text{Mg}}+\underset{\substack{2\times 16\\=32\text{ g}}}{\text{O}_2}\longrightarrow\underset{\substack{2(24+16)\\=80\text{ g}}}{2\text{MgO}}$$

$$48\text{ g of Mg require oxygen}=32\text{ g}$$

1 g of Mg requires oxygen $= \frac{32}{48} = 0.66$ g

But only 0.5 g oxygen is available. Hence, O_2 is a limiting agent and a part of magnesium will not burn.

$\therefore$ Magnesium will be left in excess.

(ii) 32 g of O_2 react with magnesium = 48 g

0.5 g of O_2 will react with magnesium $= \frac{48}{32} \times 0.5 = 0.75$ g

Hence, the mass of excess magnesium

$$= (1.0 - 0.75) = 0.25 \text{ g}$$

Example 10. *The reaction,*

$$2C(s) + O_2(g) \longrightarrow 2CO(g)$$

is carried out by taking 24 g of carbon and 96 g O_2. Find out:

(*a*) *Which reactant is left in excess?*

(*b*) *How much of it is left?*

(*c*) *How many moles of CO are formed?*

(*d*) *How many grams of other reactant should be taken so that nothing is left at the end of the reaction?*

Solution: $\underset{\substack{2\text{ mol}\\24\text{ g}}}{2C(s)} + \underset{\substack{1\text{ mol}\\32\text{ g}}}{O_2(g)} \longrightarrow \underset{\substack{2\text{ mol}\\56\text{ g}}}{2CO(g)}$

Let carbon be completely consumed.

24 g carbon give 56 g CO

Let O_2 is completely consumed.

$\because$ 32 g O_2 give 56 g CO

$\therefore$ 96 g O_2 will give $\frac{56}{32} \times 96$ g CO = 168 g CO

Since, carbon gives least amount of product, *i.e.*, 56 g CO or 2 mole CO, hence carbon will be the limiting reactant.

$\therefore$ Excess reactant is O_2.

Amount of O_2 used = 56 − 24 = 32 g

Amount of O_2 left = 96 − 32 = 64 g

32 g O_2 react with 24 g carbon

$\therefore$ 96 g O_2 will react with 72 g carbon.

Thus, carbon should be taken 72 g so that nothing is left at the end of the reaction.

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

6. 0.5 mole $BaCl_2$ is mixed with 0.2 mole Na_3PO_4; the maximum number of moles of $Ba_3(PO_4)_2$ that can be formed is:

(a) 0.7 (b) 0.5 (c) 0.2 (d) 0.1

[**Ans.** (d)]

[**Hint:** $3BaCl_2 + 2Na_3PO_4 \longrightarrow Ba_3(PO_4)_2 + 6NaCl$

Number of moles of $Ba_3(PO_4)_2$ formed by $BaCl_2$

$$= \frac{1}{3} \times 0.5 = 0.166$$

Number of moles of $Ba_3(PO_4)_2$ formed by 0.2 mole Na_3PO_4

$$= \frac{1}{2} \times 0.2 = 0.1$$

Thus, Na_3PO_4 will be limiting and actual amount of product will be 0.1 mole.]

7. In the following reaction:

$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(l)$$

when 1 mole ammonia and 1 mole of O_2 are mixed, then the number of moles of NO formed will be:

(a) 0.8 (b) 0.7 (c) 0.6 (d) 0.5

[**Ans.** (a)]

[**Hint:** 1 mole of NH_3 (on complete reaction) gives 1 mole NO. Similarly, 1 mole of O_2 (on complete reaction) gives $\frac{4}{5}$, *i.e.*, 0.8 mole NO. Thus, O_2 will be limiting reactant and actual amount of NO formed in the reaction will be 0.8 mole.]

8. 30 g Mg and 30 g O_2 are reacted and the residual mixture contains:

(a) 60 g of MgO only

(b) 40 g of MgO and 20 g of O_2

(c) 45 g of MgO and 15 g of O_2

(d) 50 g of MgO and 10 g of O_2

[**Ans.** (d)]

[**Hint:** $\underset{\substack{2\text{ mol}\\2\times24\text{ g}}}{2Mg(s)} + \underset{\substack{1\text{ mol}\\1\times32\text{ g}}}{O_2(g)} \longrightarrow \underset{\substack{2\text{ mol}\\2\times40\text{ g}}}{2MgO(g)}$

30 g Mg gives $\left(\frac{80}{48} \times 30\right)$ g MgO on complete reaction,

i.e., 30 g Mg ≡ 50 g MgO

30 g O_2 gives $\left(\frac{80}{32} \times 30\right)$ g MgO on complete reaction,

i.e., 30 g O_2 ≡ 75 g MgO

$\therefore$ Mg is limiting reactant and MgO formed in the reaction will be 50 g.

Unreacted amount of O_2 = 30 − 20 = 10 g

$\therefore$ Mixture contains 50 g MgO and 10 g O_2.]

9. 254 g of iodine and 142 g of chlorine are made to react completely to give a mixture of ICl and ICl_3. How many moles of each are formed?

(a) 0.1 mole of ICl and 0.1 mole of ICl_3

(b) 1 mole of ICl and 1 mole of ICl_3

(c) 0.5 mole of ICl and 0.1 mole of ICl_3

(d) 0.5 mole of ICl and 1 mole of ICl_3

[**Ans.** (b)]

[**Hint:** Both reactants are completely consumed, hence, both are limiting.

$$I_2 + 2Cl_2 \longrightarrow ICl + ICl_3$$

254 g or 1 mole I_2 and 142 g or 2 mole Cl_2 will react to give 1 mole ICl and 1 mole ICl_3.]

10. Magnesium hydroxide, $Mg(OH)_2$ is the white milky substance in milk of magnesia. What mass of $Mg(OH)_2$ is formed when 15 mL of 0.18 *M* NaOH are combined with 12 mL of 0.14 *M* $MgCl_2$? The molar mass of $Mg(OH)_2$ is 58.3 g mol^{-1}.

(a) 0.079 g (b) 0.097 g (c) 0.16 g (d) 0.31 g

[**Ans.** (a)]

[**Hint:**
$$n_{MgCl_2} = \frac{MV}{1000} = \frac{12 \times 0.14}{1000} = 1.68 \times 10^{-3}$$
$$n_{NaOH} = \frac{15 \times 0.18}{1000} = 2.7 \times 10^{-3}$$

NaOH will be limiting reagent because on complete consumption, NaOH gives least amount of $Mg(OH)_2$.

$$\text{Mass of } Mg(OH)_2 = \frac{1}{2} \times 2.7 \times 10^{-3} \times 58.3 = 0.079 \text{ g}]$$

Calculations involving per cent yield

In general, when a reaction is carried out in the laboratory we do not obtain actually the theoretical amount of the product. The amount of the product that is actually obtained is called the actual yield. Knowing the actual yield and theoretical yield the per cent yield can be calculated by the given formula:

$$\text{Per cent yield} = \frac{\text{Actual yield}}{\text{Theoretical yield}} \times 100$$

Example 11. *For the reaction,*

$$CaO + 2HCl \longrightarrow CaCl_2 + H_2O$$

1.23 g of CaO is reacted with excess of hydrochloric acid and 1.85 g of $CaCl_2$ is formed. What is the per cent yield?

Solution: The balanced equation is:

$$\underset{\substack{1\text{ mol}\\56\text{ g}}}{CaO} + 2HCl \longrightarrow \underset{\substack{1\text{ mol}\\111\text{ g}}}{CaCl_2} + H_2O$$

$$56 \text{ g of CaO produce } CaCl_2 = 111 \text{ g}$$
$$1.23 \text{ g of CaO produce } CaCl_2 = \frac{111}{56} \times 1.23 = 2.43 \text{ g}$$

Thus, Theoretical yield = 2.43 g

Actual yield = 1.85 g

$$\text{Per cent yield} = \frac{1.85}{2.43} \times 100 = 76.1$$

Calculations involving per cent purity

Depending upon the mass of the product, the equivalent amount of the reactant present can be determined with the help of a chemical equation. Knowing the actual amount of the reactant taken and the amount calculated with the help of a chemical equation the percentage purity can be determined.

Example 12. *Chlorine evolved by the reaction of 45.31 g of pyrolusite (impure) and excess of HCl is found to combine completely with the hydrogen produced by the reaction of 10 g of magnesium and excess of dilute hydrochloric acid. Find the percentage of purity of MnO_2 in the given pyrolusite.*

Solution:
$$\underset{24\text{ g}}{Mg} + \underset{(2\times 36.5)\text{ g}}{2HCl} \longrightarrow MgCl_2 + \underset{2\text{ g}}{H_2}$$
$$\underset{87\text{ g}}{MnO_2} + 4HCl \longrightarrow MnCl_2 + \underset{71\text{ g}}{Cl_2} + 2H_2O$$
$$\underset{2\text{ g}}{H_2} + \underset{71\text{ g}}{Cl_2} \longrightarrow 2HCl$$

2 g of hydrogen obtained by using 24 g of Mg will combine completely with 71 g of chlorine produced from 87 g of pure MnO_2.

Thus, when 10 g of Mg are used,

$$\text{the mass of the pure } MnO_2 \text{ required is} = \frac{87}{24} \times 10 = 36.25 \text{ g}$$

So, 45.31 g of pyrolusite contain MnO_2 (pure) = 36.25 g

$\therefore$ 100 g of pyrolusite contain MnO_2 (pure)

$$= \frac{36.25}{45.31} \times 100 = 80.00 \text{ g}$$

$\therefore$ Percentage of purity = 80.00

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

11.
$$\underset{\substack{\text{Salicylic acid}\\(138.12\text{ g mol}^{-1})}}{C_7H_6O_3} + \underset{\substack{\text{Acetic anhydride}\\(102.09\text{ g mol}^{-1})}}{C_4H_6O_3} \longrightarrow \underset{\substack{\text{Aspirin}\\(180.15\text{ g mol}^{-1})}}{C_9H_8O_4} + \underset{\substack{\text{Acetic acid}\\(60.05\text{ g mol}^{-1})}}{C_2H_4O_2}$$

What is the percentage yield if 0.85 g of aspirin formed in the reaction of 1 g of salicylic acid with excess of acetic anhydride?

(a) 65% (b) 77% (c) 85% (d) 91%

[**Ans.** (a)]

[**Hint:** Mass of aspirin (theoretical) formed from 1 g salicylic acid $= \frac{180.15}{138.12} = 1.304$g

$$\% \text{ yield} = \frac{\text{Actual amount of product}}{\text{Theoretical amount of product}} \times 100$$
$$= \frac{0.85}{1.304} \times 100 \approx 65\%]$$

12. A sample of impure silver (1.5 g) is heated with sulphur to form Ag_2S. The mass of Ag_2S formed was 0.124 g. What was the percentage yield of silver sulphide?

(a) 6.41% (b) 7.20% (c) 8.27% (d) 10.8%

[**Ans.** (b)]

[**Hint:**
$$\underset{\substack{2\text{ mol}\\2\times 108 = 216\text{ g}}}{2Ag} + S \longrightarrow \underset{\substack{1\text{ mol}\\248\text{ g}}}{Ag_2S}$$

Amount of Ag_2S that can be formed from 1.5 g silver

$$= \frac{248}{216} \times 1.5 = 1.722 \text{ g}$$
$$\% \text{ yield of } Ag_2S = \frac{0.124}{1.722} \times 100 = 7.2\,]$$

13. Magnetite, Fe_3O_4, can be converted into metallic iron by heating with carbon monoxide as represented by this equation:

$$Fe_3O_4 + 4CO \longrightarrow 3Fe + 4CO_2$$

How many kilogram of Fe_3O_4 must be processed in this way to obtain 5 kg iron; if the process is 85% efficient? (Molar mass of Fe_3O_4 is 232 g mol^{-1}.)

(a) 6.92 kg (b) 8.12 kg (c) 20.8 kg (d) 24.4 kg

[**Ans.** (b)]

[**Hint:** 1 mole Fe_3O_4 (232 g) = 3 mole Fe (168 g)

$$\text{Amount of } Fe_3O_4 \text{ required for 5 kg iron} = \frac{232}{168} \times 5 \text{ kg}$$
$$= 6.904 \text{ kg}$$

Since, efficiency of the reaction is 85%, hence, the actual required amount of Fe_3O_4 will be

$$= \frac{100 \times 6.904}{85} \text{ kg, } i.e., = 8.12 \text{ kg}]$$

14. Iodobenzene is prepared from aniline ($C_6H_5NH_2$) in a two step process as shown here:

$$C_6H_5NH_2 + HNO_2 + HCl \longrightarrow C_6H_5N_2^+Cl^- + 2H_2O$$

$$C_6H_5N_2^+Cl^- + KI \longrightarrow C_6H_5I + N_2 + KCl$$

In an actual preparation, 9.30 g of aniline was converted to 12.32 g of iodobenzene. The percentage yield of iodobenzene is:

(a) 8% (b) 50%
(c) 75% (d) 80%

[Ans. (d)]

[Hint: 1 mole of $C_6H_5NH_2$ (123 g) ≡ 1 mole of C_6H_5I (204 g)

$\therefore$ 9.3 g aniline will give $= \left(\frac{204}{123} \times 9.3\right)$ g iodobenzene

$= 15.424$ g iodobenzene

$$\% \text{ yield} = \frac{\text{Actual amount of product}}{\text{Calculated amount of product}} \times 100$$

$$= \frac{12.32}{15.424} \times 100 \approx 80\%]$$

15. Benzamide can be prepared by the action of concentrated ammonia upon benzoyl chloride.

$$\underset{\text{Benzoyl chloride}}{C_6H_5COCl} + 2NH_3 \longrightarrow \underset{\text{Benzamide}}{C_6H_5CONH_2} + NH_4Cl$$

In one such experiment, 65 cc of concentrated ammonia (in excess) was reacted with 15 g of benzoyl chloride to give 11.1 g of pure benzamide. Molar masses: benzoyl chloride (141); benzamide (121). The percentage yield of benzamide is:

(a) $\frac{11.1}{15} \times 100$ (b) $\frac{(15 - 11.1)}{15} \times 100$
(c) $\frac{11.1}{65} \times 100$ (d) $\frac{121}{141} \times 100$
(e) $\frac{11.1 \times 141}{121 \times 15} \times 100$

[Ans. (e)]

[Hint: Amount of benzamide from 15 g benzoyl chloride $= \frac{121}{141} \times 15$ g

Actual amount of benzamide formed = 11.1 g

$$\% \text{ yield} = \frac{\text{Actual amount of product}}{\text{Calculated amount of product}} \times 100$$

$$= \frac{11.1 \times 100}{\left(\frac{121}{141} \times 15\right)} = \frac{11.1 \times 141}{121 \times 15} \times 100]$$

Analysis of mixtures: In such problems, one of the components is supposed to be x g and the other will be the difference from the total. Balanced chemical equations for the reactions of both the components are now written and the total amount of the common product produced by the components of the mixture is calculated. It is equated with the data given and the unknown factors are, thus, worked out.

SOME SOLVED EXAMPLES

Example 13. *A solid mixture (5.0 g) consisting of lead nitrate and sodium nitrate was heated below 600°C until the mass of the residue was constant. If the loss in mass is 28.0 per cent, find the amount of lead nitrate and sodium nitrate in the mixture.* (IIT 1990)

Solution: Let the amount of $NaNO_3$ in the mixture be $= x$ g

$\therefore$ The amount of $Pb(NO_3)_2$ in the mixture $= (5.0 - x)$ g

$$\underset{(2 \times 85)\text{ g}}{2NaNO_3} \xrightarrow{\text{Heat}} 2NaNO_2 + \underset{32\text{ g}}{O_2}$$

$$\underset{\substack{(2 \times 331)\text{ g} \\ 662\text{ g}}}{2Pb(NO_3)_2} \xrightarrow{\text{Heat}} 2PbO + \underbrace{\underset{(4 \times 46)\text{ g}}{4NO_2} + \underset{32\text{ g}}{O_2}}_{216\text{ g}}$$

170 g of $NaNO_3$ evolve oxygen = 32 g

x g of $NaNO_3$ evolve oxygen $= \frac{32}{170} \times x$ g

662 g of $Pb(NO_3)_2$ evolve gases = 216 g

$(50 - x)$ g of $Pb(NO_3)_2$ evolve gases $= \frac{216}{662} \times (5.0 - x)$ g

$$\text{Total loss} = \frac{32}{170} \times x + \frac{216}{662} \times (5.0 - x)$$

$$\text{Loss given in the problem} = \frac{28}{100} \times 5 = 1.4 \text{ g}$$

$$\therefore \quad \frac{32}{170}x + \frac{216}{662}(5.0 - x) = 1.4$$

On solving, $x = 1.676$ g

Thus, Mass of $NaNO_3$ = 1.676 g

Mass of $Pb(NO_3)_2 = (5.0 - 1.676)$ g $= 3.324$ g

Example 14. *3.68 g of a mixture of calcium carbonate and magnesium carbonate when heated strongly leaves 1.92 g of a white residue. Find the percentage composition of the mixture.*

Solution: Let x g of $CaCO_3$ be present in the mixture.

The mass of $MgCO_3$ in the mixture $= (3.68 - x)$ g.

$$\underset{100\text{ g}}{CaCO_3} \xrightarrow{\text{Heat}} \underset{56\text{ g}}{CaO} + CO_2$$

$$\underset{84\text{ g}}{MgCO_3} \xrightarrow{\text{Heat}} \underset{40\text{ g}}{MgO} + CO_2$$

$$\therefore \quad \frac{56 \times x}{100} + \frac{40 \times (3.68 - x)}{84} = 1.92$$

On solving, $x = 2$

$$\text{Percentage of } CaCO_3 = \frac{2}{3.68} \times 100 = 54.35\%$$

$$\text{Percentage of } MgCO_3 = 100 - 54.35 = 45.65\%$$

Example 15. *0.5 g of a mixture of K_2CO_3 and Li_2CO_3 required 30 mL of 0.25 N HCl solution for neutralization. What is the percentage composition of the mixture?*

Solution: Let the amount of K_2CO_3 be 'x' g.

$$\therefore \quad \text{Amount of } Li_2CO_3 = (0.5 - x)\text{ g}$$

$$\text{Number of equivalents} = \frac{x}{138/2} + \frac{(0.5-x)}{74/2} \qquad \ldots\text{(i)}$$

Number of equivalents of HCl used

$$= \frac{NV}{1000} = \frac{0.25 \times 30}{1000} = 7.5 \times 10^{-3} \qquad \ldots\text{(ii)}$$

Comparing eqs. (i) and (ii), we get

$$x = 0.48\text{ g}$$

$$\therefore \quad \text{Mass of } K_2CO_3 = 0.48\text{ g}$$

$$\text{Mass of } Li_2CO_3 = 0.02\text{ g}$$

$$\%\, K_2CO_3 = \frac{0.48}{0.5} \times 100 = 96$$

$$\%\, Li_2CO_3 = \frac{0.02}{0.5} \times 100 = 4$$

(iii) Calculations based on mass-volume relationship

In such calculations, masses of reactants are given and volume of the product is required and *vice-versa.*

1 mole of a gas occupies 22.4 litre volume at STP mass of a gas can be related to volume according to the following gas equation:

$$PV = nRT$$

$$PV = \frac{w}{m} RT$$

Example 16. *What volume of $NH_3(g)$ at 27° C and 1 atm pressure will be obtained by thermal decomposition of 26.25 g NH_4Cl?*

Solution: Ammonium chloride undergoes decomposition as;

$$\underset{\substack{1\text{ mol}\\53.5\text{ g}}}{NH_4Cl(s)} \longrightarrow \underset{\substack{1\text{ mol}\\1\text{ mol}}}{NH_3(g)} + HCl(g)$$

$\because$ 53.5 g NH_4Cl give 1 mol NH_3

$\therefore$ 26.25 g NH_4Cl will give $\frac{1}{53.5} \times 26.25$ mole NH_3

$$= 0.5\text{ mole}$$

$$PV = nRT$$

$$1 \times V = 0.5 \times 0.0821 \times 300$$

$$V = 12.315\text{ litre}$$

Example 17. *What quantity of copper(II) oxide will react with 2.80 litre of hydrogen at NTP?*

Solution: The balanced equation is:

$$\underset{\substack{1\text{ mol}\\79.5\text{ g}}}{CuO} + \underset{\substack{1\text{ mol}\\22.4\text{ litre at NTP}}}{H_2} \longrightarrow Cu + H_2O$$

22.4 litre of hydrogen at NTP reduce CuO = 79.5 g

2.80 litre of hydrogen at NTP will reduce CuO

$$= \frac{79.5}{22.4} \times 2.80\text{ g} = 9.95\text{ g}$$

Example 18. *Calculate the volume of carbon dioxide at NTP evolved by strong heating of 20 g calcium carbonate.*

Solution: The balanced equation is:

$$\underset{\substack{1\text{ mol}\\100\text{ g}}}{CaCO_3} \longrightarrow CaO + \underset{\substack{1\text{ mol}\\= 22.4\text{ litre at NTP}}}{CO_2}$$

100 g of $CaCO_3$ evolve carbon dioxide = 22.4 litre

20 g $CaCO_3$ will evolve carbon dioxide

$$= \frac{22.4}{100} \times 20 = 4.48\text{ litre}$$

Example 19. *Calculate the volume of hydrogen liberated at 27° C and 760 mm pressure by treating 1.2 g of magnesium with excess of hydrochloric acid.*

Solution: The balanced equation is:

$$\underset{\substack{1\text{ mol}\\24\text{ g}}}{Mg} + 2HCl \longrightarrow MgCl_2 + \underset{\substack{1\text{ mol}\\22.4\text{ litre at NTP}}}{H_2}$$

24 g of Mg liberate hydrogen = 22.4 litre

1.2 g Mg will liberate hydrogen $= \frac{22.4}{24} \times 1.2 = 1.12$ litre

Volume of hydrogen under given condition can be calculated by applying

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$

$P_1 = 760$ mm $\qquad P_2 = 760$ mm

$T_1 = 273$ K $\qquad T_2 = (27 + 273) = 300$ K

$V_1 = 1.12$ litre $\qquad V_2 = ?$

$$V_2 = \frac{760 \times 1.12}{273} \times \frac{300}{760} = 1.2308\text{ litre}$$

Example 20. *A solid mixture (5 g) consisting of lead nitrate and sodium nitrate was heated below 600° C until the weight of the residue is constant. If the loss in weight is 28%, find the amount of lead nitrate and sodium nitrate in the mixture.*

(IIT 1990)

Solution: Loss in weight is due to formation of NO_2 and O_2 gases (weight loss $= \frac{5}{100} \times 28 = 1.4$ g).

$$\underset{x\text{ g}}{Pb(NO_3)_2} \longrightarrow \underset{(x-y)\text{ g}}{PbO} + \underbrace{NO_2 + O_2}_{y\text{ g}}$$

$$\underset{(5-x)}{NaNO_3} \longrightarrow \underset{(3.6-x+y)}{NaNO_2} + \underset{(1.4-y)}{\tfrac{1}{2}O_2}$$

Number of moles of $Pb(NO_3)_2$ = Number of moles of PbO

$$\frac{x}{331} = \frac{(x-y)}{223} \qquad \ldots(i)$$

∵ M.w. $Pb(NO_3)_2 = 331$, M.w. $PbO = 223$

Number of moles of $NaNO_3$ = Number of moles of $NaNO_2$

$$\frac{5-x}{85} = \frac{3.6-x+y}{69} \qquad \ldots(ii)$$

Solving eqs. (i) and (ii), we get

$$\text{Mass of } Pb(NO_3)_2 = x = 3.3246 \text{ g}$$

$$\text{Mass of } NaNO_3 = 5 - 3.3246 = 1.6754 \text{ g}$$

(iv) Calculations based on volume-volume relationship

These calculations are based on two laws:

(i) Avogadro's law (ii) Gay-Lussac's law

For example:

$$\underset{\substack{1\text{ mol}\\ 1\times 22.4\text{ L}}}{N_2(g)} + \underset{\substack{3\text{ mol}\\ 3\times 22.4\text{ L}}}{3H_2(g)} \longrightarrow \underset{\substack{2\text{ mol}\\ 2\times 22.4\text{ L}}}{2NH_3(g)} \quad \text{(Avogadro's law)}$$

(under similar conditions of temperature and pressure, equal moles of gases occupy equal volumes)

$$\underset{1\text{ vol.}}{N_2(g)} + \underset{3\text{ vol.}}{3H_2(g)} \longrightarrow \underset{2\text{ vol.}}{2NH_3(g)}$$

under similar conditions, ratio of coefficients by mole is equal to ratio of coefficient by volume.

Example 21. *1 litre mixture of CO and CO_2 is taken. This is passed through a tube containing red hot charcoal. The volume now becomes 1.6 litre. The volumes are measured under the same conditions. Find the composition of mixture by volume.*

Solution: Let there be x mL CO in the mixture, hence, there will be $(1000-x)$ mL CO_2. The reaction of CO_2 with red hot charcoal may be given as,

$$\underset{\substack{1\text{ vol.}\\ (1000-x)}}{CO_2(g)} + C(s) \longrightarrow \underset{\substack{2\text{ vol.}\\ 2(1000-x)}}{2CO(g)}$$

Total volume of the gas becomes $= x + 2(1000-x)$

$$x + 2000 - 2x = 1600$$

$$x = 400 \text{ mL}$$

∴ Volume of CO = 400 mL and volume of CO_2 = 600 mL

Example 22. *What volume of air containing 21% oxygen by volume is required to completely burn 1 kg of carbon containing 100% combustible substances?*

Solution: Combustion of carbon may be given as,

$$\underset{\substack{1\text{ mol}\\ 12\text{ g}}}{C(s)} + \underset{\substack{1\text{ mol}\\ 1\text{ mol}}}{O_2(g)} \longrightarrow CO_2(g)$$

∵ 12 g carbon requires 1 mole O_2 for complete combustion

∴ 1000 g carbon will require $\frac{1}{12} \times 1000$ mole O_2 for combustion, *i.e.*, 83.33 mole O_2

Volume of O_2 at NTP $= 83.33 \times 22.4$ litre $= 1866.592$ litre

∵ 21 litre O_2 is present in 100 litre air

∴ 1866.592 litre O_2 will be present in $\frac{100}{21} \times 1866.592$ litre O_2

$$= 8888.5 \text{ litre} = 8.8885 \times 10^3 \text{ litre}$$

Example 23. *What volume of oxygen gas at NTP is necessary for complete combustion of 20 litre of propane measured at 27° C and 760 mm pressure?*

Solution: The balanced equation is:

$$\underset{\substack{1\text{ vol.}\\ 1\text{ litre}}}{C_3H_8} + \underset{\substack{5\text{ vol.}\\ 5\text{ litre}}}{5O_2} \longrightarrow 3CO_2 + 4H_2O$$

1 litre of propane requires = 5 litre of oxygen

20 litre of propane will require $= 5 \times 20 = 100$ litre of oxygen at 760 mm pressure and 27° C.

This volume will be converted to NTP conditions.

Given conditions	NTP conditions
$P_1 = 760$ mm	$P_2 = 760$ mm
$V_1 = 100$ litre	$V_2 = ?$
$T_1 = 27 + 273 = 300$ K	$T_2 = 273$

Applying $\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$

$$V_2 = \frac{P_1V_1}{T_1} \times \frac{T_2}{P_2}$$

$$= \frac{760 \times 100}{300} \times \frac{273}{760} = 91.0 \text{ litre}$$

Example 24. *One litre of oxygen at NTP is allowed to react with three times of carbon monoxide at NTP. Calculate the volume of each gas found after the reaction.*

Solution: The desired equation is:

$$\underset{2\text{ vol.}}{2CO} + \underset{1\text{ vol.}}{O_2} \longrightarrow \underset{2\text{ vol.}}{2CO_2}$$

1 vol. of O_2 reacts with 2 vol. of CO

or 1 litre of O_2 reacts with 2 litre of CO

Thus, 1 litre of CO remains unreacted.

1 vol. of O_2 produces CO_2 = 2 vol.

or 1 litre of O_2 will produce CO_2 = 2 litre

Thus, gaseous mixture after the reaction consists

Volume of CO = 1 litre

Volume of CO_2 = 2 litre

ILLUSTRATIONS OF OBJECTIVE QUESTIONS

16. 10 litre of O_2 gas is reacted with 30 litre of CO gas at STP. The volumes of each gas present at the end of reaction are: **[CMC (Vellore) 2008]**

(a) CO (10 litre), CO_2 (20 litre)
(b) O_2 (10 litre), CO (30 litre)
(c) CO (20 litre), CO_2 (10 litre)
(d) O_2 (10 litre), CO_2 (20 litre)
(e) O_2 (10 litre), CO (10 litre)

[**Ans.** (a)]

[**Hint:**
$$\begin{array}{lccc} & CO(g) & +\ \frac{1}{2}O_2(g) \longrightarrow & CO_2(g) \\ t=0 & 30\ L & 10\ L & 0 \\ \text{After reaction} & (30-20)L & 0 & 20\ L] \end{array}$$

17. When 10 g of 90% pure limestone is heated, the volume of CO_2 (in litre) liberated at STP is: **[JEE (WB) 2007]**

(a) 22.4 litre (b) 2.24 litre
(c) 20.16 litre (d) 2.016 litre

[**Ans.** (d)]

[**Hint:** Mass of $CaCO_3$ in the sample $= 10 \times \frac{90}{100} = 9$ g

$$\begin{array}{ccc} CaCO_3(s) \longrightarrow & CaO(s) + & CO_2(g) \\ 1\ \text{mol} & & 1\ \text{mol} \\ 100\ \text{g} & & 22.4\ \text{L} \end{array}$$

9 gm $CaCO_3$ will give $\left(\frac{22.4}{100} \times 9\right)$ litre of CO_2, *i.e.*, 2.016 litre of CO_2 .]

18. 100 mL of PH_3 on heating forms P_4 and H_2, volume changes in the reaction is: **(DPMT 2009)**

(a) an increase of 50 mL (b) an increase of 100 mL
(c) an increase of 150 mL (d) a decrease of 50 mL

[**Ans.** (a)]

[**Hint:** $\underset{\substack{4\ \text{mol} \\ 4\ \text{mL}}}{4PH_3(g)} \longrightarrow P_4(s) + \underset{\substack{6\ \text{mol} \\ 6\ \text{mL}}}{6H_2(g)}$

volume of H_2 produced by 100 mL PH_3 $= \frac{6}{4} \times 100 = 150$ mL

Thus, there is increase of 50 mL.]

MISCELLANEOUS NUMERICAL EXAMPLES

Example 1. *Calculate the weight of CaO required to remove the hardness of* 1000000 *litre of water containing* 1.62 g *of* $CaCO_3$ *per litre.*

Solution: Mass of $Ca(HCO_3)_2$ in the water

$$= 1.62 \times 1000000$$
$$= 1620000\ \text{g} = 1620\ \text{kg}$$

Reaction involved in the removal of hardness may be given as,

$$\underset{162\ \text{kg}}{Ca(HCO_3)_2} + \underset{56\ \text{kg}}{CaO} \longrightarrow 2CaCO_3 + H_2O$$

∵ 162 kg $Ca(HCO_3)_2$ require 56 kg CaO.

∴ 1620 kg $Ca(HCO_3)_2$ will require 560 kg CaO.

Example 2. *A mixture in which the mole ratio of* H_2 *and* O_2 *is* 2 : 1 *is used to prepare water by the reaction,*

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

The total pressure in the container is 0.8 *atm at* 20° C *before the reaction. Determine the final pressure at* 120° C *after reaction assuming* 80% *yield of water.* **(IIT 1999)**

Solution: $p_{H_2} = \frac{2}{3} \times 0.8 = 0.533$ atm

$$p_{O_2} = \frac{1}{3} \times 0.8 = 0.266\ \text{atm}$$

$$\begin{array}{lccc} & 2H_2\quad + & O_2 \quad\longrightarrow & 2H_2O \\ t=0 & 0.533 & 0.266 & 0 \\ \text{After the reaction} & \frac{0.533 \times 20}{100} & \frac{0.266 \times 20}{100} & \frac{0.533 \times 80}{100} \\ & = 0.1066 & = 0.0533 & = 0.4264 \end{array}$$

Total pressure $= 0.1066 + 0.0533 + 0.4264 = 0.5863$ atm

Using Gay-Lussac's law, $\frac{P_1}{T_1} = \frac{P_2}{T_2}$

$$\frac{0.5863}{293} = \frac{P_2}{393}$$
$$P_2 = 0.7864\ \text{atm}$$

Example 3. *An impure sample of calcium carbonate contains* 80% *pure calcium carbonate.* 25 g *of the impure sample reacted with excess of hydrochloric acid. Calculate the volume of carbon dioxide at NTP obtained from this sample.*

Solution: 100 g of impure calcium carbonate contain

$$= 80\ \text{g pure calcium carbonate}$$

25 g of impure calcium carbonate sample contain

$$= \frac{80}{100} \times 25$$
$$= 20\ \text{g pure calcium carbonate}$$

The desired equation is:

$$\underset{\substack{1\ \text{mol} \\ 100\ \text{g}}}{CaCO_3} + 2HCl \longrightarrow CaCl_2 + \underset{\substack{22.4\ \text{litre} \\ \text{at NTP}}}{CO_2} + H_2O$$

100 g pure $CaCO_3$ liberate = 22.4 litre CO_2

20 g pure $CaCO_3$ liberate $= \frac{22.4}{100} \times 20$

$$= 4.48\ \text{litre } CO_2$$

Example 4. *The weight of* 1 *litre sample of ozonised oxygen at NTP was found to be* 1.5 g. *When* 100 mL *of this mixture at NTP were treated with turpentine oil, the volume was reduced to* 90 mL. *Hence, calculate the molecular weight of ozone.*

Solution: Volume of ozone

= volume absorbed in turpentine oil
= 10 mL

Volume of oxygen = 90 mL

Mass of 100 mL mixture $= \frac{10}{22400} \times M + \frac{90}{22400} \times 32 = 0.15$

On solving, we get $M = 48$

∴ Molecular mass of ozone = 48

Example 5. *A mixture of $NaHCO_3$ and Na_2CO_3 weighed 1.0235 g. The dissolved mixture was reacted with excess of $Ba(OH)_2$ to form 2.1028 g $BaCO_3$, by the following reactions:*

$$Na_2CO_3 + Ba(OH)_2 \longrightarrow BaCO_3 + 2NaOH$$

$$NaHCO_3 + Ba(OH)_2 \longrightarrow BaCO_3 + NaOH + H_2O$$

What was the percentage of $NaHCO_3$ in the original mixture?

Solution: Let x g of $NaHCO_3$ be present in the mixture.

Mass of Na_2CO_3 in the mixture $= (1.0235 - x)$ g

$$\text{Number of moles of } NaHCO_3 = \frac{x}{84}$$

$$\text{Number of moles of } Na_2CO_3 = \frac{(1.0235 - x)}{106}$$

Number of moles of $BaCO_3$

$$= \text{Number of moles of } NaHCO_3 + \text{Number of moles of } Na_2CO_3$$

$$\frac{2.1028}{197} = \frac{x}{84} + \frac{(1.0235 - x)}{106}$$

$\therefore$ $x = 0.4122$

Amount of $NaHCO_3$ = 0.4122 g

$$\text{Percentage of } NaHCO_3 = \frac{0.4122}{1.0235} \times 100 = 40.27$$

Example 6. *A mixture of ethane and ethene occupies 40 litre at 1.00 atm and at 400 K. The mixture reacts completely with 130 g of O_2 to produce CO_2 and H_2O. Assuming ideal gas behaviour, calculate the mole fractions of C_2H_6 and C_2H_4 in the mixture.* **(IIT 1995)**

Solution: Volume of the mixture at NTP

$$= \frac{40 \times 1}{400} \times \frac{273}{1} = 27.3 \text{ litre}$$

Let the volume of ethane = x litre

Volume of ethene = $(273 - x)$ litre

Balanced equations:

$$\underset{1\text{ vol.}}{C_2H_6} + \underset{7/2\text{ vol.}}{7/2\,O_2} \longrightarrow 2CO_2 + 3H_2O$$

$$\underset{1\text{ vol.}}{C_2H_4} + \underset{3\text{ vol.}}{3O_2} \longrightarrow 2CO_2 + 2H_2O$$

Total volume of oxygen required for complete combustion of the mixture is:

$$\left[\frac{7}{2}x + (27.3 - x) \times 3\right] \text{litre}$$

or

$$\left[\frac{7x + (27.3 - x) \times 6}{2}\right] \text{litre}$$

$$\text{Mass of oxygen} = \left[\frac{7x + (27.3 - x) \times 6}{2}\right] \times \frac{32}{22.4}$$

$$130 = (x + 163.8) \times \frac{16}{22.4}$$

$\therefore$ $x = 18.2$

$$\text{Hence, mole fraction of ethane} = \frac{18.2}{27.3} \times 100 = 66.66$$

Mole fraction of ethene = 33.34

Example 7. *A mixture of HCOOH and $H_2C_2O_4$ is heated with concentrated H_2SO_4. The gas produced is collected and on treating with KOH solution, the volume of the gas decreases by 1/6th. Calculate the molar ratio of the two acids in the original mixture.* **(IIT 1990)**

Solution:

$$\underset{1\text{ mol}}{HCOOH} \xrightarrow[\text{Heat}]{\text{Conc. } H_2SO_4} \underset{1\text{ mol}}{CO} + H_2O$$

$$\underset{1\text{ mol}}{H_2C_2O_4} \xrightarrow[\text{Heat}]{\text{Conc. } H_2SO_4} \underset{1\text{ mol}}{CO} + \underset{1\text{ mol}}{CO_2} + H_2O$$

Let a moles of HCOOH and b moles of $H_2C_2O_4$ be present in the original mixture.

Moles of CO formed = $a + b$

Moles of CO_2 formed = b

Total moles of gases = $a + b + b = a + 2b$

CO_2 is absorbed by KOH and the volume reduces by 1/6th.

$$\text{Moles of } CO_2 = \frac{a + 2b}{6}$$

or $$b = \frac{a + 2b}{6}$$

or $$a = 4b$$

or $$\frac{a}{b} = 4$$

or $$a : b = 4 : 1$$

Example 8. *3.6 g mixture of sodium chloride and potassium chloride is dissolved in water. The solution is treated with excess of silver nitrate solution. 7.74 g of silver chloride is obtained. Find the percentage of sodium chloride and potassium chloride in the mixture.*

Solution: The balanced equation between NaCl and $AgNO_3$ is:

$$\underset{\substack{1\text{ mol}\\58.5\text{ g}}}{NaCl} + AgNO_3 \longrightarrow \underset{\substack{1\text{ mol}\\143.5\text{ g}}}{AgCl} + NaNO_3$$

Let x g of NaCl be present in the mixture.

58.5 g NaCl produce = 143.5 g AgCl

$$x \text{ g NaCl will produce} = \frac{143.5}{58.5} \times x \text{ g AgCl}$$

The balanced equation between KCl and $AgNO_3$ is:

$$\underset{\substack{1\text{ mol}\\74.5\text{ g}}}{KCl} + AgNO_3 \longrightarrow \underset{\substack{1\text{ mol}\\143.5\text{ g}}}{AgCl} + KNO_3$$

KCl present in the mixture = $(3.60 - x)$ g

74.5 g of Cl produce = 143.5 g of AgCl

$$(3.6 - x) \text{ g of KCl will produce} = \frac{143.5}{74.5} \times (3.6 - x) \text{ g of AgCl}$$

$$\text{Thus, } \frac{143.5}{58.5}x + \frac{143.5}{74.5}(3.6 - x) = 7.74$$

$$x = 1.54$$

$$\% \text{ of NaCl} = \frac{1.54}{3.60} \times 100 = 42.7$$

$$\% \text{ of KCl} = \frac{(3.60 - 1.54)}{3.60} \times 100 = 57.3$$

Example 9. *5 g of K_2SO_4 were dissolved in 250 mL of solution. How many mL of this solution should be used so that 1.2 g of $BaSO_4$ may be precipitated from $BaCl_2$ solution?*

Solution: The desired equation is:

$$BaCl_2 + \underset{\substack{2\times 39+32+64\\ =174\,g}}{K_2SO_4} \longrightarrow \underset{\substack{137+32+64\\ =233\,g}}{BaSO_4} + 2KCl$$

233 g of $BaSO_4$ obtained from 174 g of K_2SO_4

1.2 g of $BaSO_4$ will be obtained from $\frac{174}{233} \times 1.2$

$$= 0.8961 \text{ g of } K_2SO_4$$

5 g of K_2SO_4 are present in 250 mL of solution

So, 0.8961 g of K_2SO_4 will be present in $\frac{250}{5} \times 0.8961$

$$= 44.8 \text{ mL of solution}$$

Example 10. *A 2.00 g of sample containing Na_2CO_3 and $NaHCO_3$ loses 0.248 g when heated to 300° C, the temperature at which $NaHCO_3$ decomposes into Na_2CO_3, CO_2 and steam. What is the percentage of Na_2CO_3 in the mixture?*

Solution: $$\underset{168\,g}{2NaHCO_3} \longrightarrow Na_2CO_3 + \underbrace{\underset{44}{CO_2} + \underset{18}{H_2O}}_{62\,g}$$

The loss comes due to evolution of CO_2 and steam.

62 g loss occurs when the quantity of $NaHCO_3$ is 168 g.

0.248 g loss will occur when the quantity of $NaHCO_3$

$$= \frac{168}{62} \times 0.248 = 0.672 \text{ g}$$

Quantity of Na_2CO_3 in the sample $= (2.0 - 0.672) = 1.328$ g

$$\% \text{ of } Na_2CO_3 = \frac{1.328}{2} \times 100 = 66.4$$

Example 11. *A 1.00 g sample of $KClO_3$ was heated under such conditions that a part of it was decomposed according to the equation,*

$$2KClO_3 \longrightarrow 2KCl + 3O_2 \qquad \ldots (i)$$

and the remaining underwent change according to the equation,

$$4KClO_3 \longrightarrow 3KClO_4 + KCl \qquad \ldots (ii)$$

If the amount of oxygen evolved was 146.8 mL at STP, calculate the percentage by mass of $KClO_4$ in the residue.

Solution: $$\underset{\substack{2(39+35.5+48)\\ 245\,g}}{2KClO_3} \longrightarrow \underset{\substack{2(39+35.5)\\ 149\,g}}{2KCl} + \underset{\substack{3\times 22.4 \text{ litre}\\ 67.2 \text{ litre}}}{3O_2}$$

67.2 litre of oxygen evolved from 245 g of $KClO_3$

0.1468 litre of oxygen will be evolved $= \frac{245}{67.2} \times 0.1468$

$$= 0.5352 \text{ g of } KClO_3$$

Hence, $KClO_3$ left for eq. (ii) reaction,

$$(1.00 - 0.5352) = 0.4648 \text{ g}$$

245 g $KClO_3$ will yield KCl = 149 g

0.5352 g $KClO_3$ will yield KCl $= \frac{149}{245} \times 0.5352 \text{ g} = 0.3254$ g

Considering eq. (ii),

$$\underset{\substack{4(39+35.5+48)\\ 490\,g}}{4KClO_3} \longrightarrow \underset{\substack{3(39+35.5+64)\\ 415.5\,g}}{3KClO_4} + \underset{\substack{(39+35.5)\\ 74.5\,g}}{KCl}$$

490 g of $KClO_3$ yield = 415.5 g of $KClO_4$

0.4648 g of $KClO_3$ will yield $= \frac{415.5}{490} \times 0.4648$

$$= 0.3941 \text{ g of } KClO_4$$

490 g $KClO_3$ yield = 74.5 g of KCl

0.4648 g of $KClO_3$ will yield $= \frac{74.5}{490} \times 0.4648$

$$= 0.0707 \text{ g of KCl}$$

Total mass of residue = 0.3254 + 0.3941 + 0.0707

$$= 0.7902 \text{ g}$$

$$\% \ KClO_4 = \frac{0.3941}{0.7902} \times 100 = 49.8$$

Example 12. *A mixture of FeO and Fe_3O_4 when heated in air to a constant weight gains 5% in its mass. Find the composition of the initial mixture.*

Solution: Let the % of FeO in the mixture be $= x$

So, % of Fe_3O_4 in the mixture $= (100 - x)$

FeO on heating is converted into Fe_2O_3.

$$\underset{288\,g}{4FeO} + O_2 \longrightarrow \underset{320\,g}{2Fe_2O_3}$$

288 g of FeO yield = 320 g of Fe_2O_3

x g of FeO will yield $= \frac{320}{288} x$ g of Fe_2O_3

$$\underset{464\,g}{2Fe_3O_4} + \frac{1}{2} O_2 \longrightarrow \underset{480\,g}{3Fe_2O_3}$$

464 g of Fe_3O_4 yield = 480 g of Fe_2O_3

$(100 - x)$ g of Fe_2O_3 will yield $= \frac{480}{464}(100 - x)$ of Fe_2O_3

$$\text{Total } Fe_2O_3 = \frac{320}{288} x + \frac{480}{464}(100 - x)$$

According to the question,

$$\frac{320}{288} x + \frac{480}{464}(100 - x) = 105$$

$$x = 20.2$$

So, percentage of FeO = 20.2

and percentage of $Fe_3O_4 = 79.8$

Example 13. *A mixture in which the mole ratio of H_2 and O_2 is 2 : 1, is used to prepare water by the reaction:*

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

The total pressure in the container is 0.8 atm at 20° C before the reaction. Determine the final pressure at 120° C after the reaction, assuming 80% yield of water. **(IIT 1999)**

Solution: The given reaction is:

$$\begin{array}{lccc} & 2H_2(g) & + \; O_2(g) \longrightarrow & 2H_2O(g) \\ \text{Initial moles} & 2n & n & 0 \\ \text{Final moles} & (2n-2x) & (n-x) & 2x \end{array}$$

$$\%\ \text{yield} = 80$$

$$\therefore \quad \frac{2x}{2n} \times 100 = 80$$

$$x = 0.8\,n$$

After the reaction,

Number of moles of $H_2 = 2n - 2 \times 0.8n = 0.4n$

Number of moles of $O_2 = 0.2n$

Number of moles of $H_2O = 1.6n$

$$\text{Total moles} = 0.4n + 0.2n + 1.6n = 2.2n$$

Initial state: $PV = nRT$

$$0.8 \times V = 3n \times R \times 293 \qquad \ldots(i)$$

After the reaction, $P \times V = 2.2n \times R \times 393$ ...(ii)

Solving eqs. (i) and (ii), we get

$$P = 0.787 \text{ atm}$$

Questions

1. 500 mL of 0.25 *M* Na_2SO_4 solution is added to an aqueous solution of 15 g of $BaCl_2$ resulting in the formation of a white precipitate of insoluble $BaSO_4$. How many moles and how many grams of $BaSO_4$ are formed?
2. Zinc and hydrochloric acid react according to the reaction:
$$Zn(s) + 2HCl(aq.) \longrightarrow ZnCl_2(aq.) + H_2(g)$$
If 0.3 mole Zn are added to hydrochloric acid containing 0.52 mole HCl, how many moles of H_2 are produced?
3. Calcium carbonate reacts with aqueous HCl to give $CaCl_2$ and CO_2 according to the reaction:
$$CaCO_3(s) + 2HCl(aq.) \longrightarrow CaCl_2(aq.) + H_2O + CO_2(g)$$
What mass of $CaCO_3$ is required to react completely with 25 mL of 0.75 *M* HCl?
4. Calculate the mass of iron which will be converted into its oxide by the action of 18 g of steam. **(MLNR 1996)**
5. How much potassium chlorate is needed to obtain 2.4 litre oxygen at NTP?
6. Calculate the volume of carbon dioxide obtained at NTP by heating 8.4 g of sodium bicarbonate.
7. Calculate the volume of air needed for the combustion of 1 kg of carbon.
[**Hint:** 100 parts of air contain 21 parts of oxygen by volume.]
8. How many grams of oxygen will be formed by the action of 12 g of sodium peroxide on water? Calculate also the volume of the gas at NTP.
9. A gaseous compound of carbon and nitrogen containing 53.8% by weight of nitrogen was found to have a vapour density of 25.8. What is the molecular formula of the compound?
10. Calculate the weight of lime (CaO) that can be obtained by heating 200 kg of limestone which is 93% pure.
11. How many moles of impure potassium chlorate of 75% purity are required to produce 48 g of oxygen?
12. What weight of zinc will react with dil. sulphuric acid to liberate 1000 mL of hydrogen at 27°C and 750 mm pressure?
13. 1.2 g sample of Na_2CO_3 and K_2CO_3 was dissolved in water to form 100 mL solution. 20 mL of this solution required 40 mL of 0.1 *N* HCl for complete neutralization. Calculate the weight of Na_2CO_3 in the mixture. If another 20 mL of this solution is treated with excess of $BaCl_2$, what will be the weight of the precipitate? **(IIT 1997)**
14. Calculate the volume of air containing 21% by volume of oxygen at NTP required to convert 294 mL of SO_2 into SO_3 under the same conditions.
15. 4 g of an impure sample of $CaCO_3$ on treatment with excess HCl produce 0.88 g CO_2. What is the per cent purity of $CaCO_3$ sample?
16. What weight of AgCl will be precipitated when a solution containing 4.77 g of NaCl is added to a solution of 5.77 g of $AgNO_3$?
[**Hint:** $AgNO_3$ is a limiting reagent in this problem.]
17. 1.0 g of an alloy of aluminium and magnesium is treated with excess of dil. HCl. The evolved hydrogen collected over mercury at 0°C has a volume of 1.20 litre at 0.29 atm pressure. Calculate the percentage composition of the alloy.
18. How much iron can be theoretically obtained by the reduction of 1.0 kg of Fe_2O_3? (At. wt. of Fe = 56)
19. 34 g of pure H_2O_2 is decomposed. Calculate the mass and volume at NTP of oxygen that will be evolved.
20. Find the percentage composition of iron and magnesium, 5.0 g, which when dissolved in acid, gave 2.81 litre of H_2 at NTP.
21. Equal weights of Hg and iodine are allowed to react completely to form a mixture of mercurous iodide and mercuric iodide. Calculate the ratio of the masses of mercurous and mercuric iodides formed. (Hg = 201, I = 117)
[**Hint:** $\underset{201\text{ g}}{Hg} + \underset{254\text{ g}}{I_2} \longrightarrow \underset{455\text{ g}}{HgI_2}$;

$$\underset{402\text{ g}}{2\text{Hg}} + \underset{254\text{ g}}{\text{I}_2} \longrightarrow \underset{656\text{ g}}{\text{Hg}_2\text{I}_2}$$

Let the wt. of Hg_2I_2 formed be x and HgI_2 formed be y.

In the case of $Hg_2I_2, Hg = \frac{402}{656}x, I_2 = \frac{254}{656}x$

In the case of HgI_2, $Hg = \frac{201}{455}y, I_2 = \frac{254}{455}y$

So, $$\frac{402}{656}x + \frac{201}{455}y = \frac{254}{656}x + \frac{254}{455}y$$

From this equation, x/y can be calculated.]

22. A mixture of NaI and NaCl gave with sulphuric acid, Na_2SO_4 equal in mass to the original mixture taken. Find the percentage composition of the mixture.

23. A mixture of calcium and magnesium carbonates weighing 1.4 g was strongly heated until no further loss of weight was perceived. The residue weighed 0.76 g. What percentage of $MgCO_3$ was present in the mixture?

Answers

1. 0.072 mol, 16.8 g
2. 0.26
3. $CaCO_3$ = 0.94 g
4. 42 g
5. 8.75 g
6. 1.12 L
7. 8890 L
8. 2.462 g; 1.723 L
9. C_2N_2
10. 104.16 kg
11. 1.33 mol
12. 2.245 g of zinc
13. Na_2CO_3 = 0.5962 g, K_2CO_3 = 0.6038 g, $BaCO_3$ = 0.394 g
14. 700 mL
15. 50%
16. AgCl = 4.87 g
17. Al = 54.87%, Mg = 45.13%
18. 700 g
19. 16 g; 11.2 litre
20. Fe = 69.60%, Mg = 30.40%
21. 0.513 : 1
22. NaI = 28.86%, NaCl = 71.14%
23. 20.45%

OBJECTIVE QUESTIONS

Set–1 : Questions with single correct answer

1. The formula which represents the simple ratio of atoms in a compound is called:
(a) empirical formula (b) molecular formula
(c) structural formula (d) rational formula

2. The empirical formula of a compound is CH. Its molecular weight is 78. The molecular formula of the compound will be:
(a) C_2H_2 (b) C_3H_3 (c) C_4H_4 (d) C_6H_6

3. An organic compound on analysis gave C = 5.45%, H = 9.1% by mass. Its empirical formula is:
(a) CHO_2 (b) CH_2O (c) C_2H_4O (d) C_3H_4O

4. The chloride of a metal has the formula MCl_3. The formula of its phosphate will be:
(a) M_2PO_4 (b) MPO_4 (c) M_3PO_4 (d) $M(PO_4)_2$

5. The formula of chloric acid is $HClO_3$. The formula for calcium chlorate is:
(a) $CaClO_3$ (b) $Ca(ClO_3)_2$
(c) Ca_2ClO_3 (d) $Ca(ClO_3)_3$

6. An element A is tetravalent and another element B is divalent. The formula of the compound formed from these elements will be:
(a) A_2B (b) AB (c) AB_2 (d) A_2B_3

7. A compound of aluminium and chlorine is composed of 9.0 g Al for every 35.5 g of chlorine. The empirical formula of the compound is:
(a) $AlCl$ (b) $AlCl_2$ (c) $AlCl_4$ (d) $AlCl_3$

8. Two elements A (At. mass = 75) and B (At. mass = 16) combine to yield a compound. The % by mass of A in the compound was found to be 75.08. The formula of the compound is: (MLNR 1991)
(a) A_2B (b) AB (c) AB_2 (d) A_2B_3

9. On analysis, a certain compound was found to contain iodine and oxygen in the ratio of 254 : 80. The formula of the compound is: (At. mass I = 127, O = 16)
(a) IO (b) I_2O (c) I_5O_2 (d) I_2O_5

10. The haemoglobin from red corpuscles of most mammals contains approximately 0.33% of iron by weight. The molecular weight of haemoglobin is 67,200. The number of iron atoms in each molecule of haemoglobin is:
(a) 1 (b) 2 (c) 3 (d) 4

11. 24.9 g of sodium thiosulphate (Mol. mass = 249) is weighed by a chemist. The moles of sodium thiosulphate he has weighed, are:
(a) $\frac{1}{10}$ (b) $\frac{1}{5}$ (c) $\frac{1}{2}$ (d) 1

12. The mass of sulphuric acid needed for dissolving 3 g magnesium carbonate is:
(a) 3.5 g (b) 7.0 g (c) 1.7 g (d) 17.0 g

13. 10 mL of a solution of H_2O_2 liberated 0.5 g of iodine from KI solution. The percentage of H_2O_2 in the solution is:
(a) 0.27 g (b) 0.67 g (c) 0.47 g (d) 0.87 g

14. The mass of CO_2 obtained when 60 g of calcium carbonate is treated with excess of hydrochloric acid is:
(a) 30.0 g (b) 15.0 g (c) 13.2 g (d) 26.4 g

15. The % loss in mass after heating a pure sample of potassium chlorate (Mol. mass = 122.5) will be:
(a) 12.25 (b) 24.50 (c) 39.17 (d) 49.0

16. The volume of oxygen required for complete oxidation of 2.0 litre methane at NTP is:
(a) 2 litre (b) 4 litre (c) 1 litre (d) 3 litre

17. 3 volumes of hydrogen are required to combine with one volume of nitrogen to form 2 volumes of ammonia. When 1 mole of hydrogen is allowed to react with the mole of nitrogen, the two gases:
(a) do not combine
(b) combine and both the gases are used up completely
(c) 2/3 mole of nitrogen remains unreacted
(d) some hydrogen remains uncombined

18. The percentage of nitrogen in urea is about:
(a) 38.4 (b) 46.6 (c) 59.1 (d) 61.3

19. If a mixture containing 3 moles of hydrogen and 1 mole of nitrogen is converted completely into ammonia, the ratio of initial and final volumes under the same temperature and pressure would be:
(a) 3 : 1 (b) 1 : 3 (c) 2 : 1 (d) 1 : 2

20. The mass of residue left after strongly heating 1.38 g of silver carbonate will be:
(a) 1.16 g (b) 1.33 g (c) 2.66 g (d) 1.08 g

21. The mass of oxygen with which 13.5 g of aluminium will completely react is:
(a) 4 g (b) 8 g (c) 12 g (d) 16 g

22. 1.6 g of an organic compound on combustion gave 4.4 g carbon dioxide. The % of carbon in the organic compound is:
(a) 30 (b) 45 (c) 60 (d) 75

23. At NTP, 10 litre of hydrogen sulphide gas reacted with 10 litre of sulphur dioxide gas. The volume of gas, after the reaction is complete, would be:
(a) 5 litre (b) 10 litre (c) 15 litre (d) 20 litre

24. A substance contains 0.25% iron by weight. The molecular mass of the substance is 89600. The number of iron atoms per molecule of the substance is:
(a) 5 (b) 4 (c) 3 (d) 2

25. The minimum amount of hydrogen required to reduce 7.95 g of CuO (Mol. mass = 79.5) will be:
(a) 2 g (b) 4 g
(c) 2240 mL at NTP (d) 22400 mL at NTP

26. 2.0 g mixture of sodium carbonate and sodium bicarbonate on heating to constant mass gave 224 mL of CO_2 at NTP. The % mass of sodium bicarbonate in the mixture is:
(a) 50 (b) 54 (c) 80 (d) 84

27. What volume of hydrogen at NTP will be liberated when 3.25 g of zinc completely dissolve in dilute HCl? (At. mass of Zn = 65)
(a) 1.12 litre (b) 11.20 litre
(c) 2.24 litre (d) 22.40 litre

28. The volume of oxygen at NTP evolved when 1.70 g of sodium nitrate is heated to a constant mass is:
(a) 0.112 litre (b) 0.224 litre (c) 22.4 litre (d) 11.2 litre

29. 50 g limestone is heated. The quantity of quicklime produced is:
(a) 56 g (b) 28 g (c) 14 g (d) 10 g

30. Assuming that petrol is octane (C_8H_{18}) and has a density of 0.8 g mL^{-1}, 1.425 litre of petrol on combustion will consume:
(a) 100 mole of oxygen (b) 124 mole of oxygen
(c) 150 mole of oxygen (d) 175 mole of oxygen

31. 1 mole of calcium phosphide on reaction with excess of water gives: **(IIT 1999)**
(a) 1 mole of phosphine
(b) 2 mole of phosphine
(c) 2 mole of phosphoric acid
(d) 1 mole of phosphorus pentoxide

32. Assuming fully decomposed, the volume of CO_2 released at STP on heating 9.85 g of $BaCO_3$ will be: (Atomic mass of Ba = 137) **[CBSE (PMT) 2004]**
(a) 0.84 L (b) 2.24 L (c) 4.06 L (d) 1.12 L

33. MnO_4^{2-} (1 mole) in neutral aqueous medium disproportionates to: **(AIIMS 2003)**
(a) 2/3 mole MnO_4^- and 1/3 mole MnO_2
(b) 1/3 mole MnO_4^- and 2/3 mole MnO_2
(c) 1/3 mole Mn_2O_7 and 1/3 mole MnO_2
(d) 2/3 mole Mn_2O_7 and 1/3 mole of MnO_2

34. 56 g of nitrogen and 8 g of hydrogen gas are heated in a closed vessel. At equilibrium 34 g of ammonia are present. The equilibrium number of moles of nitrogen, hydrogen and ammonia are respectively: **(KCET 2004)**
(a) 1, 2, 2 (b) 2, 2, 1 (c) 1, 1, 2 (d) 2, 1, 2

35. If 30 mL of H_2 and 20 mL of O_2 reacts to form H_2O, what is left at the end of the reaction? **(AFMC 200**
(a) 10 mL of H_2 (b) 5 mL of H_2
(c) 10 mL of O_2 (d) 5 mL of O_2

[**Hint:** $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(g)$]

	$H_2(g)$	$O_2(g)$	$H_2O(g)$
Initially	30	20	0
After the reaction	0	(20 – 15)	30

36. For the formation of 3.65 g of hydrogen chloride gas, what volumes of hydrogen gas and chlorine gas are required at NTP conditions? **[PMT (Kerala) 2005]**
(a) 1.12 L, 1.12 L (b) 1.12 L, 2.24 L
(c) 3.65 L, 1.83 L (d) 1 L, 1 L

37. An alkaloid contains 17.28% of nitrogen and its molecular mass is 162. The number of nitrogen atoms present in one molecule of alkaloid is: **[PMT (Kerala) 2005]**
(a) five (b) four (c) three (d) two

38. *x* gm of $CaCO_3$ was completely burnt in air. The weight of the solid residue formed is 28 g. What is the value of '*x*' in grams? **(EAMCET 2005)**
(a) 44 (b) 200 (c) 150 (d) 50

39. Sodium bicarbonate on heating decomposes to form sodium carbonate, CO_2 and water. If 0.2 mole of sodium bicarbonate is completely decomposed, how many mole of sodium carbonate is formed? **[CET (J&K) 2006; SCRA 2009]**
(a) 0.1 (b) 0.2 (c) 0.05 (d) 0.025
[**Hint:** The reaction involved is :

$$2NaHCO_3(s) \xrightarrow{\Delta} Na_2CO_3(s) + CO_2(g) + H_2O(l)\,]$$

40. One mole of acidified $K_2Cr_2O_7$ on reaction with excess of KI will liberate . . . . moles of I_2. **[PET (Kerala) 2006]**
(a) 6 (b) 1 (c) 7 (d) 3
[**Hint:** $Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$]

41. The decomposition of a certain mass of $CaCO_3$ gave 11.2 dm^3 of CO_2 gas at STP. The mass of KOH required to completely neutralise the gas is: **[KCET 2006; Indraprastha (Engg.) 2007]**
(a) 56 g (b) 28 g (c) 42 g (d) 20 g

42. At *T* K, 100 litre of dry oxygen is present in a sealed container. It is subjected to silent electric discharge, till the volumes of oxygen and ozone become equal. What is the volume (in litre) of ozone formed at *T* K? **[EAMCET (Engg.) 2006]**
(a) 50 L (b) 60 L (c) 30 L (d) 40 L
[**Hint:**

	$3O_2$	$\longrightarrow 2O_3$
$t = 0$	100	0
After the reaction	$100 - 3x$	$2x$

$\because$ $100 - 3x = 2x$ or $x = 20$
$\therefore$ Volume of ozone $= 2x = 40$ L]

43. In the reaction,
$2Al(s) + 6HCl(aq.) \longrightarrow 2Al^{3+}(aq.) + 6Cl^-(aq.) + 3H_2(g)$: **(AIEEE 2007)**
(a) 11.2 L $H_2(g)$ at STP is produced for every mole of $HCl(aq.)$ consumed
(b) 6 L $HCl(aq.)$ is consumed for every 3 L $H_2(g)$ produced
(c) 33.6 L $H_2(g)$ is produced regardless of temperature and pressure for every mole of Al that reacts
(d) 67.2 L $H_2(g)$ at STP is produced for every mole of Al that reacts

44. The weight of iron which will be converted into its oxide (Fe_3O_4) by the action of 18 g of steam on it will be: (Atomic mass of Fe = 56) **[CMC (Vellore) 2007]**
(a) 168 g (b) 84 g (c) 42 g (d) 21 g
[**Hint:** $3Fe(s) + 4H_2O(g) \longrightarrow Fe_3O_4(s) + 4H_2(g)$

$3Fe(s)$	$4H_2O(g)$
3 mol	4 mol
3×56	4×18
= 168 g	= 72 g

$\because$ 72 g steam reacts with 168 g of iron
$\therefore$ 18 g steam will react with 42 g of iron.]

45. Match the following :

List-I	List-II (at STP)
(A) 10 g $CaCO_3 \xrightarrow[\text{Decomposition}]{\Delta}$	(i) 0.224 L CO_2
(B) 1.06 g $Na_2CO_3 \xrightarrow{\text{Excess HCl}}$	(ii) 4.48 L CO_2
	(iii) 0.448 L CO_2
(C) 2.4 g C $\xrightarrow[\text{Combustion}]{\text{Excess } O_2}$	(iv) 2.24 L CO_2
(D) 0.56 g CO $\xrightarrow[\text{Combustion}]{\text{Excess } O_2}$	(v) 22.4 L CO_2

The correct match is: [EAMCET (Engg.) 2008]

	A	B	C	D
(a)	(iv)	(i)	(ii)	(iii)
(b)	(v)	(i)	(ii)	(iii)
(c)	(iv)	(i)	(iii)	(ii)
(d)	(i)	(iv)	(ii)	(iii)

[**Hint:** (A) $$\underset{\substack{100\text{ g}\\10\text{ g}}}{CaCO_3} \xrightarrow{\Delta} CaO + \underset{\substack{22.4\text{ L}\\2.24\text{ L}}}{CO_2}$$

(B) $$\underset{\substack{1\text{ mol }(106\text{ g})\\1.06\text{ g}}}{Na_2CO_3} + 2HCl \longrightarrow 2NaCl + H_2O + \underset{\substack{22.4\text{ L}\\0.224\text{ L}}}{CO_2}$$

(C) $$\underset{\substack{12\text{ g}\\2.4\text{ g}}}{C} + O_2 \longrightarrow \underset{\substack{22.4\text{ L}\\4.48\text{ L}}}{CO_2}$$

(D) $$\underset{\substack{28\text{ g}\\0.56\text{ g}}}{CO} + \frac{1}{2}O_2 \longrightarrow \underset{\substack{22.4\text{ L}\\0.448\text{ L}}}{CO_2}\ ]$$

46. $Fe^{2+} \longrightarrow Fe^{3+} + e^-$, $MnO_4^- + 5e^- \longrightarrow Mn^{2+}$, the ratio of stoichiometric coefficient of Fe^{2+} and MnO_4^- is: (DPMT 2008)

(a) 1 : 5 (b) 5 : 1 (c) 2 : 3 (d) 6 : 1

47. What volume of oxygen gas (O_2) measured at 0°C and 1 atm, is needed to burn completely 1L of propane gas (C_3H_8) measured under the same conditions ? [CBSE-PMT (Pre.) 2008]

(a) 5 L (b) 10 L (c) 7 L (d) 6 L

[**Hint:** $$\underset{\substack{1\text{ vol.}\\1\text{ L}}}{C_3H_8(g)} + \underset{\substack{5\text{ vol.}\\5\text{ L}}}{5O_2(g)} \longrightarrow \underset{\substack{3\text{ vol.}\\3\text{ L}}}{3CO_2(g)} + \underset{\substack{4\text{ vol.}\\4\text{ L}}}{4H_2O(g)}\ ]$$

48. How many moles of lead (II) chloride will be formed from a reaction between 6.5 g PbO and 3.2 g HCl ? [CBSE-PMT (Pre.) 2008]

(a) 0.011 (b) 0.029 (c) 0.044 (d) 0.333

[**Hint:** $n_{PbO} = \frac{6.5}{224} = 0.029$; $n_{HCl} = \frac{3.2}{36.5} = 0.087$

The reaction is,

$$PbO + 2HCl \longrightarrow PbCl_2 + H_2O$$

PbO will be limiting reagent because on complete consumption, it gives least amount of product, *i.e.*, 0.029 mol $PbCl_2$.]

49. 1 mole of methylamine on reaction with nitrous acid gives at NTP:

(a) 1 litre of nitrogen (b) 22.4 litre of nitrogen
(c) 11.2 litre of nitrogen (d) 5.6 litre of nitrogen

[**Hint:** $$\underset{1\text{ mol}}{CH_3{-}NH_2} + HONO \longrightarrow CH_3{-}OH + \underset{\substack{22.4\text{ litre}\\\text{at STP}}}{N_2} + H_2O]$$

50. The value of 'n' in the reaction :

$$Cr_2O_7^{2-} + 14H^+ + nFe^{2+} \longrightarrow 2Cr^{3+} + nFe^{3+} + 7H_2O$$

will be : [PET (MP) 2008]

(a) 2 (b) 3 (c) 6 (d) 7

51. In the complex with formula $MCl_3 \cdot 4H_2O$, the coordination number of the metal M is six and there is no molecule of hydration in it. The volume of 0.1 M $AgNO_3$ solution needed to precipitate the free chloride ions in 200 mL of 0.01 M solution of the complex is: [PMT (Kerala) 2008]

(a) 40 mL (b) 20 mL (c) 60 mL (d) 80 mL

[**Hint:** The complex will be $[M(H_2O)_4Cl_2]Cl$, the complex will have free chloride ion concentration of (0.01 M).

$$1\,Cl^- + 1AgNO_3 \longrightarrow AgCl + NO_3^-$$

$$\frac{M_1V_1}{n_1} = \frac{M_2V_2}{n_2} \text{ or } \frac{0.01 \times 200}{1} = \frac{0.1 \times V_2}{1}$$

$$V_2 = 20 \text{ mL}\ ]$$

52. 1.5 g $CdCl_2$ was found to contain 0.9 g Cd. Calculate the atomic weight of Cd. [EAMCET (Engg.) 2009]

(a) 118 (b) 112 (c) 106.5 (d) 53.25

[**Hint:** ∵ 0.6 g chlorine combines with 0.9 g Cd

∴ 71 g chlorine will combine with $\frac{0.9}{0.6} \times 71$ g Cd, *i.e*, 106.5 g Cd

∴ Atomic weight of Cd = 106.5]

53. 10 g of hydrogen and 64 g of oxygen were filled in a steel vessel and exploded. Amount of water produced in this reaction will be : (AIPMT 2009)

(a) 1 mol (b) 2 mol (c) 3 mol (d) 4 mol

[**Hint:** 10 g H_2, *i.e.*, 5 mol is mixed with 64 g O_2, *i.e.*, 2 mol

$$\underset{2\text{ mol}}{2H_2(g)} + \underset{1\text{ mol}}{O_2(g)} \longrightarrow \underset{2\text{ mol}}{2H_2O(g)}$$

Case I : **Let H_2 is completely consumed**

∵ 2 mol H_2 gives 2 mol H_2O

∴ 5 mol H_2 gives 5 mol H_2O

Case II : **Let O_2 is completely consumed**

∵ 1 mol O_2 gives 2 mol H_2O

∴ 2 mol O_2 gives 4 mol H_2O

Since O_2 gives least amount of product on complete consumption hence it is limiting reagent and amount of H_2O formed will be 4 mol.]

54. In an experiment, 4 g of M_2O_x oxide was reduced to 2.8 g of the metal. If the atomic mass of the metal is 56 g mol^{-1}, the number of oxygen atoms in the oxide is: (AFMC 2010)

(a) 1 (b) 2 (c) 3 (d) 4

55. A vessel fitted with a weightless, frictionless piston of 0.025 m^2 area contains conc. HCl. The piston moved 1 m outward when 0.075 kg of iron fillings were added at 300 K. The solution left behind was found to contain Fe(II). The approximate purity of the iron sample is: (ISAT 2010)

(a) 50% (b) 75% (c) 90% (d) 40%

[**Hint:** Volume of H_2 gas produced = 0.025 × 1 = 0.025 m^3

= 25 L

$$PV = nRT$$

$$1 \times 25 = n \times 0.082 \times 300$$

$$n_{H_2} = 1.016$$

The reaction involved is :

$$Fe + 2HCl \longrightarrow FeCl_2 + H_2\uparrow$$

Thus, number of moles of iron will be 1.016.

i.e., Mas iron is 1.016 × 56 *i.e.*, 56.896 g

$$\% \text{ purity of iron sample} = \frac{56.896}{75} \times 100 \approx 75\%]$$

56. The reaction of calcium with water is represented by the equation:

$$Ca + 2H_2O \longrightarrow Ca(OH)_2 + H_2\uparrow$$

What volume of H_2 at STP would be liberated when 8 g of calcium completely reacts with water? **(AIIMS 2010)**

(a) 0.2 cm^3 (b) 0.4 cm^3 (c) 224 cm^3 (d) 4480 cm^3

57. What volume of hydrogen will be liberated at NTP by the reaction of Zn on 50 mL dilute H_2SO_4 of specific gravity 1.3 and having purity 40%? **[BHU (Mains) 2010]**

(a) 3.5 litre (b) 8.25 litre (c) 6.74 litre (d) 5.94 litre

[Hint: Mass of $H_2SO_4 = \frac{50 \times 1.3 \times 40}{100} = 26$ g

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$$

Volume of H_2 at NTP $= \frac{22.4}{98} \times 26 = 5.94$ litre]

Answers : OBJECTIVE QUESTIONS

1. (a)	**2.** (d)	**3.** (c)	**4.** (b)	**5.** (b)	**6.** (c)	**7.** (d)	**8.** (b)

BRAIN STORMING PROBLEMS

OBJECTIVE QUESTIONS for IIT ASPIRANTS

The following questions contain single correct option:

1. What mass of $Mg(OH)_2$ is required to neutralize 125 mL of 0.136 M hydrochloric acid solution?
Molar mass of $Mg(OH)_2 = 58.33\text{ g mol}^{-1}$.
(a) 0.248 g (b) 0.496 g (c) 0.992 g (d) 1.98 g
[Hint: $Mg(OH)_2 + 2HCl \longrightarrow MgCl_2 + 2H_2O$

$$\text{Number of moles of HCl} = \frac{MV}{1000} = \frac{0.136 \times 125}{1000} = 0.017$$

2 mole HCl is neutralized by 58.33 g of $Mg(OH)_2$

$$\therefore 0.017 \text{ mole HCl will be neutralized by } \frac{58.33}{2} \times 0.017 \text{ g of } Mg(OH)_2 = 0.496 \text{ g}]$$

2. Calculate the mass of ammonia that can be produced from the decomposition of a sample of $(NH_4)_2PtCl_6$ containing 0.1 g Pt: Molar mass of $(NH_4)_2PtCl_6$ is 443.9 g mol^{-1}.
(a) 0.0811 g (b) 0.0766 g (c) 0.0175 g (d) 0.00766 g

3. Consider the following data:

Element	**Atomic mass**
A	12.01
B	35.5

A and B combine to form new substance X. If 4 moles of B combine with 1 mole of A to give 1 mole of X, then weight of one mole of X is:
(a) 154 g (b) 74 g (c) 47.5 g (d) 166 g
[Hint: $A + 4B \longrightarrow X$

Molar mass of $X = 12.01 + 4 \times 35.5 = 154\text{ g mol}^{-1}$]

4. Chlorine can be prepared by reacting HCl with MnO_2. The reaction is represented by this equation:

$$MnO_2(s) + 4HCl(aq.) \longrightarrow Cl_2(g) + MnCl_2(aq.) + 2H_2O(l)$$

Assuming the reaction goes to completion, what mass of concentrated HCl solution (36% HCl by mass) is needed to produce 2.5 g of Cl_2?
(a) 5.15 g (b) 14.3 g (c) 19.4 g (d) 26.4 g

5. What volume of 3 M Na_2SO_4 must be added to 25 mL of 1 M $BaCl_2$ to produce 5 g $BaSO_4$?
(a) 7.2 mL (b) 8.3 mL (c) 10 mL (d) 14 mL
[Hint: $Na_2SO_4 + BaCl_2 \longrightarrow BaSO_4 + 2NaCl$

$$\text{Number of moles of } BaSO_4 = \frac{\text{Mass}}{\text{Molar mass}} = \frac{5}{233} = 0.0215$$

Number of moles of Na_2SO_4 needed = 0.0215

$$\frac{MV}{1000} = 0.0215$$

$$\frac{3 \times V}{1000} = 0.0215$$

$$V = 7.2 \text{ mL}]$$

6. When $FeCl_3$ is ignited in an atmosphere of pure oxygen, this reaction takes place:

$$4FeCl_3(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s) + 6Cl_2(g)$$

If 3 moles of $FeCl_3$ are ignited in the presence of 2 moles of O_2 gas, how much of which reagent is present in excess and therefore, remains unreacted?
(a) 0.33 mole $FeCl_3$ remains unreacted
(b) 0.67 mole $FeCl_3$ remains unreacted
(c) 0.25 mole O_2 remains unreacted
(d) 0.50 mole O_2 remains unreacted

7. A self-contained breathing apparatus uses potassium superoxide, KO_2, to convert the carbon dioxide and water in exhaled air into oxygen, as shown by the equation:

$$4KO_2(s) + 2H_2O(g) + 4CO_2(g) \longrightarrow 4KHCO_3(s) + 3O_2(g)$$

How many molecules of oxygen gas will be produced from 0.0468 g of carbon dioxide that is exhaled in a typical breath?
(a) 4.8×10^{20} (b) 6.4×10^{20} (c) 8.5×10^{20} (d) 1.9×10^{21}
[Hint: $\because$ 4 mole CO_2 gives 3 mole O_2

$$\therefore \left(\frac{0.0468}{44}\right) \text{ mole } CO_2 \text{ will give } \frac{3}{4} \times \frac{0.0468}{44} \text{ mole } O_2 = 7.977 \times 10^{-4} \text{ mol}$$

$$\text{Number of molecules of } O_2 = 7.977 \times 10^{-4} \times 6.023 \times 10^{23} = 4.8 \times 10^{20}]$$

8. Antimony reacts with chlorine according to this equation:

$$2Sb + 3Cl_2 \rightleftharpoons 2SbCl_3$$

How many grams of $SbCl_3$ can be prepared if 0.012 mole of antimony are reacted with 0.02 mole of chlorine? The molar mass of $SbCl_3$ equals 228.2 g mol^{-1}.
(a) 1.52 g (b) 1.83 g (c) 2.74 g (d) 4.56 g

9. A gaseous mixture of propane and butane of volume 3 L on complete combustion produces 10 L of CO_2 under standard conditions of temperature and pressure. The ratio of volumes of propane to butane is:
(a) 1 : 2 (b) 2 : 1 (c) 3 : 2 (d) 3 : 1

10. What amount of silver will be obtained on thermal decomposition of 2.76 g of silver carbonate, Ag_2CO_3 (276 amu)?
(a) 2.16 g (b) 0.216 g (c) 216 g (d) 21.6 g

11. $PH_3(g)$ decomposes on heating to produce phosphorous and hydrogen. The change in volume when 100 mL of such gas decomposed is:
(a) +50 mL (b) +500 mL (c) −50 mL (d) −500 mL
[Hint: $4PH_3(g) \xrightarrow{\text{Heat}} P_4(s) + 6H_2(g)$

Volume of H_2 formed by decomposition of 100 mL PH_3

$$= \frac{6}{4} \times 100 = 150 \text{ mL}$$

Thus, change in volume = (150 − 100) = 50 mL]

12. What amount of $BaSO_4$ can be obtained on mixing 0.5 mole $BaCl_2$ with 1 mole of H_2SO_4?
(a) 0.5 mol (b) 0.15 mol (c) 0.1 mol (d) 0.2 mol
[Hint:

$$\begin{array}{lccccc} & BaCl_2 & + \; H_2SO_4 & \longrightarrow & BaSO_4 & + \; 2HCl \,] \\ \text{Initially} & 0.5 & 1 & & 0 & 0 \\ \text{After the reaction} & 0 & (1-0.5) & & 0.5 & 2 \times 0.5 \end{array}$$

13. In the reaction,

$$CrO_5 + H_2SO_4 \longrightarrow Cr_2(SO_4)_3 + H_2O + O_2$$

one mole of CrO_5 will liberate how many moles of O_2?

(a) 5/2 (b) 5/4
(c) 9/2 (d) None of these

14. Calcium carbonate decomposes on heating according to the equation;

$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

At STP, the volume of CO_2 obtained by thermal decomposition of 50 g of $CaCO_3$ will be:

(a) 22.4 litre (b) 44 litre (c) 11.2 litre (d) 1 litre

15. The volume in litre of CO_2 liberated at STP when 10 g of 90% pure limestone is heated completely, is:

(a) 22.4 L (b) 2.24 L (c) 20.16 L (d) 2.016 L

[Hint: $\underset{\substack{\text{1 mole}\\ \text{(100 g)}}}{CaCO_3} \longrightarrow CaO + \underset{\text{22.4 litre at STP}}{CO_2(g)}$

$\because$ 100 g $CaCO_3 \equiv$ 22.4 L CO_2 at STP

$\therefore$ 9 g $CaCO_3 \equiv \dfrac{22.4}{100} \times 9$ L CO_2 at STP

= 2.016 L CO_2 at STP]

16. A metal oxide has the formula Z_2O_3. It can be reduced by hydrogen to give free metal and water. 0.1596 g of the metal requires 6 mg of hydrogen for complete reduction. The atomic mass of the metal is:

(a) 27.9 g mol^{-1} (b) 159.6 g mol^{-1}
(c) 79.8 g mol^{-1} (d) 55.8 g mol^{-1}

[Hint: $Z_2O_3 + 3H_2(g) \longrightarrow 2Z + 3H_2O$

$\because$ 6 g H_2 gives 2 mole Z

$\therefore$ 6×10^{-3} g H_2 will give 0.002 mole Z

$$\text{Number of moles} = \frac{\text{Mass}}{\text{Molar mass}}$$

$$0.002 = \frac{0.1596}{\text{Molar mass}}$$

$\therefore$ $\text{Molar mass} = \dfrac{0.1596}{0.002} = 79.8 \text{ g mol}^{-1}$]

17. 10 g $CaCO_3$ is completely decomposed to X and CaO. X is passed into an aqueous solution containing one mole of sodium carbonate. What is the number of moles of sodium bicarbonate formed?
[Molar mass: $CaCO_3$(100); Na_2CO_3(106); $NaHCO_3$(84)].

(a) 0.2 (b) 0.1 (c) 0.01 (d) 10

18. Chlorine gas can be produced by reacting sulphuric acid with a mixture of MnO_2 and NaCl. The reaction follows the equation:

$$2NaCl + MnO_2 + 3H_2SO_4 \longrightarrow 2NaHSO_4 + MnSO_4 + Cl_2 + 2H_2O$$

What volume of chlorine can be produced from 1 g of sodium chloride under standard conditions of temperature and pressure?

(a) 1.915 L (b) 19.15 L (c) 20.22 L (d) 0.191 L

[Hint: 2 mole NaCl (117 g) $\equiv$ 1 mole Cl_2 (22.4 L at STP)

$\therefore$ 1 g NaCl will give $= \dfrac{22.4}{117}$ L Cl_2 at STP

= 0.191 L Cl_2 at STP]

19. 1 mole of a gaseous aliphatic compound $C_nH_{3n}O_m$ is completely burnt in an excess of oxygen. The contraction in volume is:

(a) $\left(1 + \frac{1}{2}n - \frac{3}{4}m\right)$ (b) $\left(1 + \frac{3}{4}n - \frac{1}{4}m\right)$
(c) $\left(1 - \frac{1}{2}n - \frac{3}{4}m\right)$ (d) $\left(1 + \frac{3}{4}n - \frac{1}{2}m\right)$

20. A mixture of CH_4 and C_2H_4 was completely burnt in an excess of oxygen, yielding equal volumes of CO_2 and steam. Calculate the percentages of the compounds in the original mixture:

(a) 25% CH_4 and 75% C_2H_4 (b) 30% CH_4 and 70% C_2H_4
(c) 75% CH_4 and 25% C_2H_4 (d) 50% CH_4 and 50% C_2H_4

21. When same amount of zinc is treated separately with excess of H_2SO_4 and NaOH, the ratio of volumes of H_2 evolved is:

(a) 1 : 1 (b) 1 : 2 (c) 2 : 1 (d) 9 : 4

[Hint: $Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$

$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2$]

22. 10 mole of SO_2 and 15 mole of O_2 were passed over a catalyst to produce 8 mole of SO_3. The ratio of SO_2 and SO_3 moles in mixture is:

(a) 5/4 (b) 1/4 (c) 1/2 (d) 3/4

[Hint:
$$\begin{array}{llll} & SO_2(g) + & \frac{1}{2}O_2(g) \xrightarrow{\text{Catalyst}} & SO_3(g) \\ t = 0 & 10 & 15 & 0 \\ \text{Final} & 10 - x & 15 - \frac{x}{2} & x \end{array}$$

$x = 8$

$\therefore$ $n_{SO_2} = 10 - x = 2, n_{SO_3} = 8$

$\dfrac{n_{SO_2}}{n_{SO_3}} = \dfrac{2}{8} = \dfrac{1}{4}$]

23. $HgCl_2 + 4KI \longrightarrow K_2[HgI_4] + 2KCl$

1 mole each of Hg^{2+} and I^- will fc [illegible] ow many moles of HgI_4^{2-}?

(a) 1 mol (b) 0.5 mol (c) 0.25 mol (d) 2 mol

24. 25 mL of 0.15 M $Pb(NO_3)_2$ reacts completely with 20 mL of $Al_2(SO_4)_3$. The molar concentration of $Al_2(SO_4)_3$ will be:

$$3Pb(NO_3)_2(aq.) + Al_2(SO_4)_3(aq.) \longrightarrow 3PbSO_4(s) + 2Al(NO_3)_3(aq.)$$

(a) 0.0625 M (b) 0.0242 M
(c) 0.1875 M (d) 0.2346 M

[Hint: $\dfrac{M_1V_1}{n_1} Pb(NO_3)_2 = \dfrac{M_2V_2}{n_2} Al_2(SO_4)_3$

$$\frac{0.15 \times 25}{3} = \frac{M_2 \times 20}{1}$$

$M_2 = 0.0625$]

25. In the reaction,

$$2NH_3(g) + 5F_2 \longrightarrow N_2F_4 + 6HF$$

3.56 g N_2F_4 is obtained by mixing 2 g NH_3 and 8 g F_2. The percentage yield of the production is:

(a) 81.28% (b) 71.2% (c) 68% (d) 79%

[Hint: $\underset{34\text{ g}}{2NH_3(g)} + \underset{190\text{ g}}{5F_2} \longrightarrow \underset{104\text{ g}}{N_2F_4} + 6HF$

Amount of N_2F_4 formed by 2 g $NH_3 = \dfrac{104}{34} \times 2 = 6.12$ g

Amount of N_2F_4 formed by 8 g $F_2 = \frac{104}{190} \times 8 = 4.38$ g

N_2F_4 will be limiting and actual amount of product is 3.56 g

$$\therefore \quad \% \text{ yield} = \frac{\text{Actual amount of product}}{\text{Calculated amount of product}} \times 100$$

$$= \frac{3.56}{4.38} \times 100$$

$$= 81.28\% \,]$$

The following questions may have more than one correct options:

1. 1.5 g of oxygen is produced by heating $KClO_3$. How much KCl is produced in the reaction?
(a) 4.15×10^{-2} mol (b) 4.33 g
(c) 1.78×10^{-2} mol (d) 1.33 g

2. Calculate the amount of lime that can be produced by heating 100 g of 90% pure limestone:
(a) 50.4 g (b) 0.98 mol (c) 0.9 mol (d) 56 g
[**Hint:** $\underset{100\text{ g}}{CaCO_3} \longrightarrow \underset{56\text{ g}}{CaO} + CO_2$

$$100 \text{ g } CaCO_3 \equiv 56 \text{ g } CaO$$

$$\therefore \quad 90 \text{ g } CaCO_3 \equiv \frac{56}{100} \times 90 \text{ g CaO, } i.e., 50.4 \text{ g CaO}$$

$$\text{Number of moles of CaO} = \frac{50.4}{56} = 0.9]$$

3. In an experiment, the following four gases were produced. 11.2 L of which two gases at STP will weigh 14 g?
(a) N_2O (b) NO_2 (c) N_2 (d) CO

4. 2 mole of CO_2 is required to prepare:
(a) 336 g of $NaHCO_3$ (b) 168 g of $NaHCO_3$
(c) 462 g of $Ca(HCO_3)_2$ (d) 162 g of $Ca(HCO_3)_2$

5. 8.7 g of pure MnO_2 is heated with an excess of HCl and the gas evolved is passed into a solution of KI. Calculate the amount of the iodine liberated (Mn = 55, Cl = 35.5, I = 127):
(a) 0.1 mol (b) 25.4 g
(c) 15.4 g (d) 7.7 g

6. 100 mL of gaseous mixture containing CO, CO_2 and O_2 was sparked; there was contraction of 80 mL volume when the mixture was passed through aqueous caustic potash KOH. The composition of initial gaseous mixture will be respectively:
(a) 20 mL, 70 mL, 10 mL (b) 50 mL, 30 mL, 20 mL
(c) 30 mL, 50 mL, 20 mL (d) 30 mL, 60 mL, 10 mL
[**Hint :** (d) $CO + \frac{1}{2}O_2 \longrightarrow CO_2$

10 mL O_2 will give 20 mL CO_2 in above reaction. Thus, total volume of CO_2 will be 80 mL which will be absorbed in caustic potash KOH.

Similarly in (c) option, 30 mL CO_2 will be formed on sparking.

$$\underset{\substack{30\text{ mL}\\(\text{Limiting})}}{CO} + \frac{1}{2}O_2 \longrightarrow \underset{30\text{ mL}}{CO_2}$$

Total volume of CO_2 will be 80 mL]

7. SO_2 gas is slowly passed through an aqueous suspension containing 12 g $CaSO_3$ till the milkiness just disappears, what amount of SO_2 would be required? [BHU (Mains) 2010]
(a) 12.8 g (b) 6.4 g (c) 0.2 mole (d) 0.1 mole
[**Hint :** The reaction involved is

$$\underset{\substack{\text{milky}\\1\text{ mol}\\120\text{ g}}}{CaSO_3} + H_2O + \underset{\substack{1\text{ mol}\\64\text{ g}}}{SO_2} \longrightarrow \underset{\text{colourless}}{Ca(HSO_3)_2}$$

12 g $CaSO_3$ will react with 6.4 g SO_2 or 0.1 mol SO_2.]

LINKED COMPREHENSION TYPE QUESTIONS

• Passage 1

In a reaction vessel, 100 g H_2 *and* 100 g Cl_2 *are mixed and suitable conditions are provided for the following reaction:*

$$H_2(g) + Cl_2(g) \xrightarrow{?} 2HCl(g)$$

Quantum yield of this reaction is $\phi = 10^5$.

Answer the following questions:

1. Select the correct statement(s) for the above reaction:
(a) Presence of light is required for this reaction
(b) It is a chain reaction
(c) Catalyst is required
(d) All of the above

2. The limiting reagent in this reaction will be:
(a) H_2 (b) Cl_2
(c) both (d) cannot be predicted

3. The actual amount of HCl formed in this reaction is:
(a) 102.8 g (b) 73 g
(c) 36.5 g (d) 142 g

4. The amount of excess reactant remaining is:
(a) 50 g (b) 97.2 g
(c) 46 g (d) 64 g

5. The amount of HCl formed (at 90% yield) will be:
(a) 36.8 g (b) 62.5 g
(c) 80 g (d) 92.53 g

• Passage 2

Dissolved oxygen in water is determined by using a redox reaction. Following equations describe the procedure:

$$\text{I. } 2Mn^{2+}(aq.) + 4OH^-(aq.) + O_2(g) \longrightarrow 2MnO_2(s) + 2H_2O(l)$$

$$\text{II. } MnO_2(s) + 2I^-(aq.) + 4H^+(aq.) \longrightarrow Mn^{2+}(aq.) + I_2(aq.) + 2H_2O(l)$$

$$\text{III. } 2S_2O_3^{2-}(aq.) + I_2(aq.) \longrightarrow S_4O_6^{2-}(aq.) + 2I^-(aq.)$$

Answer the following questions:

1. How many moles of $S_2O_3^{2-}$ are equivalent to each mole of O_2?
(a) 0.5 (b) 1 (c) 2 (d) 4

2. What amount of I_2 will be liberated from 8 g dissolved oxygen?
(a) 127 g (b) 254 g (c) 504 g (d) 1008 g

3. If 3×10^{-3} moles O_2 is dissolved per litre of water, then what will be the molarity of I^- produced in the given reaction?
(a) $3 \times 10^{-3}\ M$ (b) $4 \times 3 \times 10^{-3}\ M$
(c) $2 \times 3 \times 10^{-3}\ M$ (d) $\frac{1}{2} \times 3 \times 10^{-3}\ M$

4. Number of which two chemical species will be same in the given procedure?
(a) MnO_2 (b) I_2 (c) I^- (d) $S_2O_3^{2-}$

5. 8 mg dissolved oxygen will consume:
(a) 5×10^{-4} mol Mn^{2+} (b) 2.5×10^{-4} mol Mn^{2+}
(c) 10^{-3} mol Mn^{2+} (d) 2 mol Mn^{2+}

SELF ASSESSMENT

ASSIGNMENT NO. 15

Straight Objective Type Questions

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d), out of which only one is correct.

1. An oxide of iodine contains 25.4 g of iodine for 8 g of oxygen. Its molecular formula will be:

(a) I_2O_3 (b) I_2O (c) I_2O_5 (d) I_2O_7

2. 2 g H_2 and 1 g O_2 are allowed to react according to following equation:

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

Amount of H_2O formed in the reaction will be:

(a) 3 g (b) 1.125 g

(c) 4.5 g (d) 2.50 g

3. 20 cc of CO_2 gas is passed over red hot coke. The volume of carbon monoxide evolved is:

(a) 10 cc (b) 20 cc (c) 30 cc (d) 40 cc

4. In the Haber process:

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

30 L of H_2 and 30 L of N_2 were taken for reaction which yielded only 50% of expected product. What will be the composition of the gaseous mixture in the end ?

(a) 20 L NH_3, 25 L N_2 and 20 L H_2

(b) 10 L NH_3, 25 L N_2 and 15 L H_2

(c) 20 L NH_3, 10 L N_2 and 30 L H_2

(d) 20 L NH_3, 25 L N_2 and 15 L H_2

5. $KMnO_4$ reacts with oxalic acid according to the equation:

$$2MnO_4^- + 5C_2O_4^{2-} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

20 mL of 0.1 *M* $KMnO_4$ will react with:

(a) 120 mL of 0.25 *M* oxalic acid

(b) 150 mL of 0.1 *M* oxalic acid

(c) 50 mL of 0.1 *M* oxalic acid

(d) 50 mL of 0.2 *M* oxalic acid

6. Orthoboric acid, on heating, decomposes in two ways:

$$\text{(I) } H_3BO_3 \longrightarrow HBO_2 + H_2O$$
$$\text{(II) } H_3BO_3 \longrightarrow B_2O_3 + H_2O$$

If 9 moles of H_3BO_3 decomposes by (I) pathway and remaining by (II) pathway. If total 11 moles of water are formed, then the number of moles of B_2O_3 formed is:

(a) 6 (b) 5 (c) 3 (d) 2

7. 2 moles of H_2S and 11.2 L of SO_2 at NTP react to give *x* mole of sulphur. The value of '*x*' will be:

Reaction: $SO_2(g) + 2H_2S(g) \longrightarrow 3S + 2H_2O$

(a) 1.5 (b) 3 (c) 11.2 (d) 6

8. A sample of argentite ore contains 1.34% of Ag_2S by mass. How many grams of this ore would give 1 g of Ag on extraction?

(a) 134 g (b) 108 g (c) 85.7 g (d) 74.6 g

9. What mass of HNO_3 is needed to convert 5 g of iodine into iodic acid according to the reaction?

$$I_2 + HNO_3 \longrightarrow HIO_3 + NO_2 + H_2O$$

(a) 12.4 g (b) 24.8 g (c) 0.248 g (d) 49.6 g

10. $$KI + I_2 + HNO_3 \longrightarrow HIO_3 + KIO_3 + NO_2$$

If 3 moles of KI and 2 moles of I_2 are mixed with excess HNO_3, then volume of NO_2 gas evolved at NTP is:

(a) 716.8 litre (b) 1075.2 litre

(c) 44.8 litre (d) 67.2 litre

11. The decomposition of certain mass of $CaCO_3$ gave 11.2 dm^3 of CO_2 gas at STP. The mass of KOH required to completely neutralise the gas is : **[BHU (Screening) 2010]**

(a) 56 g (b) 28 g (c) 42 g (d) 20 g

Answers

1. (c) **2.** (b) **3.** (d) **4.** (b) **5.** (c) **6.** (d) **7.** (a) **8.** (c)

9. (a) **10.** (a) **11.** (a)

SPONTANEOUS ASSESSMENT SECTION

MODULE–1

IIT Entrance Test Paper

There are 59 questions in this module.

(1) Q. 1 – 20. *Have single correct answer.*
(2) Q. 21 – 30. *Have more than one correct answers.*
(3) Q. 31 – 35. *True/false problems.*
(4) Q. 36 – 40. *Statement/explanation problems.*
(5) Q. 41 – 48. *Thought type/comprehensive problems.*
(6) Q. 49 – 53. *Multiple true/false problems.*
(7) Q. 54 – 58. *True or false type questions.*
(8) Q. 59. *Matching type question.*

1. Kinetic energy of 0.3 mole of 'He' gas in a container of maximum capacity of 4 litre at 5 atm, must be: ($R = 0.0821$ atm litre $\text{mol}^{-1}\ \text{K}^{-1}$)

(a) 30 atm litre (b) 100 atm litre
(c) 9 atm litre (d) 11.11 atm litre

[**Hint:** $PV = \frac{1}{3} mnc^2$

$$\frac{3}{2} PV = \frac{1}{2} mnc^2 = \text{KE}$$

$$\text{KE} = \frac{3}{2} PV = \frac{3}{2} \times 5 \times 4 = 30 \text{ atm litre}]$$

2. What will be the maximum spin multiplicity for 4*d*- orbital?

(a) 4 (b) 6 (c) 5 (d) 10

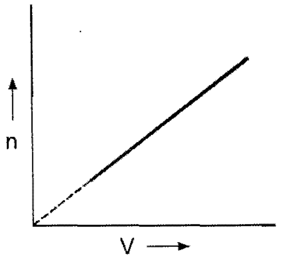
[**Hint:** Spin multiplicity $= 2\Sigma\, s + 1$

$$= 2 \times 5 \times \frac{1}{2} + 1 = 6]$$

3. Number of 'He' atoms in 52 amu sample is:

(a) $2 \times 6.023 \times 10^{23}$ (b) 13
(c) 4 (d) $4 \times 6.023 \times 10^{23}$

4. For a given one mole of ideal gas kept at 6.5 atm in a container of capacity 2.463 litre. The Avogadro proportionality constant for the hypothesis is: (see figure)



(a) 0.406 (b) 2.46
(c) 22.4 (d) none of

[**Hint:** $PV = nRT$

$$6.5 \times 2.463 = 1 \times 0.0821 \times T$$

$$T = 195 \text{ K}$$

$$V = n\left[\frac{RT}{P}\right]$$

Avogadro proportionality constt. $= \frac{RT}{P} = \frac{0.0821 \times 195}{6.5} = 2.461]$

5. $A(s) \rightleftharpoons B(g) + C(g)$. Total pressure at time of equilibrium is 40 atmosphere. If all the contents of this reactor have been shifted to another reactor of double capacity, then the total equilibrium pressure in the new reactor will be: (in atmosphere)

(a) 20 (b) 40 (c) 400 (d) 1600

[**Hint:** Since, gaseous species are not present on both sides, hence the equilibrium will not shift.]

6. Gadolinium-153 is used in the detection of osteoporosis disease of bones. Half life of gadolinium-153 is 500 days. After how many days, on an average, the nuclide can be considered absent from the body of patients?

(a) 500 days (b) 1000 days
(c) Infinite (d) 350 days

[**Hint:** The radioactive element will disappear from the body of patient after infinite time.]

7. Amount of energy required to excite an electron of an atom from the lower energy state to its next higher energy state is defined as:

(a) ionization potential (b) electron affinity
(c) critical potential (d) reduction potential

8. Consider the values for $\Delta H°$ (in kJ mol^{-1}) and for $\Delta S°$ (in J $\text{mol}^{-1}\ \text{K}^{-1}$) given for four different reactions. For which reaction will $\Delta G°$ increase the most (becoming more positive), when the temperature is increased from 0°C to 25°C?

(a) $\Delta H° = 50, \Delta S° = 50$ (b) $\Delta H° = 90, \Delta S° = 20$
(c) $\Delta H° = -20, \Delta S° = -50$ (d) $\Delta H° = -90, \Delta S° = -20$
(e) None of these

9. The energy of the orbitals decreases in the order:

(a) $s > p > sp^3 > sp > sp^2$ (b) $p > sp^3 > sp^2 > sp > s$
(c) $sp^3 > sp^2 > sp > s > p$ (d) $s > sp > sp^2 > sp^3 > p$
(e) none of these

[**Hint:** Greater the percentage of '*p*' character, more is the energy of the orbital.]

10. These are the first eight ionization energies for a particular neutral atom. All values are expressed in MJ mol^{-1}. How many valence electrons do/does this atom possess?

1st	2nd	3rd	4th	5th	6th	7th	8th
1.31	3.39	5.30	7.47	10.99	13.33	71.33	84.01

(a) 1 (b) 2 (c) 4 (d) 6
(e) None of these

11. Consider the reaction:

$$2H_2(g) + 2NO(g) \longrightarrow N_2(g) + 2H_2O(g)$$

The rate law for this reaction is,

$$\text{Rate} = k\,[H_2][NO]^2$$

Under what conditions could these steps represent the mechanism?

Step 1. $2NO \rightleftharpoons N_2O_2$

Step 2. $N_2O_2 + H_2 \longrightarrow N_2O + H_2O$

Step 3. $N_2O + H_2 \longrightarrow N_2 + H_2O$

(a) These steps cannot be the mechanism under any circumstances
(b) These steps could be the mechanism if step 1 is the slowest step
(c) These steps could be the mechanism if step 2 is the slowest step
(d) These steps could be the mechanism if step 3 is the slowest step
(e) None of the above

12. Match the following:

1. Energy of ground state of He^+	(i) -6.04 eV
2. Potential energy of 1st orbit of H-atom	(ii) -27.2 eV
3. Kinetic energy of 2nd excited state of He^+	(iii) 8.7×10^{-18} J
4. Ionisation potential of He^+	(iv) -54.4 eV

(a) 1–(i); 2–(ii); 3–(iii); 4–(iv)
(b) 1–(iv); 2–(iii); 3–(ii); 4–(i)
(c) 1–(iv); 2–(ii); 3–(i); 4–(iii)
(d) 1–(ii); 2–(iii); 3–(i); 4–(iv)

13. If electrons are transited from n_2 excited state to n_1 excited state, then number of lines observed in the spectrum will be:

(a) $\frac{(n_2 - n_1)(n_2 - n_1 + 1)}{2}$ (b) $\frac{(n_1 - n_2)(n_2 - n_1 + 1)}{2}$
(c) $\frac{(n_2 + n_1)(n_1 + n_2 + 1)}{2}$ (d) $2(n_1 - n_2)(n_1 + n_2 - 1)^2$

14. When an electron is transited from $2E$ to E energy level, the wavelength of photon produced is λ_1. In making electronic transition from $\frac{4}{3}E$ to E level, the wavelength λ_2 is:

(a) $\lambda_2 = \lambda_1$ (b) $\lambda_2 = \frac{3\lambda_1}{4}$ (c) $\lambda_2 = 3\lambda_1$ (d) $\lambda_2 = \frac{4\lambda_1}{3}$

15. Completely filled orbitals have special stability and are spherically symmetrical like d^{10}, p^6, f^{14}, etc. The species among Cl^-, Ar and N_3^- which have such orbitals are:

(a) Cl^-, Ar (b) N_3^-, Cl^-
(c) Ar, N_3^- (d) Ar, Cl^-, N_3^-

16. An atom has x energy levels; then total number of lines in the emission spectrum will be:

(a) $1 + 2 + 3 + \ldots + (x + 1)$
(b) $1 + 2 + 3 + \ldots + x^2$
(c) $1 + 2 + 3 + \ldots + x$
(d) $1 + 2 + 3 + \ldots + (x - 1)$

17. Carbon atom has electronic configuration, $C = 1s^2$, $2s^2$ and $2p^2$. The spin multiplicity of carbon atom is:

(a) 3 (b) 2 (c) 1 (d) 4

18. An electron moves around protons (nucleus) in a circle of radius r. Assuming that the uncertainty of momentum of electron is of the same order as the momentum itself, the momentum of the electron will be:

(a) $\frac{h}{4\pi r}$ (b) $\frac{h}{2\pi r}$ (c) $4\pi hr$ (d) $2\pi hr$

19. The oxidation state of iron in sodium nitroprusside is:

(a) –3 or –2 (b) +3 or –3 (c) +2 or –2 (d) –2 or –3

20. The oxidation state of sodium in sodium amalgam is:

(a) +1 (b) –1 (c) zero (d) +2

Question 21 *to* 30 *have more than one correct answers:*

21. The substance(s) which can act as oxidising as well as reducing agent is/are:

(a) H_2O_2 (b) O_3
(c) $NH_2 — NH_2$ (d) HNO_3

22. Which of the following statements is/are correct?

(a) The electronic configuration of Cr is [Ar] $3d^5 4s^1$
(b) The magnetic quantum number may have negative value
(c) In silver, 23 electrons have a spin of one type and 24 of the opposite type
(d) The oxidation state of hydrogen in NH_3 is +3

23. Which of the following statement(s) about wave function ψ of an electron is/are correct?

(a) ψ has no physical significance
(b) ψ^2 represents the probability of finding electrons
(c) $\psi\psi^* = \psi^2 = |\psi|^2$
(d) ψ is continuous, definite, finite and single valued

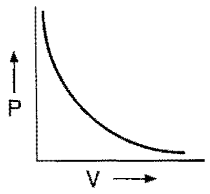
24. Loss of a β-particle is equivalent to:

(a) increase in number of protons by one
(b) decrease in number of neutrons by one
(c) change in atomic mass by one unit
(d) none of the above

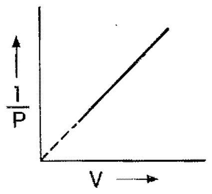
25. The maximum velocity of liquid molecules up to which its flow is streamline is called critical velocity. The critical velocity of a liquid depends upon:

(a) coefficient of viscosity (b) radius of the tube
(c) density of the liquid (d) mass of the tube

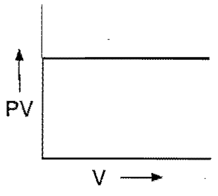
26. Which of the following curves represent(s) Boyle's law?



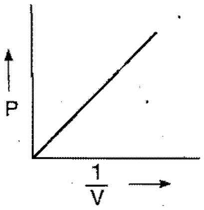
(a)



(b)



(c)



(d)

27. Which of the following set(s) of compounds is/are used as semipermeable membrane?
(a) Calcium phosphate, cellulose nitrate
(b) Calcium phosphate, copper ferrocyanide
(c) Cellulose nitrate, copper ferrocyanide
(d) Copper ferrocyanide, copper sulphate

28. For exact determination of molecular mass:
(a) solute must be volatile
(b) solution must be very dilute
(c) solvent must be non-volatile
(d) solute must not be dissociated or associated

29. For the reaction to be spontaneous:
(a) ΔS should be positive
(b) $(\Delta H - T\Delta S)$ should be negative
(c) $(\Delta H + T\Delta S)$ should be negative
(d) ΔH should be negative

30. When a colloidal solution X is converted into two different solutions Y and Z, the osmotic pressures of Y and Z were found to be respectively higher and lower than X. This indicates that:
(a) X is a colloidal solution and Y is suspension
(b) X is a colloidal solution and Z is true solution
(c) X is colloidal solution and Z is suspension
(d) X is a colloidal solution and Y is true solution

In the following questions (31–35), indicate 'a' if the statement is true and 'b' if the statement is false:

31. The plot of PV *versus* P at constant temperature is a straight line passing through origin.

32. Bohr model could not explain the fine line spectrum of hydrogen.

33. $_{21}$Sc and Cr^{3+} are isoelectronic, hence they have same electronic configuration.

34. van't Hoff factor is equal to unity if the solute undergoes 100% dissociation.

35. A mixture of ideal gas is cooled up to liquid helium temperature (4.22 K) to form an ideal solution.

*In each of the following questions, a **Statement (S)** and **Explanation (E)** are given. Choose the correct answer from the codes a, b, c and d given for each question:*

(*a*) ***S** is correct but **E** is wrong.*
(*b*) ***S** is wrong but **E** is correct.*
(*c*) *Both **S** and **E** are correct and **E** is the correct explanation of **S**.*
(*d*) *Both **S** and **E** are correct but **E** is not correct explanation of **S**.*

36. (S) All Arrhenius acids are also Bronsted acids.
(E) All Bronsted bases are also Lewis bases.

37. (S) 1 amu equals to 1.66×10^{-24} g.
(E) 1.66×10^{-24} g equals 1/12th mass of ^{12}C atom.

38. (S) Spectral lines are not observed for $2p_x - 2p_z$ transition.
(E) p_x, p_y and p_z are three-fold degenerate orbitals.

39. (S) Compressibility factor (Z) for non-ideal gas is always greater than unity.
(E) Non-ideal gases exert less pressure compared to ideal gases under identical conditions.

40. (S) If in zero order reaction, the concentration of the reactant is doubled, the half life period is also doubled.
(E) For a zero order reaction, the rate of reaction is independent of initial concentration.

When 2 g non-volatile solute is dissolved in 100 g of benzene, the vapour pressure of benzene at 20°C is lowered from 74.66 mm to 74.01 mm.

Answer the following questions:

41. Mole fraction of benzene in the solution will be:
(a) 0.89 (b) 0.69 (c) 0.99 (d) 0.79

42. The molar mass of solute will be:
(a) 200 (b) 277.624 (c) 177.624 (d) 350

43. Molecular formula of solute may be:
(a) $C_{14}H_{10}$ (b) $C_{12}H_{26}$ (c) $C_{14}H_{30}$ (d) $C_{14}H_{28}$

44. If the solute is a hydrocarbon containing 94.4% carbon, then the number of moles of carbon in 1 mol of it will be:
(a) 12 (b) 10 (c) 16 (d) 14

45. Molality of solution will be:
(a) 0.013 (b) 0.06 (c) 0.23 (d) 0.05

The age of articles of organic origin can be estimated by radiocarbon dating. The radio-isotope carbon-14 is produced continuously in the upper atmosphere as the nitrogen atoms capture cosmic ray neutrons.

$$^{14}_{7}N + ^{1}_{0}n \longrightarrow ^{14}_{6}C + ^{1}_{1}H$$

The ^{14}C atoms react with oxygen molecules to form $^{14}CO_2$. $^{14}CO_2$ is absorbed by the plants in photosynthesis. Carbon-14 decays with a half life of 5730 years.

$$^{14}_{6}C \longrightarrow ^{14}_{7}N + ^{0}_{-1}e$$

After death, the plant no longer carries out photosynthesis, so it no longer takes-up $^{14}CO_2$. Other organisms that consume plants for food stop doing so at death. The emission from ^{14}C in dead tissue then decreases with the passage of time. The activity per gram of carbon is a measure of the length of time elapsed since death. The carbon-14 technique is useful only for dating objects for a limited period of time.

Answer the following questions:

46. Which one is correct?
(a) Carbon dating is predicted only for wood not older than 60000 years.
(b) Carbon dating is predicted only for wood not older than 600 years.
(c) Age of any older wood can be predicted by the radio carbon dating.
(d) Radio carbon dating is used only for wooden objects.

47. A piece of wood taken from a cave dwelling in New Mexico is found to have a carbon-14 activity (per gram of carbon) only 0.636 times that of wood cut today. Estimate the age of the wood:
(a) 7430 yr (b) 3740 yr (c) 4370 yr (d) 7340 yr

48. In carbon dating:
(a) the decay rate of ${}^{14}_{6}C$ is studied
(b) the rate of accumulation of ${}^{14}_{6}C$ is studied
(c) the rate of decay of ${}^{12}_{6}C$ is studied
(d) the rate of formation of ${}^{13}_{6}C$ is studied

In each of the following questions, three statements I, II, III are given. Mark:
(*a*) *if all the statements are correct*
(*b*) *if II and III are correct*
(*c*) *if I and III are correct*
(*d*) *if only II is correct*

49. In CrO_5:
(I) Oxidation number of Cr is +6.
(II) Four oxygen atoms are involved in peroxy linkage.
(III) Only one oxygen atom has –2 state.

50. (I) The conductance of molten NaCl is due to movement of Na^+ and Cl^- ions.
(II) Molten NaCl is a good conductor due to mobility of free electrons.
(III) Solid NaCl is a bad conductor of electricity.

51. (I) Resistance of metals increases on heating.
(II) Unit of cell constant is cm^{-1}.
(III) Specific conductance decreases on dilution.

52. (I) Oxidation number is same as formal charge.
(II) The numerical value of oxidation number and valency may differ.
(III) Absolute value of electrode potential cannot be determined.

53. (I) Cathode is –ve terminal in both electrolytic and electrochemical cells.
(II) Reduction occurs at cathode, both in electrolytic and electrochemical cells.
(III) Chemical change in electrolytic cell is non- spontaneous.

Predict whether the following statements are True or False:

54. At Curie point, ferromagnetic solid changes to paramagnetic solid.
(a) True (b) False (c) cannot be predicted

55. pH of 10^{-10} M HCl is 10.
(a) True (b) False (c) cannot be predicted

56. Specific conductance of electrolyte solution decreases on dilution.
(a) True (b) False (c) cannot be predicted

57. 3*s*-orbital has 2 nodes, inclusive of radial and angular nodes.
(a) True (b) False (c) cannot be predicted

58. Conductance of LiCl is greater than NaCl at infinite dilution.
(a) True (b) False (c) cannot be predicted

59. [A] Match the Column-I with Column-II. Choose the correct one from the alternatives (a), (b), (c) and (d).

Column-I	**Column-II**
P. Wilkinson catalyst	I. *trans*-$IrCl(CO)(PPh_3)_2$
Q. Speier catalyst	II. Hydrosilylation
R. Water gas shift catalyst	III. $RhCl(PPh_3)_3$
S. Zeolite ZSM-5 catalyst	IV. Synthetic gasoline
	V. Hydroformylation
	VI. Zinc-copper oxide

(a)	(b)	(c)	(d)
P–III	P–I	P–V	P–III
Q–II	Q–V	Q–II	Q–VI
R–VI	R–III	R–VI	R–IV
S–IV	S–IV	S–IV	S–II

[B] Match the Column-I with Column-II. Choose the correct one from the alternatives (a), (b), (c) and (d).

Column-I	**Column-II**
P. Low temperature	I. $\frac{a}{V^2}$
Q. Mean speed	II. Maxwellian distribution
R. Internal pressure	III. b
S. Excluded volume	IV. Adiabatic demagnetisation
	V. $\left(a+\frac{b}{V^2}\right)$

(a)	(b)	(c)	(d)
P–IV	P–V	P–I	P–IV
Q–II	Q–IV	Q–II	Q–V
R–I	R–II	R–III	R–III
S–III	S–III	S–IV	S–II

Answers

MODULE–2

IIT Entrance Test Paper

Following questions have single correct option:

1. The frequency of de Broglie wave associated with a microscopic particle of mass 10^{-27} gm is 2.5×10^4 MHz, then the velocity of the particle will be:
(a) 4.08 km/s (b) 5.81 km/s
(c) 17.32 km/s (d) 1.22 km/s

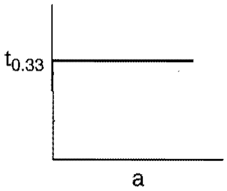
2. The total number of nodes for 4*d*-orbital will be:
(a) 2 (b) 3 (c) 0 (d) 1

3. $N_2 + 3H_2 \rightleftharpoons 2NH_3$ + heat. The activation energy for the forward as well as backward reaction is decreased by 100 J, then the equilibrium amount of NH_3 will:
(a) increase (b) decrease
(c) remain constant (d) cannot be predicted

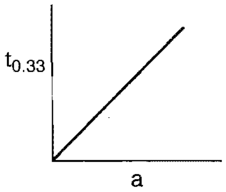
4. During *K*-electron capture mainly:
(a) γ-rays are emitted (b) β-particles are emitted
(c) positron are emitted (d) X-rays are emitted

5. The magnetic moment of an iron compound is 5.918 BM, then the oxidation state of iron in this compound will be:
(a) 0 (b) 1 (c) 2 (d) 3

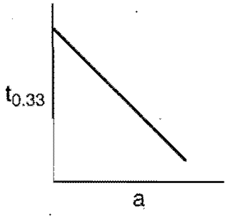
6. Which of the following graphs represents a first order reaction?



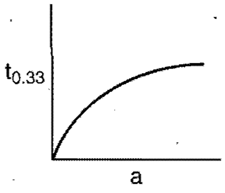
(a)



(b)



(c)



(d)

7. For the reaction,

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(l); \quad \Delta U = -2810 \text{ kJ/mol}$$

ΔH in kJ/mol is:
(a) 845 (b) −890 (c) −2810 (d) −2864

8. The standard emf of the cell, set-up from the reaction,

$$2Cu^+(aq.) \rightleftharpoons Cu(s) + Cu^{2+}(aq.)$$

is 0.36 V at 298 K. The standard free energy in kJ/mol for this reaction is:
(a) − 34.73 (b) − 69.46 (c) − 3473 (d) − 6946

9. When the reaction is first order in *A* and zero order in *B*, rate constant is:
(a) $\left\{-\frac{1}{t[A]_0}\right\} \ln \frac{[A]_0}{[A]_t}$ (b) $\left(-\frac{1}{t}\right) \ln \frac{[A]_0}{[A]_t}$
(c) $\frac{1}{t} \ln \frac{[A]_0}{[A]_t}$ (d) $\frac{1}{t[A]_0} \ln \frac{[A]_0}{[A]_t}$

10. A hypothetical reaction, $2X + Y_2 \longrightarrow 2XY$ follows the mechanism:

$$X + X \rightleftharpoons X_2 \quad \text{(fast)}$$
$$X_2 + Y_2 \rightleftharpoons 2XY \quad \text{(slow)}$$

then the order of reaction is:
(a) 1 (b) 2 (c) 3 (d) undefined

11. The inversion of cane sugar in aqueous acidic medium is a reaction of:
(a) zero order (b) first order
(c) second order (d) third order

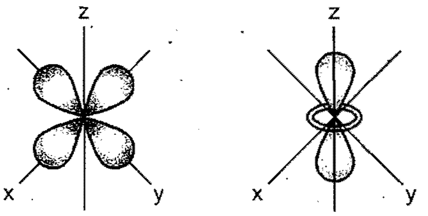
12. Which of the following belongs to, *e.g.*, (double grade) orbitals?
(a) d_{xy}, d_{yz} (b) d_{yz}, d_{zx}
(c) d_{xy}, d_{zx} (d) $d_{x^2-y^2}, d_{z^2}$

13. Which among the following is correct about the energy sequence (in case of H-atom)?
(a) $3s < 3p < 3d$ (b) $3s = 3p = 3d$
(c) $3s > 3p > 3d$ (d) $3s > 3p < 3d$

14. If the equivalent weight of an element is 32, then the percentage of oxygen in its oxide is:
(a) 16 (b) 40 (c) 32 (d) 20

15. Which of the following statements are true?
(a) For gases, in general, viscosity increases with increase in temperature.
(b) For liquids, viscosity varies directly with pressure.
(c) For gases, viscosity is independent of pressure.
(d) All of the above are true.
(e) None of the above

16. The following figures show the angular probability distribution of:



(a) d_{xy} and d_{yz} orbitals (b) $d_{x^2-y^2}$ and d_{z^2} orbitals
(c) d_{xy} and d_{xz} orbitals (d) none of these

17. The equation $E = h\nu$ indicates that:
(a) photons have both particle and wave nature
(b) photons are waves
(c) photons are stream of particles
(d) no such inference can be drawn from the given equation

18. In which of the following conditions, the density of N_2 is maximum?
(a) STP (b) 273 K and 2 atm
(c) 546 K and 1 atm (d) 546 K and 2 atm

19. A sample of natural gas contains 85% CH_4 and 15% C_2H_6. What is the molecular mass of the mixture?
(a) 16.6 (b) 26.6 (c) 30.6 (d) 20.6

20. Match the List-I and List-II:

	List-I	List-II
(A)	The limits of pH values of buffer solution.	(i) 5×10^{-12}
(B)	The $[H_3O]^+$ concentration in 0.001 M $Ba(OH)_2$ solution.	(ii) Equal
(C)	The buffer capacity of a solution is maximum when conc. of salt to that acid is:	(iii) 1st order reaction
(D)	Hydrolysis of ethyl acetate in acidic solution.	(iv) $pK_a \pm 1$

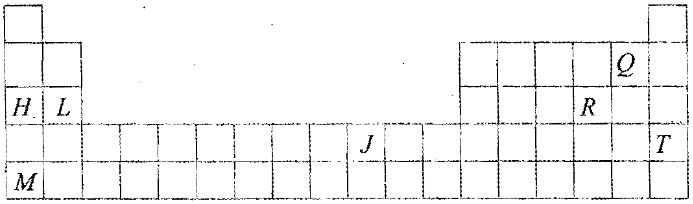
Codes:	(A)	(B)	(C)	(D)
(a)	iv	ii	i	iii
(b)	iv	i	iii	ii
(c)	i	iv	ii	iii
(d)	iv	i	ii	iii

21. Match the List-I and List-II:

	List-I	List-II
(A)	Rate constant has the same unit as the rate of reaction.	(i) One
(B)	Reactions having apparent molecularity more than three.	(ii) Zero order reaction
(C)	Reactions having molecularity two but order of reaction is one.	(iii) Complex reaction
(D)	For a reaction, $A \rightarrow B$, the rate of reaction doubles as the concentration of A is doubled.	(iv) Pseudo unimolecular reaction

Codes:	(A)	(B)	(C)	(D)
(a)	ii	iv	iii	i
(b)	ii	iii	iv	i
(c)	iii	ii	iv	i
(d)	ii	iv	i	iii

The diagram below shows part of the skeleton of the periodic table in which elements are indicated by letters which are not their usual symbols.



Select whether the following statements are True or False:
True (*a*) *False* (*b*)

22. The greatest ionic character of compounds formed by reaction of pairs of the listed elements would be exhibited by the compound with the formula, M_2Q.

23. The J^{2+} ion is coloured and has an electronic configuration of $1s^2, 2s^2\,2p^6, 3s^2\,3p^6\,3d^7$.

24. The carbonate of compound H is insoluble in water.

25. Element R is a gas at room temperature.

26. Element T is an inert gas with an electronic configuration $1s^2, 2s^2\,2p^6, 3s^2\,3p^6\,3d^{10}, 4s^2\,4p^6$.

20 cm^3 of a gaseous element X reacts with excess of an element Y to form 40 cm^3 of a gaseous compound of X and Y. All volumes are measured under the same conditions of temperature and pressure.

Select whether the following statements are True or False.
True (*a*) *False* (*b*)

27. Molecule of X contains at least two atoms of X.

28. The formula of the compound formed is XY.

29. Molecules of X cannot consist of more than two atoms.

30. X is less dense than the compound of X and Y.

31. Y is less dense than the compound of X and Y.

Assertion-Reason Type Questions:

In the questions 32 to 36, statements are given for ***Assertion(A)*** *and* ***Reason (R)****. Choose the correct answers from the codes given below:*

(*a*) *Both (A) and (R) are correct and (R) is the correct explanation of (A).*
(*b*) *Both (A) and (R) are correct but (R) is not the correct explanation of (A).*
(*c*) *(R) is correct but (A) is wrong.*
(*d*) *(A) is correct but (R) is wrong.*

32. (A) In hydrogen spectrum (6569 Å) line is observed in Balmar series.
(R) Balmar lines are found in ultraviolet region.

33. (A) All Arrhenius acids are also Bronsted acids.
(R) All Bronsted bases are also Lewis bases.

34. (A) All p-orbitals are directional.
(R) p-orbitals are oriented along axes.

35. (A) 0.1 M NaCl + 0.05 M HCl solution on mixing in equal volume forms a buffer solution.
(R) The solution is a mixture of salt and acid thus act as a buffer.

36. (A) Number of revolution per second by an electron is same in all shells.
(R) Orbital frequency $= \dfrac{v}{2\pi r}$.

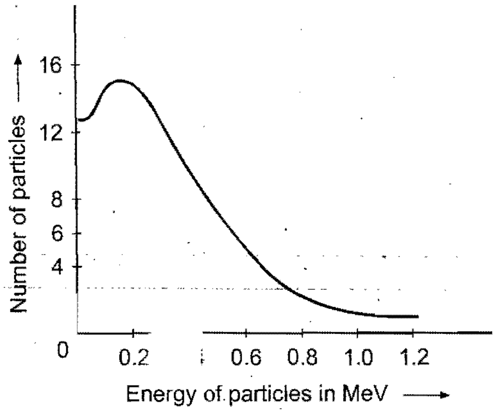
Questions with more than one correct options:

37. The substance(s) which can act as oxidising as well as reducing agent is/are:
(a) H_2O_2 (b) O_3
(c) $NH_2 - NH_2$ (d) HNO_3

38. Which of the following statement(s) is/are correct?
(a) The electronic configuration of Cr is [Ar] $3d^5, 4s^1$.
(b) The magnetic quantum number may have a negative value.
(c) In silver, 23 electrons have clockwise spin and 24 electrons have anticlockwise spin.
(d) The oxidation number of N in N_3H is –3.

39. Loss of a β-particle is equivalent to:
(a) increase in number of protons by one
(b) decrease in number of neutrons by one
(c) change in atomic mass by one unit
(d) none of the above

40. Following curve shows the energy spectrum of β-particles in the figure:



The curve indicates:
(a) β-rays spectrum is continuous
(b) different β-particles (emitted) have different energies
(c) the energy spectrum of β-particles of all the elements is the same
(d) no β-particle has energy more than 1 MeV

41. Maximum velocity of a liquid up to which its flow is stream line is called critical velocity. The critical velocity of a liquid depends upon:
(a) coefficient of viscosity (b) radius of the tube
(c) density of the liquid (d) mass of the tube

42. When a liquid solidifies, generally, there is:
(a) decrease in enthalpy (b) decrease in entropy
(c) increase in enthalpy (d) increase in entropy

43. Which of the following set(s) of chemical compounds is/are used as semipermeable membrane?
(a) calcium phosphate, cellulose nitrate
(b) calcium phosphate, copper ferrocyanide
(c) cellulose nitrate, copper ferrocyanide
(d) copper ferrocyanide, copper sulphate

44. For the depression in freezing point. The correct statement(s) is/are:
(a) The vapour pressure of pure solvent is more than that of solution.
(b) The vapour pressure of pure solvent is less than that of solution.
(c) Only solute molecules solidify at the freezing point.
(d) Only solvent molecules solidify at the freezing point.

45. For exact determination of molecular mass:
(a) solute must be volatile
(b) solution must be very dilute
(c) solution must be of similar components
(d) solute must not be dissociated or associated

46. Match the Column-I with Column-II:

	Column-I		Column-II
(a)	de Broglie equation	(p)	$\lambda = \frac{h}{p}$
(b)	Lyman series	(q)	$\lambda = \frac{h}{\sqrt{2Em}}$
(c)	Wavelength associated with particle of mass *m*	(r)	Transition from higher shell to *K*-shell
(d)	6.6×10^{-19} J energy per photon	(s)	Ultraviolet radiation

(a)	ⓟ	ⓠ	ⓡ	ⓢ
(b)	ⓟ	ⓠ	ⓡ	ⓢ
(c)	ⓟ	ⓠ	ⓡ	ⓢ
(d)	ⓟ	ⓠ	ⓡ	ⓢ

47. Match the Column-I with Column-II:

	Column-I		Column-II
(a)	Mn	(p)	Radius ratio (0.732–1)
(b)	Body-centred cubic	(q)	Hexagonal close-packed
(c)	ABC ABC ABC	(r)	Packing (0.68)
(d)	Be	(s)	Number of constituent units in one unit cell (1)

(a)	ⓟ	ⓠ	ⓡ	ⓢ
(b)	ⓟ	ⓠ	ⓡ	ⓢ
(c)	ⓟ	ⓠ	ⓡ	ⓢ
(d)	ⓟ	ⓠ	ⓡ	ⓢ

48. 75.2 g of C_6H_5COOH is dissolved in a kg of benzene to lower its freezing point by 7 K. K_f for benzene is 14 K kg mol^{-1}. Calculate the percentage association when it forms a dimer.

●	●	⓪	⓪

⑧	⑧	⑧	⑧
⑨	⑨	⑨	⑨

[**Hint:** $\Delta T = i \times K_f \times \dfrac{w_B \times 1000}{m_B \times w_A}$

$$7 = i \times 14 \times \frac{75.2 \times 1000}{122 \times 1000}$$

$$i = 0.81$$

$$\alpha = \frac{1-i}{1-1/n} = \frac{1-0.81}{1-1/2} = 0.38$$

Percentage association = $\alpha \times 100 = 38$]

49. A sample of gas present in a cylinder fitted with a frictionless piston expands against a constant pressure of 1 atm from a volume of 2 L to 12 L. During this process, it absorbs 600 J heat from its surroundings. Calculate the decrease in the internal energy of the system in joule.

[**Hint:** $q = 600\,\text{J}, \Delta V = 12 - 2 = 10\,\text{L}, P = 1\,\text{atm}$

$$w = -P\Delta V = -1 \times 10 \times 101.3 = -1013\,\text{J}$$

$$\Delta U = q + w = 600 - 1013 = -413\,\text{J}]$$

Predict whether the following statements are True/False:

50. For mixing of two ideal gases at 25°C and 1 atm, $\Delta G_{\text{mix}} = 0$.
(a) True (b) False

51. For mixing of two ideal gases at 25°C and 1 atm, $\Delta S_{\text{mix}} = 0$.
(a) True (b) False

52. Isobaric thermal coefficient of an ideal gas is 'R'.
(a) True (b) False

53. The criterion for the spontaneity of a process is $\Delta S_{\text{system}} > 0$.
(a) True (b) False

54. The radioactive element undergoes complete decay in twice of half life.
(a) True (b) False

IIT ENTRANCE TEST PAPERS

TEST SERIES I

SECTION-I

REASONING APTITUDE (For IIT & AIIMS Aspirants)

The questions given below (1 to 10) consist of an **'Assertion'** (A) in column (1) and **'Reason'** (R) in column (2). Use the following keys to choose the appropriate answer:

(a) If both assertion and reason are correct and reason is the correct explanation of the assertion.
(b) If both assertion and reason are correct but reason is not correct explanation of the assertion.
(c) If assertion is correct but reason is incorrect.
(d) If assertion is incorrect but reason is correct.

Assertion (Column 1)	**Reason (Column 2)**
1. Noble gases can be liquefied.	Attractive forces can exist between non-polar molecules.
2. Boiling point of a solvent increases when a non-volatile solute is dissolved in it.	The boiling point of a liquid is the temperature at which vapour pressure of a liquid equals the vapour pressure of the atmosphere.
3. A mixture of sodium acetate and sodium propionate forms a buffer solution.	A buffer solution reacts with small quantities of hydrogen or hydroxyl ions and keeps the pH almost same.
4. The pressure of a fixed amount of an ideal gas is proportional to its temperature at constant volume.	Ideal gas molecules neither attract nor repel each other.
5. In a radioactive disintegration, an electron is emitted by the nucleus.	Electrons are always present inside the nucleus.
6. The ratio C_P/C_V for a diatomic gas is more than that for a monoatomic gas.	The molecules of a monoatomic gas have less degrees of freedom than those of a diatomic gas.
7. Many endothermic reactions that are not spontaneous at room temperature, become spontaneous at high temperature.	Entropy of the system increases with increase in temperature.
8. No two electrons in an atom can have the same values of four quantum numbers.	No two electrons in an atom can be simultaneously in the same shell, subshell, orbitals and have same spin.
9. In radioactive disintegrations, $_2He^4$ nuclei can come out of the nucleus but lighter $_2He^3$ cannot.	Binding energy of $_2He^3$ is more than that of $_2He^4$.
10. A crystal having fcc structure is more closely packed than a crystal having bcc structure.	Packing fraction for fcc structure is double than that of bcc structure.

SECTION-II

SELECT CORRECT ALTERNATIVE AMONG THE GIVEN OPTIONS (For AIEEE & Medical Entrance Aspirants)

11. Pick out the pair in which the energy change of one is reverse of the energy change in the other:
(1) radio (2) fluorescent lamp (3) toaster (4) photoelectric cell
(a) 1 and 2 (b) 2 and 3 (c) 2 and 4 (d) 3 and 4

12. Consider the following statements about first order reaction:
(1) The rate of reaction is directly proportional to the concentration of the reactant.
(2) Its half life period is always constant.
(3) Concentration of reactant falls exponentially.
(4) It has low activation energy.
Of these statements:
(a) 1, 3 and 4 are correct (b) 1, 2 and 4 are correct
(c) 1, 2 and 3 are correct (d) 2, 3 and 4 are correct

13. Which one of the following is the correct order of energies of $3p$, $3d$, $4s$ and $4p$ orbitals as per Aufbau principle?
(a) $3p < 3d < 4s < 4p$ (b) $3p < 4s < 3d < 4p$
(c) $3d < 4s < 4p < 3p$ (d) $3d < 3p < 4p < 4s$

14. In the emission line spectra of hydrogen atom, how many lines can be accounted for by all possible electron transitions between five lowest energy levels within the atom?
(a) 4 (b) 5 (c) 10 (d) 20

15. In a closed container at 1 atm pressure, 2 mole of $SO_2(g)$ and 1 mole of $O_2(g)$ were allowed to react to form $SO_3(g)$ under the influence of a catalyst. The following reaction occurred:

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

At equilibrium it was found that 50% of $SO_2(g)$ was converted to $SO_3(g)$. The partial pressure of $O_2(g)$ at equilibrium will be:
(a) 0.66 atm (b) 0.493 atm (c) 0.33 atm (d) 0.2 atm

16. The electronic configuration $1s^2, 2s^2 2p^5, 3s^1$ describes which one of the following?
(a) An excited state of fluorine atom
(b) The ground state of neon
(c) The excited state of O^{2-}
(d) The ground state of fluoride ion F^-

17. When acetone and chloroform are mixed, hydrogen bonding takes place between them; such a liquid pair will cause:
(a) positive deviation from Raoult's law
(b) negative deviation from Raoult's law
(c) no deviation from Raoult's law
(d) cannot be predicted

18. A maxima or minima obtained in the temperature. Composition curve of a mixture of two liquids indicates:
(a) that the liquids are immiscible with one another
(b) that the liquids are partially miscible at the maximum or minimum
(c) an azeotropic mixture
(d) a eutectic formation

19. The electrode reactions for charging of a lead battery are:

$$PbSO_4 + 2e \longrightarrow Pb + SO_4^{2-}$$

$$PbSO_4 + 2H_2O \longrightarrow PbO_2 + SO_4^{2-} + 4H^+ + 2e$$

The electrolyte in the battery is an aqueous solution of H_2SO_4. After this battery has been charged:

(a) the sulphuric acid will be more concentrated
(b) the sulphuric acid will be less concentrated
(c) the concentration of H_2SO_4 will be unchanged
(d) H_2SO_4 will have been completely decomposed

20. At 291 K, the molar conductivity at infinite dilution of NH_4Cl, NaOH, NaCl are 129.8, 217.4, 108.9 $ohm^{-1}\ cm^2\ mol^{-1}$ respectively. If the molar conductivity of centinormal solution of NH_4OH is 9.33 $ohm^{-1}\ cm^2\ mol^{-1}$, what is the percentage dissociation of NH_4OH at this dilution?

(a) 0.392 (b) 39.2 (c) 3.92 (d) 0.039

21. Through molten $AlCl_3$, a charge equal to the charge of 1 mole N^{3-} was passed. Volume of Cl_2 evolved at anode will be:

(a) 22.4 litre (b) 67.2 litre (c) 33.6 litre (d) 11.2 litre

22. The rate constant of a reaction will be equal to pre-exponential factor when:

(a) temperature in centigrade is zero
(b) absolute temperature is zero
(c) absolute temperature is infinity
(d) no suitable answer

23. The energy levels of A, B and C of certain atoms correspond to increasing values of energy, *i.e.*,

$$E_A < E_B < E_C$$

If λ_1, λ_2 and λ_3 are wavelengths C to B, B to A and C to A respectively; which of the following relation is correct?

(a) $\lambda_3 = \lambda_1 + \lambda_2$ (b) $\lambda_3 = \lambda_1\lambda_2/(\lambda_1 + \lambda_2)$
(c) $\lambda_1 + \lambda_2 + \lambda_3 = 0$ (d) $\lambda_3^2 = \lambda_1^2 + \lambda_2^2$

24. A stationary hydrogen atom emits a photon corresponding to the first line of Lyman series. What velocity does the atom acquire?

(a) 3.25 m/sec (b) 2.35 m/sec
(c) 3.52 m/sec (d) 5.23 m/sec

25. Which of the following transitions is not allowed in the normal electronic spectrum of an atom?

(a) $2p \to 1s$ (b) $3d \to 2p$ (c) $5p \to 3s$ (d) $2s \to 1s$

26. How many spectral lines can be observed when an excited electron returns from 7th to 2nd shell?

(a) 10 (b) 15 (c) 20 (d) 14

27. Two lines of Balmer series of hydrogen are 486.1 and 410.2 nm. If the difference of wave numbers of these lines corresponds to the wave number of a line in the series, to which of following series does the line belong?

(a) Brackett (b) Paschen (c) Pfund (d) Humphrey

28. For a third order reaction, half life is given as:

(a) $t_{1/2} \propto \frac{1}{a}$ (b) $t_{1/2} \propto \frac{1}{a^2}$ (c) $t_{1/2} \propto a^2$ (d) $t_{1/2} \propto a$

29. What specific name can be given to the following sequence of steps?

$$Hg + h\nu \longrightarrow Hg^*$$

$$Hg^* + H_2 \longrightarrow Hg + H_2^*$$

$$H_2^* \longrightarrow 2H$$

(a) Photosensitization (b) Photosorption
(c) Phosphorescence (d) Chemiluminescence

30. If the tetrahedral sites in a ccp array of negative ions (B) were half filled with cations (A), the empirical formula of the compound will be:

(a) A_2B_3 (b) A_2B (c) AB_2 (d) AB

31. An electron in the p-orbital has an orbital angular momentum of:

(a) $\sqrt{2}\,h$ (b) $\frac{\sqrt{2}h}{2\pi}$ (c) $\frac{h}{\pi}$ (d) $\frac{h}{2\pi}$

32. An electron of velocity 'v' is found to have a certain value of de Broglie wavelength. The velocity to be possessed by a neutron to have the same de Broglie wavelength is:

(a) $1840v$ (b) $v/1840$ (c) v (d) $1840/v$

33. van't Hoff factor for a dilute aqueous solution of HCN is 1.00002. The percentage degree of dissociation of the acid is:

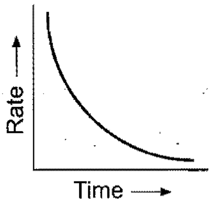
(a) 2×10^{-5} (b) 1×10^{-5} (c) 2×10^{-3} (d) 1×10^{-3}

34. The average life of a radioactive element is 10 minute. In 10 minute what percentage of a radioactive element will decay?

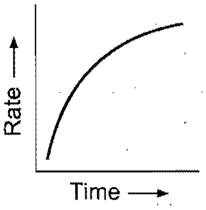
(a) 50% (b) 63.21% (c) 75% (d) 100%

35. Which of the following corresponds to zero order reaction?

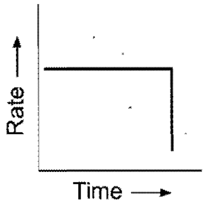
(a)



(b)



(c)

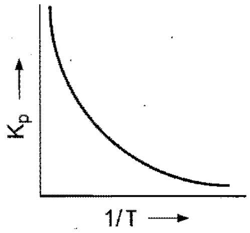


(d) None of these

36. The equilibrium constant K_p for the reaction,

$$X(g) + Y(g) \rightleftharpoons Z(g)$$

is found to vary with temperature in the diagram as shown:



(a) The reaction is exothermic in forward reaction
(b) The equilibrium mixture contains a high proportion of Z at higher pressure
(c) The equilibrium mixture contains a high proportion of Z at high temperature
(d) The equilibrium is unaffected by addition of inert gas

37. Helium was discovered in sun's atmosphere by analysing:

(a) Mayer hoff bands (b) Fraunhofer lines
(c) spectrum (d) spectrometer

38. For an ideal solution of miscible components:

$$\Delta S_{mix} = -R\ \Sigma\ n_2 \log x_1$$

(a) ΔS_{mix} is a negative quantity
(b) ΔS_{mix} is a positive quantity
(c) ΔS_{mix} is zero
(d) ΔS_{mix} is sometimes negative and sometimes positive

39. Specific conductance of a conductivity solution:

(a) increases with dilution
(b) decreases with dilution

(c) is independent of concentration
(d) depends upon the cell constant

40. In the oxide of a compound 'A', oxide ions are arranged in hexagonal close packing and A^{3+} ions occupy two-thirds of the octahedral voids. What is the formula of corundum?
(a) AO (b) A_2O (c) A_2O_3 (d) AO_2

41. Spinel structure is shown by:
(a) $MgAl_2O_4$ (b) $ZnAl_2O_4$ (c) $MgFe_2O_4$ (d) all of these

42. Which of the following atomic orbitals does not have the four lobes lying symmetrically between the axial directions?
(a) $3d_{xy}$ (b) $3d_{xz}$ (c) $3d_{yz}$ (d) $3d_{x^2-y^2}$

43. The degree of dissociation (α) of a weak electrolyte A_xB_y is related to van't Hoff factor 'i' by expression:
(a) $\alpha = \dfrac{i-1}{x+y-1}$ (b) $\alpha = \dfrac{i-1}{x+y+1}$
(c) $\alpha = \dfrac{x+y-1}{i-1}$ (d) $\alpha = \dfrac{x+y+1}{i-1}$

44. The solubility of mercurous chloride in water will be given as:
(a) $S = K_{sp}$ (b) $S = K_{sp}/4$
(c) $S = (K_{sp}/4)^{1/2}$ (d) $S = (K_{sp}/4)^{1/3}$

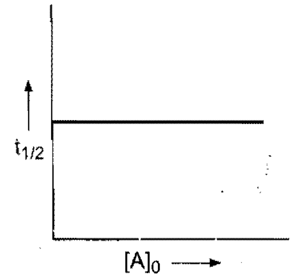
45. The activation energies of two reactions are E_{a_1} and E_{a_2}. If the temperature of the reacting systems is increased from T_1 to T_2, predict which of the following alternatives is correct?
(a) $\dfrac{k_1'}{k_1} = \dfrac{k_2'}{k_2}$ (b) $\dfrac{k_1'}{k_1} > \dfrac{k_2'}{k_2}$
(c) $\dfrac{k_1'}{k_1} < \dfrac{k_2'}{k_2}$ (d) $\dfrac{k_1'}{k_1} < 2\dfrac{k_2'}{k_2}$
where, k_1' and k_2' are rate constants at higher temperature.

46. In a cubic unit cell, seven of the eight corners are occupied by atoms 'A' and centres of faces are occupied by atoms 'B'. The general formula of the compound is:
(a) A_7B_6 (b) A_7B_{12} (c) A_7B_{24} (d) $A_{24}B_7$

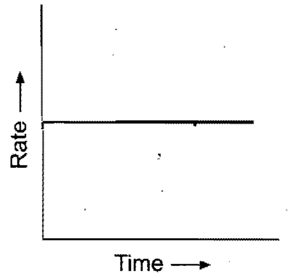
47. The rate law of a reaction of 'A' and 'B',

$$\text{rate} = k[A]^n[B]^m$$

may be determined by plotting $t_{1/2}$ *versus* $[A]_0$ (plot 1) and rate *versus* time for 'B' (plot 2).



(plot 1)



(plot 2)

The rate law superscripts, 'n' and 'm' are:
(a) 0, 0 (b) 0, 1 (c) 1, 0 (d) 1, 1

48. For 1*s*-orbital of hydrogen, the radial electron probability has a maximum value at:
(a) 0.1 Å (b) 0.40 Å (c) 0.53 Å (d) 2.1 Å

49. Which of the following expressions correctly represents the relationship between average kinetic energy of CO and N_2 molecules at the same temperature?
(a) $E_{CO} > E_{N_2}$
(b) $E_{CO} < E_{N_2}$
(c) $E_{CO} = E_{N_2}$
(d) Cannot be predicted unless volumes of the gases are given

50. On the basis of Hardy-Schulze rule, which of the following sequences represents the coagulating power of cations?
(a) $Ba^{2+} > Al^{3+} > Na^+$ (b) $Ba^{2+} > Na^+ > Al^{3+}$
(c) $Al^{3+} > Na^+ > Ba^{2+}$ (d) $Al^{3+} > Ba^{2+} > Na^+$

51. Adiabatic expansion of an ideal gas is accompanied by:
(a) increase in temperature
(b) decrease in ΔS
(c) decrease in ΔE
(d) no change in any one of the above properties

52. For a cyclic process, which of the following is not true?
(a) $W = 0$ (b) $\Delta E = 0$ (c) $\Delta H = 0$ (d) $\Delta G = 0$

53. Radius of nucleus is related to the mass number 'A' by:
(a) $R = R_0A^{1/2}$ (b) $R = R_0A$
(c) $R = R_0A^2$ (d) $R = R_0A^{1/3}$

54. A catalyst:
(a) increases the average kinetic energy of molecules
(b) increases the activation energy
(c) alters the reaction mechanism
(d) increases the frequency of collisions of reacting species

55. A chemist wishes to prepare a buffer solution of pH = 3.85 that efficiently resists changes in pH yet contains only small concentration of the buffering agents. Which one of the following weak acids together with its sodium salt would be best to use?
(a) *m*-chlorobenzoic acid ($pK_a = 3.98$)
(b) *p*-chlorocinnamic acid ($pK_a = 4.41$)
(c) 2,5-hydroxybenzoic acid ($pK_a = 2.97$)
(d) Aceto-acetic acid ($pK_a = 3.58$)

56. For coordination number 4, the geometry that is not possible is:
(a) trigonal planar (b) tetrahedral
(c) irregular tetrahedral (d) trigonal pyramidal

57. The rate constant, the activation energy and the Arrhenius parameter of a chemical reaction at 25°C are $3 \times 10^{-4}\ sec^{-1}$, 104.4 kJ mol^{-1} and $6 \times 10^{14}\ sec^{-1}$ respectively. The value of rate constant as $T \to \infty$ is:
(a) $2 \times 10^{18}\ s^{-1}$ (b) $6 \times 10^{14}\ s^{-1}$
(c) infinity (d) $3.6 \times 10^{30}\ s^{-1}$

58. Emission of one 'α' and two 'β' particles successively from an element forms:
(a) isotope of parent element (b) isobar of parent element
(c) isotone of parent element (d) isomer of parent element

59. Fraction of the total volume occupied by atoms in a simple cube is:
(a) $\dfrac{\pi}{2}$ (b) $\dfrac{\sqrt{3}\pi}{8}$ (c) $\dfrac{\sqrt{2}\pi}{6}$ (d) $\dfrac{\pi}{6}$

60. Which of the following statements is wrong?
(a) Crystalline solids are optically anisotropic
(b) Glass is amorphous solid
(c) There are 14 Bravais lattices
(d) There are only 10 crystal symmetries

61. Which of the following pairs is correctly matched?

	Experimental observation	**Phenomenon**
(a)	X-ray spectra	Charge on the nucleus
(b)	α-particle scattering	Quantized electron orbit
(c)	Emission spectra	Quantization of energy
(d)	The photoelectric effect	The nuclear atom

62. Arrangement of the following group of orbitals in which they fill with electrons:

$$(5f, 6p, 4p, 6s, 4d, 4f)$$

(a) $4p, 4d, 6s, 4f, 6p, 5f$ (b) $6s, 4d, 4f, 5f, 4p, 6p$
(c) $6s, 4p, 4d, 4f, 5f, 6p$ (d) $4d, 4p, 4f, 5f, 6s, 6p$

63. π° meson is exchanged between:
(a) proton and neutron
(b) proton and proton
(c) neutron and neutron
(d) may be between two protons or two neutrons

64. If nucleons in an excited state fall to a lower energy level, energy is emitted as:
(a) α-rays (b) β-rays (c) γ-rays (d) X-rays

65. Minimum amount of energy required to remove a proton is approximately:
(a) 2 MeV (b) 4 MeV (c) 6 MeV (d) 8 MeV

66. Mark the incorrect statement:
(a) Semiconductors are basically insulator
(b) In metal crystal conduction occurs because molecular orbitals extend over the whole crystal and there is no energy gap between filled and unfilled molecular orbital
(c) Mobile electrons account for high thermal and electrical conduction of metals
(d) When a metal is heated with a non-metal, the resulting compound is never an ionic compound

67. Given:
(i) $NH_3(g) + 3Cl_2(g) \longrightarrow NCl_3(g) + 3HCl(g)$; ΔH_1
(ii) $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$; ΔH_2
(iii) $H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$; ΔH_3

Express the enthalpy of formation of $NCl_3(g)$ (ΔH_f) in terms of ΔH_1, ΔH_2 and ΔH_3:

(a) $\Delta H_f = \Delta H_1 - \frac{\Delta H_2}{2} + \frac{3}{2}\Delta H_3$

(b) $\Delta H_f = \Delta H_1 + \frac{1}{2}\Delta H_2 - \frac{3}{2}\Delta H_3$

(c) $\Delta H_f = \Delta H_1 - \frac{1}{2}\Delta H_2 - \frac{3}{2}\Delta H_3$

(d) $\Delta H_f = \Delta H_1 + \frac{1}{2}\Delta H_2 + \frac{3}{2}\Delta H_3$

68. A spontaneous process may be defined as:
(a) a process which is exothermic and evolves a lot of heat
(b) a process which is slow and reversible
(c) a process which takes place only in presence of a catalyst
(d) a process that occurs without any input from the surroundings

69. In the sequence of reaction,

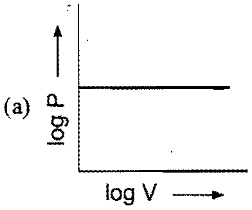
$$L \xrightarrow{k_1} M \xrightarrow{k_2} N \xrightarrow{k_3} O$$

$$k_3 > k_2 > k_1$$

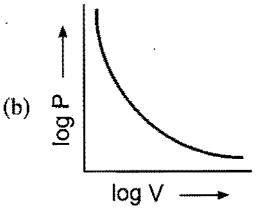
The rate determining step of the reaction is:
(a) $L \longrightarrow M$ (b) $M \longrightarrow N$ (c) $N \longrightarrow O$ (d) $L \longrightarrow O$

70. The plot of log V against log P at constant temperature for a fixed mass of gas is:

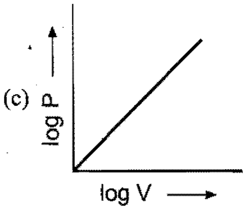
(a)



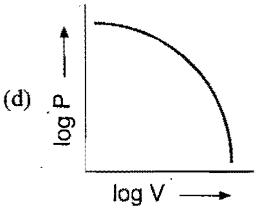
(b)



(c)



(d)



71. When mercuric iodide is added to aqueous solution of KI:
(a) freezing point is raised
(b) freezing point does not change
(c) freezing point is lowered
(d) boiling point does not change

72. The van der Waals' constant 'b' for water vapour is 0.03 litre mol^{-1}. The radius of water vapour molecule is:
(a) 1.448 cm (b) 1.448 Å (c) 1.448 pm (d) 1.448 nm

73. For a reaction $A \begin{matrix} \nearrow^{k_1} C \\ \searrow_{k_2} B \end{matrix}$, the overall rate constant is related to individual rate constants by:
(a) $k = k_1 - k_2$ (b) k_1/k_2 (c) k_1k_2 (d) $k_1 + k_2$

74. N_2O_5 decomposes to N_2O_4 and O_2 as:

$$N_2O_5 \longrightarrow N_2O_4 + \tfrac{1}{2}O_2$$

The pressure P_t at any stage is related to p_0 and 'x', the fraction of dissociation, as:

(a) p_0 (b) $(1 + \frac{1}{2}x)\,p_0$
(c) $1 - \frac{3}{2}p_0$ (d) $\frac{3}{2}xp_0$

SECTION III

MULTIPLE CHOICE QUESTIONS (For IIT, AIIMS and BHU Medical Entrance)

This section includes those questions in which two or more options may be correct. Few of them have single correct choice.

75. An ideal gas:
(a) has no intermolecular attraction
(b) molecules do not collide with each other
(c) the product of P and V is constant at a fixed temperature for definite mass
(d) can be liquefied easily

76. Extensive properties among the following is/are:
(a) refractive index (b) volume
(c) density (d) mass

77. Which of the following statements regarding equilibrium is /are true?
(a) Equilibrium constant varies with temperature
(b) Equilibrium constant varies with catalyst
(c) The reaction stops when the equilibrium is reached
(d) The equilibrium constant depends on the concentration of reactants

78. When mercuric iodide is added to aqueous KI solution:
(a) freezing point is raised (b) osmotic pressure is raised
(c) boiling point is elevated (d) vapour pressure is raised

79. The correct statements are:
(a) Smoke is carbon dispersed in air
(b) Butter is water dispersed in fat
(c) Greater is the valency of ion more will be its coagulating power
(d) More is the gold number of a lyophobic sol, more is protecting power

80. Select the correct statements among the following:
(a) Order can be zero.
(b) Order cannot have fractional value.
(c) Order is a theoretical quantity.
(d) Order is equal to molecularity for decomposition of N_2O_5 giving N_2O_4 and O_2.

81. Rate law for a chemical reaction is:

$$\text{Rate} = k[A]^{1/2}[B]^1$$

Choose the correct options among the following:
(a) Order of the reaction is 3/2.
(b) Unit of its rate constant is $\text{litre}^{1/2}\ \text{mol}^{-1/2}\ \text{sec}^{-1}$.
(c) Unit of rate is $\text{mol litre}^{-1}\ \text{sec}^{-1}$.
(d) Its molecularity is always 3.

82. Liquid benzene burns in oxygen according to:

$$2C_6H_6 + 15O_2 \longrightarrow 12CO_2 + 6H_2O$$

If density of liquid benzene is 0.88 g/cc, what volume of O_2 at STP is needed to complete the combustion of 39 cc of liquid benzene?
(a) 11.2 litre (b) 74 litre (c) $0.074\ m^3$ (d) $37\ dm^3$

83. For the reaction;

$$N_2H_4(l) + 2H_2O_2(l) \longrightarrow N_2(g) + 4H_2O(g)$$

heats of formation of N_2H_4, H_2O_2, H_2O are 12, − 45 and −57.8 kcal mol^{-1}. Internal energy change for this reaction is/are at 298 K:
(a) $-153.2\ \text{kcal mol}^{-1}$ (b) $-641.142\ \text{kJ mol}^{-1}$
(c) $-24.8\ \text{kcal mol}^{-1}$ (d) $-309\ \text{kcal mol}^{-1}$

84. Which of the following electrolytes have same osmotic pressure as that of 0.1 *M* KCl?
(a) 0.1 *M* HCl (b) 0.1 *M* NaCl
(c) 0.1 *M* CsCl (d) None of these

85. Select the correct statements about the following reaction:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g);\quad \Delta H = -22.4\ \text{kcal mol}^{-1}$$

(a) Increase in pressure will favour forward reaction.
(b) Addition of inert gas forms more NH_3.
(c) At low temperature, there is forward shift.
(d) Catalyst will increase the amount of NH_3.

86. Which among the following is/are correct about penetrating power?
(a) α-rays are less penetrating than β-rays.
(b) β-rays are less penetrating than γ-rays.
(c) α, β, γ rays have equal penetrating power.
(d) γ-rays are most penetrating.

87. Select the natural series among the following:
(a) $(4n + 1)$ (b) $(4n + 2)$ (c) $4n$ (d) $(4n + 3)$

88. Select the correct conclusion(s) about average life:
(a) Average life = 1/λ
(b) Average life = $1.44 \times t_{1/2}$
(c) The time in which 63.2% element decays is called average life
(d) None of the above

89. Which of the following statements are correct?
(a) 1 faraday is the charge of 1 mole electron.
(b) 1 faraday is used to deposit 1 g equivalent of a substance.
(c) 5.6 litre O_2 will be evolved at STP by 1 faraday charge.
(d) 11.2 litre Cl_2 will be evolved at STP by 1 faraday charge.

90. Select the species having zero oxidation state at the underlined elements:
(a) $(CH_3)_2\underline{S}O$ (b) $\underline{C}_{12}H_{22}O_{11}$ (c) $H_2\underline{S}_2O_3$ (d) $\underline{N}_2H_4$

91.

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

'α' is the degree of dissociation of PCl_5 at equilibrium pressure '*P*'. Which among the following is the correct expression for degree of dissociation of 'α'?
(a) $\alpha = \sqrt{\dfrac{K_p}{P + K_p}}$ (b) $\alpha = \sqrt{\dfrac{P + K_p}{K_p}}$
(c) $\alpha = \sqrt{K_p P}$ (d) $\alpha = \sqrt{P/K_p}$

92. In Wilson Cloud Chamber, the track is formed by:
(a) α-rays (b) β-rays (c) γ-rays (d) all of these

93. Select the correct relation:
(a) $N_0 = N \cdot 10^{\lambda t/2.303}$ (b) $N_0 = Ne^{\lambda t}$
(c) $N_0 = N \dfrac{\lambda}{10^{2.303t}}$ (d) $N = N_0 e^{-\lambda t}$

94. For the first order reaction, $t_{99\%} = x \times t_{90\%}$, the value of '*x*' will be:
(a) 10 (b) 6 (c) 3 (d) 2

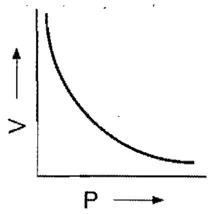
95. Which among the following has same kinetic energy as O_2 gas at NTP?
(a) H_2 (b) N_2 (c) CO_2 (d) None of these

96. Which among the following is correct about γ-rays?
(a) High energy electrons
(b) Low energy electrons
(c) High energy electromagnetic waves
(d) High energy positrons

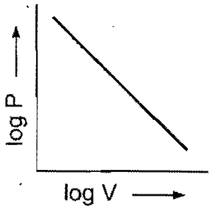
97. The RMS speed at NTP of a gas can be calculated from the expression:
(a) $\sqrt{3P/d}$ (b) $\sqrt{3PV/M}$ (c) $\sqrt{3RT/M}$ (d) $\sqrt{3d/P}$

98. The graph representing Boyle's law is(are):

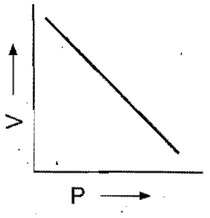
(a)



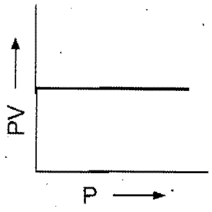
(b)



(c)



(d)



99. For diatomic molecules; the correct relation is/are:
(a) $C_P = \frac{7}{2}R$ (b) $C_V = \frac{5}{2}R$ (c) $\gamma = 1.4$ (d) $C_P = \frac{3}{2}R$

100. Which of the following aqueous solutions produce the same osmotic pressure?
(a) 0.1 M NaCl solution
(b) 0.1 M glucose solution
(c) 0.6 g urea in 100 mL solution
(d) 1.0 g of a non-electrolyte solute in 50 mL solution (Molar mass = 200)

Answers with Hints for Selected Questions

SECTION I

1. (b) **2.** (b) **3.** (b) **4.** (b) **5.** (c)

6. (d) Degree of freedom = $3n$
where, n = no. of atoms in the molecule.

7. (b) At high temperature, $T\,\Delta S > \Delta H$

$$\therefore \quad \Delta G = \Delta H - T\Delta S = -\text{ ve}$$

and process will be spontaneous.

8. (a)

9. (c) Binding energy has no role in emission of α-particle. n/p ratio determines the mode of emission.

$$4\,[{}_1\text{H}^1\,] \longrightarrow {}_2\text{He}^4 + 2\,[{}_{+1}e^0\,] + \text{Energy}$$

10. (c) Packing fraction (fcc) = 74%
Packing fraction (bcc) = 67.9%

SECTION II

11. (c)

12. (c) Rate = $k\,[A]^1$ (for first order)

$$t_{1/2} = \frac{0.693}{k} = \text{constant}$$

13. (b) Lower the value of $(n + l)$, lesser is the energy of orbital.

14. (c) No. of lines = $\dfrac{(n_2 - n_1)\,(n_2 - n_1 + 1)}{2}$

n_2 = higher shell
n_1 = lower shell

15. (d) $p_A = x_A \times p = \frac{1}{2} \times 1 = 0.5$ atm, $x_A = \frac{1}{2}$ = mole fraction of O_2.

16. (c)

17. (b) Greater is the intermolecular force on mixing, more negative will be the deviation $p < p_A^0 x_A + p_B^0 x_B$
Experimental vapour pressure will be less than calculated vapour pressure.

18. (c) Non-ideal solutions form low or high boiling azeotrope, hence, maxima and minima in the curve are obtained.

19. (a)

20. (c) $\Lambda_m^\infty \text{ NH}_4\text{OH} = \Lambda_m^\infty \text{ NH}_4\text{Cl} + \Lambda_m^\infty \text{ NaOH} - \Lambda_m^\infty \text{ NaCl}$

$$= 129.8 + 217.4 - 108.9$$

$$= 238.3 \text{ ohm}^{-1}\text{ cm}^2\text{ mol}^{-1}$$

$$\alpha = \frac{\Lambda_m}{\Lambda_m^\infty} = \frac{9.33}{238.3} = 0.03915$$

% Ionization = 3.92

21. (c)

22. (c) $k = Ae^{-E_a/RT}$ When $T = \infty$, $k = Ae^0 = A$

23. (b) $\dfrac{hc}{\lambda_3} = \dfrac{hc}{\lambda_1} + \dfrac{hc}{\lambda_2}$

$$\frac{1}{\lambda_3} = \frac{1}{\lambda_1} + \frac{1}{\lambda_2}$$

$$\lambda_3 = \frac{\lambda_1\lambda_2}{\lambda_1 + \lambda_2}$$

24. (a) **25.** (d)

26. (b) $n_2 = 7, \quad n_1 = 2$

$$\text{No. of lines} = \frac{(n_2 - n_1)(n_2 - n_1 + 1)}{2}$$

$$= \frac{(7-2)(7-2+1)}{2}$$

$$= \frac{5 \times 6}{2} = 15$$

27. (c) The difference fall in far infrared series.

28. (b) $t_{1/2} \propto \dfrac{1}{a^{n-1}}$, where, n = order of reaction.

29. (a)

30. (d) Number of 'B' atoms = n
Number of tetrahedral void = $2n$
Number of 'A' atoms = $\dfrac{2n}{2} = n$

$$A : B = n : n = 1 : 1$$

Formula = AB

31. (b) Orbital angular momentum = $\sqrt{l\,(l+1)}\,\dfrac{h}{2\pi}$

$l = 1$ for 'p' subshell.

32. (b)

33. (c) $\alpha = \dfrac{i-1}{n-1}$, $\quad n = 2$ for HCN

$$\alpha = \frac{1.00002 - 1}{2 - 1} = 0.00002$$

% dissociation = 0.002

34. (b)

35. (c) Rate of zero order reaction is constant.

36. (b) **37.** (b) (b)

39. (b) Number of ion per unit volume decreases on dilution

40. (c)

41. (d) AB_2O_4 has spinel structure.

42. (d) **43.** (a)

44. (d) $\underset{S}{\text{Hg}_2\text{Cl}_2} \longrightarrow \underset{S}{\text{Hg}_2^{2+}} + \underset{2S}{2\text{Cl}^-}$

$$K_{sp} = [\text{Hg}_2^{2+}\,][\text{Cl}^-\,]^2 = [S\,][2S]^2 = 4S^3$$

45. (b) Use the relation,

$$\log_{10}\left(\frac{k_2}{k_1}\right) = \frac{E_a}{2.303R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

When $\quad E_{a_1} > E_{a_2}$

$$\frac{k_2}{k_1} > \frac{k_2'}{k_1'} \quad \text{or} \quad \frac{k_1'}{k_1} \quad \frac{k'}{k_2}$$

46. (c)

47. (c) $t_{1/2}$ of first order reaction is constant (plot 1).

$$t_{1/2} = \frac{0.693}{R}$$

Rate of zero order reaction is constant (plot 2).

$$\text{Rate} = k\,[A]^0$$

48. (c) **49.** (c) **50.** (d)

51. (c) Adiabatic expansion results into decrease in internal energy and temperature of system.

52. (d) **53.** (d)

54. (c) Catalyst forms new intermediate of either low or high activation energy.

55. (a)

56. (a) Either square planar or tetrahedral geometry is possible.

57. (b) **58.** (a) **59.** (d) **60.** (d)

61. (c) In emission spectra quantum of electromagnetic radiations are released.

62. (a) **63.** (d)

64. (c) γ-rays are evolved due to secondary effect of α, β emission.

65. (a) **66.** (d) **67.** (b) **68.** (d)

69. (a) Slowest step is $L \xrightarrow{k_1} M$; it will be rate determining.

70. (b)

71. (a) $HgI_2 + 2KI \longrightarrow K_2[HgI_4]$

Nessler's reagent $K_2[HgI_4]$ is formed which lowers the overall number of particles in the solution. Thus, on mixing the two components freezing point will be raised.

72. (b) $b = 4NV' = 4N\left(\frac{4}{3}\pi r^3\right)$

V' = volume occupied by single molecule.

73. (d)

74. (b)

$$\begin{array}{lccc} & N_2O_5(g) & \longrightarrow N_2O_4(g) + & (\tfrac{1}{2})\,O_2(g) \\ t=0 & p_0 & 0 & 0 \\ \text{At } `t\text{'} & p_0(1-x) & p_0x & p_0x/2 \end{array}$$

$$P_t = p_0(1-x) + p_0\,x + \frac{p_0\,x}{2} = p_0\left(1 + \frac{x}{2}\right)$$

SECTION III

75. (a, c) **76.** (b, d) **77.** (a, b)

78. (a, d) KI reacts with HgI_2 to form Nessler's reagent. Number of particles are lowered.

$$2KI + HgI_2 \longrightarrow K_2[HgI_4]$$

79. (a, b, c) **80.** (a, d) **81.** (a, b, c) **82.** (b, c)

83. (a, b)

84. (a, b, c) van't Hoff factor will be same for the given electrolytes.

85. (a, b, c) **86.** (a, b, d) **87.** (b, c, d) **88.** (a, b, c)

89. (a, b, c, d) **90.** (a, b) **91.** (a) **92.** (a, b)

93. (a, b, d) **94.** (d) **95.** (a, b, c) **96.** (c)

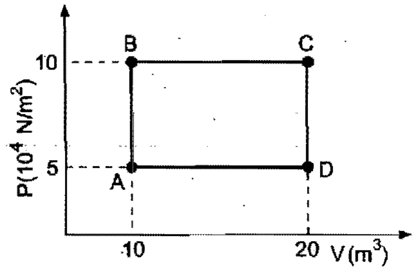
97. (a, b, c) **98.** (a, b, d) **99.** (a, b, c) **100.** (b, c, d)

IIT ENTRANCE TEST PAPERS

TEST SERIES II

(Graphical Aptitude)

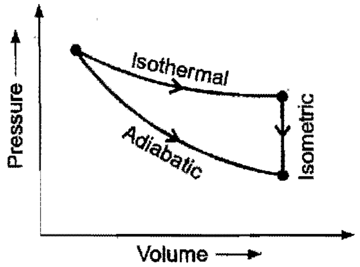
1. A sample of 2 kg of helium (assumed ideal) is taken through the process *ABC* and another sample of 2 kg of the same gas is taken through the process *ADC*. Then the temperature of the states *A* and *B* are: (Given, $R = 8.3$ joules/mol K)



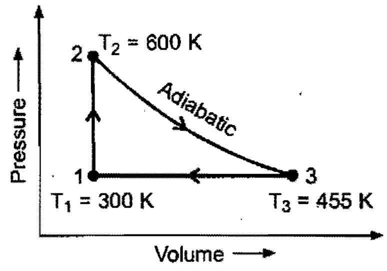
(a) $T_A = 120.5\text{ K}, T_B = 120.5\text{ K}$
(b) $T_A = 241\text{ K}, T_B = 241\text{ K}$
(c) $T_A = 120.5\text{ K}, T_B = 241\text{ K}$
(d) $T_A = 241\text{ K}, T_B = 482\text{ K}$

2. An ideal diatomic gas is caused to pass through a cycle shown on the $P-V$ diagram in figure, where $V_2 = 3.00\,V_1$. If P_1, V_1 and T_1 specify the state 1, then the temperature of the state 3 is:

(a) $(T_1/3)^{1.4}$ (b) $T_1/3^{1.4}$
(c) $T_1/3^{0.4}$ (d) cannot be determined

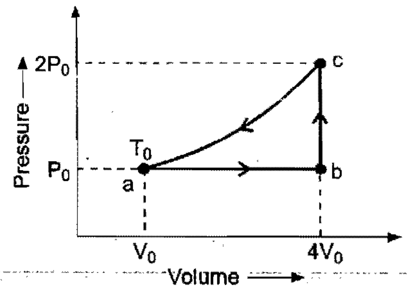


3. A heat engine carries one mole of an ideal monoatomic gas around the cycle as shown in the figure. Process 1 → 2 takes place at constant volume, process 2 → 3 is adiabatic and process 3 → 1 takes place at constant pressure. Then the amount of heat added in the process 1 → 2 is:



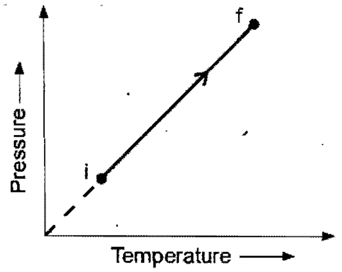
(a) 3740 J (b) −3740 J (c) 1810 J (d) 3220 J

4. One mole of an ideal monoatomic gas is caused to go through the cycle shown in figure. Then the change in the internal energy in expanding the gas from *a* to *c* along the path *abc* is:



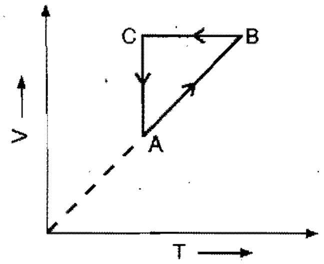
(a) $3P_0V_0$ (b) $6RT_0$ (c) $4.5RT_0$ (d) $10.5RT_0$

5. A thermodynamic system consists of a cylinder-piston arrangement with ideal gas in it. It goes from the state *i* to the state *f* as shown in the figure. The work done by the gas during the process:

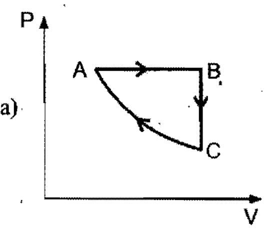


(a) is zero (b) is negative
(c) is positive (d) nothing can be predicted

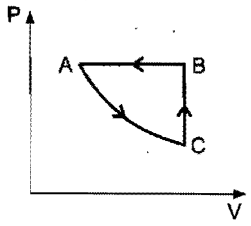
6. A cyclic process *ABCA* is shown in a $V-T$ diagram. The corresponding $P-V$ diagram is:



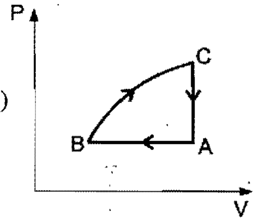
(a)



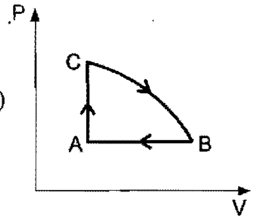
(b)



(c)

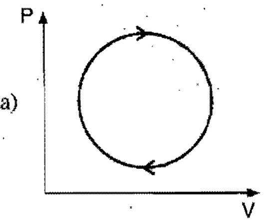


(d)

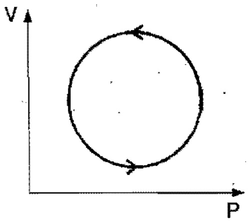


7. The following are the $P-V$ diagrams for cyclic processes for a gas. In which of these processes heat is not absorbed by the gas?

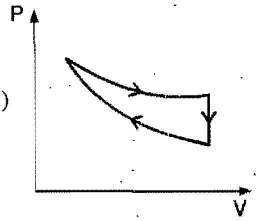
(a)



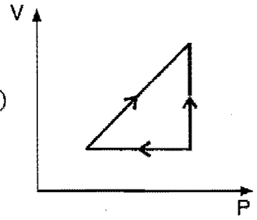
(b)



(c)

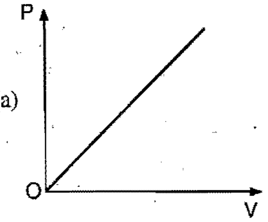


(d)

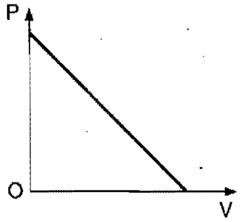


8. The graph between P and V at constant temperature should look like:

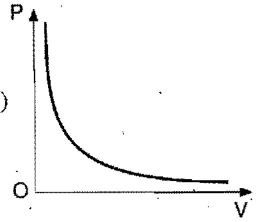
(a)



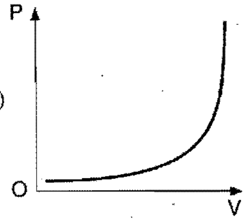
(b)



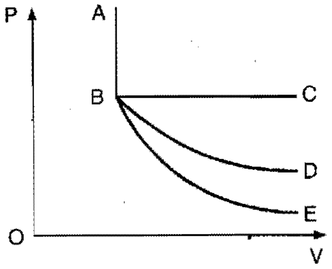
(c)



(d)

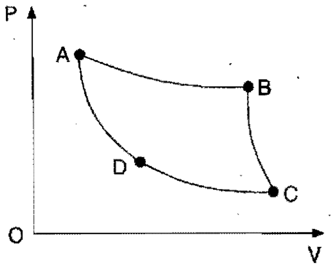


9. In $P-V$ diagram shown below:



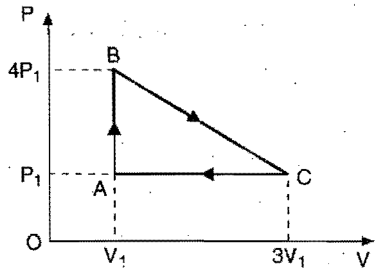
(a) AB represents adiabatic process
(b) AB represents isothermal process
(c) AB represents isobaric process
(d) AB represents isochoric process

10. The pressure-volume graph of an ideal gas cycle is shown below. The adiabatic process is described by:



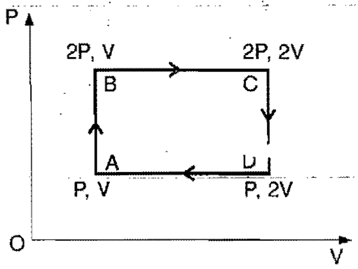
(a) AB and BC (b) AB and CD
(c) AD and BC (d) BC and CD

11. An ideal gas is taken around the cycle $ABCA$ shown in $P-V$ diagram. The net work done by the gas during the cycle is equal to: (BHU 1994)



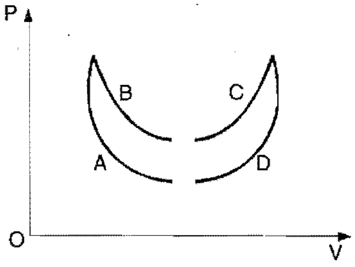
(a) $12P_1V_1$ (b) $6P_1V_1$ (c) $3P_1V_1$ (d) P_1V_1

12. An ideal monoatomic gas is taken round the cycle $ABCDA$ as shown in figure. The work done during cycle is:



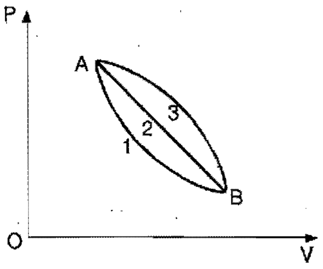
(a) PV (b) $2PV$ (c) $\frac{1}{2}PV$ (d) zero

13. Four curves A, B, C and D are drawn in figure for a given amount of gas. The curve which represents adiabatic and isothermal changes are:



(a) C and D respectively (b) D and C respectively
(c) A and B respectively (d) B and A respectively

14. A given mass of gas expands from the state A to the state B by three paths 1, 2 and 3 as shown in the figure. If W_1, W_2 and W_3 respectively be the work done by the gas along three paths then: (CPMT 1992)

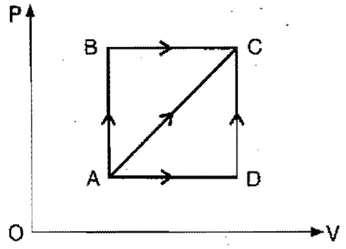


(a) $W_1 > W_2 > W_3$ (b) $W_1 < W_2 < W_3$
(c) $W_1 = W_2 = W_3$ (d) $W_1 < W_2$; $W_1 < W_3$

15. A thermodynamic process is shown in the following figure. The pressure and volumes corresponding to some points in the figure are:

$P_A = 3\times10^4\text{Pa}, V_A = 2\times10^{-3}\ \text{m}^3$;

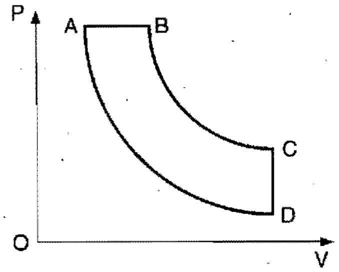
$P_B = 8\times10^4\text{Pa}, V_D = 5\times10^{-3}\ \text{m}^3$



In process AB, 600 J of heat is added to the system and in the process BC, 200 J of heat is added to the system. The change in internal energy of the system in the process AC would be: **(CBSE 1992)**

(a) 560 J (b) 800 J (c) 600 J (d) 640 J

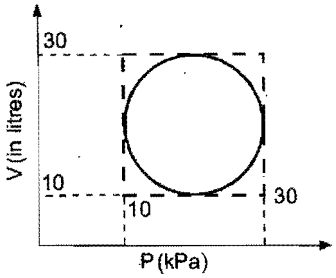
16. In the pressure-volume diagram given below, the isochoric, isothermal, isobaric and isoentropic parts respectively are:



(a) BA, AD, DC, CB (b) DC, CB, BA, AD

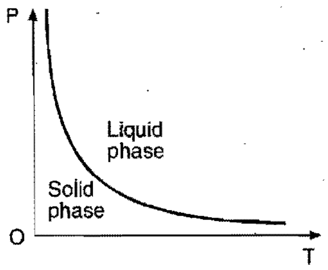
(c) AB, BC, CD, DA (d) CD, DA, AB, BC

17. Heat energy absorbed by a system in going through a cyclic process shown in figure is: **(AIIMS 1995)**



(a) $10^7\pi$ J (b) $10^4\pi$ J (c) $10^2\pi$ J (d) $10^{-3}\pi$ J

18. The pressure-temperature ($P-T$) phase diagram shown below corresponds to the: **[CEE (Haryana) 1996]**



(a) Curve of fusion of solids that expand on solidification

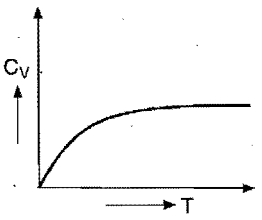
(b) Curve of sublimation of solids that directly go over to the vapour phase

(c) Curve of fusion of solids that contract on solidification

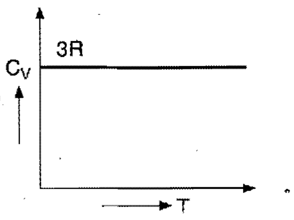
(d) Curve of fusion of solids that do not change in volume upon solidification

19. Graph of specific heat at constant volume for a monoatomic gas is:

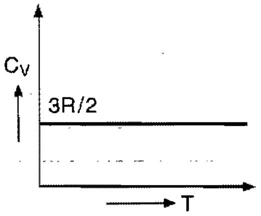
(a)



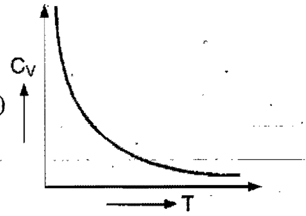
(b)



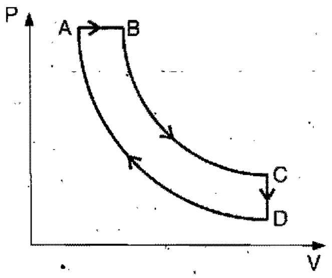
(c)



(d)

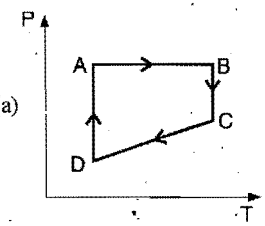


20.

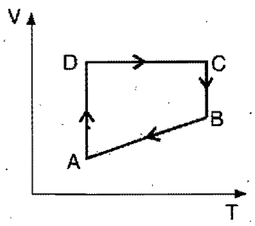


A cyclic process $ABCD$ is shown in the $P-V$ diagram. Which of the following curves represents the same process?

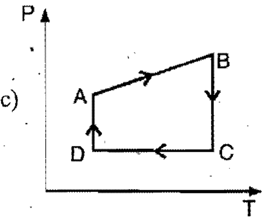
(a)



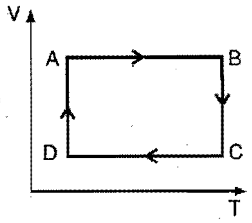
(b)



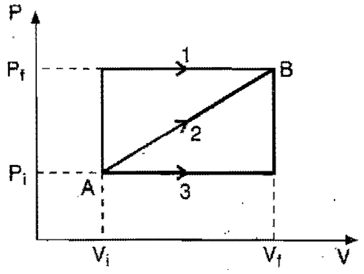
(c)



(d)

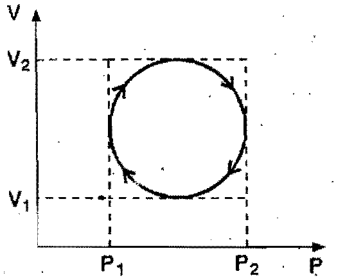


21. A system is taken from state A to B through three different paths 1, 2 and 3. The work done is maximum in: **(CPMT 1997)**



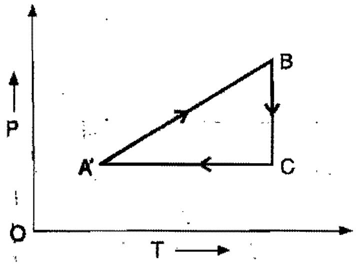
(a) process 1 (b) process 2
(c) process 3 (d) equal in all processes

22. In the cyclic process shown on $P-V$ diagram, the magnitude of the work done is:



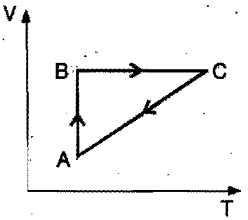
(a) $\pi\left(\frac{P_2-P_1}{2}\right)^2$ (b) $\pi\left(\frac{V_2-V_1}{2}\right)^2$
(c) $\frac{\pi}{4}(P_2-P_1)(V_2-V_1)$ (d) $\pi(P_2V_2 = P_1V_1)$

23. A cyclic process is shown in the $P-T$ diagram:

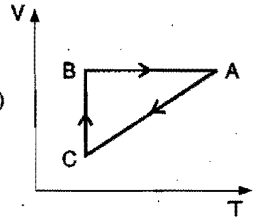


Which of the curves shows the same process on a $V-T$ diagram?

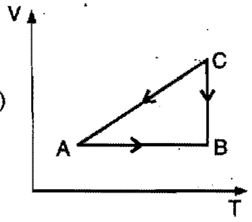
(a)



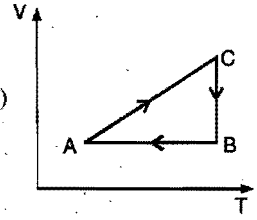
(b)



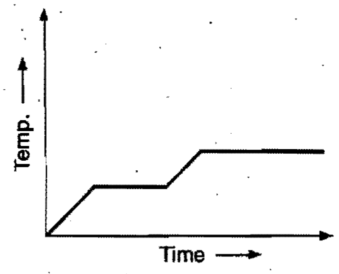
(c)



(d)

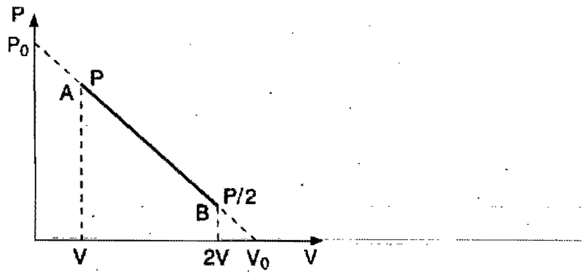


24. Heat is supplied to a certain homogeneous sample of matter, at a uniform rate. Its temperature is plotted against time, as shown. Which of the following conclusions can be drawn?



(a) Its specific heat capacity is greater in the solid state than in the liquid state.
(b) Its specific heat capacity is smaller in the solid state than in the liquid stat.
(c) Its latent heat of vaporization is greater than its latent heat of fusion.
(d) Its latent heat of vaporization is smaller than its latent heat of fusion.

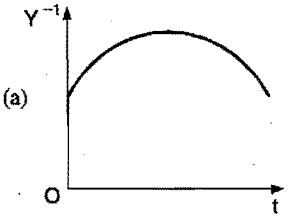
25. An ideal gas is taken from the state A (pressure P, volume V) to the state B (pressure $P/2$, volume $2V$) along a straight line path in the $P-V$ diagram. Select the wrong statement from the following:



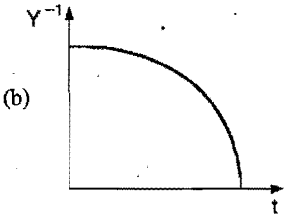
(a) The work done by the gas in the process A to B exceeds the work that would be done by it if the system were taken from A to B along the isotherm
(b) In the $T-V$ diagram, the path AB becomes a part of parabola
(c) In the $P-T$ diagram, the path AB becomes a part of hyperbola
(d) In going from A to B, the temperature T of the gas first increases to a maximum value and then decreases

26. The radioactive nucleus of an element X decays to a stable nucleus of element Y. A graph of the rate of formation of Y against time would look like:

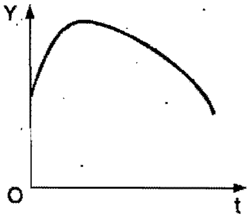
(a)



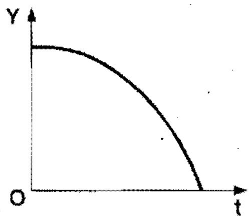
(b)



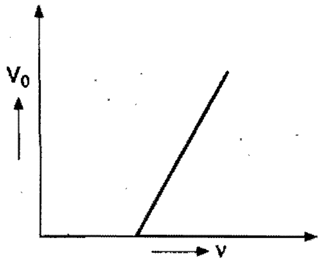
(c)



(d)



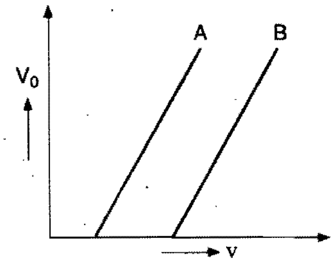
27. In photoelectric effect the slope of straight line graph between stopping potential (V_0) and frequency of incident light (ν) gives:



(a) charge on electron
(b) work function of emitter

(c) Planck's constant
(d) ratio of Planck's constant to charge on electron

28. The sloping potential as a function of frequency of incident radiation is plotted for two different photoelectric surfaces A and B. The graphs show that the work function of A is:

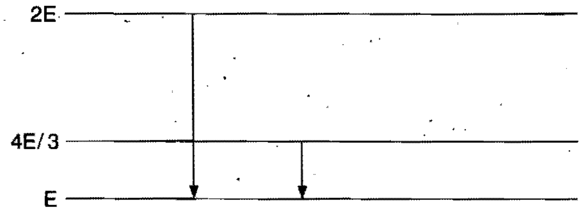


(a) greater than that of B
(b) smaller than that of B
(c) same as that of B
(d) ~~such that~~ no comparison can be done from given graphs

29. Which of the following is the graph between the frequency (ν) of the incident radiations and the stopping potential?

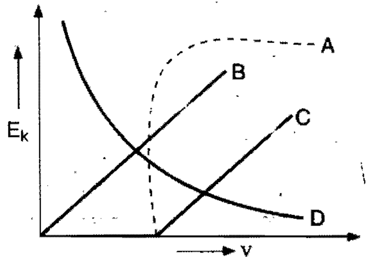
(a) 
(b) 
(c) 
(d) 
30. Which of the following figures represents the variations of particle momentum and associated de Broglie wavelength?

(a) 
(b) 
(c) 
(d) 
31. The given figure indicates the energy levels of a certain atom. When the system moves from $2E$ level to E, a photon of wavelength λ is emitted. The wavelength of photon produced during the transition from level $4E/3$ to level E is:



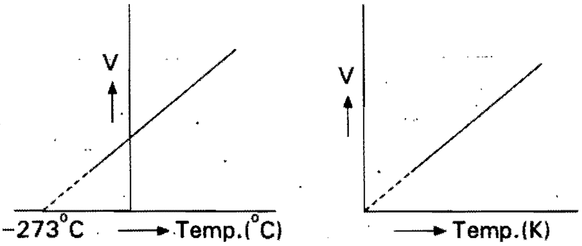
(a) $\lambda/3$ (b) $3\lambda/4$ (c) $4\lambda/3$ (d) 3λ

32. The maximum kinetic energy (E_k) of the photoelectron varies with frequency (ν) of the incident light as shown by the curve:



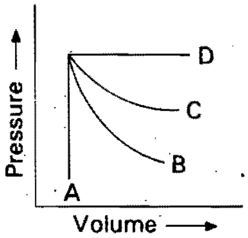
(a) A (b) B (c) C (d) D

33. The following graphs illustrate:



(a) Dalton's law (b) Charles' law
(c) Boyle's law (d) Gay-Lussac's law

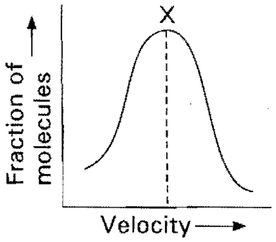
34. In the following graph:



(a) 'A' represents isochoric process
(b) 'B' represents adiabatic process
(c) 'C' represents isothermal process
(d) 'D' represents isobaric process

35. The variation of Λ_m of acetic acid with concentration is correctly represented by:

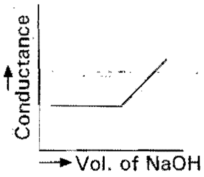
(a) 
(b) 
(c) 
(d) 
36. Distribution of fraction of molecules with velocity is represented in the figure. Velocity corresponding to X is:



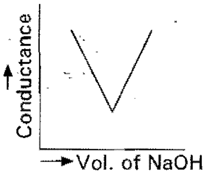
(a) $\sqrt{\frac{2RT}{M}}$ (b) $\sqrt{\frac{3RT}{M}}$ (c) $\sqrt{\frac{8RT}{\pi M}}$ (d) none of these

37. CH_3COOH is neutralized by NaOH. Conductometric titration curve will be of the type:

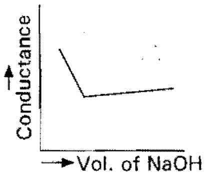
(a)



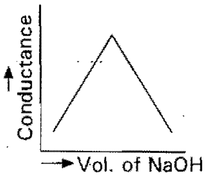
(b)



(c)

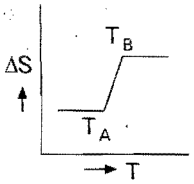


(d)

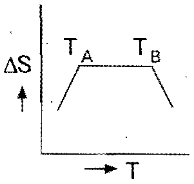


38. If for a given substance, T_B is the m.pt. and T_A is the freezing point, then correct variation of entropy by graph between entropy change (ΔS) and temperature is:

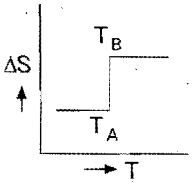
(a)



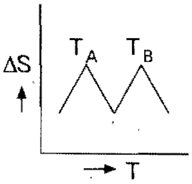
(b)



(c)

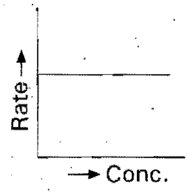


(d)

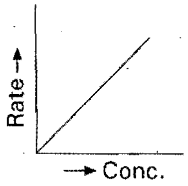


39. Which of the following represents zero order reaction?

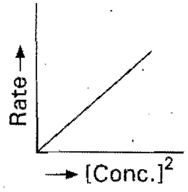
(a)



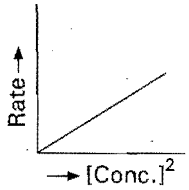
(b)



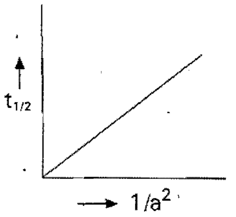
(c)



(d)

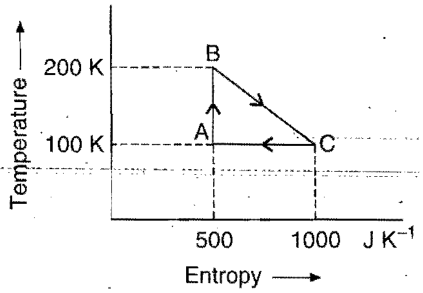


40. This graph represents:



(a) first order reaction (b) zero order reaction
(c) second order reaction (d) third order reaction

41. The efficiency of the reversible cycle shown in the given figure is:

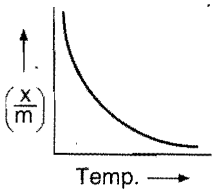


(a) 33.33% (b) 56% (c) 66% (d) 16.7%

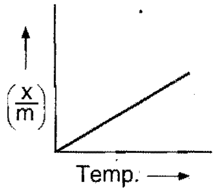
[Hint: $\text{Efficiency} = \frac{\text{Area bounded by the curve}}{\text{Total area under the line BC}} \times 100$]

42. Which of the following curves represents the chemical adsorption?

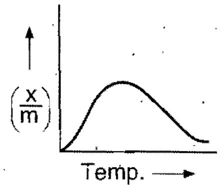
(a)



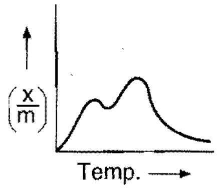
(b)



(c)

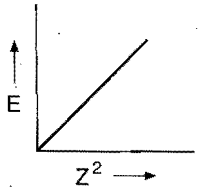


(d)

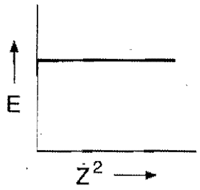


43. Energy of electron varies with atomic number as the following curve/line:

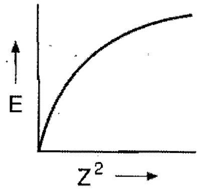
(a)



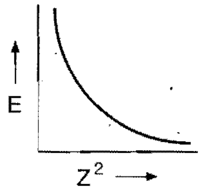
(b)



(c)

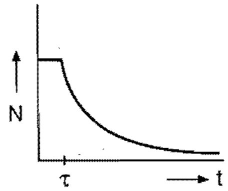


(d)

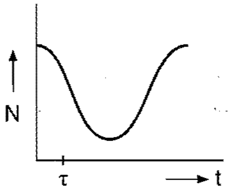


[**Hint:** $E = -\frac{Z^2}{n^2} \times 13.6 \text{ eV}, E \propto \frac{1}{Z^2}$; therefore, E will decrease exponentially with increase in Z^2.]

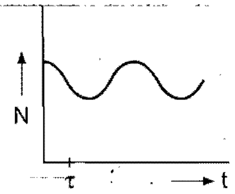
44. A radioactive sample consists of two distinct species having equal number of atoms initially. The mean life of one of the species τ and that of the other is 5τ. The decay products in both the cases are stable. A plot is made of total number of radioactive nuclei as the function of time. Which of the following figures best represents the form of this plot?



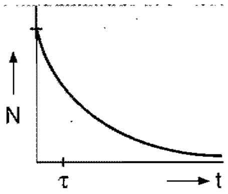
(a)



(b)



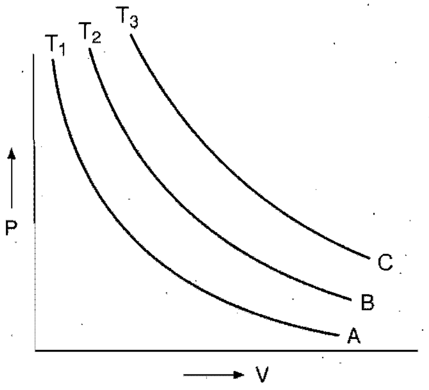
(c)



(d)

[**Hint:** The activity will decay spontaneously with passage of time.]

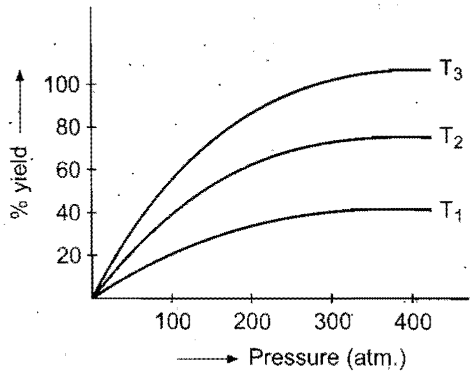
45. In following isothermal graphs A, B and C at temperatures T_1, T_2 and T_3; the correct order of temperatures will be:



(a) $T_1 > T_2 > T_3$ (b) $T_1 > T_3 > T_2$
(c) $T_3 > T_2 > T_1$ (d) $T_3 > T_1 > T_2$

46. $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$; $\Delta H° = -22.4 \text{ kJ mol}^{-1}$. Percentage yield of the reaction against pressure is plotted at three different temperatures T_1, T_2 and T_3, then:

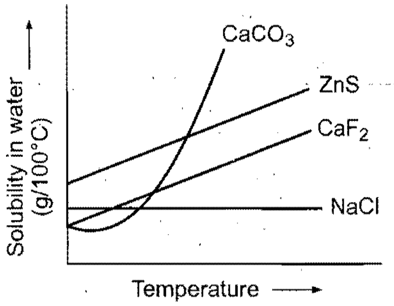
(a) $T_3 > T_2 > T_1$ (b) $T_1 > T_2 > T_3$
(c) $T_1 = T_2 = T_3$ (d) none of these



[**Hint:** Reaction is exothermic; hence, the reaction will shift in forward direction to give better yield.

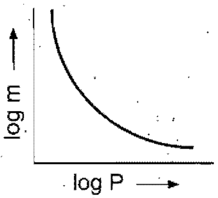
$\therefore \xrightarrow[\text{Decreasing yield of reaction}]{T_1 > T_2 > T_3}$]

47. From the given graph, predict the compound which would be most easily purified by recrystallisation from aqueous solution:
(a) ZnS
(b) $CaCO_3$
(c) CaF_2
(d) NaCl

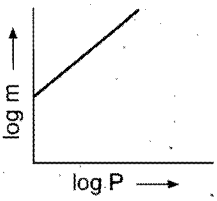


48. Which of the following curves represents the Henry's law?

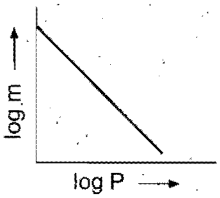
(a)



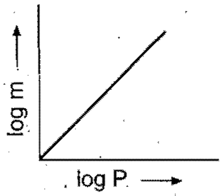
(b)



(c)



(d)



Answers

1. (c)	**2.** (c)	**3.** (a)	**4.** (d)	**5.** (a)	**6.** (a)	**7.** (d)	**8.** (a)

TEST OF MATCHING APTITUDE

TEST SERIES III

1. Match the List-I with List-II and pick up the correct matching from the codes given below:

List-I	List-II
A. $\left(\frac{\partial E}{\partial V}\right)_T = 0$	1. Isothermal process
B. $W = -\Delta E$	2. $-nFE°$
C. $\Delta E = 0$	3. Adiabatic reaction
D. $\Delta G°$	4. van der Waals' gas
E. $\left(\frac{\partial T}{\partial P}\right)_H \neq 0$	5. Ideal gas

Codes:

(a)	A–2	B–1	C–4	D–5	E–3
(b)	A–2	B–5	C–1	D–4	E–3
(c)	A–3	B–1	C–2	D–5	E–4
(d)	A–5	B–4	C–1	D–2	E–3
(e)	A–5	B–3	C–1	D–2	E–4

2. Match the Column-I with Column-II:

Column-I	Column-II
(I). $^{40}_{20}\text{Ca}$	1. Unstable, α-emitter
(II). $^{133}_{53}\text{I}$	2. Unstable, β-emitter
(III). $^{121}_{53}\text{I}$	3. Unstable, positron emitter
(IV). $^{232}_{90}\text{Th}$	4. Stable

Codes:

(a)	I–1	II–2	III–3	IV–4
(b)	I–4	II–3	III–2	IV–1
(c)	I–4	II–2	III–3	IV–1
(d)	I–4	II–3	III–1	IV–2

3. Match the List-I with List-II and select the correct answer using the options given below the lists:

List-I (Electrochemical parameter)	List-II (Units)
(I). Ionic mobility	1. cm^{-1}
(II). Cell constant	2. $\text{ohm}^{-1}\ \text{cm}^{-1}$
(III). Specific conductance	3. $\text{ohm}^{-1}\ \text{cm}^2\ \text{mol}^{-1}$
(IV). Molar conductance	4. $\text{cm}^2\ \text{V}^{-1}\ \text{s}^{-1}$

Codes:

(a)	I–4	II–1	III–2	IV–3
(b)	I–2	II–3	III–4	IV–1
(c)	I–3	II–1	III–2	IV–4
(d)	I–1	II–2	III–3	IV–4

4. Match the Column-I with Column-II and select the correct answer using the sequences given below:

Column-I (Compounds)	Column-II (Oxidation state of nitrogen)
A. NaN_3	1. +5
B. N_2H_4	2. +1
C. NH_2OH	3. $-1/3$
D. N_2O_5	4. -2

Codes:

	A	B	C	D
(a)	3	4	2	1
(b)	4	3	1	2
(c)	3	4	1	2
(d)	4	3	2	1

5. Match the Column-I with Column-II and pick up the correct alternate:

Column-I	Column-II
(I). For spontaneous reaction	A. $\Sigma(\text{BE})_R - \Sigma(\text{BE})_P$
(II). For endothermic reaction	B. $\Delta H = \Delta E$
(III). Bond dissociation energy	C. $\Delta G = -$ ve
(IV). For solids and liquids in a thermochemical reaction	D. $\Sigma H_P > \Sigma H_R$

Codes:

(a)	I – C	II–A	III–D	IV–B
(b)	I – B	II–D	III–A	IV– C
(c)	I – C	II–D	III–B	IV–A
(d)	I – C	II–D	III–A	IV–B

6. Match the Column-I with Column-II and pick up the correct answer:

Column-I	Column-II
(I). Nickel	A. Conversion of alcohol to gasoline
(II). ZSM-5	B. Alkylation of benzene
(III). SiO_2	C. Hydrogenation of oil

Codes:

(a)	I – C	II–A	III–B
(b)	I – A	II–B	III– C
(c)	I – C	II–B	III–A
(d)	I – B	II– C	III–B

7. Match the List-I (enzymes) with List-II (metals) and select the correct answer using the codes given below the lists:

List-I	List-II
A. Nitrogenase	1. Cu
B. Cytochrome oxidase	2. Mo
C. Cytochrome-C	3. Zn
D. Carboxypeptidase	4. Fe

Codes:

	A	B	C	D
(a)	1	2	4	3
(b)	2	1	3	4
(c)	2	1	4	3
(d)	1	2	3	4

8. Match the Column-I with Column-II and select the correct answer:

Column-I	Column-II
(I). Curie	A. 10^6 dis sec^{-1}
(II). Rutherford	B. 3.7×10^{10} dis sec^{-1}
(III). Becquerel	C. 1 dis sec^{-1}

Codes:

(a)	I–B	II–A	III–C
(b)	I–B	II–C	III–A
(c)	I–A	II–B	III–C
(d)	I–C	II–B	III–A

9. Match the List-I with List-II:

List-I	List-II
(I). $\Delta H = q_P$	1. $\Delta S^\circ = 0$
(II). Kirchhoff's equation	2. State function
(III). $H^+(aq.)$	3. Path function
(IV). Spontaneous process	4. $\Delta G > 0$
	5. $\Delta S^\circ_{Total} > 0$
	6. $\Delta H_2 - \Delta H_1 = \Delta C_p(T_2 - T_1)$

Codes:

	(I)	(II)	(III)	(IV)
(a)	1	2	4	5
(b)	5	4	3	6
(c)	2	6	1	5
(d)	6	2	5	1

10. Match the List-I with List-II:

List-I	List-II
(I). Mixing of two ideal gases	1. $\Delta G_{mix} = 0$
(II). Criterion for irreversibility	2. $1/P$
(III). Isobaric thermal coefficient of an ideal gas	3. $1/T$
(IV). Joule-Thomson effect	4. $\Delta S_{Total} > 0$
	5. $\Delta G_{mix} < 0$
	6. $\Delta H = 0$

Codes:

	(I)	(II)	(III)	(IV)
(a)	1	2	4	5
(b)	5	4	3	6
(c)	2	6	1	5
(d)	6	2	5	1

11. Match the List-I with List-II:

List-I	List-II
(I). Translational kinetic energy	1. $\frac{3}{2}P$
(II). Rotational kinetic energy of CO_2	2. 15/13
(III). Translational kinetic energy per unit volume	3. 7/5
(IV). γ for CO_2 at very high temperature	4. Function of T only
	5. RT
	6. $\frac{3}{2}RT$

Codes:

	(I)	(II)	(III)	(IV)
(a)	2	4	5	1
(b)	4	5	1	2
(c)	5	6	2	3
(d)	6	1	3	4

12. Match the Column-X with Column-Y:

Column-X (Colloids)	Column-Y (Classification)
(I). Rain cloud	A. Sol
(II). Milk of magnesia	B. Aerosol
(III). Soap suds	C. Gel
(IV). Butter	D. Foam

Codes:

	(I)	(II)	(III)	(IV)
(a)	A	B	C	D
(b)	A	C	B	D
(c)	B	A	D	C
(d)	B	A	C	D

13. Match the List-I with List-II and select the correct answer from given codes:

List-I (Spectrum)	List-II (Region)
A. Lyman	1. Ultraviolet
B. Paschen	2. Visible
C. Balmer	3. Near infrared
D. Pfund	4. Far infrared

Codes:

	A	B	C	D
(a)	1	3	2	4
(b)	1	2	3	4
(c)	4	3	2	1
(d)	1	2	4	3

14. Match the List-I with List-II and select the correct answer:

List-I	List-II
A. Critical temperature	1. a/Rb
B. Boyle temperature	2. $2a/Rb$
C. Inversion temperature	3. T/T_c
D. Reduced temperature	4. $8a/27Rb$

Codes:

	A	B	C	D
(a)	4	1	2	3
(b)	2	1	4	3
(c)	4	3	2	1
(d)	2	3	1	4

15. Match the List-I, List-II and List-III and select the answer from the given codes:

List-I (Order)	List-II (Unit of rate constant)	List-III (Relation between half life and initial concentration)
A. Zero	(i) $L^2\ mol^{-2}\ s^{-1}$	1. $t_{1/2} = \text{Constant}$
B. First	(ii) $L\ mol^{-1}\ s^{-1}$	2. $t_{1/2} \propto \frac{1}{a}$
C. Second	(iii) s^{-1}	3. $t_{1/2} \propto a$
D. Third	(iv) $mol\ L^{-1}\ s^{-1}$	4. $t_{1/2} \propto \frac{1}{a^2}$

Codes:

	A	B	C	D
(a)	i–2	ii–4	iii–3	iv–1
(b)	i–4	iv–3	ii–2	iii–1
(c)	iv–3	iii–1	ii–2	i–4
(d)	ii–2	i–1	iii–3	iv–4

16. Match the List-I (solutions of salts) with List-II (pH of the solutions) and select the correct answer using the codes given below the lists:

List-I	**List-II**
A. Weak acid and strong base	1. $\frac{1}{2}\,pK_w$
B. Strong acid and weak base	2. $\frac{1}{2}[pK_w - pK_b + pK_a]$
C. Weak acid and weak base	3. $\frac{1}{2}[pK_w - pK_b - \log c]$
D. Strong acid and strong base	4. $\frac{1}{2}[pK_w + pK_a + \log c]$

Codes:

	A	B	C	D
(a)	4	3	2	1
(b)	1	2	3	4
(c)	2	3	4	1
(d)	3	2	1	4

17. Match the List-I with List-II and choose the correct answer from the codes:

List-I (Electrolyte)	**List-II (Solubility product)**
A. Bi_2S_3	1. $4s^3$
B. $Al(OH)_3$	2. $27s^4$
C. CdS	3. $108s^5$
D. CaF_2	4. s^2

Codes:

	A	B	C	D
(a)	1	2	3	4
(b)	2	3	1	4
(c)	4	3	2	1
(d)	3	2	4	1

18. Match the following combinations of electrical units with their terms as single unit:

Electrical unit	**Single unit**
(I). ampere-second	A. coulomb
(II). volt-ampere	B. ohm
(III). volt-ampere^{-1}	C. ampere
(IV). watt/ampere ohm	D. watt
(V). joule /ampere second	E. volt

Codes:

	A	B	C	D	E
(a)	I	III	IV	II	V
(b)	I	II	III	IV	V
(c)	V	IV	III	II	I
(d)	I	V	IV	II	III

19. Match the List-I with List-II and select the correct answer from the given codes:

List-I (Thermodynamic properties)	**List-II (Relation)**
A. Free energy change of a reaction (ΔG)	1. $-RT \log K$
B. Standard enthalpy change (ΔH°) of a reaction	2. $RT^2\left(\frac{d \ln K}{dT}\right)_P$
C. Standard entropy change (ΔS°)	3. $-nFE$
D. Standard free energy change (ΔG°)	4. $-\left(\frac{d\,\Delta G}{dT}\right)_P$

Codes:

	A	B	C	D
(a)	3	2	4	1
(b)	1	2	3	4
(c)	4	3	2	1
(d)	2	3	1	4

20. Match the List-I, List-II and List-III:

List-I	**List-II**	**List-III**
A. $\Delta G > 0$	X. $\Delta S > 0$	1. Non-spontaneous
B. $\Delta G < 0$	Y. $\Delta S < 0$	2. Spontaneous
C. $\Delta G = 0$	Z. $\Delta S = 0$	3. Equilibrium

Select the correct answer from the following codes:

	A	B	C
(a)	(Y, 1)	(X, 2)	(Z, 3)
(b)	(X, 2)	(Y, 3)	(Z, 1)
(c)	(X, 3)	(Y, 1)	(Z, 2)
(d)	(Y, 1)	(X, 3)	(Z, 2)

21. Match the Column-I with Column-II:

Column-I	**Column-II**
(a) Spontaneous process	(p) $\Delta H = -$ ve
(b) Heat flow from high temperature of system towards low temperature of surroundings	(q) $\Delta G = +$ ve
(c) Exergonic process	(r) $\Delta S_{\text{Total}} = +$ ve
(d) Increase in the randomness of system by heating	(s) $\Delta G = -$ ve

(a)	ⓟ	ⓠ	ⓡ	ⓢ
(b)	ⓟ	ⓠ	ⓡ	ⓢ
(c)	ⓟ	ⓠ	ⓡ	ⓢ
(d)	ⓟ	ⓠ	ⓡ	ⓢ

22. Match the items of Column-I with the items of Column-II:

Column-I (Metal)	**Column-II (Packing/coordination number)**
(a) Na	(p) ccp
(b) Cu	(q) bcc
(c) Au	(r) 12
(d) K	(s) 8

23. Match the Column-I with Column-II and Column-III:

l = Edge length of unit cell;

r = Radius of spherical constituent unit

Column-I	**Column-II**	**Column-III**
(a) Simple cubic unit cell	(p) $l\sqrt{3} = 4r$	(u) 74% occupied space
(b) Face-centred cubic unit cell	(q) $l = 2r$	(v) 67.98% occupied space
(c) Body-centred cubic unit cell	(r) $l\sqrt{2} = 4r$	(w) 52.33% occupied space

24. Match the List-I with List-II:

List-I	**List-II**
(a) Silicon doped with phosphorus	(p) Acceptor level above valence bond
(b) Metal excess non-stoichiometry in NaCl	(q) n-type semiconductor
(c) Ge doped with Ga	(r) Donor level just below the conduction band
(d) Anion vacancy with trapped electron	(s) F-centre

25. Match the solids in List-I with their properties in List-II:

List-I	List-II
(a) MnO	(p) Ferromagnetic solid
(b) ZnO	(q) Antiferromagnetic solid
(c) CrO_2	(r) Zero magnetic moment
(d) TiO	(s) Attracted in magnetic field

26. Match the List-I with List-II:

List-I	List-II
(a) The highest temperature at which liquid CO_2 exists	(p) $\frac{V_{\text{real}}}{V_{\text{ideal}}}$
(b) $8a/27Rb$	(q) Critical temperature
(c) Compressibility factor $Z = 3/8$ at	(r) Ideal gas
(d) Compressibility factor $Z = 1$ for	(s) 30.98° C

27. Match the physical properties of Column-I with their values in Column-II:

Column-I	Column-II
(a) SATP	(p) 1 bar/1 atm
(b) Temperature in STP	(q) 99.6° C
(c) Pressure in NTP	(r) 273.15 K
(d) Standard boiling point of water	(s) 298.15 K

SATP $\longrightarrow$ Standard ambient temperature and pressure
STP $\longrightarrow$ Standard temperature and pressure
NTP $\longrightarrow$ Normal temperature and pressure

28. Match the quantities in Column-I with their units in Column-II:

Column-I	Column-II
(a) Coefficient of viscosity	(p) L mol^{-1}
(b) van der Waals' constant '*b*'	(q) N s m^{-2}
(c) Molar volume of gas at STP = 22.4 ...	(r) Pas
(d) van der Waals' constant '*a*'	(s) L^2 atm mol^{-2}

29. Match the temperature in List-I with its value in List-II:

List-I	List-II
(a) Critical temperature	(p) a/Rb
(b) Boyle's temperature	(q) θ
(c) 1/2 [Inversion temperature]	(r) T/T_c
(d) Reduced temperature	(s) $8a/27Rb$

30. Match the items of Column-I with its proportional term in the items of Column-II:

Column-I	Column-II
(a) Kinetic energy	(p) Mole fraction
(b) Partial pressure of a gas	(q) Density
(c) Rate of diffusion	(r) Molar mass
(d) Vapour pressure of a liquid	(s) Absolute temperature

31. Match the List-I with List-II and List-III:

List-I (Solids)	List-II (Unit cell)	List-III (Coordination number)
(a) Rock salt	(p) Face-centred cubic, anion in tetrahedral void	(w) 6
(b) Fluorite	(q) Face-centred cubic, cation in octahedral void	(x) Cation (8), anion (4)
(c) AgI, ZnS	(r) Face-centred cubic, cation in alternate tetrahedral void	(y) Cation (4), anion (8)
(d) Na_2O	(s) Face-centred cubic, cation in tetrahedral void	(z) Cation (4), anion (4)

TEST OF REASONING APTITUDE

TEST SERIES IV

REASON AND ASSERTION

(For IIT & AIIMS Aspirants)

In each of the following questions, a statement of **Assertion (A)** is given followed by corresponding statement of **Reason (R)** just below it. Mark the correct answer as:

(a) Both (R) and (A) are true and reason is the correct explanation of assertion.
(b) Both (R) and (A) are true but reason is not correct explanation of assertion.
(c) Assertion (A) is true but reason (R) is false.
(d) Assertion (A) and reason (R) both are false.
(e) Assertion (A) is false but reason (R) is true.

1. (A) CH_4 and CO_2 have the value of Z (compressibility factor) less than one.
(R) $Z < 1$ is due to repulsive forces among the molecules.

2. (A) More is the value of van der Waals' constant 'a', greater is the tendency of liquefaction.
(R) 'a' measures the magnitude of force of attraction among the molecules.

3. (A) Crystalline solids are anisotropic.
(R) Crystalline solids are not as closely packed as amorphous solids.

4. (A) Antiferromagnetic substances possess zero magnetic moment.
(R) MnO is an antiferromagnetic substance.

5. (A) Isotonic solutions do not show osmosis.
(R) Isotonic solutions have equal osmotic pressure.

6. (A) In a gaseous reaction, K_c is unitless when $\Delta n = 0$.
(R) Unit of $K_c = (\text{mol L}^{-1})^{\Delta n}$.

7. (A) Strength of acidic character of oxyacids lies in the following sequence:

$$HClO_4 > HBrO_4 > HIO_4$$

(R) Greater is the oxidation state of a halogen, more is the acidic character of its oxyacid.

8. (A) The molecularity of the following reaction is 2

$$H_2 + Br_2 \longrightarrow 2HBr$$

(R) The order of reaction is 3/2.

9. (A) Half-life of a first order reaction is independent of the initial concentration of reactant.
(R) $t_{1/2}$ (first order) $= \dfrac{\tau}{1.44}$
where, τ = average life.

10. (A) For the reaction,

$$2NH_3(g) \longrightarrow N_2(g) + 3H_2(g)$$

$\Delta H > \Delta U$.
(R) The enthalpy change is always greater than internal energy change.

11. (A) $^{20}N_e$ and $^{22}N_e$ are isotones.
(R) Noble gases do not exist as isotopes as they are not reactive.

12. (A) $3d_{z^2}$ orbital is spherically symmetrical.
(R) $3d_{z^2}$ orbital is the only d-orbital which is spherical in shape.

13. (A) The kinetic energy of the photoelectron ejected increases with increase in intensity of incident radiation.
(R) Increase in intensity of incident light increases the rate of emission.

14. (A) $^{133}_{56}Be + e^- \longrightarrow\, ^{133}_{55}Cs + X\text{-ray}$
It is a process of K-electron capture.
(R) The atomic number decreases by one unit as a result of K-capture.

15. (A) Vapour pressure is a colligative property.
(R) Colligative property depends on the number of solute particles dissolved in the solution.

16. (A) Entropy decreases when an egg is boiled.
(R) It is solidified due to denaturation of albumin.

17. (A) 1 faraday = 96,500 coulomb.
It is a charge of 1 mole electrons.
(R) 1 faraday charge liberates one gram equivalent of substance at an electrode.

18. (A) The electrical resistance of a column of 0.05 M NaOH solution of diameter 1 cm and length 50 cm is 5.55×10^3 ohm.
(R) Its resistivity is equal to 76.234 ohm-cm.

19. (A) If water is heated to 350 K, then pOH will increase to 8.
(R) K_w increases with increase in temperature.

20. (A) Magnetic quantum number can have the value $0, \ldots, (n-1)$.
(R) Magnetic quantum number specifies the number of orbitals.
