**Self-test 12.3** Which of the molecules  $\text{H}_2$ ,  $\text{NO}$ ,  $\text{N}_2\text{O}$ , and  $\text{CH}_4$  can have a pure rotational spectrum? [ $\text{NO}$ ,  $\text{N}_2\text{O}$ ]

The specific rotational selection rules are found by evaluating the transition dipole moment between rotational states. We show in *Further information 12.2* that, for a linear molecule, the transition moment vanishes unless the following conditions are fulfilled:

$$\Delta J = \pm 1 \quad \Delta M_J = 0, \pm 1 \quad \text{Rotational selection rules for linear rotors} \quad (12.18)$$

The transition  $\Delta J = +1$  corresponds to absorption and the transition  $\Delta J = -1$  corresponds to emission. The allowed change in  $J$  in each case arises from the conservation of angular momentum when a photon, a spin-1 particle, is emitted or absorbed (Fig. 12.15).

When the transition moment is evaluated for all possible relative orientations of the molecule to the line of flight of the photon, it is found that the total  $J + 1 \leftrightarrow J$  transition intensity is proportional to

$$|\mu_{J+1,J}|^2 = \left( \frac{J+1}{2J+1} \right) \mu_0^2 \quad (12.19)$$

where  $\mu_0$  is the permanent electric dipole moment of the molecule. The intensity is proportional to the square of the permanent electric dipole moment, so strongly polar molecules give rise to much more intense rotational lines than less polar molecules.

For symmetric rotors, an additional selection rule states that  $\Delta K = 0$ . To understand this rule, consider the symmetric rotor  $\text{NH}_3$ , where the electric dipole moment lies parallel to the figure axis. Such a molecule cannot be accelerated into different states of rotation around the figure axis by the absorption of radiation, so  $\Delta K = 0$ . Therefore, for symmetric rotors the selection rules are:

$$\Delta J = \pm 1 \quad \Delta M_J = 0, \pm 1 \quad \Delta K = 0 \quad \text{Rotational selection rules for symmetric rotors} \quad (12.20)$$

**(b) The appearance of rotational spectra**

When these selection rules are applied to the expressions for the energy levels of a rigid spherical or linear rotor, it follows that the wavenumbers of the allowed  $J + 1 \leftarrow J$  absorptions are

$$\tilde{\nu}(J+1 \leftarrow J) = \tilde{F}(J+1) - \tilde{F}(J) = 2\tilde{B}(J+1) \quad J = 0, 1, 2, \dots \quad (12.21a)$$

When centrifugal distortion is taken into account, the corresponding expression obtained from eqn 12.16 is

$$\tilde{\nu}(J+1 \leftarrow J) = 2\tilde{B}(J+1) - 4\tilde{D}_J(J+1)^3 \quad (12.21b)$$

However, because the second term is typically very small compared with the first, the appearance of the spectrum closely resembles that predicted from eqn 12.21a.

**Fig. 12.14** To a stationary observer, a rotating polar molecule looks like an oscillating dipole that can stir the electromagnetic field into oscillation (and vice versa for absorption). This picture is the classical origin of the gross selection rule for rotational transitions.

**Fig. 12.15** When a photon is absorbed by a molecule, the angular momentum of the combined system is conserved. If the molecule is rotating in the same sense as the spin of the incoming photon, then  $J$  increases by 1.

**Fig. 12.16** The rotational energy levels of a linear rotor, the transitions allowed by the selection rule  $\Delta J = \pm 1$ , and a typical pure rotational absorption spectrum (displayed here in terms of the radiation transmitted through the sample). The intensities reflect the populations of the initial level in each case and the strengths of the transition dipole moments.

### Example 12.3 Predicting the appearance of a rotational spectrum

Predict the form of the rotational spectrum of  $^{14}\text{NH}_3$ .

**Method** We calculated the energy levels in Example 12.2. The  $^{14}\text{NH}_3$  molecule is a polar symmetric rotor, so the selection rules  $\Delta J = \pm 1$  and  $\Delta K = 0$  apply. For absorption,  $\Delta J = +1$  and we can use eqn 12.21a.

**Answer** Because  $\tilde{B} = 9.977 \text{ cm}^{-1}$ , we can draw up the following table for the  $J + 1 \leftarrow J$  transitions.

|                              |       |       |       |       |     |
|------------------------------|-------|-------|-------|-------|-----|
| $J$                          | 0     | 1     | 2     | 3     | ... |
| $\tilde{\nu}/\text{cm}^{-1}$ | 19.95 | 39.91 | 59.86 | 79.82 | ... |
| $\nu/\text{GHz}$             | 598.1 | 1197  | 1795  | 2393  | ... |

The line spacing is  $19.95 \text{ cm}^{-1}$  (598.1 GHz).

**Self-test 12.4** Repeat the problem for  $\text{C}^{35}\text{ClH}_3$  (see Self-test 12.2 for details).  
[Lines of separation  $0.944 \text{ cm}^{-1}$  (28.3 GHz)]

The form of the spectrum predicted by eqn 12.21 is shown in Fig. 12.16. The most significant feature is that it consists of a series of lines with wavenumbers  $2\tilde{B}$ ,  $4\tilde{B}$ ,  $6\tilde{B}$ , ... and of separation  $2\tilde{B}$ . The measurement of the line spacing gives  $\tilde{B}$ , and hence the moment of inertia perpendicular to the principal axis of the molecule. Because the masses of the atoms are known, it is a simple matter to deduce the bond length of a diatomic molecule. However, in the case of a polyatomic molecule such as OCS or  $\text{NH}_3$ , the analysis gives only a single quantity,  $I_{\perp}$ , and it is not possible to infer both bond lengths (in OCS) or the bond length and bond angle (in  $\text{NH}_3$ ). This difficulty can be overcome by using isotopically substituted molecules, such as ABC and  $A'BC$ ; then, by assuming that  $R(A-B) = R(A'-B)$ , both A–B and B–C bond lengths can be extracted from the two moments of inertia. A famous example of this procedure is the study of OCS; the actual calculation is worked through in Problem 12.7. The assumption that bond lengths are unchanged by isotopic substitution is only an approximation, but it is a good approximation in most cases. Nuclear spin, which differs from one isotope to another, also affects the appearance of high-resolution rotational spectra because spin is a source of angular momentum and can couple with the rotation of the molecule itself and hence affect the rotational energy levels.

The intensities of spectral lines increase with increasing  $J$  and pass through a maximum before tailing off as  $J$  becomes large. The most important reason for the maximum in intensity is the existence of a maximum in the population of rotational levels. The Boltzmann distribution (*Fundamentals F.5*) implies that the population of each state decays exponentially with increasing  $J$ , but the degeneracy of the levels increases, and these two opposite trends result in the population of the energy levels (as distinct from the individual states) passing through a maximum. Specifically, the population of a rotational energy level  $J$  is given by the Boltzmann expression

$$N_J \propto N g_J e^{-E_J/kT}$$

where  $N$  is the total number of molecules and  $g_J$  is the degeneracy of the level  $J$ . The value of  $J$  corresponding to a maximum of this expression is found by treating  $J$  as a continuous variable, differentiating with respect to  $J$ , and then setting the result equal to zero. The result is (see Problem 12.26)

$$J_{\max} \approx \left( \frac{kT}{2hc\tilde{B}} \right)^{1/2} - \frac{1}{2} \quad (12.22)$$

For a typical molecule (for example, OCS, with  $\tilde{B} = 0.2 \text{ cm}^{-1}$ ) at room temperature,  $kT \approx 1000hc\tilde{B}$ , so  $J_{\text{max}} \approx 30$ . However, it must be recalled that the intensity of each transition also depends on the value of  $J$  (eqn 12.19) and on the population difference between the two states involved in the transition. Hence the value of  $J$  corresponding to the most intense line is not quite the same as the value of  $J$  for the most highly populated level.

## 12.6 Rotational Raman spectra

**Key points** A molecule must be anisotropically polarizable for it to be rotationally Raman active. The specific selection rules are: (i) linear rotors,  $\Delta J = 0, \pm 2$ ; (ii) symmetric rotors,  $\Delta J = 0, \pm 1, \pm 2$ ;  $\Delta K = 0$ .

The gross selection rule for rotational Raman transitions is *that the molecule must be anisotropically polarizable*. We begin by explaining what this means. A formal derivation of this rule is given in *Further information 12.2*.

The distortion of a molecule in an electric field is determined by its polarizability,  $\alpha$  (Section 17.2). More precisely, if the strength of the field is  $\mathcal{E}$ , then the molecule acquires an induced dipole moment of magnitude

$$\mu = \alpha \mathcal{E} \quad (12.23)$$

in addition to any permanent dipole moment it may have. An atom is isotropically polarizable. That is, the same distortion is induced whatever the direction of the applied field. The polarizability of a spherical rotor is also isotropic. However, non-spherical rotors have polarizabilities that do depend on the direction of the field relative to the molecule, so these molecules are anisotropically polarizable (Fig. 12.17). The electron distribution in  $\text{H}_2$ , for example, is more distorted when the field is applied parallel to the bond than when it is applied perpendicular to it, and we write  $\alpha_{\parallel} > \alpha_{\perp}$ .

All linear molecules and diatomics (whether homonuclear or heteronuclear) have anisotropic polarizabilities, and so are rotationally Raman active. This activity is one reason for the importance of rotational Raman spectroscopy, for the technique can be used to study many of the molecules that are inaccessible to microwave spectroscopy. Spherical rotors such as  $\text{CH}_4$  and  $\text{SF}_6$ , however, are rotationally Raman inactive as well as microwave inactive. This inactivity does not mean that such molecules are never found in rotationally excited states. Molecular collisions do not have to obey such restrictive selection rules, and hence collisions between molecules can result in the population of any rotational state.

We show in *Further information 12.2* that the specific rotational Raman selection rules are

|                   |                                                  |                                     |         |
|-------------------|--------------------------------------------------|-------------------------------------|---------|
| Linear rotors:    | $\Delta J = 0, \pm 2$                            | Rotational Raman<br>selection rules | (12.24) |
| Symmetric rotors: | $\Delta J = 0, \pm 1, \pm 2; \quad \Delta K = 0$ |                                     |         |

The  $\Delta J = 0$  transitions do not lead to a shift in frequency of the scattered photon in pure rotational Raman spectroscopy, and contribute to the unshifted Rayleigh radiation.

We can predict the form of the Raman spectrum of a linear rotor by applying the selection rule  $\Delta J = \pm 2$  to the rotational energy levels (Fig. 12.18). When the molecule makes a transition with  $\Delta J = +2$ , the scattered radiation leaves the molecule in a higher rotational state, so the wavenumber of the incident radiation, initially  $\tilde{\nu}_i$ , is decreased. These transitions account for the Stokes lines in the spectrum:

**Fig. 12.17** An electric field applied to a molecule results in its distortion, and the distorted molecule acquires a contribution to its dipole moment (even if it is nonpolar initially). The polarizability may be different when the field is applied (a) parallel or (b) perpendicular to the molecular axis (or, in general, in different directions relative to the molecule); if that is so, then the molecule has an anisotropic polarizability.

**Fig. 12.18** The rotational energy levels of a linear rotor and the transitions allowed by the  $\Delta J = \pm 2$  Raman selection rules. The form of a typical rotational Raman spectrum is also shown. The Rayleigh line is much stronger than depicted in the figure; it is shown as a weaker line to improve visualization of the Raman lines.

$$\tilde{\nu}(J+2 \leftarrow J) = \tilde{\nu}_i - \{\tilde{F}(J+2) - \tilde{F}(J)\} = \tilde{\nu}_i - 2\tilde{B}(2J+3) \quad (12.25a)$$

The Stokes lines appear at low frequency of the incident radiation and at displacements  $6\tilde{B}$ ,  $10\tilde{B}$ ,  $14\tilde{B}$ , ... from  $\tilde{\nu}_i$  for  $J = 0, 1, 2, \dots$ . When the molecule makes a transition with  $\Delta J = -2$ , the scattered photon emerges with increased energy. These transitions account for the anti-Stokes lines of the spectrum:

$$\tilde{\nu}(J-2 \leftarrow J) = \tilde{\nu}_i - \{\tilde{F}(J) - \tilde{F}(J-2)\} = \tilde{\nu}_i + 2\tilde{B}(2J-1) \quad (12.25b)$$

The anti-Stokes lines occur at displacements of  $6\tilde{B}$ ,  $10\tilde{B}$ ,  $14\tilde{B}$ , ... (for  $J = 2, 3, 4, \dots$ ;  $J = 2$  is the lowest state that can contribute under the selection rule  $\Delta J = -2$ ) to high frequency of the incident radiation. The separation of adjacent lines in both the Stokes and the anti-Stokes regions is  $4\tilde{B}$ , so from its measurement  $I_\perp$  can be determined and then used to find the bond lengths exactly as in the case of microwave spectroscopy.

#### Example 12.4 Predicting the form of a Raman spectrum

Predict the form of the rotational Raman spectrum of  $^{14}\text{N}_2$ , for which  $\tilde{B} = 1.99 \text{ cm}^{-1}$ , when it is exposed to 336.732 nm laser radiation.

**Method** The molecule is rotationally Raman active because end-over-end rotation modulates its polarizability as viewed by a stationary observer. The Stokes and anti-Stokes lines are given by eqn 12.25.

**Answer** Because  $\lambda_i = 336.732 \text{ nm}$  corresponds to  $\tilde{\nu}_i = 29\,697.2 \text{ cm}^{-1}$ , eqns 12.25a and 12.25b give the following line positions:

| $J$                          | 0        | 1        | 2        | 3        |
|------------------------------|----------|----------|----------|----------|
| Stokes lines                 |          |          |          |          |
| $\tilde{\nu}/\text{cm}^{-1}$ | 29 685.3 | 29 677.3 | 29 669.3 | 29 661.4 |
| $\lambda/\text{nm}$          | 336.868  | 336.958  | 337.048  | 337.139  |
| Anti-Stokes lines            |          |          |          |          |
| $\tilde{\nu}/\text{cm}^{-1}$ |          |          | 29 709.1 | 29 717.1 |
| $\lambda/\text{nm}$          |          |          | 336.597  | 336.507  |

There will be a strong central line at 336.732 nm accompanied on either side by lines of increasing and then decreasing intensity (as a result of transition moment and population effects). The spread of the entire spectrum is very small, so the incident light must be highly monochromatic.

**Self-test 12.5** Repeat the calculation for the rotational Raman spectrum of  $\text{NH}_3$  ( $\tilde{B} = 9.977 \text{ cm}^{-1}$ ).

[Stokes lines at 29 637.3, 29 597.4, 29 557.5, 29 517.6  $\text{cm}^{-1}$ ,  
anti-Stokes lines at 29 757.1, 29 797.0  $\text{cm}^{-1}$ ]

## 12.7 Nuclear statistics and rotational states

**Key point** The appearance of rotational spectra is affected by nuclear statistics, the selective occupation of rotational states that stems from the Pauli principle.

If eqn 12.25 is used in conjunction with the rotational Raman spectrum of  $\text{CO}_2$ , the rotational constant is inconsistent with other measurements of C–O bond lengths. The results are consistent only if it is supposed that the molecule can exist in states with even values of  $J$ , so the Stokes lines are  $2 \leftarrow 0$ ,  $4 \leftarrow 2$ , ... and not  $5 \leftarrow 3$ ,  $3 \leftarrow 1$ , ...

The explanation of the missing lines is the Pauli principle and the fact that  $^{16}\text{O}$  nuclei are spin-0 bosons: just as the Pauli principle excludes certain electronic states, so too does it exclude certain molecular rotational states. The form of the Pauli principle given in Section 9.4b states that, when two identical bosons are exchanged, the overall wavefunction must remain unchanged in every respect, including sign. When a  $\text{CO}_2$  molecule rotates through  $180^\circ$ , two identical O nuclei are interchanged, so the overall wavefunction of the molecule must remain unchanged. However, inspection of the form of the rotational wavefunctions (which have the same form as the s, p, etc. orbitals of atoms) shows that they change sign by  $(-1)^J$  under such a rotation (Fig. 12.19). Therefore, only even values of  $J$  are permissible for  $\text{CO}_2$ , and hence the Raman spectrum shows only alternate lines.

The selective occupation of rotational states that stems from the Pauli principle is termed **nuclear statistics**. Nuclear statistics must be taken into account whenever a rotation interchanges equivalent nuclei. However, the consequences are not always as simple as for  $\text{CO}_2$  because there are complicating features when the nuclei have nonzero spin: there may be several different relative nuclear spin orientations consistent with even values of  $J$  and a different number of spin orientations consistent with odd values of  $J$ . For molecular hydrogen and fluorine, for instance, with their two identical spin- $\frac{1}{2}$  nuclei, we show in the following *Justification* that there are three times as many ways of achieving a state with odd  $J$  than with even  $J$ , and there is a corresponding 3:1 alternation in intensity in their rotational Raman spectra (Fig. 12.20). In general, for a homonuclear diatomic molecule with nuclei of spin  $I$ , the numbers of ways of achieving states of odd and even  $J$  are in the ratio

$$\frac{\text{Number of ways of achieving odd } J}{\text{Number of ways of achieving even } J} = \begin{cases} (I+1)/I & \text{for half-integral spin nuclei} \\ I/(I+1) & \text{for integral spin nuclei} \end{cases} \quad (12.26)$$

For hydrogen,  $I = \frac{1}{2}$ , and the ratio is 3:1. For  $\text{N}_2$ , with  $I = 1$ , the ratio is 1:2.

#### Justification 12.1 The effect of nuclear statistics on rotational spectra

Hydrogen nuclei are fermions, so the Pauli principle requires the overall wavefunction to change sign under particle interchange. However, the rotation of an  $\text{H}_2$  molecule through  $180^\circ$  has a more complicated effect than merely relabelling the nuclei, because it interchanges their spin states too if the nuclear spins are paired ( $\uparrow\downarrow$ ;  $I_{\text{total}} = 0$ ) but not if they are parallel ( $\uparrow\uparrow$ ,  $I_{\text{total}} = 1$ ).

First, consider the case when the spins are parallel and their state is  $\alpha(A)\alpha(B)$ ,  $\alpha(A)\beta(B) + \alpha(B)\beta(A)$ , or  $\beta(A)\beta(B)$ . The  $\alpha(A)\alpha(B)$  and  $\beta(A)\beta(B)$  combinations are unchanged when the molecule rotates through  $180^\circ$  so the rotational wavefunction must change sign to achieve an overall change of sign. Hence, only odd values of  $J$  are allowed. Although at first sight the spins must be interchanged in the combination  $\alpha(A)\beta(B) + \alpha(B)\beta(A)$  so as to achieve a simple  $A \leftrightarrow B$  interchange of labels (Fig. 12.21),  $\beta(A)\alpha(B) + \beta(B)\alpha(A)$  is the same as  $\alpha(A)\beta(B) + \alpha(B)\beta(A)$  apart from the order of terms, so only odd values of  $J$  are allowed for it too. In contrast, if the nuclear spins are paired, their wavefunction is  $\alpha(A)\beta(B) - \alpha(B)\beta(A)$ . This combination changes sign when  $\alpha$  and  $\beta$  are exchanged (in order to achieve a simple  $A \leftrightarrow B$  interchange overall). Therefore, for the overall wavefunction to change sign in this case requires the rotational wavefunction *not* to change sign. Hence, only even values of  $J$  are allowed if the nuclear spins are paired. In accord with the prediction of eqn 12.26, there are three ways of achieving odd  $J$  but only one of achieving even  $J$ .

**Fig. 12.19** The symmetries of rotational wavefunctions (shown here, for simplicity as a two-dimensional rotor) under a rotation through  $180^\circ$ . Wavefunctions with  $J$  even do not change sign; those with  $J$  odd do change sign.

**Fig. 12.20** The rotational Raman spectrum of a diatomic molecule with two identical spin- $\frac{1}{2}$  nuclei shows an alternation in intensity as a result of nuclear statistics. The Rayleigh line is much stronger than depicted in the figure; it is shown as a weaker line to improve visualization of the Raman lines.

**Fig. 12.21** The interchange of two identical fermion nuclei results in the change in sign of the overall wavefunction. The relabelling can be thought of as occurring in two steps: the first is a rotation of the molecule; the second is the interchange of unlike spins (represented by the different colours of the nuclei). The wavefunction changes sign in the second step if the nuclei have antiparallel spins.

**Fig. 12.22** When hydrogen is cooled, the molecules with parallel nuclear spins accumulate in their lowest available rotational state, the one with  $J = 1$ . They can enter the lowest rotational state ( $J = 0$ ) only if the spins change their relative orientation and become antiparallel. This is a slow process under normal circumstances, so energy is slowly released.

Different relative nuclear spin orientations change into one another only very slowly, so an  $\text{H}_2$  molecule with parallel nuclear spins remains distinct from one with paired nuclear spins for long periods. The two forms of hydrogen can be separated by physical techniques, and stored. The form with parallel nuclear spins is called *ortho-hydrogen* and the form with paired nuclear spins is called *para-hydrogen*. Because *ortho*-hydrogen cannot exist in a state with  $J = 0$ , it continues to rotate at very low temperatures and has an effective rotational zero-point energy (Fig. 12.22). This energy is of some concern to manufacturers of liquid hydrogen, for the slow conversion of *ortho*-hydrogen into *para*-hydrogen (which can exist with  $J = 0$ ) as nuclear spins slowly realign releases rotational energy, which vaporizes the liquid. Techniques are used to accelerate the conversion of *ortho*-hydrogen to *para*-hydrogen to avoid this problem. One such technique is to pass hydrogen over a metal surface: the molecules adsorb on the surface as atoms, which then recombine in the lower energy *para*-hydrogen form.

## The vibrations of diatomic molecules

In this section, we adopt the same strategy of finding expressions for the energy levels, establishing the selection rules, and then discussing the form of the spectrum. We shall also see how the simultaneous excitation of rotation modifies the appearance of a vibrational spectrum.

### 12.8 Molecular vibrations

**Key point** The vibrational energy levels of a diatomic molecule modelled as a harmonic oscillator depend on a force constant  $k_f$  (a measure of the bond's stiffness) and the molecule's effective mass.

We base our discussion on Fig. 12.23, which shows a typical potential energy curve (as in Fig. 10.1) of a diatomic molecule. In regions close to  $R_e$  (at the minimum of the curve) the potential energy can be approximated by a parabola, so we can write

$$V = \frac{1}{2}k_f x^2 \quad x = R - R_e \quad \text{Parabolic potential energy} \quad (12.27)$$

where  $k_f$  is the **force constant** of the bond. The steeper the walls of the potential (the stiffer the bond), the greater the force constant.

To see the connection between the shape of the molecular potential energy curve and the value of  $k_f$ , note that we can expand the potential energy around its minimum by using a Taylor series, which is a common way of expressing how a function varies near a selected point (in this case, the minimum of the curve at  $x = 0$ ):

$$V(x) = V(0) + \left(\frac{dV}{dx}\right)_0 x + \frac{1}{2}\left(\frac{d^2V}{dx^2}\right)_0 x^2 + \dots \quad (12.28)$$

The notation  $(\dots)_0$  means that the derivatives are first evaluated and then  $x$  is set equal to 0. The term  $V(0)$  can be set arbitrarily to zero. The first derivative of  $V$  is zero at the minimum. Therefore, the first surviving term is proportional to the square of the displacement. For small displacements we can ignore all the higher terms, and so write

$$V(x) \approx \frac{1}{2}\left(\frac{d^2V}{dx^2}\right)_0 x^2 \quad (12.29)$$

**Fig. 12.23** A molecular potential energy curve can be approximated by a parabola near the bottom of the well. The parabolic potential leads to harmonic oscillations. At high excitation energies the parabolic approximation is poor (the true potential is less confining), and it is totally wrong near the dissociation limit.

**Fig. 12.24** The force constant is a measure of the curvature of the potential energy close to the equilibrium extension of the bond. A strongly confining well (one with steep sides, a stiff bond) corresponds to high values of  $k_f$ .

Therefore, the first approximation to a molecular potential energy curve is a parabolic potential, and we can identify the force constant as

$$k_f = \left( \frac{d^2V}{dx^2} \right)_0 \quad \text{Formal definition of the force constant} \quad [12.30]$$

We see that, if the potential energy curve is sharply curved close to its minimum, then  $k_f$  will be large. Conversely, if the potential energy curve is wide and shallow, then  $k_f$  will be small (Fig. 12.24).

The Schrödinger equation for the relative motion of two atoms of masses  $m_1$  and  $m_2$  with a parabolic potential energy is

$$-\frac{\hbar^2}{2m_{\text{eff}}} \frac{d^2\psi}{dx^2} + \frac{1}{2}k_f x^2 \psi = E\psi \quad (12.31)$$

where  $m_{\text{eff}}$  is the **effective mass**:

$$m_{\text{eff}} = \frac{m_1 m_2}{m_1 + m_2} \quad \text{Effective mass} \quad (12.32)$$

These equations are derived in the same way as in *Further information 9.1*, but here the separation of variables procedure is used to separate the relative motion of the atoms from the motion of the molecule as a whole.

The Schrödinger equation in eqn 12.31 is the same as eqn 8.23 for a particle of mass  $m$  undergoing harmonic motion. Therefore, we can use the results of Section 8.4 to write down the permitted vibrational energy levels:

$$E_v = \left( v + \frac{1}{2} \right) \hbar \omega \quad \omega = \left( \frac{k_f}{m_{\text{eff}}} \right)^{1/2} \quad v = 0, 1, 2, \dots \quad \text{Vibrational energy levels of a diatomic molecule} \quad (12.33)$$

**A note on good practice** Distinguish *effective mass* from *reduced mass*. The former is a measure of the mass that is moved during a vibration. The latter is the quantity that emerges from the separation of relative internal and overall translational motion. For a diatomic molecule the two are the same, but that is not true in general for vibrations of polyatomic molecules. Many, however, do not make this distinction and refer to both quantities as the ‘reduced mass’.

The **vibrational terms** of a molecule, the energies of its vibrational states expressed as wavenumbers, are denoted  $\tilde{G}(v)$ , with  $E_v = hc\tilde{G}(v)$ , so

$$\tilde{G}(v) = (v + \tfrac{1}{2})\tilde{\nu} \quad \tilde{\nu} = \frac{1}{2\pi c} \left( \frac{k_f}{m_{\text{eff}}} \right)^{1/2} \quad \text{Vibrational terms of a diatomic molecule} \quad (12.34)$$

The vibrational wavefunctions are the same as those discussed in Section 8.5.

It is important to note that the vibrational terms depend on the *effective* mass of the molecule, not directly on its total mass. This dependence is physically reasonable for, if atom 1 were as heavy as a brick wall, then we would find  $m_{\text{eff}} \approx m_2$ , the mass of the lighter atom. The vibration would then be that of a light atom relative to that of a stationary wall (this is approximately the case in HI, for example, where the I atom barely moves and  $m_{\text{eff}} \approx m_{\text{H}}$ ). For a homonuclear diatomic molecule  $m_1 = m_2$ , and the effective mass is half the total mass:  $m_{\text{eff}} = \frac{1}{2}m$ .

#### • A brief illustration

An HCl molecule has a force constant of  $516 \text{ N m}^{-1}$ , a reasonably typical value for a single bond. The effective mass of  $^1\text{H}^{35}\text{Cl}$  is  $1.63 \times 10^{-27} \text{ kg}$  (note that this mass is very close to the mass of the hydrogen atom,  $1.67 \times 10^{-27} \text{ kg}$ , so the Cl atom is acting like a brick wall). These values imply  $\omega = 5.63 \times 10^{14} \text{ s}^{-1}$ ,  $\nu = 89.5 \text{ THz}$  ( $1 \text{ THz} = 10^{12} \text{ Hz}$ ),  $\tilde{\nu} = 2987 \text{ cm}^{-1}$ ,  $\lambda = 3.35 \mu\text{m}$ . These characteristics correspond to electromagnetic radiation in the infrared region. •

## 12.9 Selection rules

**Key points** The gross selection rule for infrared spectra is that the electric dipole moment of the molecule must change when the atoms are displaced relative to one another. The specific selection rule is  $\Delta v = \pm 1$ .

**Fig. 12.25** The oscillation of a molecule, even if it is nonpolar, may result in an oscillating dipole that can interact with the electromagnetic field.

The gross selection rule for a change in vibrational state brought about by absorption or emission of radiation is that *the electric dipole moment of the molecule must change when the atoms are displaced relative to one another*. Such vibrations are said to be **infrared active**. The classical basis of this rule is that the molecule can shake the electromagnetic field into oscillation if its dipole changes as it vibrates, and vice versa (Fig. 12.25); its formal basis is given in *Further information 12.2*. Note that the molecule need not have a permanent dipole: the rule requires only a change in dipole moment, possibly from zero. Some vibrations do not affect the molecule's dipole moment (for instance, the stretching motion of a homonuclear diatomic molecule), so they neither absorb nor generate radiation: such vibrations are said to be **infrared inactive**. Homonuclear diatomic molecules are infrared inactive because their dipole moments remain zero however long the bond; heteronuclear diatomic molecules are infrared active.

#### • A brief illustration

Of the molecules  $\text{N}_2$ ,  $\text{CO}_2$ ,  $\text{OCS}$ ,  $\text{H}_2\text{O}$ ,  $\text{CH}_2=\text{CH}_2$ , and  $\text{C}_6\text{H}_6$ , all except  $\text{N}_2$  possess at least one vibrational mode that results in a change of dipole moment, so all except  $\text{N}_2$  can show a vibrational absorption spectrum. Not all the modes of complex molecules are vibrationally active. For example, the symmetric stretch of  $\text{CO}_2$ , in which the O–C–O bonds stretch and contract symmetrically, is inactive because it leaves the dipole moment unchanged (at zero). •

Weak infrared transitions can be observed from homonuclear diatomic molecules trapped within various nanomaterials. For instance, when incorporated into solid  $C_{60}$ ,  $H_2$  molecules interact through van der Waals forces with the surrounding  $C_{60}$  molecules and acquire dipole moments, with the result that they have observable infrared spectra.

**Self-test 12.6** Which of the molecules  $H_2$ ,  $NO$ ,  $N_2O$ , and  $CH_4$  have infrared active vibrations? [NO,  $N_2O$ ,  $CH_4$ ]

The specific selection rule, which is obtained from an analysis of the expression for the transition moment and the properties of integrals over harmonic oscillator wavefunctions (as shown in *Further information 12.2*), is

$$\Delta v = \pm 1 \quad \text{Specific vibrational selection rule} \quad (12.35)$$

Transitions for which  $\Delta v = +1$  correspond to absorption and those with  $\Delta v = -1$  correspond to emission. It follows that the wavenumbers of allowed vibrational transitions, which are denoted  $\Delta \tilde{G}_{v+1/2}$  for the transition  $v+1 \leftarrow v$ , are

$$\Delta \tilde{G}_{v+1/2} = \tilde{G}(v+1) - \tilde{G}(v) = \tilde{\nu} \quad (12.36)$$

As we have seen,  $\tilde{\nu}$  lies in the infrared region of the electromagnetic spectrum, so vibrational transitions absorb and generate infrared radiation.

At room temperature  $kT/hc \approx 200 \text{ cm}^{-1}$ , and most vibrational wavenumbers are significantly greater than  $200 \text{ cm}^{-1}$ . It follows from the Boltzmann distribution that almost all the molecules will be in their vibrational ground states initially. Hence, the dominant spectral transition will be the **fundamental transition**,  $1 \leftarrow 0$ . As a result, the spectrum is expected to consist of a single absorption line. If the molecules are formed in a vibrationally excited state, such as when vibrationally excited HF molecules are formed in the reaction  $H_2 + F_2 \rightarrow 2 \text{ HF}^*$ , the transitions  $5 \rightarrow 4$ ,  $4 \rightarrow 3$ , . . . may also appear (in emission). In the harmonic approximation, all these lines lie at the same frequency, and the spectrum is also a single line. However, as we shall now show, the breakdown of the harmonic approximation causes the transitions to lie at slightly different frequencies, so several lines are observed.

## 12.10 Anharmonicity

**Key points** (a) The Morse potential energy function can be used to describe anharmonic motion. (b) A Birge–Sponer plot may be used to determine the dissociation energy of the bond in a diatomic molecule.

The vibrational terms in eqn 12.34 are only approximate because they are based on a parabolic approximation to the actual potential energy curve. A parabola cannot be correct at all extensions because it does not allow a bond to dissociate. At high vibrational excitations the swing of the atoms (more precisely, the spread of the vibrational wavefunction) allows the molecule to explore regions of the potential energy curve where the parabolic approximation is poor and additional terms in the Taylor expansion of  $V$  (eqn 12.28) must be retained. The motion then becomes **anharmonic**, in the sense that the restoring force is no longer proportional to the displacement. Because the actual curve is less confining than a parabola, we can anticipate that the energy levels become less widely spaced at high excitations.

**Fig. 12.26** The dissociation energy of a molecule,  $\tilde{D}_0$ , differs from the depth of the potential well,  $\tilde{D}_e$ , on account of the zero-point energy of the vibrations of the bond.

**Fig. 12.27** The Morse potential energy curve reproduces the general shape of a molecular potential energy curve. The corresponding Schrödinger equation can be solved, and the values of the energies obtained. The number of bound levels is finite.

### (a) The convergence of energy levels

One approach to the calculation of the energy levels in the presence of anharmonicity is to use a function that resembles the true potential energy more closely. The **Morse potential energy** is

$$V = hc\tilde{D}_e \{1 - e^{-a(R-R_e)}\}^2 \quad a = \left( \frac{m_{\text{eff}} \omega^2}{2hc\tilde{D}_e} \right)^{1/2} \quad \text{Morse potential energy} \quad (12.37)$$

where  $\tilde{D}_e$  is the depth of the potential minimum (Fig. 12.26). Near the well minimum the variation of  $V$  with displacement resembles a parabola (as can be checked by expanding the exponential as far as the first term) but, unlike a parabola, eqn 12.37 allows for dissociation at large displacements. The Schrödinger equation can be solved for the Morse potential and the permitted energy levels are

$$\tilde{G}(v) = (v + \frac{1}{2})\tilde{\nu} - (v + \frac{1}{2})^2 x_e \tilde{\nu} \quad x_e = \frac{a^2 \hbar}{2m_{\text{eff}} \omega} = \frac{\tilde{\nu}}{4\tilde{D}_e} \quad (12.38)$$

The parameter  $x_e$  is called the **anharmonicity constant**. The number of vibrational levels of a Morse oscillator is finite, and  $v = 0, 1, 2, \dots, v_{\text{max}}$ , as shown in Fig. 12.27 (see also Problem 12.24). The second term in the expression for  $\tilde{G}$  subtracts from the first with increasing effect as  $v$  increases, and hence gives rise to the convergence of the levels at high quantum numbers.

Although the Morse oscillator is quite useful theoretically, in practice the more general expression

$$\tilde{G}(v) = (v + \frac{1}{2})\tilde{\nu} - (v + \frac{1}{2})^2 x_e \tilde{\nu} + (v + \frac{1}{2})^3 y_e \tilde{\nu} + \dots \quad (12.39)$$

where  $x_e, y_e, \dots$  are empirical dimensionless constants characteristic of the molecule, is used to fit the experimental data and to find the dissociation energy of the molecule. When anharmonicities are present, the wavenumbers of transitions with  $\Delta v = +1$  are

$$\Delta \tilde{G}_{v+\frac{1}{2}} = \tilde{G}(v+1) - \tilde{G}(v) = \tilde{\nu} - 2(v+1)x_e \tilde{\nu} + \dots \quad (12.40)$$

Equation 12.40 shows that, when  $x_e > 0$ , the transitions move to lower wavenumbers as  $v$  increases.

Anharmonicity also accounts for the appearance of additional weak absorption lines corresponding to the transitions  $2 \leftarrow 0, 3 \leftarrow 0, \dots$ , even though these first, second,  $\dots$  **overtones** are forbidden by the selection rule  $\Delta v = \pm 1$ . The first overtone, for example, gives rise to an absorption at

$$\tilde{G}(v+2) - \tilde{G}(v) = 2\tilde{\nu} - 2(2v+3)x_e \tilde{\nu} + \dots \quad (12.41)$$

The reason for the appearance of overtones is that the selection rule is derived from the properties of harmonic oscillator wavefunctions, which are only approximately valid when anharmonicity is present. Therefore, the selection rule is also only an approximation. For an anharmonic oscillator, all values of  $\Delta v$  are allowed, but transitions with  $\Delta v > 1$  are allowed only weakly if the anharmonicity is slight.

### (b) The Birge–Spencer plot

When several vibrational transitions are detectable, a graphical technique called a **Birge–Spencer plot** may be used to determine the dissociation energy,  $hc\tilde{D}_0$ , of the bond. The basis of the Birge–Spencer plot is that the sum of successive intervals  $\Delta \tilde{G}_{v+\frac{1}{2}}$  from the zero-point level to the dissociation limit is the dissociation energy:

$$\tilde{D}_0 = \Delta \tilde{G}_{1/2} + \Delta \tilde{G}_{3/2} + \dots = \sum_v \Delta \tilde{G}_{v+\frac{1}{2}} \quad (12.42)$$

**Fig. 12.28** The dissociation energy is the sum of the separations of the vibrational energy levels up to the dissociation limit just as the length of a ladder is the sum of the separations of its rungs.

**Fig. 12.29** The area under a plot of transition wavenumber against vibrational quantum number is equal to the dissociation energy of the molecule. The assumption that the differences approach zero linearly is the basis of the Birge–Sponer extrapolation.

**Fig. 12.30** The Birge–Sponer plot used in Example 12.5. The area is obtained simply by counting the squares beneath the line or using the formula for the area of a right triangle (area =  $\frac{1}{2} \times \text{base} \times \text{height}$ ).

just as the height of the ladder is the sum of the separations of its rungs (Fig. 12.28). The construction in Fig. 12.29 shows that the area under the plot of  $\Delta\tilde{G}_{v+\frac{1}{2}}$  against  $v + \frac{1}{2}$  is equal to the sum, and therefore to  $\tilde{D}_0$ . The successive terms decrease linearly when only the  $x_e$  anharmonicity constant is taken into account and the inaccessible part of the spectrum can be estimated by linear extrapolation. Most actual plots differ from the linear plot as shown in Fig. 12.29, so the value of  $\tilde{D}_0$  obtained in this way is usually an overestimate of the true value.

#### Example 12.5 Using a Birge–Sponer plot

The observed vibrational intervals of  $\text{H}_2^+$  lie at the following values for  $1 \leftarrow 0$ ,  $2 \leftarrow 1, \dots$ , respectively (in  $\text{cm}^{-1}$ ): 2191, 2064, 1941, 1821, 1705, 1591, 1479, 1368, 1257, 1145, 1033, 918, 800, 677, 548, 411. Determine the dissociation energy of the molecule.

**Method** Plot the separations against  $v + \frac{1}{2}$ , extrapolate linearly to the point cutting the horizontal axis, and then measure the area under the curve.

**Answer** The points are plotted in Fig. 12.30, and a linear extrapolation is shown. The area under the curve (use the formula for the area of a triangle or count the squares) is 214. Each square corresponds to  $100 \text{ cm}^{-1}$  (refer to the scale of the vertical axis); hence the dissociation energy is  $21\,400 \text{ cm}^{-1}$  (corresponding to  $256 \text{ kJ mol}^{-1}$ ).

**Self-test 12.7** The vibrational levels of  $\text{HgH}$  converge rapidly, and successive intervals are 1203.7 (which corresponds to the  $1 \leftarrow 0$  transition), 965.6, 632.4, and  $172 \text{ cm}^{-1}$ . Estimate the dissociation energy. [35.6  $\text{kJ mol}^{-1}$ ]

**Fig. 12.31** A high-resolution vibration-rotation spectrum of HCl. The lines appear in pairs because  $\text{H}^{35}\text{Cl}$  and  $\text{H}^{37}\text{Cl}$  both contribute (their abundance ratio is 3:1). There is no Q branch, because  $\Delta J = 0$  is forbidden for this molecule.

**Fig. 12.32** The formation of P, Q, and R branches in a vibration-rotation spectrum. The intensities reflect the populations of the initial rotational levels.

## 12.11 Vibration-rotation spectra

**Key points** (a) The P branch consists of vibration-rotation infrared transitions with  $\Delta J = -1$ ; the Q branch has transitions with  $\Delta J = 0$ ; the R branch has transitions with  $\Delta J = +1$ . (b) The Q branch (if it exists) consists of a series of closely spaced lines. The lines of the R branch converge slightly as  $J$  increases and those of the P branch diverge.

Each line of the high resolution vibrational spectrum of a gas-phase heteronuclear diatomic molecule is found to consist of a large number of closely spaced components (Fig. 12.31). Hence, molecular spectra are often called **band spectra**. The separation between the components is less than  $10 \text{ cm}^{-1}$ , which suggests that the structure is due to rotational transitions accompanying the vibrational transition. A rotational change should be expected because classically we can think of the vibrational transition as leading to a sudden increase or decrease in the instantaneous bond length. Just as ice-skaters rotate more rapidly when they bring their arms in, and more slowly when they throw them out, so the molecular rotation is either accelerated or retarded by a vibrational transition.

### (a) Spectral branches

A detailed analysis of the quantum mechanics of simultaneous vibrational and rotational changes shows that the rotational quantum number  $J$  changes by  $\pm 1$  during the vibrational transition of a diatomic molecule. If the molecule also possesses angular momentum about its axis, as in the case of the electronic orbital angular momentum of the paramagnetic molecule NO, then the selection rules also allow  $\Delta J = 0$ .

The appearance of the vibration-rotation spectrum of a diatomic molecule can be discussed in terms of the combined vibration-rotation terms,  $\tilde{S}$ :

$$\tilde{S}(v, J) = \tilde{G}(v) + \tilde{F}(J) \quad (12.43)$$

If we ignore anharmonicity and centrifugal distortion we can use eqn 12.34 for the first term on the right and eqn 12.14 for the second, and obtain

$$\tilde{S}(v, J) = (v + \frac{1}{2})\tilde{\nu} + \tilde{B}J(J+1) \quad (12.44)$$

In a more detailed treatment,  $\tilde{B}$  is allowed to depend on the vibrational state because, as  $v$  increases, the molecule swells slightly and the moment of inertia changes. We shall continue with the simple expression initially.

When the vibrational transition  $v+1 \leftarrow v$  occurs,  $J$  changes by  $\pm 1$  and in some cases by 0 (when  $\Delta J = 0$  is allowed). The absorptions then fall into three groups called **branches** of the spectrum. The **P branch** consists of all transitions with  $\Delta J = -1$ :

$$\tilde{\nu}_P(J) = \tilde{S}(v+1, J-1) - \tilde{S}(v, J) = \tilde{\nu} - 2\tilde{B}J \quad \text{P branch transitions} \quad (12.45a)$$

This branch consists of lines at  $\tilde{\nu} - 2\tilde{B}$ ,  $\tilde{\nu} - 4\tilde{B}$ , ... with an intensity distribution reflecting both the populations of the rotational levels and the magnitude of the  $J-1 \leftarrow J$  transition moment (Fig. 12.32). The **Q branch** consists of all lines with  $\Delta J = 0$ , and its wavenumbers are all

$$\tilde{\nu}_Q(J) = \tilde{S}(v+1, J) - \tilde{S}(v, J) = \tilde{\nu} \quad \text{Q branch transitions} \quad (12.45b)$$

for all values of  $J$ . This branch, when it is allowed (as in NO), appears at the vibrational transition wavenumber. In Fig. 12.31 there is a gap at the expected location of the Q branch because it is forbidden in HCl. The **R branch** consists of lines with  $\Delta J = +1$ :

$$\tilde{\nu}_R(J) = \tilde{S}(v+1, J+1) - \tilde{S}(v, J) = \tilde{\nu} + 2\tilde{B}(J+1) \quad \text{R branch transitions} \quad (12.45c)$$

This branch consists of lines displaced from  $\tilde{\nu}$  to high wavenumber by  $2\tilde{B}$ ,  $4\tilde{B}$ , ...

The separation between the lines in the P and R branches of a vibrational transition gives the value of  $\tilde{B}$ . Therefore, the bond length can be deduced without needing to take a pure rotational microwave spectrum. However, the latter is more precise because microwave frequencies can be measured with greater precision than infrared frequencies.

### (b) Combination differences

The rotational constant of the vibrationally excited state,  $\tilde{B}_1$  (in general,  $\tilde{B}_v$ ), is different from that of the ground vibrational state,  $\tilde{B}_0$ . One contribution to the difference is the anharmonicity of the vibration, which results in a slightly extended bond in the upper state. However, even in the absence of anharmonicity, the average value of  $1/R^2$  ( $\langle 1/R^2 \rangle$ , which is not the same as  $1/\langle R^2 \rangle$ ) varies with the vibrational state (see Problems 12.19 and 12.20). As a result, the Q branch (if it exists) consists of a series of closely spaced lines. The lines of the R branch converge slightly as  $J$  increases; and those of the P branch diverge:

$$\begin{aligned}\tilde{\nu}_P(J) &= \tilde{\nu} - (\tilde{B}_1 + \tilde{B}_0)J + (\tilde{B}_1 - \tilde{B}_0)J^2 \\ \tilde{\nu}_Q(J) &= \tilde{\nu} + (\tilde{B}_1 - \tilde{B}_0)J(J+1) \\ \tilde{\nu}_R(J) &= \tilde{\nu} + (\tilde{B}_1 + \tilde{B}_0)(J+1) + (\tilde{B}_1 - \tilde{B}_0)(J+1)^2\end{aligned}\quad (12.46)$$

To determine the two rotational constants individually, we use the method of **combination differences**. This procedure is used widely in spectroscopy to extract information about a particular state. It involves setting up expressions for the difference in the wavenumbers of transitions to a common state; the resulting expression then depends solely on properties of the other state.

As can be seen from Fig. 12.33, the transitions  $\tilde{\nu}_R(J-1)$  and  $\tilde{\nu}_P(J+1)$  have a common upper state, and hence can be anticipated to depend on  $\tilde{B}_0$ . Indeed, it is easy to show from eqn 12.46 that

$$\tilde{\nu}_R(J-1) - \tilde{\nu}_P(J+1) = 4\tilde{B}_0(J + \tfrac{1}{2}) \quad (12.47a)$$

Therefore, a plot of the combination difference against  $J + \frac{1}{2}$  should be a straight line of slope  $4\tilde{B}_0$ , so the rotational constant of the molecule in the state  $v=0$  can be determined. (Any deviation from a straight line is a consequence of centrifugal distortion, so that effect can be investigated too.) Similarly,  $\tilde{\nu}_R(J)$  and  $\tilde{\nu}_P(J)$  have a common lower state, and hence their combination difference gives information about the upper state:

$$\tilde{\nu}_R(J) - \tilde{\nu}_P(J) = 4\tilde{B}_1(J + \tfrac{1}{2}) \quad (12.47b)$$

The two rotational constants of  $^1\text{H}^{35}\text{Cl}$  found in this way are  $\tilde{B}_0 = 10.440\text{ cm}^{-1}$  and  $\tilde{B}_1 = 10.136\text{ cm}^{-1}$ .

## 12.12 Vibrational Raman spectra of diatomic molecules

**Key points** For a vibration to be Raman active, the polarizability must change as the molecule vibrates. The specific selection rule is  $\Delta v = \pm 1$ . In gas-phase spectra, the Stokes and anti-Stokes lines have a branch structure: the O branch ( $\Delta J = -2$ ), the Q branch ( $\Delta J = 0$ ), and the S branch ( $\Delta J = +2$ ).

The gross selection rule for vibrational Raman transitions is that *the polarizability should change as the molecule vibrates*. As homonuclear and heteronuclear diatomic molecules swell and contract during a vibration, the control of the nuclei over the electrons varies, and hence the molecular polarizability changes. Both types of diatomic molecule are therefore vibrationally Raman active. The specific selection rule for

**Fig. 12.33** The method of combination differences makes use of the fact that some transitions share a common level.

**Fig. 12.34** The formation of O, Q, and S branches in a vibration-rotation Raman spectrum of a linear rotor. Note that the frequency scale runs in the opposite direction to that in Fig. 12.32, because the higher energy transitions (on the right) extract more energy from the incident beam and leave it at lower frequency.

**Fig. 12.35** The structure of a vibrational line in the vibrational Raman spectrum of carbon monoxide, showing the O, Q, and S branches.

vibrational Raman transitions in the harmonic approximation is  $\Delta v = \pm 1$ . The formal basis for the gross and specific selection rules is given in *Further information 12.2*.

The lines to high frequency of the incident radiation, the anti-Stokes lines, are those for which  $\Delta v = -1$ . The lines to low frequency, the Stokes lines, correspond to  $\Delta v = +1$ . The intensities of the anti-Stokes and Stokes lines are governed largely by the Boltzmann populations of the vibrational states involved in the transition. It follows that anti-Stokes lines are usually weak because very few molecules are in an excited vibrational state initially.

In gas-phase spectra, the Stokes and anti-Stokes lines have a branch structure arising from the simultaneous rotational transitions that accompany the vibrational excitation (Fig. 12.34). The selection rules are  $\Delta J = 0, \pm 2$  (as in pure rotational Raman spectroscopy), and give rise to the **O branch** ( $\Delta J = -2$ ), the **Q branch** ( $\Delta J = 0$ ), and the **S branch** ( $\Delta J = +2$ ):

$$\begin{aligned}\tilde{\nu}_O(J) &= \tilde{\nu}_i - \tilde{\nu} - 2\tilde{B} + 4\tilde{B}J && \text{O branch transitions} \\ \tilde{\nu}_Q(J) &= \tilde{\nu}_i - \tilde{\nu} && \text{Q branch transitions} \\ \tilde{\nu}_S(J) &= \tilde{\nu}_i - \tilde{\nu} - 6\tilde{B} - 4\tilde{B}J && \text{S branch transitions}\end{aligned}\quad (12.48)$$

where  $\tilde{\nu}_i$  is the wavenumber of the incident radiation. Note that, unlike in infrared spectroscopy, a Q branch is obtained for all linear molecules. The spectrum of CO, for instance, is shown in Fig. 12.35: the structure of the Q branch arises from the differences in rotational constants of the upper and lower vibrational states.

The information available from vibrational Raman spectra adds to that from infrared spectroscopy because homonuclear diatomics can also be studied. The spectra can be interpreted in terms of the force constants, dissociation energies, and bond lengths, and some of the information obtained is included in Table 12.2.

## The vibrations of polyatomic molecules

There is only one mode of vibration for a diatomic molecule, the bond stretch. In polyatomic molecules there are several modes of vibration because all the bond lengths and angles may change and the vibrational spectra are very complex. Nonetheless, we shall see that infrared and Raman spectroscopy can be used to obtain information about the structure of systems as large as animal and plant tissues. Raman spectroscopy is particularly useful for characterizing nanomaterials, especially carbon nanotubes.

**Table 12.2\*** Properties of diatomic molecules

|                            | $\tilde{\nu}/\text{cm}^{-1}$ | $R_e/\text{pm}$ | $\tilde{B}/\text{cm}^{-1}$ | $k/(\text{N m}^{-1})$ | $\tilde{D}_0/(\text{kJ mol}^{-1})$ |
|----------------------------|------------------------------|-----------------|----------------------------|-----------------------|------------------------------------|
| $^1\text{H}_2$             | 4400                         | 74              | 60.86                      | 575                   | 432                                |
| $^1\text{H}^{35}\text{Cl}$ | 2991                         | 127             | 10.59                      | 516                   | 428                                |
| $^1\text{H}^{127}\text{I}$ | 2308                         | 161             | 6.51                       | 314                   | 295                                |
| $^{35}\text{Cl}_2$         | 560                          | 199             | 0.244                      | 323                   | 239                                |

\* More values are given in the *Data section*.

### 12.13 Normal modes

**Key points** A normal mode is an independent, synchronous motion of atoms or groups of atoms that may be excited without leading to the excitation of any other normal mode. The number of normal modes is  $3N - 6$  (for nonlinear molecules) or  $3N - 5$  (linear molecules).

We begin by calculating the total number of vibrational modes of a polyatomic molecule. We then see that we can choose combinations of these atomic displacements that give the simplest description of the vibrations.

As shown in the following *Justification*, for a nonlinear molecule that consists of  $N$  atoms, there are  $3N - 6$  independent modes of vibration. If the molecule is linear, there are  $3N - 5$  independent vibrational modes.

#### • A brief illustration

Water,  $\text{H}_2\text{O}$ , is a nonlinear triatomic molecule, and has three modes of vibration (and three modes of rotation);  $\text{CO}_2$  is a linear triatomic molecule, and has four modes of vibration (and only two modes of rotation). Even a middle-sized molecule such as naphthalene ( $\text{C}_{10}\text{H}_8$ ) has 48 distinct modes of vibration. •

#### Justification 12.2 The number of vibrational modes

The total number of coordinates needed to specify the locations of  $N$  atoms is  $3N$ . Each atom may change its location by varying one of its three coordinates ( $x$ ,  $y$ , and  $z$ ), so the total number of displacements available is  $3N$ . These displacements can be grouped together in a physically sensible way. For example, three coordinates are needed to specify the location of the centre of mass of the molecule, so three of the  $3N$  displacements correspond to the translational motion of the molecule as a whole. The remaining  $3N - 3$  are non-translational ‘internal’ modes of the molecule.

Two angles are needed to specify the orientation of a linear molecule in space: in effect, we need to give only the latitude and longitude of the direction in which the molecular axis is pointing (Fig. 12.36a). However, three angles are needed for a nonlinear molecule because we also need to specify the orientation of the molecule around the direction defined by the latitude and longitude (Fig. 12.36b). Therefore, two (linear) or three (nonlinear) of the  $3N - 3$  internal displacements are rotational. This leaves  $3N - 5$  (linear) or  $3N - 6$  (nonlinear) displacements of the atoms relative to one another: these are the vibrational modes. It follows that the number of modes of vibration  $N_{\text{vib}}$  is  $3N - 5$  for linear molecules and  $3N - 6$  for nonlinear molecules.

The next step is to find the best description of the modes. One choice for the four modes of  $\text{CO}_2$ , for example, might be the ones in Fig. 12.37. This illustration shows the stretching of one bond (the mode  $\nu_L$ ), the stretching of the other ( $\nu_R$ ), and the two perpendicular bending modes ( $\nu_2$ ). The description, while permissible, has a disadvantage: when one CO bond vibration is excited, the motion of the C atom sets the other CO bond in motion, so energy flows backwards and forwards between  $\nu_L$  and  $\nu_R$ . Moreover, the position of the centre of mass of the molecule varies in the course of either vibration.

The description of the vibrational motion is much simpler if linear combinations of  $\nu_L$  and  $\nu_R$  are taken. For example, one combination is  $\nu_1$  in Fig. 12.37b: this mode is the **symmetric stretch**. In this mode, the C atom is buffeted simultaneously from each side and the motion continues indefinitely. Another mode is  $\nu_3$ , the **antisymmetric stretch**, in which the two O atoms always move in the same direction as each other and opposite to that of the C atom. Both modes are independent in the sense that, if one is

**Fig. 12.36** (a) The orientation of a linear molecule requires the specification of two angles. (b) The orientation of a nonlinear molecule requires the specification of three angles.

**Fig. 12.37** Alternative descriptions of the vibrations of  $\text{CO}_2$ . (a) The stretching modes are not independent and, if one C–O group is excited, the other begins to vibrate. They are not normal modes of vibration of the molecule. (b) The symmetric and antisymmetric stretches are independent, and one can be excited without affecting the other: they are normal modes. (c) The two perpendicular bending motions are also normal modes.

**Fig. 12.38** The three normal modes of  $\text{H}_2\text{O}$ . The mode  $\nu_2$  is predominantly bending, and occurs at lower wavenumber than the other two.

excited, then it does not excite the other. They are two of the ‘normal modes’ of the molecule, its independent, collective vibrational displacements. The two other normal modes are the bending modes  $\nu_3$ . In general, a **normal mode** is an independent, synchronous motion of atoms or groups of atoms that may be excited without leading to the excitation of any other normal mode and without involving translation or rotation of the molecule as a whole.

The four normal modes of  $\text{CO}_2$ , and the  $N_{\text{vib}}$  normal modes of polyatomics in general, are the key to the description of molecular vibrations. Each normal mode,  $q$ , behaves like an independent harmonic oscillator (if anharmonicities are neglected), so each has a series of terms

$$\tilde{G}_q(v) = (v + \frac{1}{2})\tilde{\nu}_q \quad \tilde{\nu}_q = \frac{1}{2\pi c} \left( \frac{k_q}{m_q} \right)^{1/2} \quad \text{Vibrational terms of normal modes} \quad (12.49)$$

where  $\tilde{\nu}_q$  is the wavenumber of mode  $q$  and depends on the force constant  $k_q$  for the mode and on the effective mass  $m_q$  of the mode. The effective mass of the mode is a measure of the mass that is swung about by the vibration and in general is a complicated function of the masses of the atoms. For example, in the symmetric stretch of  $\text{CO}_2$ , the C atom is stationary, and the effective mass depends on the masses of only the O atoms. In the antisymmetric stretch and in the bends, all three atoms move, so all contribute to the effective mass. The three normal modes of  $\text{H}_2\text{O}$  are shown in Fig. 12.38: note that the predominantly bending mode ( $\nu_2$ ) has a lower frequency than the others, which are predominantly stretching modes. It is generally the case that the frequencies of bending motions are lower than those of stretching modes. One point that must be appreciated is that only in special cases (such as the  $\text{CO}_2$  molecule) are the normal modes purely stretches or purely bends. In general, a normal mode is a composite motion of simultaneous stretching and bending of bonds. Another point in this connection is that heavy atoms generally move less than light atoms in normal modes.

### 12.14 Infrared absorption spectra of polyatomic molecules

**Key points** A normal mode is infrared active if it is accompanied by a change of dipole moment. The specific selection rule is  $\Delta v_q = \pm 1$ .

The gross selection rule for infrared activity is that *the motion corresponding to a normal mode should be accompanied by a change of dipole moment*. Deciding whether this is so can sometimes be done by inspection. For example, the symmetric stretch of  $\text{CO}_2$  leaves the dipole moment unchanged (at zero, see Fig. 12.37), so this mode is infrared inactive. The antisymmetric stretch, however, changes the dipole moment because the molecule becomes unsymmetrical as it vibrates, so this mode is infrared active. Because the dipole moment change is parallel to the principal axis, the transitions arising from this mode are classified as **parallel bands** in the spectrum. Both bending modes are infrared active: they are accompanied by a changing dipole perpendicular to the principal axis, so transitions involving them lead to a **perpendicular band** in the spectrum. The latter bands eliminate the linearity of the molecule, and as a result a Q branch is observed; a parallel band does not have a Q branch.

The active modes are subject to the specific selection rule  $\Delta v_q = \pm 1$  in the harmonic approximation, so the wavenumber of the fundamental transition (the ‘first harmonic’) of each active mode is  $\tilde{\nu}_q$ . From the analysis of the spectrum, a picture may be constructed of the stiffness of various parts of the molecule, that is, we can establish its **force field**, the set of force constants corresponding to all the displacements of

the atoms. The force field may also be estimated by using the semi-empirical, *ab initio*, and DFT computational techniques described in Section 10.7. Superimposed on the simple force field scheme are the complications arising from anharmonicities and the effects of molecular rotation. Very often the sample is a liquid or a solid, and the molecules are unable to rotate freely. In a liquid, for example, a molecule may be able to rotate through only a few degrees before it is struck by another, so it changes its rotational state frequently. This random changing of orientation is called **tumbling**.

The lifetimes of rotational states in liquids are very short, so in most cases the rotational energies are ill-defined. Collisions occur at a rate of about  $10^{13} \text{ s}^{-1}$  and, even allowing for only a 10 per cent success rate in knocking the molecule into another rotational state, a lifetime broadening (eqn 9.39, in the form  $\delta\tilde{\nu} \approx 1/2\pi c\tau$ ) of more than  $1 \text{ cm}^{-1}$  can easily result. The rotational structure of the vibrational spectrum is blurred by this effect, so the infrared spectra of molecules in condensed phases usually consist of broad lines spanning the entire range of the resolved gas-phase spectrum, and showing no branch structure.

One very important application of infrared spectroscopy to condensed phase samples, and one for which the blurring of the rotational structure by random collisions is a welcome simplification, is to chemical analysis. The vibrational spectra of different groups in a molecule give rise to absorptions at characteristic frequencies because a normal mode of even a very large molecule is often dominated by the motion of a small group of atoms. The intensities of the vibrational bands that can be identified with the motions of small groups are also transferable between molecules. Consequently, the molecules in a sample can often be identified by examining its infrared spectrum and referring to a table of characteristic frequencies and intensities (Table 12.3).

### IMPACT ON ENVIRONMENTAL SCIENCE

#### 12.2 Climate change<sup>1</sup>

Solar energy strikes the top of the Earth's atmosphere at a rate of  $343 \text{ W m}^{-2}$ . About 30 per cent of this energy is reflected back into space by the Earth or the atmosphere. The Earth-atmosphere system absorbs the remaining energy and re-emits it into space as black-body radiation, with most of the intensity being carried by infrared radiation in the range  $200\text{--}2500 \text{ cm}^{-1}$  ( $4\text{--}50 \text{ }\mu\text{m}$ ). The Earth's average temperature is maintained by an energy balance between solar radiation absorbed by the Earth and black-body radiation emitted by the Earth.

The trapping of infrared radiation by certain gases in the atmosphere is known as the *greenhouse effect*, so called because it warms the Earth as if the planet were enclosed in a huge greenhouse. The result is that the natural greenhouse effect raises the average surface temperature well above the freezing point of water and creates an environment in which life is possible. The major constituents to the Earth's atmosphere,  $\text{O}_2$  and  $\text{N}_2$ , do not contribute to the greenhouse effect because homonuclear diatomic molecules cannot absorb infrared radiation. However, the minor atmospheric gases, water vapour and  $\text{CO}_2$ , do absorb infrared radiation and hence are responsible for the greenhouse effect (Fig. 12.39). Water vapour absorbs strongly in the ranges  $1300\text{--}1900 \text{ cm}^{-1}$  ( $5.3\text{--}7.7 \text{ }\mu\text{m}$ ) and  $3550\text{--}3900 \text{ cm}^{-1}$  ( $2.6\text{--}2.8 \text{ }\mu\text{m}$ ), whereas  $\text{CO}_2$  shows strong absorption in the ranges  $500\text{--}725 \text{ cm}^{-1}$  ( $14\text{--}20 \text{ }\mu\text{m}$ ) and  $2250\text{--}2400 \text{ cm}^{-1}$  ( $4.2\text{--}4.4 \text{ }\mu\text{m}$ ).

**Table 12.3\*** Typical vibrational wavenumbers

| Vibration type    | $\tilde{\nu}/\text{cm}^{-1}$ |
|-------------------|------------------------------|
| C—H stretch       | 2850–2960                    |
| C—H bend          | 1340–1465                    |
| C—C stretch, bend | 700–1250                     |
| C=C stretch       | 1620–1680                    |

\* More values are given in the *Data section*.

**Fig. 12.39** The intensity of infrared radiation that would be lost from Earth in the absence of greenhouse gases is shown by the brown line. The blue line is the intensity of the radiation actually emitted. The maximum wavelength of radiation absorbed by each greenhouse gas is indicated.

<sup>1</sup> This section is based on a similar contribution initially prepared by Loretta Jones and appearing in *Chemical principles*, Peter Atkins and Loretta Jones, W.H. Freeman and Co., New York (2010).

Increases in the levels of greenhouse gases, which also include methane, dinitrogen oxide, ozone, and certain chlorofluorocarbons, as a result of human activity have the potential to enhance the natural greenhouse effect, leading to significant warming of the planet. This problem is referred to as *global warming*, and more generally as *climate change*, which we now explore in some detail.

The concentration of water vapour in the atmosphere has remained steady over time, but concentrations of some other greenhouse gases are rising. From about the year 1000 until about 1750, the  $\text{CO}_2$  concentration remained fairly stable, but, since then, it has increased by 28 per cent. The concentration of methane,  $\text{CH}_4$ , has more than doubled during this time and is now at its highest level for 160 000 years (160 ka; a is the SI unit denoting 1 year). Studies of air pockets in ice cores taken from Antarctica show that increases in the concentration of both atmospheric  $\text{CO}_2$  and  $\text{CH}_4$  over the past 160 ka correlate well with increases in the global surface temperature.

Human activities are primarily responsible for the rising concentrations of atmospheric  $\text{CO}_2$  and  $\text{CH}_4$ . Most of the atmospheric  $\text{CO}_2$  comes from the burning of hydrocarbon fuels, which began on a large scale with the Industrial Revolution in the middle of the nineteenth century. The additional methane comes mainly from the petroleum industry and from agriculture.

The temperature of the surface of the Earth has increased by about 0.8 K since the middle of the nineteenth century (Fig. 12.40). In 2007 the Intergovernmental Panel on Climate Change (IPCC) estimated that our continued reliance on hydrocarbon fuels, coupled to current trends in population growth, could result in an additional increase of 1–3 K in the temperature of the Earth by 2100, relative to the surface temperature in 2000. Furthermore, the rate of temperature change is likely to be greater than at any time in the last 10 ka. To place a temperature rise of 3 K in perspective, it is useful to consider that the average temperature of the Earth during the last ice age was only 6 K colder than at present. Just as cooling the planet (for example, during an ice age) can lead to detrimental effects on ecosystems, so too can a dramatic warming of the globe. One example of a significant change in the environment caused by a temperature increase of 3 K is a rise in sea level by about 0.5 m, which is sufficient to alter weather patterns and submerge coastal ecosystems.

Computer projections for the next 200 years predict further increases in atmospheric  $\text{CO}_2$  levels and suggest that, to maintain  $\text{CO}_2$  at its current concentration, we would have to reduce hydrocarbon fuel consumption immediately by about 50 per cent. Clearly, in order to reverse global warming trends, we need to develop alternatives to fossil fuels, such as hydrogen (which can be used in fuel cells) and solar energy technologies.

**Fig. 12.40** The average change in surface temperature of the Earth from 1855 to 2002.

## 12.15 Vibrational Raman spectra of polyatomic molecules

**Key points** The exclusion rule states that, if the molecule has a centre of symmetry, then no modes can be both infrared and Raman active. (a) Totally symmetrical vibrations give rise to polarized lines. (b) In resonance Raman spectroscopy the frequency of the incident radiation nearly coincides with the frequency of an electronic transition of the sample. (c) Coherent anti-Stokes Raman spectroscopy (CARS) is a Raman technique that relies on the use of two incident beams of radiation.

The normal modes of vibration of molecules are Raman active if they are accompanied by a changing polarizability. It is sometimes quite difficult to judge by inspection when this is so. The symmetric stretch of  $\text{CO}_2$ , for example, alternately swells and contracts the molecule: this motion changes the polarizability of the molecule, so the mode is Raman active. The other modes of  $\text{CO}_2$  leave the polarizability unchanged, so they are Raman inactive.

A more exact treatment of infrared and Raman activity of normal modes leads to the **exclusion rule**:

If the molecule has a centre of symmetry then no modes can be both infrared and Raman active.

Exclusion rule

(A mode may be inactive in both.) Because it is often possible to judge intuitively if a mode changes the molecular dipole moment, we can use this rule to identify modes that are not Raman active. The rule applies to  $\text{CO}_2$  but to neither  $\text{H}_2\text{O}$  nor  $\text{CH}_4$  because they have no centre of symmetry. In general, it is necessary to use group theory to predict whether a mode is infrared or Raman active (Section 12.16).

### (a) Depolarization

The assignment of Raman lines to particular vibrational modes is aided by noting the state of polarization of the scattered light. The **depolarization ratio**,  $\rho$ , of a line is the ratio of the intensities,  $I$ , of the scattered light with polarizations perpendicular and parallel to the plane of polarization of the incident radiation:

$$\rho = \frac{I_{\perp}}{I_{\parallel}}$$

Definition of  
depolarization ratio

[12.50]

To measure  $\rho$ , the intensity of a Raman line is measured with a polarizing filter (a 'half-wave plate') first parallel and then perpendicular to the polarization of the incident beam. If the emergent light is not polarized, then both intensities are the same and  $\rho$  is close to 1; if the light retains its initial polarization, then  $I_{\perp} = 0$ , so  $\rho = 0$  (Fig. 12.41). A line is classified as **depolarized** if it has  $\rho$  close to or greater than 0.75 and as **polarized** if  $\rho < 0.75$ . Only totally symmetrical vibrations give rise to polarized lines in which the incident polarization is largely preserved. Vibrations that are not totally symmetrical give rise to depolarized lines because the incident radiation can give rise to radiation in the perpendicular direction too.

### (b) Resonance Raman spectra

A modification of the basic Raman effect involves using incident radiation that nearly coincides with the frequency of an electronic transition of the sample (Fig. 12.42). The technique is then called **resonance Raman spectroscopy**. It is characterized by a much greater intensity in the scattered radiation. Furthermore, because it is often the case that only a few vibrational modes contribute to the more intense scattering, the spectrum is greatly simplified.

Resonance Raman spectroscopy is used to study biological molecules that absorb strongly in the ultraviolet and visible regions of the spectrum. Examples include the

**Fig. 12.41** The definition of the planes used for the specification of the depolarization ratio,  $\rho$ , in Raman scattering.

**Fig. 12.42** In the resonance Raman effect the incident radiation has a frequency close to an actual electronic excitation of the molecule. A photon is emitted when the excited state returns to a state close to the ground state.

**Fig. 12.43** The resonance Raman spectra of a protein complex that is responsible for some of the initial electron transfer events in plant photosynthesis. (a) Laser excitation of the sample at 407 nm shows Raman bands due to both chlorophyll *a* and  $\beta$ -carotene bound to the protein because both pigments absorb light at this wavelength. (b) Laser excitation at 488 nm shows Raman bands from  $\beta$ -carotene only because chlorophyll *a* does not absorb light very strongly at this wavelength. (Adapted from D.F. Ghanotakis *et al.*, *Biochim. Biophys. Acta* 974, 44 (1989).)

**Fig. 12.44** The experimental arrangement for the CARS experiment.

pigments  $\beta$ -carotene and chlorophyll, which capture solar energy during plant photosynthesis. The resonance Raman spectra of Fig. 12.43 show vibrational transitions from only the few pigment molecules that are bound to very large proteins dissolved in an aqueous buffer solution. This selectivity arises from the fact that water (the solvent), amino acid residues, and the peptide group do not have electronic transitions at the laser wavelengths used in the experiment, so their conventional Raman spectra are weak compared to the enhanced spectra of the pigments. Comparison of the spectra in Figs. 12.43a and 12.43b also shows that, with proper choice of excitation wavelength, it is possible to examine individual classes of pigments bound to the same protein: excitation at 488 nm, where  $\beta$ -carotene absorbs strongly, shows vibrational bands from  $\beta$ -carotene only, whereas excitation at 407 nm, where chlorophyll *a* and  $\beta$ -carotene absorb, reveals features from both types of pigments.

### (c) Coherent anti-Stokes Raman spectroscopy

The intensity of Raman transitions may be enhanced by **coherent anti-Stokes Raman spectroscopy** (CARS, Fig. 12.44). The technique relies on the fact that, if two laser beams of frequencies  $\nu_1$  and  $\nu_2$  pass through a sample, then they may mix together and give rise to coherent radiation of several different frequencies, one of which is

$$\nu' = 2\nu_1 - \nu_2 \quad (12.51)$$

Suppose that  $\nu_2$  is varied until it matches any Stokes line from the sample, such as the one with frequency  $\nu_1 - \Delta\nu$ ; then the coherent emission will have frequency

$$\nu' = 2\nu_1 - (\nu_1 - \Delta\nu) = \nu_1 + \Delta\nu \quad (12.52)$$

which is the frequency of the corresponding anti-Stokes line. This coherent radiation forms a narrow beam of high intensity.

An advantage of CARS is that it can be used to study Raman transitions in the presence of competing incoherent background radiation, and so can be used to observe the Raman spectra of species in flames. One example is the vibration–rotation CARS spectrum of  $N_2$  gas in a methane–air flame shown in Fig. 12.45.

## 12.16 Symmetry aspects of molecular vibrations

**Key points** (a) A normal mode is infrared active if its symmetry species is the same as any of the symmetry species of  $x$ ,  $y$ , or  $z$ . (b) A normal mode is Raman active if its symmetry species is the same as the symmetry species of a quadratic form.

One of the most powerful ways of dealing with normal modes, especially of complex molecules, is to classify them according to their symmetries. Each normal mode must belong to one of the symmetry species of the molecular point group, as discussed in Chapter 11.

### Example 12.6 Identifying the symmetry species of a normal mode

Establish the symmetry species of the normal mode vibrations of  $CH_4$ , which belongs to the group  $T_d$ .

**Method** The first step in the procedure is to identify the symmetry species of the irreducible representations spanned by all the  $3N$  displacements of the atoms, using the characters of the molecular point group. Find these characters by counting 1 if the displacement is unchanged under a symmetry operation,  $-1$  if it changes sign, and 0 if it is changed into some other displacement. Next, subtract the symmetry species of the translations. Translational displacements span the same symmetry species as  $x$ ,  $y$ , and  $z$ , so they can be obtained from the rightmost column of the

**Fig. 12.45** CARS spectrum of a methane–air flame at 2104 K. The peaks correspond to the Q branch of the vibration–rotation spectrum of  $\text{N}_2$  gas. (Adapted from J.F. Verdieck *et al.*, *J. Chem. Ed.* 59, 495 (1982).)

**Fig. 12.46** The atomic displacements of  $\text{CH}_4$  and the symmetry elements used to calculate the characters.

**Fig. 12.47** Typical normal modes of vibration of a tetrahedral molecule. There are in fact two modes of symmetry species E and three modes of each  $T_2$  symmetry species.

character table. Finally, subtract the symmetry species of the rotations, which are also given in the character table (and denoted there by  $R_x$ ,  $R_y$ , or  $R_z$ ).

**Answer** There are  $3 \times 5 = 15$  degrees of freedom, of which  $(3 \times 5) - 6 = 9$  are vibrations. Refer to Fig. 12.46. Under  $E$ , no displacement coordinates are changed, so the character is 15. Under  $C_3$ , no displacements are left unchanged, so the character is 0. Under the  $C_2$  indicated, the  $z$ -displacement of the central atom is left unchanged, whereas its  $x$ - and  $y$ -components both change sign. Therefore  $\chi(C_2) = 1 - 1 - 1 + 0 + 0 + \dots = -1$ . Under the  $S_4$  indicated, the  $z$ -displacement of the central atom is reversed, so  $\chi(S_4) = -1$ . Under  $\sigma_d$ , the  $x$ - and  $z$ -displacements of C,  $\text{H}_3$ , and  $\text{H}_4$  are left unchanged and the  $y$ -displacements are reversed; hence  $\chi(\sigma_d) = 3 + 3 - 3 = 3$ . The characters are therefore 15, 0,  $-1$ ,  $-1$ , 3. By decomposing the direct product (Section 11.5a), we find that this representation spans  $A_1 + E + T_1 + 3T_2$ . The translations span  $T_2$ ; the rotations span  $T_1$ . Hence, the nine vibrations span  $A_1 + E + 2T_2$ . The modes are shown in Fig. 12.47. We shall see in the next subsection that symmetry analysis gives a quick way of deciding which modes are active.

**Self-test 12.8** Establish the symmetry species of the normal modes of  $\text{H}_2\text{O}$ .

$$[2A_1 + B_2]$$

### (a) Infrared activity of normal modes

It is best to use group theory to judge the activities of more complex modes of vibration. This is easily done by checking the character table of the molecular point group for the symmetry species of the irreducible representations spanned by  $x$ ,  $y$ , and  $z$ , for their species are also the symmetry species of the components of the electric dipole moment. Then apply the following rule:

If the symmetry species of a normal mode is the same as any of the symmetry species of  $x$ ,  $y$ , or  $z$ , then the mode is infrared active.

Symmetry test  
for IR activity

• **A brief illustration**

To decide which modes of  $\text{CH}_4$  are IR active, we note that we found in Example 12.6 that the symmetry species of the normal modes are  $A_1 + E + 2T_2$ . Therefore, because  $x$ ,  $y$ , and  $z$  span  $T_2$  in the group  $T_d$ , only the  $T_2$  modes are infrared active. The distortions accompanying these modes lead to a changing dipole moment. The  $A_1$  mode, which is inactive, is the symmetrical ‘breathing’ mode of the molecule. •

**Self-test 12.9** Which of the normal modes of  $\text{H}_2\text{O}$  are infrared active? [All three]

**Justification 12.3** Using group theory to identify infrared active normal modes

The rule hinges on the form of the transition dipole moment between the ground-state vibrational wavefunction,  $\psi_0$ , and that of the first excited state,  $\psi_1$ . The  $x$ -component is

$$\mu_{x,10} = -e \int \psi_1^* x \psi_0 d\tau \quad (12.53)$$

with similar expressions for the two other components of the transition moment. The ground-state vibrational wavefunction is a Gaussian function of the form  $e^{-x^2}$ , so it is symmetrical in  $x$ . The wavefunction for the first excited state gives a non-vanishing integral only if it is proportional to  $x$ , for then the integrand is proportional to  $x^2$  rather than to  $xy$  or  $xz$ . Consequently, the excited state wavefunction must have the same symmetry as the displacement  $x$ .

**(b) Raman activity of normal modes**

Group theory provides an explicit recipe for judging the Raman activity of a normal mode. In this case, the symmetry species of the quadratic forms ( $x^2$ ,  $xy$ , etc.) listed in the character table are noted (they transform in the same way as the polarizability), and then we use the following rule:

If the symmetry species of a normal mode is the same as the symmetry species of a quadratic form, then the mode is Raman active.

Symmetry test for Raman activity

• **A brief illustration**

To decide which of the vibrations of  $\text{CH}_4$  are Raman active, refer to the  $T_d$  character table. It was established in Example 12.6 that the symmetry species of the normal modes are  $A_1 + E + 2T_2$ . Because the quadratic forms span  $A_1 + E + T_2$ , all the normal modes are Raman active. By combining this information with that in Example 12.6, we see how the infrared and Raman spectra of  $\text{CH}_4$  are assigned. The assignment of spectral features to the  $T_2$  modes is straightforward because these are the only modes that are both infrared and Raman active. This leaves the  $A_1$  and  $E$  modes to be assigned in the Raman spectrum. Measurement of the depolarization ratio distinguishes between these modes because the  $A_1$  mode, being totally symmetric, is polarized and the  $E$  mode is depolarized. •

**Self-test 12.10** Which of the vibrational modes of  $\text{H}_2\text{O}$  are Raman active? [All three]

## Checklist of key equations

## Further information

### Further information 12.1 Spectrometers

Here we provide additional brief details of the principles of operation of spectrometers, describing radiation sources, dispersing elements, detectors, and Fourier transform techniques. The information here is also relevant to the electronic transitions discussed in Chapter 13, where the radiation absorbed lies in the visible and ultraviolet regions of the spectrum.

#### (a) Sources of radiation

Sources of radiation are either *monochromatic*, those spanning a very narrow range of frequencies around a central value, or *polychromatic*, those spanning a wide range of frequencies. Monochromatic sources that can be tuned over a range of frequencies include the *klystron* and the *Gunn diode*, which operate in the microwave range, and lasers, which are discussed in Chapter 13.

Polychromatic sources that take advantage of black-body radiation from hot materials can be used from the infrared to the ultraviolet regions of the electromagnetic spectrum. Examples include mercury arcs inside a quartz envelope ( $35 \text{ cm}^{-1} < \tilde{\nu} < 200 \text{ cm}^{-1}$ ), *Nernst filaments* and *globars* ( $200 \text{ cm}^{-1} < \tilde{\nu} < 4000 \text{ cm}^{-1}$ ), and *quartz-tungsten-halogen lamps* ( $320 \text{ nm} < \lambda < 2500 \text{ nm}$ ).

A *gas discharge lamp* is a common source of ultraviolet and visible radiation. In a *xenon discharge lamp*, an electrical discharge excites xenon atoms to excited states, which then emit ultraviolet radiation. In a *deuterium lamp*, excited  $\text{D}_2$  molecules dissociate into electronically excited D atoms, which emit intense radiation between 200 nm and 400 nm.

For certain applications, synchrotron radiation is generated in a *synchrotron storage ring*, which consists of an electron beam travelling in a circular path with circumferences of up to several hundred metres. As electrons travelling in a circle are constantly accelerated by

**Fig. 12.48** A synchrotron storage ring. The electrons injected into the ring from the linear accelerator and booster synchrotron are accelerated to high speed in the main ring. An electron in a curved path is subject to constant acceleration, and an accelerated charge radiates electromagnetic energy.

the forces that constrain them to their path, they generate radiation (Fig. 12.48). Synchrotron radiation spans a wide range of frequencies, including the infrared and X-rays. Except in the microwave region, synchrotron radiation is much more intense than can be obtained by most conventional sources.

### (b) The dispersing element

The dispersing element in most absorption spectrometers operating in the ultraviolet to near-infrared region of the spectrum is a **diffraction grating**, which consists of a glass or ceramic plate into which fine grooves have been cut and covered with a reflective aluminium coating. The grating causes interference between waves reflected from its surface, and constructive interference occurs when

$$n\lambda = d(\sin \theta - \sin \phi) \quad (12.54)$$

where  $n = 1, 2, \dots$  is the *diffraction order*,  $\lambda$  is the wavelength of the diffracted radiation,  $d$  is the distance between grooves,  $\theta$  is the angle of incidence of the beam, and  $\phi$  is the angle of emergence of the beam (Fig. 12.49). For given values of  $n$  and  $\theta$ , larger differences in  $\phi$  are observed for different wavelengths when  $d$  is similar to the wavelength

**Fig. 12.49** One common dispersing element is a diffraction grating, which separates wavelengths spatially as a result of the scattering of light by fine grooves cut into a coated piece of glass. When a polychromatic light beam strikes the surface at an angle  $\theta$ , several light beams of different wavelengths emerge at different angles  $\phi$  (eqn 12.54).

**Fig. 12.50** A polychromatic beam is dispersed by a diffraction grating into three component wavelengths  $\lambda_1$ ,  $\lambda_2$ , and  $\lambda_3$ . In the configuration shown, only radiation with  $\lambda_2$  passes through a narrow slit and reaches the detector. Rotating the diffraction grating (as shown by the arrows on the dotted circle) allows  $\lambda_1$  or  $\lambda_3$  to reach the detector.

of radiation being analysed. Wide angular separation results in wide spatial separation between wavelengths some distance away from the grating, where a detector is placed.

In a **monochromator**, a narrow exit slit allows only a narrow range of wavelengths to reach the detector (Fig. 12.50). Turning the grating around an axis perpendicular to the incident and diffracted beams allows different wavelengths to be analysed; in this way, the absorption spectrum is built up one narrow wavelength range at a time. Typically, the grating is swept through an angle that investigates only the first order of diffraction ( $n = 1$ ). In a **polychromator**, there is no slit and a broad range of wavelengths can be analysed simultaneously by *array detectors*, such as those discussed below.

### (c) Fourier transform techniques

In a Fourier transform instrument, the diffraction grating is replaced by a Michelson interferometer, which works by splitting the beam from the sample into two and introducing a varying path difference,  $p$ , into one of them (Fig. 12.51). When the two components recombine, there is a phase difference between them, and they interfere either constructively or destructively depending on the

**Fig. 12.51** A Michelson interferometer. The beam-splitting element divides the incident beam into two beams with a path difference that depends on the location of the mirror  $M_1$ . The compensator ensures that both beams pass through the same thickness of material.

**Fig. 12.52** An interferogram produced as the path length  $p$  is changed in the interferometer shown in Fig. 12.51. Only a single frequency component is present in the signal, so the graph is a plot of the function  $I(p) = I_0(1 + \cos 2\pi\tilde{\nu}p)$ , where  $I_0$  is the intensity of the radiation.

**interActivity** Referring to Fig. 12.51, the mirror  $M_1$  moves in finite distance increments, so the path difference  $p$  is also incremented in finite steps. Explore the effect of increasing the step size on the shape of the interferogram for a monochromatic beam of wavenumber  $\tilde{\nu}$  and intensity  $I_0$ . That is, draw plots of  $I(p)/I_0$  against  $\tilde{\nu}p$ , each with a different number of data points spanning the same total distance path taken by the movable mirror  $M_1$ .

difference in path lengths. The detected signal oscillates as the two components alternately come into and out of phase as the path difference is changed (Fig. 12.52). If the radiation has wavenumber  $\tilde{\nu}$ , the intensity of the detected signal due to radiation in the range of wavenumbers  $\tilde{\nu}$  to  $\tilde{\nu} + d\tilde{\nu}$ , which we denote  $I(p, \tilde{\nu})d\tilde{\nu}$ , varies with  $p$  as

$$I(p, \tilde{\nu})d\tilde{\nu} = I(\tilde{\nu})(1 + \cos 2\pi\tilde{\nu}p)d\tilde{\nu} \quad (12.55)$$

Hence, the interferometer converts the presence of a particular wavenumber component in the signal into a variation in intensity of the radiation reaching the detector. An actual signal consists of radiation spanning a large number of wavenumbers, and the total intensity at the detector, which we write  $I(p)$ , is the sum of contributions from all the wavenumbers present in the signal (Fig. 12.53):

$$I(p) = \int_0^\infty I(p, \tilde{\nu})d\tilde{\nu} = \int_0^\infty I(\tilde{\nu})(1 + \cos 2\pi\tilde{\nu}p)d\tilde{\nu} \quad (12.56)$$

The problem is to find  $I(\tilde{\nu})$ , the variation of intensity with wavenumber, which is the spectrum we require, from the record of values of  $I(p)$ . This step is a standard technique of mathematics, and is the ‘Fourier transformation’ step from which this form of spectroscopy takes its name (see *Mathematical background 7* following Chapter 19). Specifically:

$$I(\tilde{\nu}) = 4 \int_0^\infty \{I(p) - \frac{1}{2}I(0)\} \cos 2\pi\tilde{\nu}p dp \quad (12.57)$$

where  $I(0)$  is given by eqn 12.56 with  $p = 0$ . This integration is carried out numerically in a computer connected to the spectrometer, and the output,  $I(\tilde{\nu})$ , is the transmission spectrum of the sample (Fig. 12.54).

**Fig. 12.53** An interferogram obtained when several (in this case, three) frequencies are present in the radiation.

**interActivity** For a signal consisting of only a few monochromatic beams, the integral in eqn 12.56 can be replaced by a sum over the finite number of wavenumbers. Use this information to draw your own version of Fig. 12.53. Then, go on to explore the effect of varying the wavenumbers and intensities of the three components of the radiation on the shape of the interferogram.

**Fig. 12.54** The three frequency components and their intensities that account for the appearance of the interferogram in Fig. 12.53. This spectrum is the Fourier transform of the interferogram, and is a depiction of the contributing frequencies.

**interActivity** Calculate the Fourier transforms of the functions you generated in the previous *interActivity*.

A major advantage of the Fourier transform procedure is that all the radiation emitted by the source is monitored continuously. This is in contrast to a spectrometer in which a monochromator discards most of the generated radiation. As a result, Fourier transform spectrometers have a higher sensitivity than conventional spectrometers.

#### (d) Detectors

A **detector** is a device that converts radiation into an electric current or voltage for appropriate signal processing and display. Detectors may consist of a single radiation-sensing element or of several small elements arranged in one- or two-dimensional arrays.

A microwave detector is typically a *crystal diode* consisting of a tungsten tip in contact with a semiconductor. The most common detectors found in commercial infrared spectrometers are sensitive in the mid-infrared region. In a *photovoltaic device* the potential difference changes upon exposure to infrared radiation. In a *pyroelectric device* the capacitance is sensitive to temperature and hence the presence of infrared radiation.

A common detector for work in the ultraviolet and visible ranges is the *photomultiplier tube* (PMT), in which the photoelectric effect (Section 7.2a) is used to generate an electrical signal proportional to the intensity of light that strikes the detector. A common, but less sensitive, alternative to the PMT is the *photodiode*, a solid-state device that conducts electricity when struck by photons because light-induced electron transfer reactions in the detector material create mobile charge carriers (negatively charged electrons and positively charged ‘holes’). In an *avalanche photodiode*, the photo-generated electrons are accelerated through a very large electrical potential difference. The high-energy electrons then collide with other atoms in the solid and ionize them, thus creating an avalanche of secondary charge carriers and increasing the sensitivity of the device toward photons.

The *charge-coupled device* (CCD) is a two-dimensional array of several million small photodiode detectors. With a CCD, a wide range of wavelengths that emerge from a polychromator are detected simultaneously, thus eliminating the need to measure light intensity one narrow wavelength range at a time. CCD detectors are the imaging devices in digital cameras, but are also used widely in spectroscopy to measure absorption, emission, and Raman scattering.

### Further information 12.2 Selection rules for rotational and vibrational spectroscopy

Here we derive the gross and specific selection rules for microwave, infrared, and rotational and vibrational Raman spectroscopy. The starting point for our discussion is the total wavefunction for a molecule, which can be written as

$$\psi_{\text{total}} = \psi_{\text{c.m.}} \psi$$

where  $\psi_{\text{c.m.}}$  describes the motion of the centre of mass and  $\psi$  describes the internal motion of the molecule. If we neglect the effect of electron spin, the Born–Oppenheimer approximation allows us to write  $\psi$  as the product of an electronic part,  $\psi_e$ , a vibrational part,  $\psi_v$ , and a rotational part, which for a diatomic molecule can be represented by the spherical harmonics  $Y_{J,M_f}(\theta, \phi)$  (Section 8.7). The transition dipole moment for a spectroscopic transition can now be written

$$\mu_{fi} = \int \psi_{ef}^* \psi_{if}^* Y_{J_f, M_{f,f}}^* \hat{\mu} \psi_{ei} \psi_{vi} Y_{J_i, M_{i,i}} d\tau \quad (12.58)$$

and our task is to explore conditions for which this integral vanishes or has a nonzero value.

#### (a) Microwave spectra

During a pure rotational transition the molecule does not change electronic or vibrational states. We identify  $\mu_i = \int \psi_{ei}^* \psi_{vi}^* \hat{\mu} \psi_{ei} \psi_{vi} d\tau$  with the *permanent* electric dipole moment of the molecule in the state  $i$ . Equation 12.58 becomes

$$\mu_{fi} = \int Y_{J_f, M_{f,f}}^* \mu_i Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \quad (12.59)$$

where the remaining integration is over the angles representing the orientation of the molecule. The electric dipole moment has components  $\mu_{i,x}$ ,  $\mu_{i,y}$ , and  $\mu_{i,z}$ , which, in spherical polar coordinates, are written in terms of  $\mu_0$ , the magnitude of the vector, and the angles  $\theta$  and  $\phi$  as

$$\mu_{i,x} = \mu_0 \sin \theta \cos \phi \quad \mu_{i,y} = \mu_0 \sin \theta \sin \phi \quad \mu_{i,z} = \mu_0 \cos \theta \quad (12.60)$$

Here, we have taken the  $z$ -axis to be coincident with the figure axis. The transition dipole moment has three components, given by

$$\begin{aligned} \mu_{fi,x} &= \mu_0 \int Y_{J_f, M_{f,f}}^* \sin \theta \cos \phi Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \\ \mu_{fi,y} &= \mu_0 \int Y_{J_f, M_{f,f}}^* \sin \theta \sin \phi Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \\ \mu_{fi,z} &= \mu_0 \int Y_{J_f, M_{f,f}}^* \cos \theta Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \end{aligned} \quad (12.61)$$

We see immediately that the molecule must have a permanent dipole moment in order to have a microwave spectrum. This is the gross selection rule for microwave spectroscopy.

For the specific selection rules we need to examine the conditions for which the integrals do not vanish, and we must consider each component. For the  $z$ -component, we simplify the integral by using  $\cos \theta \propto Y_{1,0}$  (Table 8.2). It follows that

$$\mu_{fi,z} \propto \int Y_{J_f, M_{f,f}}^* Y_{1,0} Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \quad (12.62a)$$

According to the properties of the spherical harmonics (Table 8.2), this integral vanishes unless  $J_f - J_i = \pm 1$  and  $M_{f,f} - M_{i,i} = 0$ . These are two of the selection rules stated in eqn 12.18.

For the  $x$ - and  $y$ -components, we use  $\cos \phi = \frac{1}{2}(e^{i\phi} + e^{-i\phi})$  to write  $\sin \phi = -\frac{1}{2}i(e^{i\phi} - e^{-i\phi})$  to write  $\sin \theta \cos \phi \propto Y_{1,1} + Y_{1,-1}$  and  $\sin \theta \sin \phi \propto Y_{1,1} - Y_{1,-1}$ . It follows that

$$\begin{aligned} \mu_{fi,x} &\propto \int Y_{J_f, M_{f,f}}^* (Y_{1,1} + Y_{1,-1}) Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \\ \mu_{fi,y} &\propto \int Y_{J_f, M_{f,f}}^* (Y_{1,1} - Y_{1,-1}) Y_{J_i, M_{i,i}} d\tau_{\text{angles}} \end{aligned} \quad (12.62b)$$

According to the properties of the spherical harmonics, these integrals vanish unless  $J_f - J_i = \pm 1$  and  $M_{f,f} - M_{i,i} = \pm 1$ . This completes the selection rules of eqn 12.18.

#### (b) Rotational Raman spectra

We can understand the origin of the gross and specific selection rules for rotational Raman spectroscopy by using a diatomic molecule as an example. The incident electric field,  $\mathcal{E}$ , of a wave of electromagnetic radiation of frequency  $\omega_i$  induces a molecular dipole moment that is given by

$$\mu_{\text{ind}} = \alpha \mathcal{E}(t) = \alpha \mathcal{E} \cos \omega_i t \quad (12.63)$$

If the molecule is rotating at a circular frequency  $\omega_R$ , to an external observer its polarizability is also time-dependent (if it is anisotropic), and we can write

**Fig. 12.55** The distortion induced in a molecule by an applied electric field returns to its initial value after a rotation of only  $180^\circ$  (that is, twice a revolution). This is the origin of the  $\Delta J = \pm 2$  selection rule in rotational Raman spectroscopy.

$$\alpha = \alpha_0 + \Delta\alpha \cos 2\omega_R t \quad (12.64)$$

where  $\Delta\alpha = \alpha_{\parallel} - \alpha_{\perp}$  and  $\alpha$  ranges from  $\alpha_0 + \Delta\alpha$  to  $\alpha_0 - \Delta\alpha$  as the molecule rotates. The 2 appears because the polarizability returns to its initial value twice each revolution (Fig. 12.55). Substituting this expression into the expression for the induced dipole moment gives

$$\begin{aligned} \mu_{\text{ind}} &= (\alpha_0 + \Delta\alpha \cos 2\omega_R t) \times (\mathcal{E} \cos \omega_i t) \\ &= \alpha_0 \mathcal{E} \cos \omega_i t + \mathcal{E} \Delta\alpha \cos 2\omega_R t \cos \omega_i t \\ &= \alpha_0 \mathcal{E} \cos \omega_i t + \frac{1}{2} \mathcal{E} \Delta\alpha \{ \cos(\omega_i + 2\omega_R)t + \cos(\omega_i - 2\omega_R)t \} \quad (12.65) \end{aligned}$$

This calculation shows that the induced dipole has a component oscillating at the incident frequency (which generates Rayleigh radiation), and that it also has two components at  $\omega_i \pm 2\omega_R$ , which give rise to the shifted Raman lines. These lines appear only if  $\Delta\alpha \neq 0$ ; hence the polarizability must be anisotropic for there to be Raman lines. This is the gross selection rule for rotational Raman spectroscopy. We also see that the distortion induced in the molecule by the incident electric field returns to its initial value after a rotation of  $180^\circ$  (that is, twice a revolution). This is the classical origin of the specific selection rule  $\Delta J = \pm 2$ . The complete quantum mechanical calculation proceeds like that for microwave transitions but is too involved to include here.<sup>2</sup>

### (c) Infrared spectra

The gross selection rule for infrared spectroscopy is based on an analysis of the transition dipole moment  $\mu_{fi} = \int \psi_{vf}^* \hat{\mu} \psi_{vi} d\tau$ , which arises from eqn 12.58 when the molecule does not change electronic or rotational states. For simplicity, we shall consider a one-dimensional oscillator (like a diatomic molecule). The electric dipole moment operator depends on the location of all the electrons and all the nuclei in the molecule, so it varies as the internuclear separation changes (Fig. 12.56). We can write its variation with displacement from the equilibrium separation,  $x$ , as

$$\mu = \mu_0 + \left( \frac{d\mu}{dx} \right)_0 x + \dots \quad (12.66)$$

<sup>2</sup> See our *Quanta, matter, and change* (2009).

**Fig. 12.56** The electric dipole moment of a heteronuclear diatomic molecule varies as shown by the purple curve. For small displacements the change in dipole moment is proportional to the displacement.

where  $\mu_0$  is the electric dipole moment operator when the nuclei have their equilibrium separation. It then follows that, with  $f \neq i$  and keeping only the term linear in the small displacement  $x$ ,

$$\mu_{fi} = \int \psi_{vf}^* \hat{\mu} \psi_{vi} dx = \mu_0 \int \psi_{vf}^* \psi_{vi} dx + \left( \frac{d\mu}{dx} \right)_0 \int \psi_{vf}^* x \psi_{vi} dx$$

The term multiplying  $\mu_0$  is zero because the states with different values of  $v$  are orthogonal. It follows that the transition dipole moment is

$$\mu_{fi} = \left( \frac{d\mu}{dx} \right)_0 \int \psi_{vf}^* x \psi_{vi} dx \quad (12.67)$$

We see that the right-hand side is zero unless the dipole moment varies with displacement. This is the gross selection rule for infrared spectroscopy.

The specific selection rule is determined by considering the value of  $\int \psi_{vf}^* x \psi_{vi} dx$ . We need to write out the wavefunctions in terms of the Hermite polynomials given in Section 8.5 and then to use their properties (Example 8.4 should be reviewed, for it gives further details of the calculation). We note that  $x = \alpha y$  with  $\alpha = (\hbar^2/m_{\text{eff}}k_f)^{1/4}$  (eqn 8.27; note that in this context  $\alpha$  is not the polarizability). Then we write

$$\int \psi_{vf}^* x \psi_{vi} dx = N_{vf} N_{vi} \int_{-\infty}^{\infty} H_{vf} x H_{vi} e^{-y^2} dx = \alpha^2 N_{vf} N_{vi} \int_{-\infty}^{\infty} H_{vf} y H_{vi} e^{-y^2} dy$$

To evaluate the integral we use the recursion relation

$$yH_v = vH_{v-1} + \frac{1}{2}H_{v+1}$$

which turns the matrix element into

$$\int \psi_{vf}^* x \psi_{vi} dx = \alpha^2 N_{vf} N_{vi} \left\{ v_i \int_{-\infty}^{\infty} H_{vf} H_{v_i-1} e^{-y^2} dy + \frac{1}{2} \int_{-\infty}^{\infty} H_{vf} H_{v_i+1} e^{-y^2} dy \right\} \quad (12.68)$$

The first integral is zero unless  $v_f = v_i - 1$  and that the second is zero unless  $v_f = v_i + 1$  (Table 8.1). It follows that the transition dipole moment is zero unless  $\Delta v = \pm 1$ .

**(d) Vibrational Raman spectra**

The gross selection rule for vibrational Raman spectroscopy is based on an analysis of the transition dipole moment  $\mu_{fi} = \int \psi_{vf}^* \hat{\mu} \psi_{vi} d\tau$ , which is written from eqn 12.58 by using the Born–Oppenheimer approximation and neglecting the effect of rotation and electron spin. For simplicity, we consider a one-dimensional harmonic oscillator (like a diatomic molecule).

First, we use eqn 12.23 to write the transition dipole moment as

$$\mu_{fi} = \int \psi_{vf}^* \alpha E \psi_{vi} d\tau = E \int \psi_{vf}^* \alpha \psi_{vi} d\tau \quad (12.69)$$

where  $\alpha(x)$  is the polarizability of the molecule, which we expect to be a function of small displacements  $x$  from the equilibrium bond length of the molecule. Now the calculation proceeds as before, but  $(dm/dx)_0$  is replaced by  $E(d\alpha/dx)_0$  in eqn 12.67. For  $f \neq i$ ,

$$\mu_f = E \left( \frac{d\alpha}{dx} \right)_0 \int \psi_{vf}^* x \psi_{vi} dx \quad (12.70)$$

Therefore, the vibration is Raman active only if  $(d\alpha/dx)_0 \neq 0$ , that is, the polarizability varies with displacement, and if  $v_f - v_i = \pm 1$ .

## Discussion questions

**12.1** Describe the physical origins of linewidths in the absorption and emission spectra of gases, liquids, and solids.

**12.2** Discuss the physical origins of the gross and specific selection rules for microwave and infrared spectroscopy.

**12.3** Discuss the physical origins of the gross and specific selection rules for rotational and vibrational Raman spectroscopy.

**12.4** Explain how nuclear spin can influence the appearance of molecular spectra.

**12.5** Consider a diatomic molecule that is highly susceptible to centrifugal distortion in its ground vibrational state. Do you expect excitation to high rotational energy levels to change the equilibrium bond length of this molecule? Justify your answer.

**12.6** In what ways may the rotational and vibrational spectra of molecules change as a result of isotopic substitution?

**12.7** Suppose that you wish to characterize the normal modes of benzene in the gas phase. Why is it important to obtain both infrared absorption and Raman spectra of your sample?

## Exercises

**12.1(a)** Which of the following molecules may show a pure rotational microwave absorption spectrum: (a)  $H_2$ , (b)  $HCl$ , (c)  $CH_4$ , (d)  $CH_3Cl$ , (e)  $CH_2Cl_2$ ?

**12.1(b)** Which of the following molecules may show a pure rotational microwave absorption spectrum: (a)  $H_2O$ , (b)  $H_2O_2$ , (c)  $NH_3$ , (d)  $N_2O$ ?

**12.2(a)** Which of the following molecules may show a pure rotational Raman spectrum: (a)  $H_2$ , (b)  $HCl$ , (c)  $CH_4$ , (d)  $CH_3Cl$ ?

**12.2(b)** Which of the following molecules may show a pure rotational Raman spectrum: (a)  $CH_2Cl_2$ , (b)  $CH_3CH_3$ , (c)  $SF_6$ , (d)  $N_2O$ ?

**12.3(a)** Calculate the moment of inertia of an  $^{31}P^{31}H_3$  molecule for rotation about its threefold axis. By how much does that moment of inertia change when  $^{32}P$  replaces  $^{31}P$ ? ( $m(^{31}P) = 30.97m_u$ ;  $R_e = 142$  pm;  $HPH$  angle =  $93.6^\circ$ .)

**12.3(b)** Calculate the moment of inertia of a  $SiH_4$  (bond length 147.98 pm) ion. By how much does that moment of inertia change when  $^2H$  replaces  $^1H$ ?

**12.4(a)** Use the information in Table 12.1 to calculate the moments of inertia and the rotational constants (as frequencies and wavenumbers) of  $^{35}Cl^{12}CH_3$ . ( $m(^{35}Cl) = 34.9688m_u$ ;  $R(C-H) = 111$  pm;  $R(C-Cl) = 178$  pm;  $HCH$  angle =  $111^\circ$ .)

**12.4(b)** Use the information in Table 12.1 to calculate the moments of inertia and the rotational constants (as frequencies and wavenumbers) of  $H^{12}C^{35}Cl_3$ . ( $m(^{35}Cl) = 34.9688m_u$ ;  $R(C-H) = 107$  pm;  $R(C-Cl) = 177$  pm;  $ClCCl$  angle =  $110^\circ$ .)

**12.5(a)** Calculate the frequency of the  $J = 4 \leftarrow 3$  transition in the pure rotational spectrum of  $^{14}N^{16}O$ . The equilibrium bond length is 115 pm.

**12.5(b)** Calculate the frequency of the  $J = 3 \leftarrow 2$  transition in the pure rotational spectrum of  $^{12}C^{16}O$ . The equilibrium bond length is 112.81 pm.

**12.6(a)** If the wavenumber of the  $J = 3 \leftarrow 2$  rotational transition of  $^1H^{35}Cl$  considered as a rigid rotator is  $63.56$   $cm^{-1}$ , what is (a) the moment of inertia of the molecule, (b) the bond length?

**12.6(b)** If the wavenumber of the  $J = 1 \leftarrow 0$  rotational transition of  $^1H^{81}Br$  considered as a rigid rotator is  $16.93$   $cm^{-1}$ , what is (a) the moment of inertia of the molecule, (b) the bond length?

**12.7(a)** Given that the spacing of lines in the microwave spectrum of  $^{27}Al^1H$  is constant at  $12.604$   $cm^{-1}$ , calculate the moment of inertia and bond length of the molecule. ( $m(^{27}Al) = 26.9815m_u$ .)

**12.7(b)** Given that the spacing of lines in the microwave spectrum of  $^{35}Cl^{19}F$  is constant at  $1.033$   $cm^{-1}$ , calculate the moment of inertia and bond length of the molecule. ( $m(^{35}Cl) = 34.9688m_u$ ,  $m(^{19}F) = 18.9984m_u$ .)

**12.8(a)** The rotational constant of  $^{127}I^{35}Cl$  is  $0.1142$   $cm^{-1}$ . Calculate the  $ICl$  bond length. ( $m(^{35}Cl) = 34.9688m_u$ ,  $m(^{127}I) = 126.9045m_u$ .)

**12.8(b)** The rotational constant of  $^{12}C^{16}O_2$  is  $0.39021$   $cm^{-1}$ . Calculate the bond length of the molecule. ( $m(^{12}C) = 12m_u$  exactly,  $m(^{16}O) = 15.9949m_u$ .)

**12.9(a)** Determine the  $HC$  and  $CN$  bond lengths in  $HCN$  from the rotational constants  $B(^1H^{12}C^{14}N) = 44.316$  GHz and  $B(^2H^{12}C^{14}N) = 36.208$  GHz.

**12.9(b)** Determine the  $CO$  and  $CS$  bond lengths in  $OCS$  from the rotational constants  $B(^{16}O^{12}C^{32}S) = 6081.5$  MHz,  $B(^{16}O^{12}C^{34}S) = 5932.8$  MHz.

**12.10(a)** The wavenumber of the incident radiation in a Raman spectrometer is  $20\,487\text{ cm}^{-1}$ . What is the wavenumber of the scattered Stokes radiation for the  $J = 2 \leftarrow 0$  transition of  $^{14}\text{N}_2$ ?

**12.10(b)** The wavenumber of the incident radiation in a Raman spectrometer is  $20\,623\text{ cm}^{-1}$ . What is the wavenumber of the scattered Stokes radiation for the  $J = 4 \leftarrow 2$  transition of  $^{16}\text{O}_2$ ?

**12.11(a)** The rotational Raman spectrum of  $^{35}\text{Cl}_2$  ( $m(^{35}\text{Cl}) = 34.9688m_u$ ) shows a series of Stokes lines separated by  $0.9752\text{ cm}^{-1}$  and a similar series of anti-Stokes lines. Calculate the bond length of the molecule.

**12.11(b)** The rotational Raman spectrum of  $^{19}\text{F}_2$  ( $m(^{19}\text{F}) = 18.9984m_u$ ) shows a series of Stokes lines separated by  $3.5312\text{ cm}^{-1}$  and a similar series of anti-Stokes lines. Calculate the bond length of the molecule.

**12.12(a)** Estimate the centrifugal distortion constant for  $^1\text{H}^{127}\text{I}$ , for which  $\tilde{B} = 6.511\text{ cm}^{-1}$  and  $\tilde{\nu} = 2308\text{ cm}^{-1}$ . By what factor would the constant change when  $^2\text{H}$  is substituted for  $^1\text{H}$ ?

**12.12(b)** Estimate the centrifugal distortion constant for  $^{79}\text{Br}^{81}\text{Br}$ , for which  $\tilde{B} = 0.0809\text{ cm}^{-1}$  and  $\tilde{\nu} = 323.2\text{ cm}^{-1}$ . By what factor would the constant change when the  $^{79}\text{Br}$  is replaced by  $^{81}\text{Br}$ ?

**12.13(a)** What is the most highly populated rotational level of  $\text{Cl}_2$  at (a)  $25^\circ\text{C}$ , (b)  $100^\circ\text{C}$ ? Take  $\tilde{B} = 0.244\text{ cm}^{-1}$ .

**12.13(b)** What is the most highly populated rotational level of  $\text{Br}_2$  at (a)  $25^\circ\text{C}$ , (b)  $100^\circ\text{C}$ ? Take  $\tilde{B} = 0.0809\text{ cm}^{-1}$ .

**12.14(a)** An object of mass  $1.0\text{ kg}$  suspended from the end of a rubber band has a vibrational frequency of  $2.0\text{ Hz}$ . Calculate the force constant of the rubber band.

**12.14(b)** An object of mass  $2.0\text{ g}$  suspended from the end of a spring has a vibrational frequency of  $3.0\text{ Hz}$ . Calculate the force constant of the spring.

**12.15(a)** Calculate the percentage difference in the fundamental vibration wavenumber of  $^{23}\text{Na}^{35}\text{Cl}$  and  $^{23}\text{Na}^{37}\text{Cl}$  on the assumption that their force constants are the same.

**12.15(b)** Calculate the percentage difference in the fundamental vibration wavenumber of  $^1\text{H}^{35}\text{Cl}$  and  $^2\text{H}^{37}\text{Cl}$  on the assumption that their force constants are the same.

**12.16(a)** The wavenumber of the fundamental vibrational transition of  $^{35}\text{Cl}_2$  is  $564.9\text{ cm}^{-1}$ . Calculate the force constant of the bond ( $m(^{35}\text{Cl}) = 34.9688m_u$ ).

**12.16(b)** The wavenumber of the fundamental vibrational transition of  $^{79}\text{Br}^{81}\text{Br}$  is  $323.2\text{ cm}^{-1}$ . Calculate the force constant of the bond ( $m(^{79}\text{Br}) = 78.9183m_u$ ,  $m(^{81}\text{Br}) = 80.9163m_u$ ).

**12.17(a)** Calculate the relative numbers of  $\text{Cl}_2$  molecules ( $\tilde{\nu} = 559.7\text{ cm}^{-1}$ ) in the ground and first excited vibrational states at (a)  $298\text{ K}$ , (b)  $500\text{ K}$ .

**12.17(b)** Calculate the relative numbers of  $\text{Br}_2$  molecules ( $\tilde{\nu} = 321\text{ cm}^{-1}$ ) in the second and first excited vibrational states at (a)  $298\text{ K}$ , (b)  $800\text{ K}$ .

**12.18(a)** The hydrogen halides have the following fundamental vibrational wavenumbers:  $4141.3\text{ cm}^{-1}$  (HF);  $2988.9\text{ cm}^{-1}$  ( $\text{H}^{35}\text{Cl}$ );  $2649.7\text{ cm}^{-1}$  ( $\text{H}^{81}\text{Br}$ );  $2309.5\text{ cm}^{-1}$  ( $\text{H}^{127}\text{I}$ ). Calculate the force constants of the hydrogen-halogen bonds.

**12.18(b)** From the data in Exercise 12.18a, predict the fundamental vibrational wavenumbers of the deuterium halides.

**12.19(a)** For  $^{16}\text{O}_2$ ,  $\Delta\tilde{G}$  values for the transitions  $\nu = 1 \leftarrow 0$ ,  $2 \leftarrow 0$ , and  $3 \leftarrow 0$  are, respectively,  $1556.22$ ,  $3088.28$ , and  $4596.21\text{ cm}^{-1}$ . Calculate  $\tilde{\nu}$  and  $x_c$ . Assume  $y_c$  to be zero.

**12.19(b)** For  $^{14}\text{N}_2$ ,  $\Delta\tilde{G}$  values for the transitions  $\nu = 1 \leftarrow 0$ ,  $2 \leftarrow 0$ , and  $3 \leftarrow 0$  are, respectively,  $2345.15$ ,  $4661.40$ , and  $6983.73\text{ cm}^{-1}$ . Calculate  $\tilde{\nu}$  and  $x_c$ . Assume  $y_c$  to be zero.

**12.20(a)** The first five vibrational energy levels of  $\text{HCl}$  are at  $1481.86$ ,  $4367.50$ ,  $7149.04$ ,  $9826.48$ , and  $12\,399.8\text{ cm}^{-1}$ . Calculate the dissociation energy of the molecule in reciprocal centimetres and electronvolts.

**12.20(b)** The first five vibrational energy levels of  $\text{HI}$  are at  $1144.83$ ,  $3374.90$ ,  $5525.51$ ,  $7596.66$ , and  $9588.35\text{ cm}^{-1}$ . Calculate the dissociation energy of the molecule in reciprocal centimetres and electronvolts.

**12.21(a)** Estimate the anharmonicity constant  $x_c$  for  $^1\text{H}^{19}\text{F}$  from the data in Table 12.2. By what factor does  $x_c$  change when  $^1\text{H}$  is replaced by  $^2\text{H}$ ? Assume a Morse potential.

**12.21(b)** Estimate the anharmonicity constant  $x_c$  for  $^1\text{H}^{81}\text{Br}$  from the data in Table 12.2. By what factor does  $x_c$  change when  $^1\text{H}$  is replaced by  $^2\text{H}$ ? Assume a Morse potential.

**12.22(a)** Infrared absorption by  $^1\text{H}^{81}\text{Br}$  gives rise to an R branch from  $\nu = 0$ . What is the wavenumber of the line originating from the rotational state with  $J = 2$ ? Use the information in Table 12.2.

**12.22(b)** Infrared absorption by  $^1\text{H}^{127}\text{I}$  gives rise to an R branch from  $\nu = 0$ . What is the wavenumber of the line originating from the rotational state with  $J = 2$ ? Use the information in Table 12.2.

**12.23(a)** Which of the following molecules may show infrared absorption spectra: (a)  $\text{H}_2$ , (b)  $\text{HCl}$ , (c)  $\text{CO}_2$ , (d)  $\text{H}_2\text{O}$ ?

**12.23(b)** Which of the following molecules may show infrared absorption spectra: (a)  $\text{CH}_3\text{CH}_3$ , (b)  $\text{CH}_4$ , (c)  $\text{CH}_3\text{Cl}$ , (d)  $\text{N}_2$ ?

**12.24(a)** How many normal modes of vibration are there for the following molecules: (a)  $\text{H}_2\text{O}$ , (b)  $\text{H}_2\text{O}_2$ , (c)  $\text{C}_2\text{H}_4$ ?

**12.24(b)** How many normal modes of vibration are there for the following molecules: (a)  $\text{C}_6\text{H}_6$ , (b)  $\text{C}_6\text{H}_6\text{CH}_3$ , (c)  $\text{HC}\equiv\text{C}-\text{C}\equiv\text{CH}$ .

**12.25(a)** Which of the three vibrations of an  $\text{AB}_2$  molecule are infrared or Raman active when it is (a) angular (bent), (b) linear?

**12.25(b)** Which of the vibrations of an  $\text{AB}_3$  molecule are infrared or Raman active when it is (a) trigonal planar, (b) trigonal pyramidal?

**12.26(a)** Consider the vibrational mode that corresponds to the uniform expansion of the benzene ring. Is it (a) Raman, (b) infrared active?

**12.26(b)** Consider the vibrational mode that corresponds to the boat-like bending of a benzene ring. Is it (a) Raman, (b) infrared active?

**12.27(a)** The molecule  $\text{CH}_2\text{Cl}_2$  belongs to the point group  $C_{2v}$ . The displacements of the atoms span  $5A_1 + 2A_2 + 4B_1 + 4B_2$ . What are the symmetries of the normal modes of vibration?

**12.27(b)** A carbon disulfide molecule belongs to the point group  $D_{\infty h}$ . The nine displacements of the three atoms span  $A_{1g} + 2A_{1u} + 2E_{1u} + E_{1g}$ . What are the symmetries of the normal modes of vibration?

## Problems\*

## Numerical problems

**12.1** The rotational constant of  $\text{NH}_3$  is equivalent to 298 GHz. Compute the separation of the pure rotational spectrum lines in gigahertz (for the frequency), reciprocal centimetres (for the wavenumber), and millimetres (for the wavelength), and show that the value of  $B$  is consistent with an N–H bond length of 101.4 pm and a bond angle of  $106.78^\circ$ .

**12.2** The rotational constant for CO is  $1.9314 \text{ cm}^{-1}$  and  $1.6116 \text{ cm}^{-1}$  in the ground and first excited vibrational states, respectively. By how much does the internuclear distance change as a result of this transition?

**12.3** Pure rotational Raman spectra of gaseous  $\text{C}_6\text{H}_6$  and  $\text{C}_6\text{D}_6$  yield the following rotational constants:  $\tilde{B}(\text{C}_6\text{H}_6) = 0.189\,60 \text{ cm}^{-1}$ ,  $\tilde{B}(\text{C}_6\text{D}_6) = 0.156\,81 \text{ cm}^{-1}$ . The moments of inertia of the molecules about any axis perpendicular to the  $\text{C}_6$  axis were calculated from these data as  $I(\text{C}_6\text{H}_6) = 1.4759 \times 10^{-45} \text{ kg m}^2$ ,  $I(\text{C}_6\text{D}_6) = 1.7845 \times 10^{-45} \text{ kg m}^2$ . Calculate the CC, CH, and CD bond lengths.

**12.4** Rotational absorption lines from  $^1\text{H}^{35}\text{Cl}$  gas were found at the following wavenumbers (R.L. Hausler and R.A. Oetjen, *J. Chem. Phys.* **21**, 1340 (1953)): 83.32, 104.13, 124.73, 145.37, 165.89, 186.23, 206.60, 226.86  $\text{cm}^{-1}$ . Calculate the moment of inertia and the bond length of the molecule. Predict the positions of the corresponding lines in  $^2\text{H}^{35}\text{Cl}$ .

**12.5** Is the bond length in HCl the same as that in DCl? The wavenumbers of the  $J = 1 \leftarrow 0$  rotational transitions for  $\text{H}^{35}\text{Cl}$  and  $^2\text{H}^{35}\text{Cl}$  are 20.8784 and 10.7840  $\text{cm}^{-1}$ , respectively. Accurate atomic masses are  $1.007825 m_u$  and  $2.0140 m_u$  for  $^1\text{H}$  and  $^2\text{H}$ , respectively. The mass of  $^{35}\text{Cl}$  is  $34.96885 m_u$ . Based on this information alone, can you conclude that the bond lengths are the same or different in the two molecules?

**12.6** Thermodynamic considerations suggest that the copper monohalides  $\text{CuX}$  should exist mainly as polymers in the gas phase, and indeed it proved difficult to obtain the monomers in sufficient abundance to detect spectroscopically. This problem was overcome by flowing the halogen gas over copper heated to 1100 K (E.L. Manson *et al.*, *J. Chem. Phys.* **63**, 2724 (1975)). For  $\text{CuBr}$  the  $J = 13 \rightarrow 14$ ,  $14 \rightarrow 15$ , and  $15 \rightarrow 16$  transitions occurred at 84 421.34, 90 449.25, and 96 476.72 MHz, respectively. Calculate the rotational constant and bond length of  $\text{CuBr}$ .

**12.7** The microwave spectrum of  $^{16}\text{O}^{12}\text{CS}$  (C.H. Townes *et al.*, *Phys. Rev.* **74**, 1113 (1948)) gave absorption lines (in GHz) as follows:

| $J$             | 1         | 2         | 3         | 4         |
|-----------------|-----------|-----------|-----------|-----------|
| $^{32}\text{S}$ | 24.325 92 | 36.488 82 | 48.651 64 | 60.814 08 |
| $^{34}\text{S}$ | 23.732 33 |           | 47.462 40 |           |

Use the expressions for moments of inertia in Table 12.1 and assume that the bond lengths are unchanged by substitution; calculate the CO and CS bond lengths in OCS.

**12.8†** In a study of the rotational spectrum of the linear  $\text{FeCO}$  radical, K. Tanaka *et al.* (*J. Chem. Phys.* **106**, 6820 (1997)) report the following  $J + 1 \leftarrow J$  transitions:

| $J$              | 24        | 25        | 26        | 27        | 28        | 29        |
|------------------|-----------|-----------|-----------|-----------|-----------|-----------|
| $\nu/\text{MHz}$ | 214 777.7 | 223 379.0 | 231 981.2 | 240 584.4 | 249 188.5 | 257 793.5 |

Evaluate the rotational constant of the molecule. Also, estimate the value of  $J$  for the most highly populated rotational energy level at 298 K and at 100 K.

**12.9** The vibrational energy levels of NaI lie at the wavenumbers 142.81, 427.31, 710.31, and 991.81  $\text{cm}^{-1}$ . Show that they fit the expression  $(v + \frac{1}{2})\tilde{\nu} - (v + \frac{1}{2})^2 x\tilde{\nu}$ , and deduce the force constant, zero-point energy, and dissociation energy of the molecule.

**12.10** Predict the shape of the nitronium ion,  $\text{NO}_2^+$ , from its Lewis structure and the VSEPR model. It has one Raman active vibrational mode at 1400  $\text{cm}^{-1}$ , two strong IR active modes at 2360 and 540  $\text{cm}^{-1}$ , and one weak IR mode at 3735  $\text{cm}^{-1}$ . Are these data consistent with the predicted shape of the molecule? Assign the vibrational wavenumbers to the modes from which they arise.

**12.11** At low resolution, the strongest absorption band in the infrared absorption spectrum of  $^{12}\text{C}^{16}\text{O}$  is centred at 2150  $\text{cm}^{-1}$ . Upon closer examination at higher resolution, this band is observed to be split into two sets of closely spaced peaks, one on each side of the centre of the spectrum at 2143.26  $\text{cm}^{-1}$ . The separation between the peaks immediately to the right and left of the centre is 7.655  $\text{cm}^{-1}$ . Make the harmonic oscillator and rigid rotor approximations and calculate from these data: (a) the vibrational wavenumber of a CO molecule, (b) its molar zero-point vibrational energy, (c) the force constant of the CO bond, (d) the rotational constant  $\tilde{B}$ , and (e) the bond length of CO.

**12.12** The HCl molecule is quite well described by the Morse potential with  $hc\tilde{D}_e = 5.33 \text{ eV}$ ,  $\tilde{\nu} = 2989.7 \text{ cm}^{-1}$ , and  $x\tilde{\nu} = 52.05 \text{ cm}^{-1}$ . Assuming that the potential is unchanged on deuteration, predict the dissociation energies ( $hc\tilde{D}_0$ ) of (a) HCl, (b) DCl.

**12.13** The Morse potential (eqn 12.37) is very useful as a simple representation of the actual molecular potential energy. When  $\text{RbH}$  was studied, it was found that  $\tilde{\nu} = 936.8 \text{ cm}^{-1}$  and  $x_e\tilde{\nu} = 14.15 \text{ cm}^{-1}$ . Plot the potential energy curve from 50 pm to 800 pm around  $R_e = 236.7 \text{ pm}$ . Then go on to explore how the rotation of a molecule may weaken its bond by allowing for the kinetic energy of rotation of a molecule and plotting  $V^* = V + hcB/J(J+1)$  with  $\tilde{B} = \hbar/4\pi c\mu R^2$ . Plot these curves on the same diagram for  $J = 40, 80$ , and 100, and observe how the dissociation energy is affected by the rotation. (Taking  $\tilde{B} = 3.020 \text{ cm}^{-1}$  at the equilibrium bond length will greatly simplify the calculation.)

**12.14†** F. Luo, *et al.* (*J. Chem. Phys.* **98**, 3564 (1993)) observed  $\text{He}_2$ , a species that had escaped detection for a long time. The fact that the observation required temperatures in the neighbourhood of 1 mK is consistent with computational studies that suggest that  $hc\tilde{D}_e$  for  $\text{He}_2$  is about 15.1 yJ,  $hc\tilde{D}_0$  about 0.02 yJ (1 yJ =  $10^{-24}$  J), and  $R_e$  about 297 pm. (a) Estimate the fundamental vibrational wavenumber, force constant, moment of inertia, and rotational constant based on the harmonic oscillator and rigid-rotor approximations. (b) Such a weakly bound complex is hardly likely to be rigid. Estimate the vibrational wavenumber and anharmonicity constant based on the Morse potential.

**12.15** As mentioned in Section 12.15, the semi-empirical, *ab initio*, and DFT methods discussed in Chapter 10 can be used to estimate the force field of a molecule. The molecule's vibrational spectrum can be simulated, and it is then possible to determine the correspondence between a vibrational frequency and the atomic displacements that give rise to a normal mode. (a) Using molecular modelling software<sup>3</sup> and the computational method of your choice (semi-empirical, *ab initio*, or DFT methods), calculate the fundamental vibrational wavenumbers and visualize the vibrational normal modes of  $\text{SO}_2$  in the gas phase. (b) The experimental values of the fundamental vibrational wavenumbers of  $\text{SO}_2$  in the gas phase are 525  $\text{cm}^{-1}$ , 1151  $\text{cm}^{-1}$ , and 1336  $\text{cm}^{-1}$ .

\* Problems denoted with the symbol † were supplied by Charles Trapp, Carmen Giunta, and Marshall Cady.

<sup>3</sup> The web site contains links to molecular modelling freeware and to other sites where you may perform molecular orbital calculations directly from your web browser.

Compare the calculated and experimental values. Even if agreement is poor, is it possible to establish a correlation between an experimental value of the vibrational wavenumber with a specific vibrational normal mode?

**12.16** Consider the molecule  $\text{CH}_3\text{Cl}$ . (a) To what point group does the molecule belong? (b) How many normal modes of vibration does the molecule have? (c) What are the symmetries of the normal modes of vibration for this molecule? (d) Which of the vibrational modes of this molecule are infrared active? (e) Which of the vibrational modes of this molecule are Raman active?

**12.17** Suppose that three conformations are proposed for the nonlinear molecule  $\text{H}_2\text{O}_2$  (4, 5, and 6). The infrared absorption spectrum of gaseous  $\text{H}_2\text{O}_2$  has bands at 870, 1370, 2869, and  $3417\text{ cm}^{-1}$ . The Raman spectrum of the same sample has bands at 877, 1408, 1435, and  $3407\text{ cm}^{-1}$ . All bands correspond to fundamental vibrational wavenumbers and you may assume that: (i) the 870 and  $877\text{ cm}^{-1}$  bands arise from the same normal mode, and (ii) the 3417 and  $3407\text{ cm}^{-1}$  bands arise from the same normal mode. (a) If  $\text{H}_2\text{O}_2$  were linear, how many normal modes of vibration would it have? (b) Give the symmetry point group of each of the three proposed conformations of nonlinear  $\text{H}_2\text{O}_2$ . (c) Determine which of the proposed conformations is inconsistent with the spectroscopic data. Explain your reasoning.

### Theoretical problems

**12.18** Show that the moment of inertia of a diatomic molecule composed of atoms of masses  $m_A$  and  $m_B$  and bond length  $R$  is equal to  $m_{\text{eff}}R^2$ , where  $m_{\text{eff}} = m_A m_B / (m_A + m_B)$ .

**12.19** Suppose that the internuclear distance may be written  $R = R_e + x$  where  $R_e$  is the equilibrium bond length. Also suppose that the potential well is symmetrical and confines the oscillator to small displacements. Deduce expressions for  $1/\langle R^2 \rangle$ ,  $1/\langle R^2 \rangle$ , and  $\langle 1/R^2 \rangle$  to the lowest nonzero power of  $\langle x^2 \rangle/R_e^2$  and confirm that values are not the same.

**12.20** Continue the development of Problem 12.19 by using the virial expression to relate  $\langle x^2 \rangle$  to the vibrational quantum number. Does your result imply that the rotational constant increases or decreases as the oscillator becomes excited to higher quantum states. What would be the effect of anharmonicity?

**12.21** Derive eqn 12.17 for the centrifugal distortion constant  $\tilde{D}_J$  of a diatomic molecule of effective mass  $m_{\text{eff}}$ . Treat the bond as an elastic spring with force constant  $k$  and equilibrium length  $r_e$  that is subjected to a centrifugal distortion to a new length  $r_c$ . Begin the derivation by letting the particles experience a restoring force of magnitude  $k(r_c - r_e)$  that is countered perfectly by a centrifugal force  $m_{\text{eff}}\omega^2 r_c$ , where  $\omega$  is the angular velocity of the rotating molecule. Then introduce quantum mechanical effects by writing the angular momentum as  $[J(J+1)]^{1/2}\hbar$ . Finally, write an expression for the energy of the rotating molecule, compare it with eqn 12.16, and write an expression for  $\tilde{D}_J$ .

**12.22** Derive an expression for the force constant of an oscillator that can be modelled by a Morse potential (eqn 12.37).

**12.23** Suppose a particle confined to a cavity in a microporous material has a potential energy of the form  $V(x) = V_0(e^{-a^2/x^2} - 1)$ . Sketch the form of the potential energy. What is the value of the force constant corresponding to this

potential energy? Would the particle undergo simple harmonic motion? Sketch the likely form of the first two vibrational wavefunctions.

**12.24** Show that there are a finite number of bound states of a Morse oscillator and find an expression for the maximum value of the vibrational quantum number. *Hint.* Show that the vibrational terms (eqn 12.38) pass through a maximum as  $v$  increases.

**12.25** In the group theoretical language developed in Chapter 11, a spherical rotor is a molecule that belongs to a cubic or icosahedral point group, a symmetric rotor is a molecule with at least a threefold axis of symmetry, and an asymmetric rotor is a molecule without a threefold (or higher) axis. Linear molecules are linear rotors. Classify each of the following molecules as a spherical, symmetric, linear, or asymmetric rotor and justify your answers with group theoretical arguments: (a)  $\text{CH}_4$ , (b)  $\text{CH}_3\text{CN}$ , (c)  $\text{CO}_2$ , (d)  $\text{CH}_3\text{OH}$ , (e) benzene, (f) pyridine.

**12.26** Derive an expression for the value of  $J$  corresponding to the most highly populated rotational energy level of a diatomic rotor at a temperature  $T$  remembering that the degeneracy of each level is  $2J+1$ . Evaluate the expression for  $\text{ICl}$  (for which  $\tilde{B} = 0.1142\text{ cm}^{-1}$ ) at  $25^\circ\text{C}$ . Repeat the problem for the most highly populated level of a spherical rotor, taking note of the fact that each level is  $(2J+1)^2$ -fold degenerate. Evaluate the expression for  $\text{CH}_4$  (for which  $\tilde{B} = 5.24\text{ cm}^{-1}$ ) at  $25^\circ\text{C}$ .

**12.27** The moments of inertia of the linear mercury(II) halides are very large, so the O and S branches of their vibrational Raman spectra show little rotational structure. Nevertheless, the peaks of both branches can be identified and have been used to measure the rotational constants of the molecules (R.J.H. Clark and D.M. Rippon, *J. Chem. Soc. Faraday Soc. II*, **69**, 1496 (1973)). Show, from a knowledge of the value of  $J$  corresponding to the intensity maximum, that the separation of the peaks of the O and S branches is given by the Placzek–Teller relation  $\delta\tilde{\nu} = (32BkT/hc)^{1/2}$ . The following widths were obtained at the temperatures stated:

|                                    | $\text{HgCl}_2$ | $\text{HgBr}_2$ | $\text{HgI}_2$ |
|------------------------------------|-----------------|-----------------|----------------|
| $\theta/^\circ\text{C}$            | 282             | 292             | 292            |
| $\delta\tilde{\nu}/\text{cm}^{-1}$ | 23.8            | 15.2            | 11.4           |

Calculate the bond lengths in the three molecules.

### Applications: to biology, environmental science, and astrophysics

**12.28** The protein haemerythrin is responsible for binding and carrying  $\text{O}_2$  in some invertebrates. Each protein molecule has two  $\text{Fe}^{2+}$  ions that are in very close proximity and work together to bind one molecule of  $\text{O}_2$ . The  $\text{Fe}_2\text{O}_2$  group of oxygenated haemerythrin is coloured and has an electronic absorption band at 500 nm. The resonance Raman spectrum of oxygenated haemerythrin obtained with laser excitation at 500 nm has a band at  $844\text{ cm}^{-1}$  that has been attributed to the O–O stretching mode of bound  $^{16}\text{O}_2$ . (a) Why is resonance Raman spectroscopy and not infrared spectroscopy the method of choice for the study of the binding of  $\text{O}_2$  to haemerythrin? (b) Proof that the  $844\text{ cm}^{-1}$  band arises from a bound  $\text{O}_2$  species may be obtained by conducting experiments on samples of haemerythrin that have been mixed with  $^{18}\text{O}_2$ , instead of  $^{16}\text{O}_2$ . Predict the fundamental vibrational wavenumber of the  $^{18}\text{O}$ – $^{18}\text{O}$  stretching mode in a sample of haemerythrin that has been treated with  $^{18}\text{O}_2$ . (c) The fundamental vibrational wavenumbers for the O–O stretching modes of  $\text{O}_2$ ,  $\text{O}_2^-$  (superoxide anion), and  $\text{O}_2^{2-}$  (peroxide anion) are 1555, 1107, and  $878\text{ cm}^{-1}$ , respectively. Explain this trend in terms of the electronic structures of  $\text{O}_2$ ,  $\text{O}_2^-$ , and  $\text{O}_2^{2-}$ . *Hint.* Review Section 10.4. What are the bond orders of  $\text{O}_2$ ,  $\text{O}_2^-$ , and  $\text{O}_2^{2-}$ ? (d) Based on the data given above, which of the following species best describes the  $\text{Fe}_2\text{O}_2$  group of haemerythrin:  $\text{Fe}_2^{2+}\text{O}_2$ ,  $\text{Fe}^{2+}\text{Fe}^{3+}\text{O}_2^-$ , or  $\text{Fe}_2^{3+}\text{O}_2^{2-}$ ? Explain your reasoning. (e) The resonance Raman spectrum of haemerythrin mixed with  $^{16}\text{O}^{18}\text{O}$  has two bands that can

be attributed to the O–O stretching mode of bound oxygen. Discuss how this observation may be used to exclude one or more of the four proposed schemes (7–10) for binding of O<sub>2</sub> to the Fe<sub>2</sub> site of haemerythrin.

**12.29†** A mixture of carbon dioxide (2.1 per cent) and helium, at 1.00 bar and 298 K in a gas cell of length 10 cm has an infrared absorption band centred at 2349 cm<sup>-1</sup> with an intensity of absorption,  $A(\tilde{\nu})$ , described by:

$$A(\tilde{\nu}) = \frac{a_1}{1 + a_2(\tilde{\nu} - a_3)^2} + \frac{a_4}{1 + a_5(\tilde{\nu} - a_6)^2}$$

where the coefficients are  $a_1 = 0.932$ ,  $a_2 = 0.005050 \text{ cm}^2$ ,  $a_3 = 2333 \text{ cm}^{-1}$ ,  $a_4 = 1.504$ ,  $a_5 = 0.01521 \text{ cm}^2$ ,  $a_6 = 2362 \text{ cm}^{-1}$ . (a) Draw a graph of  $A(\tilde{\nu})$ . What is the origin of both the band and the band width? What are the allowed and forbidden transitions of this band? (b) Calculate the transition wavenumbers and intensity of absorption of the band with a simple harmonic oscillator–rigid rotor model and compare the result with the experimental spectra. The CO bond length is 116.2 pm. (c) Within what height,  $h$ , is basically all the infrared emission from the Earth in this band absorbed by atmospheric carbon dioxide? The mole fraction of CO<sub>2</sub> in the atmosphere is  $3.3 \times 10^{-4}$  and  $T/\text{K} = 288 - 0.0065(h/\text{m})$  below 10 km. Draw a surface plot of the atmospheric absorption of the band as a function of both height and wavenumber.

**12.30** A. Dalgarno, in ‘Chemistry in the interstellar medium’, *Frontiers of Astrophysics*, E.H. Avrett (ed.), Harvard University Press, Cambridge (1976), notes that, although both CH and CN spectra show up strongly in the

interstellar medium in the constellation Ophiuchus, the CN spectrum has become the standard for the determination of the temperature of the cosmic microwave background radiation. Demonstrate through a calculation why CH would not be as useful for this purpose as CN. The rotational constant  $\tilde{B}_0$  for CH is 14.190 cm<sup>-1</sup>.

**12.31†** There is a gaseous interstellar cloud in the constellation Ophiuchus that is illuminated from behind by the star ζ-Ophiuci. Analysis of the electronic–vibrational–rotational absorption lines obtained by H.S. Uhler and R.A. Patterson (*Astrophys. J.* **42**, 434 (1915)) shows the presence of CN molecules in the interstellar medium. A strong absorption line in the ultraviolet region at  $\lambda = 387.5 \text{ nm}$  was observed corresponding to the transition  $J = 0 - 1$ . Unexpectedly, a second strong absorption line with 25 per cent of the intensity of the first was found at a slightly longer wavelength ( $\Delta\lambda = 0.061 \text{ nm}$ ) corresponding to the transition  $J = 1 - 1$  (here allowed). Calculate the temperature of the CN molecules. Gerhard Herzberg, who was later to receive the Nobel Prize for his contributions to spectroscopy, calculated the temperature as 2.3 K. Although puzzled by this result, he did not realize its full significance. If he had, his prize might have been for the discovery of the cosmic microwave background radiation.

**12.32†** The H<sub>3</sub><sup>+</sup> ion has recently been found in the interstellar medium and in the atmospheres of Jupiter, Saturn, and Uranus. The rotational energy levels of H<sub>3</sub><sup>+</sup>, an oblate symmetric rotor, are given by eqn 12.12, with  $C$  replacing  $A$ , when centrifugal distortion and other complications are ignored. Experimental values for vibrational–rotational constants are  $\tilde{\nu}(\text{E}') = 2521.6 \text{ cm}^{-1}$ ,  $\tilde{B} = 43.55 \text{ cm}^{-1}$ , and  $\tilde{C} = 20.71 \text{ cm}^{-1}$ . (a) Show that, for a nonlinear planar molecule (such as H<sub>3</sub><sup>+</sup>),  $I_C = 2I_B$ . The rather large discrepancy with the experimental values is due to factors ignored in eqn 12.12. (b) Calculate an approximate value of the H–H bond length in H<sub>3</sub><sup>+</sup>. (c) The value of  $R_C$  obtained from the best quantum mechanical calculations by J.B. Anderson (*J. Chem. Phys.* **96**, 3702 (1991)) is 87.32 pm. Use this result to calculate the values of the rotational constants  $\tilde{B}$  and  $\tilde{C}$ . (d) Assuming that the geometry and force constants are the same in D<sub>3</sub><sup>+</sup> and H<sub>3</sub><sup>+</sup>, calculate the spectroscopic constants of D<sub>3</sub><sup>+</sup>. The molecular ion D<sub>3</sub><sup>+</sup> was first produced by J.T. Shy *et al.* (*Phys. Rev. Lett.* **45**, 535 (1980)) who observed the  $\nu_2(\text{E}')$  band in the infrared.

**12.33** The space immediately surrounding stars, also called the *circumstellar space*, is significantly warmer because stars are very intense black-body emitters with temperatures of several kilokelvin. Discuss how such factors as cloud temperature, particle density, and particle velocity may affect the rotational spectrum of CO in an interstellar cloud. What new features in the spectrum of CO can be observed in gas ejected from and still near a star with temperatures of about 1000 K, relative to gas in a cloud with temperature of about 10 K? Explain how these features may be used to distinguish between circumstellar and interstellar material on the basis of the rotational spectrum of CO.

# Molecular spectroscopy 2: electronic transitions

Simple analytical expressions for the electronic energy levels of molecules cannot be given, so this chapter concentrates on the qualitative features of electronic transitions. A common theme throughout the chapter is that electronic transitions occur within a stationary nuclear framework. We pay particular attention to spontaneous radiative decay processes, which include fluorescence and phosphorescence. A specially important example of stimulated radiative decay is that responsible for the action of lasers, and we see how this stimulated emission may be achieved and employed.

The energies needed to change the electron distributions of molecules are of the order of several electronvolts (1 eV is equivalent to about  $8000\text{ cm}^{-1}$  or  $100\text{ kJ mol}^{-1}$ ). Consequently, the photons emitted or absorbed when such changes occur lie in the visible and ultraviolet regions of the spectrum (Table 13.1).

Considerable information can be obtained from the radiation emitted when excited electronic states decay radiatively back to the ground state. For instance, lasers have brought unprecedented precision to spectroscopy, made Raman spectroscopy a widely useful technique, and have made it possible to study chemical reactions on a femtosecond timescale. We shall see the principles of their action in this chapter and encounter their applications throughout the rest of the book.

## The characteristics of electronic transitions

In the lowest vibrational state of the ground electronic state of a molecule the nuclei are at their equilibrium locations and experience no net force from the electrons and other nuclei in the molecule. The electron distribution is changed when an electronic

Problems

**Fig. 13.1** The absorption spectrum of chlorophyll in the visible region. Note that it absorbs in the red and blue regions, and that green light is not absorbed.

transition occurs and the nuclei become subjected to different forces. They start to vibrate around their new equilibrium locations and the vibrational transitions that accompany the electronic transition give rise to the **vibrational structure** of the electronic transition. This structure can be resolved for gaseous samples, but in a liquid or solid the lines usually merge together and result in a broad, almost featureless band (Fig. 13.1). Superimposed on the vibrational transitions that accompany the electronic transition of a molecule in the gas phase is an additional structure that arises from rotational transitions. The electronic spectra of gaseous samples are therefore very complicated but rich in information.

### 13.1 Measurements of intensity

**Key point** The intensity of absorption is reported as the molar absorption coefficient by using the Beer–Lambert law; the total absorption is reported as the integrated absorption coefficient.

It is found empirically that the transmitted intensity  $I$  varies with the length,  $L$ , of the sample and the molar concentration,  $[J]$ , of the absorbing species  $J$  in accord with the **Beer–Lambert law**:

$$I = I_0 10^{-\epsilon[J]L} \quad \text{Beer–Lambert law} \quad (13.1)$$

where  $I_0$  is the incident intensity. The quantity  $\epsilon$  (epsilon) is called the **molar absorption coefficient** (formerly, and still widely, the ‘extinction coefficient’). The molar absorption coefficient depends on the frequency of the incident radiation and is greatest where the absorption is most intense. Its dimensions are  $1/(\text{concentration} \times \text{length})$ , and it is normally convenient to express it in cubic decimetres per mole per centimetre ( $\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1}$ ); in SI base units it is expressed in metres-squared per mole ( $\text{m}^2 \text{mol}^{-1}$ ). The latter units imply that  $\epsilon$  may be regarded as a (molar) cross-section for absorption and that, the greater the cross-sectional area of the molecule for absorption, the greater is its ability to block the passage of the incident radiation at a given frequency. The Beer–Lambert law is an empirical result. However, it is simple to account for its form as we show in the following *Justification*.

#### Justification 13.1 The Beer–Lambert law

The change in intensity,  $dI$ , that occurs when light passes through a layer of thickness  $dL$  containing an absorbing species  $J$  at a molar concentration  $[J]$  is proportional to the thickness of the layer, the concentration of  $J$ , and the intensity,  $I$ , incident on the layer. We can therefore write

$$dI = -\kappa[J]I dL$$

where  $\kappa$  (kappa) is the proportionality coefficient, or equivalently

$$\frac{dI}{I} = -\kappa[J]dL$$

This expression applies to each successive layer into which the sample can be regarded as being divided. Therefore, to obtain the intensity that emerges from a sample of thickness  $L$  when the intensity incident on one face of the sample is  $I_0$ , we sum all the successive changes:

$$\int_{I_0}^I \frac{dI}{I} = -\kappa \int_0^L [J] dL$$

If the concentration is uniform,  $[J]$  is independent of location, and the expression integrates to

$$\ln \frac{I}{I_0} = -\kappa[J]L$$

This expression gives the Beer–Lambert law when the logarithm is converted to base 10 by using  $\ln x = (\ln 10)\log x$  and replacing  $\kappa$  by  $\varepsilon \ln 10$ .

The spectral characteristics of a sample are commonly reported as the **transmittance**,  $T$ , of the sample at a given frequency:

$$T = \frac{I}{I_0} \quad \text{Definition of transmittance} \quad [13.2]$$

and the **absorbance**,  $A$ , of the sample:

$$A = \log \frac{I_0}{I} \quad \text{Definition of absorbance} \quad [13.3]$$

The two quantities are related by  $A = -\log T$  (note the common logarithm) and the Beer–Lambert law becomes

$$A = \varepsilon[J]L \quad (13.4)$$

The product  $\varepsilon[J]L$  was known formerly as the *optical density* of the sample.

#### • A brief illustration

The Beer–Lambert law implies that the intensity of electromagnetic radiation transmitted through a sample at a given wavenumber decreases exponentially with the sample thickness and the molar concentration. If the transmittance is 0.1 for a path length of 1 cm (corresponding to a 90 per cent reduction in intensity), then it would be  $(0.1)^2 = 0.01$  for a path of double the length (corresponding to a 99 per cent reduction in intensity overall). •

The maximum value of the molar absorption coefficient,  $\varepsilon_{\max}$ , is an indication of the intensity of a transition. However, as absorption bands generally spread over a range of wavenumbers, quoting the absorption coefficient at a single wavenumber might not give a true indication of the intensity of a transition. The **integrated absorption coefficient**,  $\mathcal{A}$ , is the sum of the absorption coefficients over the entire band (Fig. 13.2), and corresponds to the area under the plot of the molar absorption coefficient against wavenumber:

$$\mathcal{A} = \int_{\text{band}} \varepsilon(\tilde{\nu}) d\tilde{\nu} \quad \text{Definition of integrated absorption coefficient} \quad [13.5]$$

For lines of similar widths, the integrated absorption coefficients are proportional to the heights of the lines.

## 13.2 The electronic spectra of diatomic molecules

**Key points** (a) The term symbols of diatomic molecules express the components of electronic angular momentum around the internuclear axis. (b) Selection rules for electronic transitions are based on considerations of angular momentum and symmetry. (c) The Franck–Condon principle provides a basis for explaining the vibrational structure of electronic transitions. (d) In gas-phase samples, rotational structure is present too and can give rise to band heads.

**Fig. 13.2** The integrated absorption coefficient of a transition is the area under a plot of the molar absorption coefficient against the wavenumber of the incident radiation.

We saw in Section 9.10 how the states of atoms are expressed by using term symbols and that the selection rules for electronic transitions could be expressed in terms of these term symbols. Much the same is true of diatomic molecules, one principal difference being the replacement of full spherical symmetry of atoms by the cylindrical symmetry defined by the axis of the molecule. The second principal difference is the fact that a diatomic molecule can vibrate and rotate.

### (a) Term symbols

The term symbols of linear molecules (the analogues of the symbols  $^2P$ , etc. for atoms) are constructed in a similar way to those for atoms, with the Roman upper-case letter (the P in this instance) representing the total orbital angular momentum of the electrons around the nucleus. In a linear molecule, and specifically a diatomic molecule, a Greek upper-case letter represents the total orbital angular momentum of the electrons around the internuclear axis. If this component of orbital angular momentum is  $\Lambda\hbar$  with  $\Lambda = 0, \pm 1, \pm 2 \dots$ , we use the following designation:

|             |          |       |          |     |
|-------------|----------|-------|----------|-----|
| $ \Lambda $ | 0        | 1     | 2        | ... |
|             | $\Sigma$ | $\Pi$ | $\Delta$ | ... |

These labels are the analogues of S, P, D, ... for atoms for states with  $L = 0, 1, 2, \dots$ . To decide on the value of  $L$  for atoms we had to use the Clebsch–Gordan series to couple the individual angular momenta. The procedure to determine  $\Lambda$  is much simpler in a diatomic molecule because we simply add the values of the individual components of each electron,  $\lambda\hbar$ :

$$\Lambda = \lambda_1 + \lambda_2 + \dots \quad (13.6)$$

A single electron in a  $\sigma$  orbital has  $\lambda = 0$ : the orbital is cylindrically symmetrical and has no angular nodes when viewed along the internuclear axis. Therefore, if that is the only type of electron present,  $\Lambda = 0$ . The term symbol for the ground state of  $H_2$  with electron configuration  $1\sigma_g^2$  is therefore  $\Sigma$ . A  $\pi$  electron in a diatomic molecule has one unit of orbital angular momentum about the internuclear axis ( $\lambda = \pm 1$ ) and, if it is the only electron outside a closed shell, gives rise to a  $\Pi$  term. If there are two  $\pi$  electrons (as in the ground state of  $O_2$ , with configuration  $\dots 1\pi_g^2$ , there are two possible outcomes. If the electrons are travelling in opposite directions, then  $\lambda_1 = +1$  and  $\lambda_2 = -1$  (or vice versa) and  $\Lambda = 0$ , corresponding to a  $\Sigma$  term. Alternatively, the electrons might occupy the same  $\pi$  orbital and  $\lambda_1 = \lambda_2 = +1$  (or  $-1$ ), and  $\Lambda = \pm 2$ , corresponding to a  $\Delta$  term. In  $O_2$  it is energetically favourable for the electrons to occupy different orbitals, so the ground term is  $\Sigma$ .

As in atoms, we use a left superscript with the value of  $2S + 1$  to denote the multiplicity of the term, where  $S$  is the total spin quantum number of the electrons. For  $H_2^+$ , because there is only one electron,  $S = s = \frac{1}{2}$  and the term symbol is  $^2\Sigma$ , a doublet term. For  $H_2$ , with no net spin,  $S = 0$  and the ground state is a singlet term,  $^1\Sigma$ . In  $O_2$ , because in the ground state the two  $\pi$  electrons occupy different orbitals (as we saw above), they may have either parallel or antiparallel spins; the lower energy is obtained (as in atoms) if the spins are parallel, so  $S = 1$  and the ground state is  $^3\Sigma$ .

The overall parity of the state (its symmetry under inversion through the centre of the molecule, if it has one) is added as a right subscript to the term symbol. For  $H_2^+$  in its ground state, the parity of the only occupied orbital ( $1\sigma_g$ ) is g, so the term itself is also g, and in full dress is  $^2\Sigma_g^+$ . If there are several electrons, the overall parity is calculated by noting the parity of each occupied orbital and using

$$g \times g = g \quad u \times u = g \quad u \times g = u \quad (13.7)$$

These rules are generated by interpreting  $g$  as  $+1$  and  $u$  as  $-1$ . The term symbol for the ground state of any closed-shell homonuclear diatomic molecule is  $^1\Sigma_g$  because the spin is zero (a singlet term in which all electrons paired), there is no orbital angular momentum from a closed shell, and the overall parity is  $g$ . The parity of the ground state of  $O_2$  is also  $g \times g = g$ , so it is denoted  $^3\Sigma_g$ . If the molecule is heteronuclear, parity is irrelevant and the ground state of a closed-shell species, such as  $CO$ , is  $^1\Sigma$ .

#### • A brief illustration

An excited configuration of  $O_2$  is  $\dots 1\pi_g^2$  with both  $\pi$  electrons in the same orbital. As we have seen,  $|\Lambda| = 2$ , represented by  $\Delta$ . The two electrons must be paired if they occupy the same orbital, so  $S = 0$ . The overall parity is  $g \times g = g$ . Therefore, the term symbol is  $^1\Delta_g$ . •

We saw in Chapter 11 that angular momentum is an aspect of the symmetry of states. That remains true for linear molecules, and the term symbols can also be thought of as denoting various aspects of rotational and inversion symmetry of the electronic wavefunction of the molecule. With that in mind, there is an additional symmetry operation that distinguishes different types of  $\Sigma$  term: reflection in a plane containing the internuclear axis. A  $+$  superscript on  $\Sigma$  is used to denote a wavefunction that does not change sign under this reflection and a  $-$  sign is used if the wavefunction changes sign (Fig. 13.3).

#### • A brief illustration

If we think of  $O_2$  in its ground state as having one electron in  $1\pi_{g,x}$ , which changes sign under reflection in the  $yz$ -plane, and the other electron in  $1\pi_{g,y}$ , which does not change sign under reflection in the same plane, then the overall reflection symmetry is (closed shell)  $\times (+) \times (-) = (-)$ , and the full term symbol of the ground electronic state of  $O_2$  is  $^3\Sigma_g^-$ . •

As we saw in connection with atoms, another aspect of angular momentum that it is sometimes necessary to denote is the total angular momentum. In atoms that is denoted by the value of  $J$  and appears as a right subscript in the term symbol, as in  $^2P_{1/2}$ , with different values of  $J$  corresponding to different *levels* of a term. In a linear molecule, only the angular momentum about the internuclear axis is well defined, and has the value  $\Omega$ . For light molecules, where the spin–orbit coupling is weak,  $\Omega$  is obtained by adding together the components of orbital angular momentum around the axis (the value of  $\Lambda$ ) and the component of the electron spin on that axis (Fig. 13.4). The latter is denoted  $\Sigma$ , where  $\Sigma = S, S - 1, S - 2, \dots, -S$ . Then

$$\Omega = \Lambda + \Sigma \quad (13.8)$$

The value of  $|\Omega|$  may then be attached to the term symbol as a right subscript (just like  $J$  is used in atoms) to denote the different levels. These levels differ in energy, as in atoms, as a result of spin–orbit coupling.

#### • A brief illustration

The ground-state configuration of  $NO$  is  $\dots \pi_g^1$ , so it is a  $^2\Pi$  term with  $\Lambda = \pm 1$  and  $\Sigma = \pm \frac{1}{2}$ . Therefore, there are two levels of the term, one with  $\Omega = \pm \frac{1}{2}$  and the other with  $\pm \frac{3}{2}$ , denoted  $^2\Pi_{1/2}$  and  $^2\Pi_{3/2}$ , respectively. Each level is doubly degenerate (corresponding to the opposite signs of  $\Omega$ ). In  $NO$ ,  $^2\Pi_{1/2}$  lies slightly lower than  $^2\Pi_{3/2}$ . •

**Fig. 13.3** The  $+$  or  $-$  on a term symbol refers to the overall symmetry of a configuration under reflection in a plane containing the two nuclei.

**Fig. 13.4** The coupling of spin and orbital angular momenta in a linear molecule: only the components along the internuclear axis are conserved.

#### A brief comment

It is important to distinguish between the (upright) term symbol  $\Sigma$  and the (sloping) quantum number  $\Sigma$ .

**(b) Selection rules**

A number of selection rules govern which transitions will be observed in the electronic spectrum of a molecule. The selection rules concerned with changes in angular momentum are

$$\Delta\Lambda = 0, \pm 1 \quad \Delta S = 0 \quad \Delta\Sigma = 0 \quad \Delta\Omega = 0, \pm 1$$

Selection rules for linear molecules

As in atoms (Section 9.3), the origins of these rules are conservation of angular momentum during a transition and the fact that a photon has a spin of 1.

There are two selection rules concerned with changes in symmetry. First, as we show in the following *Justification*,

For  $\Sigma$  terms, only  $\Sigma^+ \leftrightarrow \Sigma^+$  and  $\Sigma^- \leftrightarrow \Sigma^-$  are allowed

Second, the **Laporte selection rule** for centrosymmetric molecules (those with a centre of inversion) and atoms states that *the only allowed transitions are transitions that are accompanied by a change of parity*. That is,

For centrosymmetric molecules, only  $u \rightarrow g$  and  $g \rightarrow u$  are allowed

Laporte selection rule

**Justification 13.2** *Symmetry-based selection rules*

The last two selection rules result from the fact that the electric-dipole transition moment introduced in *Justification 9.4*,  $\mu_{fi} = \int \psi_f^* \hat{\mu} \psi_i d\tau$ , vanishes unless the integrand is invariant under all symmetry operations of the molecule.

The  $z$ -component of the dipole moment operator is the component of  $\mu$  responsible for  $\Sigma \leftrightarrow \Sigma$  transitions (the other components have  $\Pi$  symmetry and cannot make a contribution). The  $z$ -component of  $\mu$  has (+) symmetry with respect to reflection in a plane containing the internuclear axis. Therefore, for a (+)  $\leftrightarrow$  (−) transition, the overall symmetry of the transition dipole moment is (+)  $\times$  (+)  $\times$  (−) = (−), so it must be zero and hence  $\Sigma^+ \leftrightarrow \Sigma^-$  transitions are not allowed. The integrals for  $\Sigma^+ \leftrightarrow \Sigma^+$  and  $\Sigma^- \leftrightarrow \Sigma^-$  transform as (+)  $\times$  (+)  $\times$  (+) = (+) and (−)  $\times$  (+)  $\times$  (−) = (+), respectively, and so both transitions are allowed.

The three components of the dipole moment operator transform like  $x$ ,  $y$ , and  $z$ , and in a centrosymmetric molecule are all  $u$ . Therefore, for a  $g \rightarrow g$  transition, the overall parity of the transition dipole moment is  $g \times u \times g = u$ , so it must be zero. Likewise, for a  $u \rightarrow u$  transition, the overall parity is  $u \times u \times u = u$ , so the transition dipole moment must also vanish. Hence, transitions without a change of parity are forbidden. For a  $g \leftrightarrow u$  transition the integral transforms as  $g \times u \times u = g$ , and is allowed.

**Fig. 13.5** A d–d transition is parity-forbidden because it corresponds to a  $g \rightarrow g$  transition. However, a vibration of the molecule can destroy the inversion symmetry of the molecule and the  $g, u$  classification no longer applies. The removal of the centre of symmetry gives rise to a vibronically allowed transition.

A forbidden  $g \rightarrow g$  transition can become allowed if the centre of symmetry is eliminated by an asymmetrical vibration, such as the one shown in Fig. 13.5. When the centre of symmetry is lost,  $g \rightarrow g$  and  $u \rightarrow u$  transitions are no longer parity-forbidden and become weakly allowed. A transition that derives its intensity from an asymmetrical vibration of a molecule is called a **vibronic transition**.

**Self-test 13.1** Which of the following electronic transitions are allowed in  $O_2$ ?

$${}^3\Sigma_g^- \leftrightarrow {}^1\Delta_g, {}^3\Sigma_g^- \leftrightarrow {}^1\Sigma_g^+, {}^3\Sigma_g^- \leftrightarrow {}^3\Delta_u, {}^3\Sigma_g^- \leftrightarrow {}^3\Sigma_u^+, {}^3\Sigma_g^- \leftrightarrow {}^3\Sigma_u^-, [{}^3\Sigma_g^- \leftrightarrow {}^3\Sigma_u^-]$$

### (c) Vibrational structure

To account for the vibrational structure in electronic spectra of molecules (Fig. 13.6), we apply the **Franck–Condon principle**:

Because the nuclei are so much more massive than the electrons, an electronic transition takes place very much faster than the nuclei can respond.

Franck–Condon principle

As a result of the transition, electron density is rapidly built up in new regions of the molecule and removed from others. In classical terms, the initially stationary nuclei suddenly experience a new force field, to which they respond by beginning to vibrate and (in classical terms) swing backwards and forwards from their original separation (which was maintained during the rapid electronic excitation). The stationary equilibrium separation of the nuclei in the initial electronic state therefore becomes a turning point in the final electronic state (Fig. 13.7). We can imagine the transition as taking place up the vertical line in Fig. 13.7. This interpretation is the origin of the expression **vertical transition**, which is used to denote an electronic transition that occurs without change of nuclear geometry.

The vibrational structure of the spectrum depends on the relative horizontal position of the two potential energy curves, and a long **vibrational progression**, a lot of vibrational structure, is stimulated if the upper potential energy curve is appreciably displaced horizontally from the lower. The upper curve is usually displaced to greater equilibrium bond lengths because electronically excited states usually have more antibonding character than electronic ground states. The separation of the vibrational lines depends on the vibrational energies of the *upper* electronic state. Hence, electronic absorption spectra may be used to assess the force fields and dissociation energies of electronically excited molecules.

The quantum mechanical version of the Franck–Condon principle refines this picture. Instead of saying that the nuclei stay at the same locations and are stationary during the transition, we say that *they retain their initial dynamic state*. In quantum mechanics, the dynamical state is expressed by the wavefunction, so an equivalent statement is that the nuclear wavefunction does not change during the electronic transition. Initially the molecule is in the lowest vibrational state of its ground electronic state with a bell-shaped wavefunction centred on the equilibrium bond length (Fig. 13.8). To find the nuclear state to which the transition takes place, we look for the vibrational wavefunction that most closely resembles this initial wavefunction, for that corresponds to the nuclear dynamical state that is least changed in the transition. Intuitively, we can see that the final wavefunction is the one with a large peak close to the position of the initial bell-shaped function. As we saw in Section 8.5, provided the vibrational quantum number is not zero, the biggest peaks of vibrational wavefunctions occur close to the edges of the confining potential, so we can expect the transition to occur to those vibrational states, in accord with the classical description. However, several vibrational states have their major peaks in similar positions, so we should expect transitions to occur to a range of vibrational states, as is observed.

The quantitative form of the Franck–Condon principle and the justification of the preceding description is derived from the expression for the transition dipole moment (as in *Justification 13.2*). The dipole moment operator is a sum over all nuclei and electrons in the molecule:

$$\hat{\mu} = -e \sum_i \mathbf{r}_i + e \sum_I Z_I \mathbf{R}_I \quad (13.9)$$

where the vectors are the distances from the centre of charge of the molecule. The intensity of the transition is proportional to the square modulus,  $|\mu_{fi}|^2$ , of the magnitude

**Fig. 13.6** The electronic spectra of some molecules show significant vibrational structure. Shown here is the ultraviolet spectrum of gaseous  $\text{SO}_2$  at 298 K. As explained in the text, the sharp lines in this spectrum are due to transitions from a lower electronic state to different vibrational levels of a higher electronic state.

**Fig. 13.7** According to the Franck–Condon principle, the most intense vibronic transition is from the ground vibrational state to the vibrational state lying vertically above it. Transitions to other vibrational levels also occur, but with lower intensity.

**Fig. 13.8** In the quantum mechanical version of the Franck–Condon principle, the molecule undergoes a transition to the upper vibrational state that most closely resembles the vibrational wavefunction of the vibrational ground state of the lower electronic state. The two wavefunctions shown here have the greatest overlap integral of all the vibrational states of the upper electronic state and hence are most closely similar.

of the transition dipole moment, and we show in the following *Justification* that this intensity is proportional to the square modulus of the overlap integral,  $S(v_f, v_i)$ , between the vibrational states of the initial and final electronic states. This overlap integral is a measure of the match between the vibrational wavefunctions in the upper and lower electronic states:  $S = 1$  for a perfect match and  $S = 0$  when there is no similarity.

#### Justification 13.3 The Franck–Condon approximation

The overall state of the molecule consists of an electronic part,  $\psi_e$ , and a vibrational part,  $\psi_v$ . Therefore, within the Born–Oppenheimer approximation, the transition dipole moment factorizes as follows:

$$\begin{aligned}\mu_{fi} &= \int \psi_{e_f}^* \psi_{v_f}^* \left\{ -e \sum_i r_i + e \sum_I Z_I R_I \right\} \psi_{e_i} \psi_{v_i} d\tau \\ &= -e \sum_i \int \psi_{e_f}^* r_i \psi_{e_i} d\tau_e \int \psi_{v_f}^* \psi_{v_i} d\tau_v + e \sum_I Z_I \int \psi_{e_f}^* \psi_{e_i} d\tau_e \int \psi_{v_f}^* R_I \psi_{v_i} d\tau_v\end{aligned}$$

The second term on the right of the second row is zero, because two different electronic states are orthogonal. Therefore,

$$\mu_{fi} = -e \sum_i \int \psi_{e_f}^* r_i \psi_{e_i} d\tau_e \int \psi_{v_f}^* \psi_{v_i} d\tau_v = \mu_{e_f e_i} S(v_f, v_i)$$

where

$$\mu_{e_f e_i} = -e \sum_i \int \psi_{e_f}^* r_i \psi_{e_i} d\tau_e \quad \text{and} \quad S(v_f, v_i) = \int \psi_{v_f}^* \psi_{v_i} d\tau_v$$

The matrix element  $\mu_{e_f e_i}$  is the electric-dipole transition moment arising from the redistribution of electrons (and a measure of the ‘kick’ this redistribution gives to the electromagnetic field, and vice versa for absorption). The factor  $S(v_f, v_i)$  is the overlap integral between the vibrational state  $\psi_{v_i}$  in the initial electronic state of the molecule, and the vibrational state  $\psi_{v_f}$  in the final electronic state of the molecule.

Because the transition intensity is proportional to the square of the magnitude of the transition dipole moment, the intensity of an absorption is proportional to  $|S(v_f, v_i)|^2$ , which is known as the **Franck–Condon factor** for the transition. It follows that, the greater the overlap of the vibrational state wavefunction in the upper electronic state with the vibrational wavefunction in the lower electronic state, the greater the absorption intensity of that particular simultaneous electronic and vibrational transition.

#### Example 13.1 Calculating a Franck–Condon factor

Consider the transition from one electronic state to another, their bond lengths being  $R_e$  and  $R'_e$  and their force constants equal. Calculate the Franck–Condon factor for the 0–0 transition and show that the transition is most intense when the bond lengths are equal.

**Method** We need to calculate  $S(0,0)$ , the overlap integral of the two ground-state vibrational wavefunctions, and then take its square. The difference between harmonic and anharmonic vibrational wavefunctions is negligible for  $n = 0$ , so harmonic oscillator wavefunctions can be used (Table 8.1).

**Answer** We use the (real) wavefunctions

$$\psi_0 = \left( \frac{1}{\alpha\pi^{1/2}} \right)^{1/2} e^{-x^2/2\alpha^2} \quad \psi'_0 = \left( \frac{1}{\alpha\pi^{1/2}} \right)^{1/2} e^{-x'^2/2\alpha^2}$$

where  $x = R - R_e$  and  $x' = R - R'_e$  with  $\alpha = (\hbar^2/mk)^{1/4}$  (Section 8.5a). The overlap integral is

$$S(0,0) = \langle 0|0 \rangle = \int_{-\infty}^{\infty} \psi'_0 \psi_0 dR = \frac{1}{\alpha\pi^{1/2}} \int_{-\infty}^{\infty} e^{-(x^2+x'^2)/2\alpha^2} dx$$

We now write  $\alpha z = R - \frac{1}{2}(R_e + R'_e)$ , and manipulate this expression into

$$S(0,0) = \frac{1}{\pi^{1/2}} e^{-(R_e - R'_e)^2/4\alpha^2} \int_{-\infty}^{\infty} e^{-z^2} dz$$

The value of the integral is  $\pi^{1/2}$ . Therefore, the overlap integral is

$$S(0,0) = e^{-(R_e - R'_e)^2/4\alpha^2}$$

and the Franck–Condon factor is

$$S(0,0)^2 = e^{-(R_e - R'_e)^2/2\alpha^2}$$

This factor is equal to 1 when  $R'_e = R_e$  and decreases as the equilibrium bond lengths diverge from each other (Fig. 13.9).

For  $\text{Br}_2$ ,  $R_e = 228$  pm and there is an upper state with  $R'_e = 266$  pm. Taking the vibrational wavenumber as  $250 \text{ cm}^{-1}$  gives  $S(0,0)^2 = 5.1 \times 10^{-10}$ , so the intensity of the 0–0 transition is only  $5.1 \times 10^{-10}$  of what it would have been if the potential curves had been directly above each other.

**Self-test 13.2** Suppose the vibrational wavefunctions can be approximated by rectangular functions of width  $W$  and  $W'$ , centred on the equilibrium bond lengths (Fig. 13.10). Find the corresponding Franck–Condon factors when the centres are coincident and  $W' < W$ .  $[S^2 = W'/W]$

#### (d) Rotational structure

Just as in vibrational spectroscopy, where a vibrational transition is accompanied by rotational excitation, so rotational transitions accompany the excitation of the vibrational excitation that accompanies electronic excitation. We therefore see P, Q, and R branches for each vibrational transition, and the electronic transition has a very rich structure. However, the principal difference is that electronic excitation can result in much larger changes in bond length than vibrational excitation causes alone, and the rotational branches have a more complex structure than in vibration–rotation spectra.

We suppose that the rotational constants of the electronic ground and excited states are  $\tilde{B}$  and  $\tilde{B}'$ , respectively. The rotational energy levels of the initial and final states are

$$E(J) = hc\tilde{B}J(J+1) \quad E(J') = hc\tilde{B}'J'(J'+1) \quad (13.10)$$

When a transition occurs with  $\Delta J = -1$  the wavenumber of the vibrational component of the electronic transition is shifted from  $\tilde{\nu}$  to

$$\tilde{\nu} + \tilde{B}'(J-1)J - \tilde{B}J(J+1) = \tilde{\nu} - (\tilde{B}' + \tilde{B})J + (\tilde{B}' - \tilde{B})J^2$$

This transition is a contribution to the P branch (just as in Section 12.11). There are corresponding transitions for the Q and R branches with wavenumbers that may be calculated in a similar way. All three branches are:

$$\text{P branch } (\Delta J = -1): \quad \tilde{\nu}_p(J) = \tilde{\nu} - (\tilde{B}' + \tilde{B})J + (\tilde{B}' - \tilde{B})J^2 \quad (13.11a)$$

Branch  
structure

Fig. 13.9 The Franck–Condon factor for the arrangement discussed in Example 13.1.

Fig. 13.10 The model wavefunctions used in Self-test 13.2.

**Fig. 13.11** When the rotational constants of a diatomic molecule differ significantly in the initial and final states of an electronic transition, the P and R branches show a head. (a) The formation of a head in the R branch when  $\tilde{B}' < \tilde{B}$ ; (b) the formation of a head in the P branch when  $\tilde{B}' > \tilde{B}$ .

$$\text{Q branch } (\Delta J = 0): \quad \tilde{\nu}_Q(J) = \tilde{\nu} + (\tilde{B}' - \tilde{B})J(J+1) \quad (13.11b)$$

$$\text{R branch } (\Delta J = +1): \quad \tilde{\nu}_R(J) = \tilde{\nu} + (\tilde{B}' + \tilde{B})(J+1) + (\tilde{B}' - \tilde{B})(J+1)^2 \quad (13.11c)$$

These expressions are the analogues of eqn 12.46.

First, suppose that the bond length in the electronically excited state is greater than that in the ground state; then  $\tilde{B}' < \tilde{B}$  and  $\tilde{B}' - \tilde{B}$  is negative. In this case the lines of the R branch converge with increasing  $J$  and when  $J$  is such that  $|\tilde{B}' - \tilde{B}|(J+1) > \tilde{B}' + \tilde{B}$  the lines start to appear at successively decreasing wavenumbers. That is, the R branch has a **band head** (Fig. 13.11a). When the bond is shorter in the excited state than in the ground state,  $\tilde{B}' > \tilde{B}$  and  $\tilde{B}' - \tilde{B}$  is positive. In this case, the lines of the P branch begin to converge and go through a head when  $J$  is such that  $|\tilde{B}' - \tilde{B}|J > \tilde{B}' + \tilde{B}$  (Fig. 13.11b).

### 13.3 The electronic spectra of polyatomic molecules

**Key points** (a) In d-metal complexes, the presence of ligands removes the degeneracy of d orbitals and vibrationally allowed transitions can occur between them. (b) Charge-transfer transitions typically involve the migration of electrons between the ligands and the central metal atom. (c) Other chromophores include double bonds ( $\pi^* \leftarrow \pi$  transitions) and carbonyl groups ( $\pi^* \leftarrow n$  transitions). (d) Circular dichroism is the differential absorption of light with opposite circular polarizations.

The absorption of a photon can often be traced to the excitation of specific types of electrons or to electrons that belong to a small group of atoms in a polyatomic molecule. For example, when a carbonyl group ( $>C=O$ ) is present, an absorption at about 290 nm is normally observed, although its precise location depends on the nature of the rest of the molecule. Groups with characteristic optical absorptions are called **chromophores** (from the Greek for ‘colour bringer’), and their presence often accounts for the colours of substances (Table 13.2).

#### (a) d-d transitions

In a free atom, all five d orbitals of a given shell are degenerate. In a d-metal complex, where the immediate environment of the atom is no longer spherical, the d orbitals are not all degenerate, and electrons can absorb energy by making transitions between them.

To see the origin of this splitting, we regard the six ligands as point negative charges that repel the d electrons of the central ion (Fig. 13.12). As a result, the orbitals fall into two groups, with  $d_{x^2-y^2}$  and  $d_{z^2}$  pointing directly towards the ligand positions, and  $d_{xy}$ ,  $d_{yz}$ , and  $d_{zx}$  pointing between them. An electron occupying an orbital of the former group has a less favourable potential energy than when it occupies any of the three orbitals of the other group, and so the d orbitals split into the two sets shown in (1) with an energy difference  $\Delta_o$ : a triply degenerate set comprising the  $d_{xy}$ ,  $d_{yz}$ , and  $d_{zx}$

**Table 13.2\*** Absorption characteristics of some groups and molecules

| Group                                     | $\tilde{\nu}/\text{cm}^{-1}$ | $\lambda_{\text{max}}/\text{nm}$ | $\epsilon/(\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1})$ |
|-------------------------------------------|------------------------------|----------------------------------|---------------------------------------------------------|
| C=C ( $\pi^* \leftarrow \pi$ )            | 61 000                       | 163                              | 15 000                                                  |
|                                           | 57 300                       | 174                              | 5 500                                                   |
| C=O ( $\pi^* \leftarrow n$ )              | 35 000–37 000                | 270–290                          | 10–20                                                   |

\* More values are given in the *Data section*.

**Fig. 13.12** The classification of d orbitals in an octahedral environment.

orbitals and labelled  $t_{2g}$ , and a doubly degenerate set comprising the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals and labelled  $e_g$ . The three  $t_{2g}$  orbitals lie below the two  $e_g$  orbitals in energy; the difference in energy is denoted  $\Delta_O$  and called the **ligand-field splitting parameter** (the O denoting octahedral symmetry). The ligand field splitting is typically about 10 per cent of the overall energy of interaction between the ligands and the central metal atom, which is largely responsible for the existence of the complex. The d orbitals also divide into two sets in a tetrahedral complex, but in this case the e orbitals lie below the  $t_2$  orbitals (the g,u classification is no longer relevant as a tetrahedral complex has no centre of inversion) and their separation is written  $\Delta_T$ .

Neither  $\Delta_O$  nor  $\Delta_T$  is large, so transitions between the two sets of orbitals typically occur in the visible region of the spectrum. The transitions are responsible for many of the colours that are so characteristic of d-metal complexes. As an example, the spectrum of  $[\text{Ti}(\text{OH}_2)_6]^{3+}$  (2) near  $20\,000\text{ cm}^{-1}$  (500 nm) is shown in Fig. 13.13, and can be ascribed to the promotion of its single d electron from a  $t_{2g}$  orbital to an  $e_g$  orbital. The wavenumber of the absorption maximum suggests that  $\Delta_O \approx 20\,000\text{ cm}^{-1}$  for this complex, which corresponds to about 2.5 eV.

According to the Laporte rule (Section 13.2b), d–d transitions are parity-forbidden in octahedral complexes because they are  $g \rightarrow g$  transitions (more specifically  $e_g \leftarrow t_{2g}$  transitions). However, d–d transitions become weakly allowed as vibronic transitions as a result of coupling to asymmetrical vibrations such as that shown in Fig. 13.5.

### (b) Charge-transfer transitions

A d-metal complex may absorb radiation as a result of the transfer of an electron from the ligands into the d orbitals of the central atom, or vice versa. In such **charge-transfer transitions** the electron moves through a considerable distance, which means that the transition dipole moment may be large and the absorption correspondingly intense. This mode of chromophore activity accounts for the intense violet colour (which arises from strong absorption within the range 420–700 nm) of the permanganate ion,  $\text{MnO}_4^-$ . In this oxoanion, the electron migrates from an orbital that is largely confined to the O atom ligands to an orbital that is largely confined to the Mn atom. It is therefore an example of a **ligand-to-metal charge-transfer transition (LMCT)**. The reverse migration, a **metal-to-ligand charge-transfer transition (MLCT)**, can also

**Fig. 13.13** The electronic absorption spectrum of  $[\text{Ti}(\text{OH}_2)_6]^{3+}$  in aqueous solution.

**Fig. 13.14** A C=C double bond acts as a chromophore. One of its important transitions is the  $\pi^* \leftarrow \pi$  transition illustrated here, in which an electron is promoted from a  $\pi$  orbital to the corresponding antibonding orbital.

**Fig. 13.15** A carbonyl group (C=O) acts as a chromophore primarily on account of the excitation of a nonbonding O lone-pair electron to an antibonding CO  $\pi$  orbital.

occur. An example is the transfer of a d electron into the antibonding  $\pi$  orbitals of an aromatic ligand. The resulting excited state may have a very long lifetime if the electron is extensively delocalized over several aromatic rings, and such species can participate in photochemically induced redox reactions (Section 21.10).

In common with other transitions, the intensities of charge-transfer transitions are proportional to the square of the transition dipole moment. We can think of the transition moment as a measure of the distance moved by the electron as it migrates from metal to ligand or vice versa, with a large distance of migration corresponding to a large transition dipole moment and therefore a high intensity of absorption. However, because the integrand in the transition dipole is proportional to the product of the initial and final wavefunctions, it is zero unless the two wavefunctions have nonzero values in the same region of space. Therefore, although large distances of migration favour high intensities, the diminished overlap of the initial and final wavefunctions for large separations of metal and ligands favours low intensities (see Problem 13.8). We encounter similar considerations when we examine electron transfer reactions (Chapter 22), which can be regarded as a special type of charge-transfer transition.

### (c) $\pi^* \leftarrow \pi$ and $\pi^* \leftarrow n$ transitions

Absorption by a C=C double bond results in the excitation of a  $\pi$  electron into an antibonding  $\pi^*$  orbital (Fig. 13.14). The chromophore activity is therefore due to a  $\pi^* \leftarrow \pi$  transition (which is normally read ' $\pi$  to  $\pi$ -star transition'). Its energy is about 7 eV for an unconjugated double bond, which corresponds to an absorption at 180 nm (in the ultraviolet). When the double bond is part of a conjugated chain, the energies of the molecular orbitals lie closer together and the  $\pi^* \leftarrow \pi$  transition moves to longer wavelength; it may even lie in the visible region if the conjugated system is long enough. An important example of a  $\pi^* \leftarrow \pi$  transition is provided by the photochemical mechanism of vision (*Impact I13.1*).

The transition responsible for absorption in carbonyl compounds can be traced to the lone pairs of electrons on the O atom. The Lewis concept of a 'lone pair' of electrons is represented in molecular orbital theory by a pair of electrons in an orbital confined largely to one atom and not appreciably involved in bond formation. One of these electrons may be excited into an empty  $\pi^*$  orbital of the carbonyl group (Fig. 13.15), which gives rise to an  $\pi^* \leftarrow n$  transition (an ' $n$  to  $\pi$ -star transition'). Typical absorption energies are about 4 eV (290 nm). Because  $\pi^* \leftarrow n$  transitions in carbonyls are symmetry forbidden, the absorptions are weak.

### (d) Circular dichroism

Electronic spectra can reveal additional details of molecular structure when experiments are conducted with **polarized light**, electromagnetic radiation with electric and magnetic fields that oscillate only in certain directions. Light is **plane polarized** when the electric and magnetic fields each oscillate in a single plane (Fig. 13.16). The plane of polarization may be oriented in any direction around the direction of propagation (the  $y$ -direction in Fig. 13.16), with the electric and magnetic fields perpendicular to that direction (and perpendicular to each other). An alternative mode of polarization is **circular polarization**, in which the electric and magnetic fields rotate around the direction of propagation in either a clockwise or a counterclockwise sense but remain perpendicular to it and each other.

When plane-polarized radiation passes through samples of certain kinds of matter, the plane of polarization is rotated around the direction of propagation. This rotation is the familiar phenomenon of optical activity, observed when the molecules in the sample are chiral (Section 11.3b). Chiral molecules have a second characteristic: they

**Fig. 13.16** Electromagnetic radiation consists of a wave of electric and magnetic fields perpendicular to the direction of propagation (in this case the  $y$ -direction), and mutually perpendicular to each other. This illustration shows a plane-polarized wave, with the electric and magnetic fields oscillating in the  $yz$ - and  $xy$ -planes, respectively.

**Fig. 13.17** In circularly polarized light, the electric field at different points along the direction of propagation rotates. The arrays of arrows in these illustrations show the view of the electric field: (a) right-circularly polarized, (b) left-circularly polarized light.

**Fig. 13.18** (a) The absorption spectra of two isomers, denoted mer and fac, of  $[\text{Co}(\text{ala})_3]$ , where ala is the conjugate base of alanine, and (b) the corresponding CD spectra. The left- and right-handed forms of these isomers give similar absorption spectra. However, the CD spectra are distinctly different, and the absolute configurations (denoted  $\Lambda$  and  $\Delta$ ) have been assigned by comparison with the CD spectra of a complex of known absolute configuration.

absorb left and right circularly polarized light to different extents. In a circularly polarized ray of light, the electric field describes a helical path as the wave travels through space (Fig. 13.17), and the rotation may be either clockwise or counterclockwise. The differential absorption of left- and right-circularly polarized light is called **circular dichroism**. In terms of the absorbances for the two components,  $A_L$  and  $A_R$ , the circular dichroism of a sample of molar concentration  $[J]$  and path-length  $L$  is reported as

$$\Delta\epsilon = \epsilon_L - \epsilon_R = \frac{A_L - A_R}{[J]L} \quad (13.12)$$

Circular dichroism is a useful adjunct to visible and UV spectroscopy. For example, the CD spectra of the enantiomeric pairs of chiral d-metal complexes are distinctly different, whereas there is little difference between their absorption spectra (Fig. 13.18). Moreover, CD spectra can be used to assign the absolute configuration of complexes by comparing the observed spectrum with the CD spectrum of a similar complex of known handedness.

## IMPACT ON BIOCHEMISTRY

### 113.1 Vision

The eye is an exquisite photochemical organ that acts as a transducer, converting radiant energy into electrical signals that travel along neurons. Here we concentrate on the events taking place in the human eye, but similar processes occur in all animals. Indeed, a single type of protein, rhodopsin, is the primary receptor for light throughout the animal kingdom, which indicates that vision emerged very early in evolutionary history, no doubt because of its enormous value for survival.

Photons enter the eye through the cornea, pass through the ocular fluid that fills the eye, and fall on the retina. The ocular fluid is principally water, and passage of light through this medium is largely responsible for the *chromatic aberration* of the eye, the blurring of the image as a result of different frequencies being brought to slightly different focuses. The chromatic aberration is reduced to some extent by the tinted region called the *macular pigment* that covers part of the retina. The pigments in this region are the carotene-like xanthophylls (3), which absorb some of the blue light and hence help to sharpen the image. They also protect the photoreceptor molecules from too great a flux of potentially dangerous high energy photons. The xanthophylls have delocalized electrons that spread along the chain of conjugated double bonds, and the  $\pi^* \leftarrow \pi$  transition lies in the visible.

3 A xanthophyll

4 11-*cis*-retinal

5 All-*trans*-retinal

About 57 per cent of the photons that enter the eye reach the retina; the rest are scattered or absorbed by the ocular fluid. Here the primary act of vision takes place, in which the chromophore of a rhodopsin molecule absorbs a photon in another  $\pi^* \leftarrow \pi$  transition. A rhodopsin molecule consists of an opsin protein molecule to which is attached a 11-*cis*-retinal molecule (4). The latter resembles half a carotene molecule, showing Nature's economy in its use of available materials. The attachment is by the formation of a protonated Schiff's base, utilizing the  $-\text{CHO}$  group of the chromophore and the terminal  $\text{NH}_2$  group of the sidechain, a lysine residue from opsin. The free 11-*cis*-retinal molecule absorbs in the ultraviolet, but attachment to the opsin protein molecule shifts the absorption into the visible region. The rhodopsin molecules are situated in the membranes of special cells (the 'rods' and the 'cones') that cover the retina. The opsin molecule is anchored into the cell membrane by two hydrophobic groups and largely surrounds the chromophore (Fig. 13.19).

Immediately after the absorption of a photon, the 11-*cis*-retinal molecule undergoes photoisomerization into all-*trans*-retinal (5). Photoisomerization takes about 200 fs and about 67 pigment molecules isomerize for every 100 photons that are absorbed. The process occurs because the  $\pi^* \leftarrow \pi$  excitation of an electron loosens one of the  $\pi$  bonds (the one indicated by the arrow in 4), its torsional rigidity is lost, and one part of the molecule swings round into its new position. At that point, the molecule returns to its ground state, but is now trapped in its new conformation. The straightened tail of all-*trans*-retinal results in the molecule taking up more space than 11-*cis*-retinal did, so the molecule presses against the coils of the opsin molecule that surrounds it. In about 0.25–0.50 ms from the initial absorption event, the rhodopsin molecule is activated both by the isomerization of retinal and deprotonation of its Schiff's base tether to opsin, forming an intermediate known as *metarhodopsin II*.

In a sequence of biochemical events known as the *biochemical cascade*, metarhodopsin II activates the protein transducin, which in turn activates a phosphodiesterase enzyme that hydrolyses cyclic guanine monophosphate (cGMP) to GMP. The reduction in the concentration of cGMP causes ion channels, proteins that mediate the movement of ions across biological membranes (*Impact I20.2*), to close. The result is an imbalance of charge that in turn creates an electrical potential across the membrane. The pulse of electric potential travels through the optical nerve and into the optical cortex, where it is interpreted as a signal and incorporated into the web of events we call 'vision'.

**Fig. 13.19** The structure of the rhodopsin molecule, consisting of an opsin protein to which is attached an 11-*cis*-retinal molecule embedded in the space surrounded by the helical regions. Only the protein is shown.

The resting state of the rhodopsin molecule is restored by a series of nonradiative chemical events powered by ATP. The process involves the escape of all-*trans*-retinal as all-*trans*-retinol (in which  $-\text{CHO}$  has been reduced to  $-\text{CH}_2\text{OH}$ ) from the opsin molecule by a process catalysed by the enzyme rhodopsin kinase and the attachment of another protein molecule, arrestin. The free all-*trans*-retinol molecule now undergoes enzyme-catalysed isomerization into 11-*cis*-retinol followed by dehydrogenation to form 11-*cis*-retinal, which is then delivered back into an opsin molecule. At this point, the cycle of excitation, photoisomerization, and regeneration is ready to begin again.

## The fates of electronically excited states

A **radiative decay process** is a process in which a molecule discards its excitation energy as a photon. A more common fate is **nonradiative decay**, in which the excess energy is transferred into the vibration, rotation, and translation of the surrounding molecules. This thermal degradation converts the excitation energy completely into thermal motion of the environment (that is, to ‘heat’). An excited molecule may also take part in a chemical reaction, as we discuss in Chapter 22.

### 13.4 Fluorescence and phosphorescence

**Key points** (a) The rates of radiative transitions are summarized by the Einstein coefficients of stimulated and spontaneous processes. (b) Fluorescence is radiative decay between states of the same multiplicity. (c) Phosphorescence is radiative decay between states of different multiplicity and persists after the exciting radiation is removed.

In **fluorescence**, spontaneous emission of radiation occurs within a few nanoseconds after the exciting radiation is extinguished (Fig. 13.20). In **phosphorescence**, the spontaneous emission may persist for long periods (even hours, but characteristically seconds or fractions of seconds). The difference suggests that fluorescence is a fast conversion of absorbed radiation into re-emitted energy, and that phosphorescence involves the storage of energy in a reservoir from which it slowly leaks.

#### (a) Stimulated and spontaneous radiative processes

Einstein identified three contributions to the transitions between states. **Stimulated absorption** is the transition from a low energy state to one of higher energy that is driven by the electromagnetic field oscillating at the transition frequency. The transition rate,  $w$ , is the rate of change of probability of the molecule being found in the upper state. The more intense the electromagnetic field (the more intense the incident radiation), the greater the rate at which transitions are induced and hence the stronger the absorption by the sample. Einstein wrote the transition rate as

$$w = B\rho \quad \boxed{\text{Rate of stimulated absorption}} \quad (13.13)$$

The constant  $B$  is the **Einstein coefficient of stimulated absorption** and  $\rho d\nu$  is the energy density of radiation in the frequency range  $\nu$  to  $\nu + d\nu$ , where  $\nu$  is the frequency of the transition. When the molecule is exposed to black-body radiation from a source of temperature  $T$ ,  $\rho$  is given by the Planck distribution (eqn 7.8):

$$\rho = \frac{8\pi h \nu^3 / c^3}{e^{h\nu/kT} - 1} \quad (13.14)$$

**Fig. 13.20** The empirical (observation-based) distinction between fluorescence and phosphorescence is that the former is extinguished very quickly after the exciting source is removed, whereas the latter continues with relatively slowly diminishing intensity.

where the slight difference between the forms of the Planck distribution shown here and in eqn 7.8 stems from the fact that it is written here as  $\rho dv$ , and  $d\lambda = (c/v^2)dv$ .

For the time being, we can treat  $B$  as an empirical parameter that characterizes the transition: if  $B$  is large, then a given intensity of incident radiation will induce transitions strongly and the sample will be strongly absorbing. The **total rate of absorption**,  $W$ , the number of molecules excited during an interval divided by the duration of the interval, is the transition rate of a single molecule multiplied by the number of molecules  $N$  in the lower state:  $W = Nw$ .

Einstein considered that the radiation was also able to induce the molecule in the upper state to undergo a transition to the lower state, and hence to generate a photon of frequency  $\nu$ . Thus, he wrote the rate of this stimulated emission as

$$w' = B'\rho \quad \text{Rate of stimulated emission} \quad (13.15)$$

where  $B'$  is the **Einstein coefficient of stimulated emission**. Note that only radiation of the same frequency as the transition can stimulate an excited state to fall to a lower state. However, he realized that stimulated emission was not the only means by which the excited state could generate radiation and return to the lower state, and suggested that an excited state could undergo **spontaneous emission** at a rate that was independent of the intensity of the radiation (of any frequency) that is already present. Einstein therefore wrote the total rate of transition from the upper to the lower state as

$$w' = A + B'\rho \quad \text{Total rate of emission} \quad (13.16)$$

The constant  $A$  is the **Einstein coefficient of spontaneous emission**.

As we demonstrate in the following *Justification*, Einstein was able to show that the two coefficients of stimulated absorption and emission are equal, and that the coefficient of spontaneous emission is related to them by

$$A = \left( \frac{8\pi h \nu^3}{c^3} \right) B \quad B' = B \quad \text{Relation between the Einstein coefficients} \quad (13.17)$$

The important features of these equations are

- The coefficient of spontaneous emission increases as the third power of the frequency and therefore the separation in energy of the upper and lower states.
- The rates of stimulated absorption and emission between two states are the same for a given intensity of incident radiation at the transition frequency.

#### Justification 13.4 The relation between the Einstein coefficients

The expressions for the rates  $w$  and  $w'$  are for the transitions of individual molecules. The total rates of emission and absorption depend on the numbers of molecules in the two states involved in the transition. That is, the total rate of absorption is  $Nw$  and the total rate of emission is  $N'w'$ , where  $N$  is the population of the lower state and  $N'$  is the population of the upper state. At thermal equilibrium the total rates of emission and absorption are equal, so

$$NB\rho = N'(A + B'\rho)$$

This expression rearranges into

$$\rho = \frac{N'A}{NB - N'B'} = \frac{A/B}{N/N' - B'/B} = \frac{A/B}{e^{h\nu/kT} - B'/B}$$

We have used the Boltzmann expression (*Fundamentals F.5*) for the ratio of populations of states of energies  $E$  and  $E'$  in the last step:

$$\frac{N'}{N} = e^{-h\nu/kT} \quad h\nu = E' - E$$

This result has the same form as the Planck distribution (eqn 13.14), which describes the radiation density at thermal equilibrium. Indeed, when we compare the two expressions for  $\rho$ , we can conclude that the coefficients are related by eqn 13.17.

### (b) Fluorescence

Figure 13.21 shows the sequence of steps involved in fluorescence. The initial stimulated absorption takes the molecule to an excited electronic state, and if the absorption spectrum were monitored it would look like the one shown in Fig. 13.22a. The excited molecule is subjected to collisions with the surrounding molecules, and as it gives up energy nonradiatively it steps down the ladder of vibrational levels to the lowest vibrational level of the electronically excited molecular state. The surrounding molecules, however, might now be unable to accept the larger energy difference needed to lower the molecule to the ground electronic state. It might therefore survive long enough to undergo spontaneous emission and emit the remaining excess energy as radiation. The downward electronic transition is vertical (in accord with the Franck–Condon principle) and the fluorescence spectrum has a vibrational structure characteristic of the *lower* electronic state (Fig. 13.22b).

Provided they can be seen, the 0–0 absorption and fluorescence transitions can be expected to be coincident. The absorption spectrum arises from 1–0, 2–0, . . . transitions that occur at progressively higher wavenumber and with intensities governed by the Franck–Condon principle. The fluorescence spectrum arises from 0–0, 0–1, . . . *downward* transitions that occur with decreasing wavenumbers. The 0–0 absorption and fluorescence peaks are not always exactly coincident, however, because the solvent may interact differently with the solute in the ground and excited states (for instance, the hydrogen bonding pattern might differ). Because the solvent molecules do not have time to rearrange during the transition, the absorption occurs in an environment characteristic of the solvated ground state; however, the fluorescence occurs in an environment characteristic of the solvated excited state (Fig. 13.23).

Fluorescence occurs at lower frequencies (longer wavelengths) than that of the incident radiation because the emissive transition occurs after some vibrational energy has been discarded into the surroundings. The vivid oranges and greens of fluorescent dyes are an everyday manifestation of this effect: they absorb in the ultraviolet and blue, and fluoresce in the visible. The mechanism also suggests that the intensity of the fluorescence ought to depend on the ability of the solvent molecules to accept the electronic and vibrational quanta. It is indeed found that a solvent composed of molecules with widely spaced vibrational levels (such as water) can in some cases accept the large quantum of electronic energy and so extinguish, or ‘quench’, the fluorescence. The rate at which fluorescence is quenched by other molecules also gives valuable kinetic information; this important aspect of fluorescence is taken further in Section 21.10.

### (c) Phosphorescence

Figure 13.24 shows the sequence of events leading to phosphorescence for a molecule with a singlet ground state. The first steps are the same as in fluorescence, but the presence of a triplet excited state plays a decisive role. The singlet and triplet excited states share a common geometry at the point where their potential energy curves intersect. Hence, if there is a mechanism for unpairing two electron spins (and achieving the conversion of  $\uparrow\downarrow$  to  $\uparrow\uparrow$ ), the molecule may undergo **intersystem crossing**, a nonradiative

**Fig. 13.21** The sequence of steps leading to fluorescence. After the initial absorption, the upper vibrational states undergo radiationless decay by giving up energy to the surroundings. A radiative transition then occurs from the vibrational ground state of the upper electronic state.

**Fig. 13.22** An absorption spectrum (a) shows a vibrational structure characteristic of the upper state. A fluorescence spectrum (b) shows a structure characteristic of the lower state; it is also displaced to lower frequencies (but the 0–0 transitions are coincident) and resembles a mirror image of the absorption.

**Fig. 13.23** The solvent can shift the fluorescence spectrum relative to the absorption spectrum. On the left we see that the absorption occurs with the solvent (the ellipses) in the arrangement characteristic of the ground electronic state of the molecule (the sphere). However, before fluorescence occurs, the solvent molecules relax into a new arrangement, and that arrangement is preserved during the subsequent radiative transition.

**Fig. 13.24** The sequence of steps leading to phosphorescence. The important step is the intersystem crossing (ISC), the switch from a singlet state to a triplet state brought about by spin–orbit coupling. The triplet state acts as a slowly radiating reservoir because the return to the ground state is spin-forbidden.

**Fig. 13.25** A Jablonski diagram (here, for naphthalene) is a simplified portrayal of the relative positions of the electronic energy levels of a molecule. Vibrational levels of a given electronic state lie above each other, but the relative horizontal locations of the columns bear no relation to the nuclear separations in the states. The ground vibrational states of each electronic state are correctly located vertically but the other vibrational states are shown only schematically. (IC: internal conversion; ISC: intersystem crossing.)

transition between states of different multiplicity, and become a triplet state. We saw in the discussion of atomic spectra (Section 9.10d) that singlet–triplet transitions may occur in the presence of spin–orbit coupling, and the same is true in molecules. We can expect intersystem crossing to be important when a molecule contains a moderately heavy atom (such as sulfur), because then the spin–orbit coupling is large.

If an excited molecule crosses into a triplet state, it continues to deposit energy into the surroundings. However, it is now stepping down the triplet’s vibrational ladder, and at the lowest energy level it is trapped because the triplet state is at a lower energy than the corresponding singlet (recall Hund’s rule, Section 9.4d). The solvent cannot absorb the final, large quantum of electronic excitation energy, and the molecule cannot radiate its energy because return to the ground state is spin-forbidden. The radiative transition, however, is not totally forbidden because the spin–orbit coupling that was responsible for the intersystem crossing also breaks the selection rule. The molecules are therefore able to emit weakly, and the emission may continue long after the original excited state was formed.

The mechanism accounts for the observation that the excitation energy seems to get trapped in a slowly leaking reservoir. It also suggests (as is confirmed experimentally) that phosphorescence should be most intense from solid samples: energy transfer is then less efficient and intersystem crossing has time to occur as the singlet excited state steps slowly past the intersection point. The mechanism also suggests that the phosphorescence efficiency should depend on the presence of a moderately heavy atom (with strong spin–orbit coupling), which is in fact the case. The confirmation of the mechanism is the experimental observation (using the sensitive magnetic resonance techniques described in Chapter 14) that the sample is paramagnetic while the reservoir state, with its unpaired electron spins, is populated.

The various types of nonradiative and radiative transitions that can occur in molecules are often represented on a schematic **Jablonski diagram** of the type shown in Fig. 13.25.

## IMPACT ON BIOCHEMISTRY

## 113.2 Fluorescence microscopy

Fluorescence is a very important technique for the study of biological molecules. In **fluorescence microscopy**, images of biological cells at work are obtained by attaching a large number of fluorescent molecules to proteins, nucleic acids, and membranes and then measuring the distribution of fluorescence intensity within the illuminated area. Apart from a small number of co-factors, such as the chlorophylls and flavins, the majority of the building blocks of proteins and nucleic acids do not fluoresce strongly. Four notable exceptions are the amino acids tryptophan ( $\lambda_{\text{abs}} \approx 280$  nm and  $\lambda_{\text{fluor}} \approx 348$  nm in water), tyrosine ( $\lambda_{\text{abs}} \approx 274$  nm and  $\lambda_{\text{fluor}} \approx 303$  nm in water), and phenylalanine ( $\lambda_{\text{abs}} \approx 257$  nm and  $\lambda_{\text{fluor}} \approx 282$  nm in water), and the oxidized form of the sequence serine–tyrosine–glycine (6) found in the green fluorescent protein (GFP) of certain jellyfish. The wild type of GFP from *Aequora victoria* absorbs strongly at 395 nm and emits maximally at 509 nm and is commonly used as a fluorescent label.

Fluorescence microscopy has been used for many years to image biological cells, but the visualization of molecules requires creative strategies. In a conventional light microscope, an image is constructed from a pattern of diffracted light waves that emanate from the illuminated object. As a result, some information about the specimen is lost by destructive interference of scattered light waves. Ultimately, this *diffraction limit* prevents the study of samples that are much smaller than the wavelength of light used as a probe. In practice, two objects will appear as distinct images under a microscope if the distance between their centres is greater than the *Airy radius*,  $r_{\text{Airy}} = 0.61\lambda/a$ , where  $\lambda$  is the wavelength of the incident beam of radiation and  $a$  is the numerical aperture of the objective lens, the lens that collects light scattered by the object. The numerical aperture of the objective lens is defined as  $a = n_r \sin \alpha$ , where  $n_r$  is the refractive index of the lens material (the greater the refractive index, the greater the bending of a ray of light by the lens) and the angle  $\alpha$  is the half-angle of the widest cone of scattered light that can be collected by the lens (so the lens collects light beams sweeping a cone with angle  $2\alpha$ ).

Most molecules—including biological polymers—have dimensions that are much smaller than visible wavelengths, so special techniques had to be developed to make single-molecule spectroscopy possible. In **near-field scanning optical microscopy** (NSOM), a very thin metal-coated optical fibre is used to deliver light to a small area. It is possible to construct fibres with tip diameters in the range of 50 to 100 nm, which are indeed smaller than visible wavelengths. The fibre tip is placed very close to the sample, in a region known as the *near field*, where, according to classical physics, waves do not undergo diffraction. In **far-field confocal microscopy**, laser light focused by an objective lens is used to illuminate about  $1\text{ }\mu\text{m}^3$  of a very dilute sample placed beyond the near field. This illumination scheme is limited by diffraction and, as a result, data from far-field microscopy have less structural detail than data from NSOM. However, far-field microscopes are very easy to construct and the technique can be used to probe single molecules as long as there is one molecule, on average, in the illuminated area.

## 13.5 Dissociation and predissociation

**Key point** Two further fates of an electronically excited species are dissociation and internal conversion to a dissociative state.

Another fate for an electronically excited molecule is **dissociation**, the breaking of bonds (Fig. 13.26). The onset of dissociation can be detected in an absorption spectrum by seeing that the vibrational structure of a band terminates at a certain energy. Absorption occurs in a continuous band above this **dissociation limit** because the

6 The chromophore of GFP

**Fig. 13.26** When absorption occurs to unbound states of the upper electronic state, the molecule dissociates and the absorption is a continuum. Below the dissociation limit the electronic spectrum shows a normal vibrational structure.

**Fig. 13.27** When a dissociative state crosses a bound state, as in the upper part of the illustration, molecules excited to levels near the crossing may dissociate. This process is called predissociation, and is detected in the spectrum as a loss of vibrational structure that resumes at higher frequencies.

final state is an unquantized translational motion of the fragments. Locating the dissociation limit is a valuable way of determining the bond dissociation energy.

In some cases, the vibrational structure disappears but resumes at higher photon energies. This **predissociation** can be interpreted in terms of the molecular potential energy curves shown in Fig. 13.27. When a molecule is excited to a vibrational level, its electrons may undergo a redistribution that results in it undergoing an **internal conversion**, a radiationless conversion to another state of the same multiplicity. An internal conversion occurs most readily at the point of intersection of the two molecular potential energy curves, because there the nuclear geometries of the two states are the same. The state into which the molecule converts may be dissociative, so the states near the intersection have a finite lifetime and hence their energies are imprecisely defined. As a result, the absorption spectrum is blurred in the vicinity of the intersection. When the incoming photon brings enough energy to excite the molecule to a vibrational level high above the intersection, the internal conversion does not occur (the nuclei are unlikely to have the same geometry). Consequently, the levels resume their well-defined, vibrational character with correspondingly well-defined energies, and the line structure resumes on the high-frequency side of the blurred region.

### 13.6 Laser action

**Key points** (a) To achieve laser action, it is necessary to generate a population inversion. (b) The characteristics of the cavity determine the resonant modes of a laser. (c) Pulses are generated by the techniques of Q-switching and mode locking.

The word laser is an acronym formed from light amplification by stimulated emission of radiation. In stimulated emission (Section 13.4), an excited state is stimulated to emit a photon by radiation of the same frequency: the more photons that are present, the greater the probability of the emission. The essential feature of laser action is positive-feedback: the more photons present of the appropriate frequency, the more photons of that frequency that will be stimulated to form.

Laser radiation has a number of striking characteristics (Table 13.3). Each of them (sometimes in combination with the others) opens up interesting opportunities in physical chemistry. As we have seen, Raman spectroscopy has flourished on account of the high intensity monochromatic radiation available from lasers and photochemistry

**Table 13.3** Characteristics of laser radiation and their chemical applications

| Characteristic  | Advantage                                                              | Application                                                                                         |

| Coherent        | Interference between separate beams                                    | CARS (Chapter 12)                                                                                   |
| Pulsed          | Precise timing of excitation                                           | Fast reactions (Chapters 21 and 22)<br>Relaxation (Chapter 21)<br>Energy transfer (Chapter 21)      |

has enabled reactions to be studied on timescales of femtosecond and even attoseconds on account of the ultrashort pulses that lasers can generate (Section 22.4e).

Lasers lie very much on the frontier of physics and chemistry, for their operation depends on details of optics and, in some cases, of solid-state processes. In this section, we discuss the mechanisms of laser action, and then explore their applications in chemistry. We discuss the modes of operation of a number of some commonly available laser systems in *Further information 13.1*.

### (a) Population inversion

One requirement of laser action is the existence of a **metastable excited state**, an excited state with a long enough lifetime for it to participate in stimulated emission. Another requirement is the existence of a greater population in the metastable state than in the lower state where the transition terminates, for then there will be a net emission of radiation. Because at thermal equilibrium the opposite is true, it is necessary to achieve a **population inversion** in which there are more molecules in the upper state than in the lower.

One way of achieving population inversion is illustrated in Fig. 13.28. The molecule is excited to an intermediate state I, which then gives up some of its energy nonradiatively and changes into a lower state A; the laser transition is the return of A to the ground state X. Because three energy levels are involved overall, this arrangement leads to a **three-level laser**. In practice, I consists of many states, all of which can convert to the upper of the two laser states A. The  $I \leftarrow X$  transition is stimulated with an intense flash of light in the process called **pumping**. The pumping is often achieved with an electric discharge through xenon or with the light of another laser. The conversion of I to A should be rapid, and the laser transitions from A to X should be relatively slow.

The disadvantage of this three-level arrangement is that it is difficult to achieve population inversion, because so many ground-state molecules must be converted to the excited state by the pumping action. The arrangement adopted in a **four-level laser** simplifies this task by having the laser transition terminate in a state A' other than the ground state (Fig. 13.29). Because A' is unpopulated initially, any population in A corresponds to a population inversion, and we can expect laser action if A is sufficiently metastable. Moreover, this population inversion can be maintained if the  $X \leftarrow A'$  transitions are rapid, for these transitions will deplete any population in A' that stems from the laser transition, and keep the state A' relatively empty.

### (b) Cavity and mode characteristics

The laser medium is confined to a cavity that ensures that only certain photons of a particular frequency, direction of travel, and state of polarization are generated abundantly. The cavity is essentially a region between two mirrors that reflect the light back and forth. This arrangement can be regarded as a version of the particle in a box, with the particle now being a photon. As in the treatment of a particle in a box (Section 8.1), the only wavelengths that can be sustained satisfy

$$n \times \frac{1}{2} \lambda = L \quad (13.18)$$

where  $n$  is an integer and  $L$  is the length of the cavity. That is, only an integral number of half-wavelengths fit into the cavity; all other waves undergo destructive interference with themselves. In addition, not all wavelengths that can be sustained by the cavity are amplified by the laser medium (many fall outside the range of frequencies of the laser transitions), so only a few contribute to the laser radiation. These wavelengths are the **resonant modes** of the laser.

**Fig. 13.28** The transitions involved in one kind of three-level laser. The pumping pulse populates the intermediate state I, which in turn populates the laser state A. The laser transition is the stimulated emission  $A \rightarrow X$ .

**Fig. 13.29** The transitions involved in a four-level laser. Because the laser transition terminates in an excited state (A'), the population inversion between A and A' is much easier to achieve.

**Fig. 13.30** A schematic illustration of the steps leading to laser action. (a) The Boltzmann population of states, with more atoms (or molecules or ions) in the ground state. (b) When the initial state absorbs, the populations are inverted (the atoms are pumped to the excited state). (c) A cascade of radiation then occurs, as one emitted photon stimulates another atom to emit, and so on. The radiation is coherent (phases in step).

Photons with the correct wavelength for the resonant modes of the cavity and the correct frequency to stimulate the laser transition are highly amplified. One photon might be generated spontaneously and travel through the medium. It stimulates the emission of another photon, which in turn stimulates more (Fig. 13.30). The cascade of energy builds up rapidly, and soon the cavity is an intense reservoir of radiation at all the resonant modes it can sustain. Some of this radiation can be withdrawn if one of the mirrors is partially transmitting.

The resonant modes of the cavity have various natural characteristics, and to some extent may be selected. Only photons that are travelling strictly parallel to the axis of the cavity undergo more than a couple of reflections, so only they are amplified, all others simply vanishing into the surroundings. Hence, laser light generally forms a beam with very low divergence. It may also be polarized, with its electric vector in a particular plane (or in some other state of polarization), by including a polarizing filter into the cavity or by making use of polarized transitions in a solid medium.

Laser radiation is **coherent** in the sense that the electromagnetic waves are all in step. In **spatial coherence** the waves are in step across the cross-section of the beam emerging from the cavity. In **temporal coherence** the waves remain in step along the beam. The latter is normally expressed in terms of a **coherence length**,  $l_c$ , the distance over which the waves remain coherent, and is related to the range of wavelengths,  $\Delta\lambda$  present in the beam:

$$l_c = \frac{\lambda^2}{2\Delta\lambda} \quad (13.19)$$

If the beam were perfectly monochromatic, with strictly one wavelength present,  $\Delta\lambda$  would be zero and the waves would remain in step for an infinite distance. When many wavelengths are present, the waves get out of step in a short distance and the coherence length is small. A typical light bulb gives out light with a coherence length of only about 400 nm; a He–Ne laser with  $\Delta\lambda \approx 2$  pm has a coherence length of about 10 cm.

### (c) Pulsed lasers

A laser can generate radiation for as long as the population inversion is maintained. A laser can operate continuously when heat is easily dissipated, for then the population of the upper level can be replenished by pumping. When overheating is a problem, the laser can be operated only in pulses, perhaps of microsecond or millisecond duration, so that the medium has a chance to cool or the lower state discard its population. However, it is sometimes desirable to have pulses of radiation rather than a continuous output, with a lot of power concentrated into a brief pulse. One way of achieving pulses is by **Q-switching**, the modification of the resonance characteristics of the laser cavity. The name comes from the ‘Q-factor’ used as a measure of the quality of a resonance cavity in microwave engineering.

#### Example 13.2 Relating the power and energy of a laser

A laser rated at 0.10 J can generate radiation in 3.0 ns pulses at a pulse repetition rate of 10 Hz. Assuming that the pulses are rectangular, calculate the peak power output and the average power output of this laser.

**Method** The power output is the energy released in an interval divided by the duration of the interval, and is expressed in watts ( $1 \text{ W} = 1 \text{ J s}^{-1}$ ). To calculate the peak power output,  $P_{\text{peak}}$ , we divide the energy released during the pulse divided by the duration of the pulse. The average power output,  $P_{\text{average}}$ , is the total energy released by a large number of pulses divided by the duration of the time interval

over which the total energy was measured. So, the average power is simply the energy released by one pulse multiplied by the pulse repetition rate.

**Answer** From the data,

$$P_{\text{peak}} = \frac{0.10 \text{ J}}{3.0 \times 10^{-9} \text{ s}} = 3.3 \times 10^7 \text{ J s}^{-1}$$

That is, the peak power output is 33 MW. The pulse repetition rate is 10 Hz, so ten pulses are emitted by the laser in every second of operation. It follows that the average power output is

$$P_{\text{average}} = 0.10 \text{ J} \times 10 \text{ s}^{-1} = 1.0 \text{ J s}^{-1} = 1.0 \text{ W}$$

The peak power is much higher than the average power because this laser emits light for only 30 ns during each second of operation.

**Self-test 13.3** Calculate the peak power and average power output of a laser with a pulse energy of 2.0 mJ, a pulse duration of 30 ps, and a pulse repetition rate of 38 MHz.  $[P_{\text{peak}} = 67 \text{ MW}, P_{\text{average}} = 76 \text{ kW}]$

The aim of Q-switching is to achieve a healthy population inversion in the absence of the resonant cavity, then to plunge the population-inverted medium into a cavity and hence to obtain a sudden pulse of radiation. The switching may be achieved by impairing the resonance characteristics of the cavity in some way while the pumping pulse is active and then suddenly to improve them (Fig. 13.31). One technique is to use the ability of some crystals, such as those of potassium dihydrogenphosphate ( $\text{KH}_2\text{PO}_4$ ), to change their optical properties when an electrical potential difference is applied. Switching the potential on and off can store and then release energy in a laser cavity, resulting in an intense pulse of stimulated emission.

The technique of **mode locking** can produce pulses of picosecond duration and less. A laser radiates at a number of different frequencies, depending on the precise details of the resonance characteristics of the cavity and in particular on the number of half-wavelengths of radiation that can be trapped between the mirrors (the cavity modes). The resonant modes differ in frequency by multiples of  $c/2L$  (as can be inferred from eqn 13.18 with  $v = c/\lambda$ ). Normally, these modes have random phases relative to each other. However, it is possible to lock their phases together. As we show in the following *Justification*, interference then occurs to give a series of sharp peaks, and the energy of the laser is obtained in short bursts (Fig. 13.32). The sharpness of the peaks depends on the range of modes superimposed and, the wider the range, the narrower the pulses. In a laser with a cavity of length 30 cm, the peaks are separated by 2 ns. If 1000 modes contribute, the width of the pulses is 4 ps.

**Justification 13.5** *The origin of mode locking*

The general expression for a (complex) wave of amplitude  $\mathcal{E}_0$  and frequency  $\omega$  is  $\mathcal{E}_0 e^{i\omega t}$ . Therefore, each wave that can be supported by a cavity of length  $L$  has the form

$$\mathcal{E}_n(t) = \mathcal{E}_0 e^{2\pi i(\nu + nc/2L)t}$$

where  $\nu$  is the lowest frequency. A wave formed by superimposing  $N$  modes with  $n = 0, 1, \dots, N-1$  has the form

$$\mathcal{E}(t) = \sum_{n=0}^{N-1} \mathcal{E}_n(t) = \mathcal{E}_0 e^{2\pi i \nu t} \sum_{n=0}^{N-1} e^{i\pi n c t / L}$$

**Fig. 13.31** The principle of Q-switching. The excited state is populated while the cavity is nonresonant. Then the resonance characteristics are suddenly restored, and the stimulated emission emerges in a giant pulse.

**Fig. 13.32** The output of a mode-locked laser consists of a stream of very narrow pulses separated by an interval equal to the time it takes for light to make a round trip inside the cavity.

A brief comment

The sum of a geometrical progression of  $N$  terms is

$$S = 1 + x + x^2 + \dots + x^{N-1} = \frac{1 - x^N}{1 - x}$$

Note also that  $e^{ix} - e^{-ix} = 2i \sin x$ .

**Fig. 13.33** The function derived in *Justification 13.5* showing in more detail the structure of the pulses generated by a mode-locked laser.

The sum is a geometrical progression of  $N$  terms:

$$\begin{aligned} \sum_{n=0}^{N-1} e^{i n \pi c t / L} &= 1 + e^{i \pi c t / L} + e^{2 i \pi c t / L} + \dots + e^{(N-1) i \pi c t / L} \\ &= \frac{\sin(N \pi c t / 2 L)}{\sin(\pi c t / 2 L)} \times e^{(N-1) i \pi c t / 2 L} \end{aligned}$$

The intensity,  $I$ , of the radiation is proportional to the square modulus of the total amplitude, so

$$I \propto \mathcal{E}^* \mathcal{E} = \mathcal{E}_0^2 \frac{\sin^2(N \pi c t / 2 L)}{\sin^2(\pi c t / 2 L)}$$

This function is shown in Fig. 13.33. We see that it is a series of peaks with maxima separated by  $t = 2L/c$ , the round-trip transit time of the light in the cavity, and that the peaks become sharper as  $N$  is increased.

Mode locking is achieved by varying the  $Q$ -factor of the cavity periodically at the frequency  $c/2L$ . The modulation can be pictured as the opening of a shutter in synchrony with the round-trip travel time of the photons in the cavity, so only photons making the journey in that time are amplified. The modulation can be achieved by linking a prism in the cavity to a transducer driven by a radiofrequency source at a frequency  $c/2L$ . The transducer sets up standing-wave vibrations in the prism and modulates the loss it introduces into the cavity. We also see in Section 19.10c that the unique optical properties of some materials can be exploited to bring about mode-locking.

## Further information

### Further information 13.1 Examples of practical lasers

Figure 13.34 summarizes the requirements for an efficient laser. In practice, the requirements can be satisfied by using a variety of different systems, and this section reviews some that are commonly available. We also include some lasers that operate by using other than electronic transitions. Noticeably absent from this discussion are solid state lasers (including the ubiquitous diode lasers), which we discuss in Chapter 19.

**Fig. 13.34** A summary of the features needed for efficient laser action.

#### (a) Gas lasers

Because gas lasers can be cooled by a rapid flow of the gas through the cavity, they can be used to generate high powers. The pumping is normally achieved using a gas that is different from the gas responsible for the laser emission itself.

In the **helium–neon laser** the active medium is a mixture of helium and neon in a mole ratio of about 5:1 (Fig. 13.35). The initial step is the excitation of an He atom to the metastable  $1s^12s^1\ ^3S$  configuration by using an electric discharge (the collisions of electrons and ions cause transitions that are not restricted by electric-dipole selection rules). The excitation energy of this transition happens to match

**Fig. 13.35** The transitions involved in a helium–neon laser. The pumping (of the neon) depends on a coincidental matching of the helium and neon energy separations, so excited He atoms can transfer their excess energy to Ne atoms during a collision.

**Fig. 13.36** The transitions involved in an argon-ion laser.

an excitation energy of neon, and during an He–Ne collision efficient transfer of energy may occur, leading to the production of highly excited, metastable Ne atoms with unpopulated intermediate states. Laser action generating 633 nm radiation (among about 100 other lines) then occurs.

The **argon-ion laser** (Fig. 13.36), one of a number of ‘ion lasers’, consists of argon at about 1 Torr, through which is passed an electric discharge. The discharge results in the formation of  $\text{Ar}^+$  and  $\text{Ar}^{2+}$  ions in excited states, which undergo a laser transition to a lower state. These ions then revert to their ground states by emitting hard ultraviolet radiation (at 72 nm), and are then neutralized by a series of electrodes in the laser cavity. One of the design problems is to find materials that can withstand this damaging residual radiation. There are many lines in the laser transition because the excited ions may make transitions to many lower states, but two strong emissions from  $\text{Ar}^+$  are at 488 nm (blue) and 514 nm (green); other transitions occur elsewhere in the visible region, in the infrared, and in the ultraviolet. The **krypton-ion laser** works similarly. It is less efficient, but gives a wider range of wavelengths, the most intense being at 647 nm (red), but it can also generate yellow, green, and violet lines.

The **carbon dioxide laser** works on a slightly different principle (Fig. 13.37), for its radiation (between 9.2  $\mu\text{m}$  and 10.8  $\mu\text{m}$ , with the strongest emission at 10.6  $\mu\text{m}$ , in the infrared) arises from vibrational transitions. Most of the working gas is nitrogen, which becomes vibrationally excited by electronic and ionic collisions in an electric discharge. The vibrational levels happen to coincide with the ladder of antisymmetric stretch ( $\nu_2$ , see Fig. 12.37) energy levels of  $\text{CO}_2$ , which pick up the energy during a collision. Laser action then occurs from the lowest excited level of  $\nu_2$  to the lowest excited level of the symmetric stretch ( $\nu_1$ ), which has remained unpopulated during the collisions. This transition is allowed by anharmonicities in the molecular potential energy. Some helium is included in the gas to help remove energy from this state and maintain the population inversion.

In a **nitrogen laser**, the efficiency of the stimulated transition (at 337 nm, in the ultraviolet, the transition  $\text{C}^3\Pi_u \rightarrow \text{B}^3\Pi_g$ ) is so great that a single passage of a pulse of radiation is enough to generate laser radiation and mirrors are unnecessary: such lasers are said to be **superradiant**.

**Fig. 13.37** The transitions involved in a carbon dioxide laser. The pumping also depends on the coincidental matching of energy separations; in this case the vibrationally excited  $N_2$  molecules have excess energies that correspond to a vibrational excitation of the antisymmetric stretch of  $CO_2$ . The laser transition is from  $v_2 = 1$  to  $v_1 = 1$ .

### (b) Exciplex lasers

The population inversion needed for laser action is achieved in an underhand way in **exciplex lasers**, for in these (as we shall see) the lower state does not effectively exist. This odd situation is achieved by forming an **exciplex**, a combination of two atoms that survives only in an excited state and which dissociates as soon as the excitation energy has been discarded. An exciplex can be formed in a mixture of xenon, chlorine, and neon (which acts as a buffer gas). An electric discharge through the mixture produces excited Cl atoms, which attach to the Xe atoms to give the exciplex  $XeCl^*$ . The exciplex survives for about 10 ns, which is time for it to participate in laser action at 308 nm (in the ultraviolet). As soon as  $XeCl^*$  has discarded a photon, the atoms separate because the molecular potential energy curve of the ground state is dissociative, and the ground state of the exciplex cannot become populated (Fig. 13.38). The  $KrF^*$  exciplex laser is another example: it produces radiation at 249 nm.

#### A brief comment

The term ‘excimer laser’ is also widely encountered and used loosely when ‘exciplex laser’ is more appropriate. An exciplex has the form  $AB^*$ , whereas an excimer, an excited dimer, is  $AA^*$ .

### (c) Dye lasers

Gas lasers and most solid state lasers operate at discrete frequencies and, although the frequency required may be selected by suitable optics, the laser cannot be tuned continuously. The tuning problem is

**Fig. 13.38** The molecular potential energy curves for an exciplex. The species can survive only as an excited state (in this case a charge-transfer complex  $A^+B^-$ , because on discarding its energy it enters the lower, dissociative state. Because only the upper state can exist, there is never any population in the lower state.

overcome by using a titanium sapphire laser (Further information 19.1) or a **dye laser**, which has broad spectral characteristics because the solvent broadens the vibrational structure of the transitions into bands. Hence, it is possible to scan the wavelength continuously (by rotating the diffraction grating in the cavity) and achieve laser action at any chosen wavelength. A commonly used dye is Rhodamine 6G in methanol (Fig. 13.39). As the gain is very high, only a short length of the optical path need be through the dye. The excited states of the active medium, the dye, are sustained by another laser or a flash lamp, and the dye solution is flowed through the laser cavity to avoid thermal degradation.

**Fig. 13.39** The optical absorption spectrum of the dye Rhodamine 6G and the region used for laser action.

## Discussion questions

**13.1** Explain the origin of the term symbol  $^3\Sigma_g^-$  for the ground state of dioxygen.

**13.2** Explain the basis of the Franck–Condon principle and how it leads to the formation of a vibrational progression.

**13.3** How do the band heads in P and R branches arise? Could the Q branch show a head?

**13.4** Explain how colour can arise from molecules.

**13.5** Suppose that you are a colour chemist and had been asked to intensify the colour of a dye without changing the type of compound, and that the dye in question was a polyene. Would you choose to lengthen or to shorten the

chain? Would the modification to the length shift the apparent colour of the dye towards the red or the blue?

**13.6** Describe the mechanism of fluorescence. In what respects is a fluorescence spectrum not the exact mirror image of the corresponding absorption spectrum?

**13.7** The oxygen molecule absorbs ultraviolet radiation in a transition from its  $^3\Sigma_g^-$  ground electronic state to an excited state that is energetically close to a dissociative  $^5\Pi_u$  state. The absorption band has a relatively large experimental linewidth. Account for this observation.

**13.8** Describe the principles of (a) continuous-wave and (b) pulsed laser action.

## Exercises

**13.1(a)** The molar absorption coefficient of a substance dissolved in hexane is known to be  $855 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$  at 270 nm. Calculate the percentage reduction in intensity when light of that wavelength passes through 2.5 mm of a solution of concentration  $3.25 \text{ mmol dm}^{-3}$ .

**13.1(b)** The molar absorption coefficient of a substance dissolved in hexane is known to be  $327 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$  at 300 nm. Calculate the percentage reduction in intensity when light of that wavelength passes through 1.50 mm of a solution of concentration  $2.22 \text{ mmol dm}^{-3}$ .

**13.2(a)** A solution of an unknown component of a biological sample when placed in an absorption cell of path length 1.00 cm transmits 20.1 per cent of light of 340 nm incident upon it. If the concentration of the component is  $0.111 \text{ mmol dm}^{-3}$ , what is the molar absorption coefficient?

**13.2(b)** When light of wavelength 400 nm passes through 3.5 mm of a solution of an absorbing substance at a concentration  $0.667 \text{ mmol dm}^{-3}$ , the transmission is 65.5 per cent. Calculate the molar absorption coefficient of the solute at this wavelength and express the answer in  $\text{cm}^2 \text{ mol}^{-1}$ .

**13.3(a)** The molar absorption coefficient of a solute at 540 nm is  $286 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ . When light of that wavelength passes through a 6.5 mm cell containing a solution of the solute, 46.5 per cent of the light was absorbed. What is the concentration of the solution?

**13.3(b)** The molar absorption coefficient of a solute at 440 nm is  $323 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ . When light of that wavelength passes through a 7.50 mm cell containing a solution of the solute, 52.3 per cent of the light was absorbed. What is the concentration of the solution?

**13.4(a)** The absorption associated with a particular transition begins at 230 nm, peaks sharply at 260 nm, and ends at 290 nm. The maximum value of the molar absorption coefficient is  $1.21 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ . Estimate the integrated absorption coefficient of the transition assuming a triangular lineshape.

**13.4(b)** The absorption associated with a certain transition begins at 199 nm, peaks sharply at 220 nm, and ends at 275 nm. The maximum value of the molar absorption coefficient is  $2.25 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ . Estimate the integrated absorption coefficient of the transition assuming an inverted parabolic lineshape (Fig. 13.40).

Fig. 13.40

**13.5(a)** The following data were obtained for the absorption by  $\text{Br}_2$  in carbon tetrachloride using a 2.0 mm cell. Calculate the molar absorption coefficient of bromine at the wavelength employed:

|                                      |        |        |        |                      |
|--------------------------------------|--------|--------|--------|----------------------|
| $[\text{Br}_2]/(\text{mol dm}^{-3})$ | 0.0010 | 0.0050 | 0.0100 | 0.0500               |
| $T/(\text{per cent})$                | 81.4   | 35.6   | 12.7   | $3.0 \times 10^{-3}$ |

**13.5(b)** The following data were obtained for the absorption by a dye dissolved in methylbenzene using a 2.50 mm cell. Calculate the molar absorption coefficient of the dye at the wavelength employed:

|                                     |        |        |        |                       |
|-------------------------------------|--------|--------|--------|-----------------------|
| $[\text{dye}]/(\text{mol dm}^{-3})$ | 0.0010 | 0.0050 | 0.0100 | 0.0500                |
| $T/(\text{per cent})$               | 73     | 21     | 4.2    | $1.33 \times 10^{-5}$ |

**13.6(a)** A 2.0-mm cell was filled with a solution of benzene in a non-absorbing solvent. The concentration of the benzene was  $0.010 \text{ mol dm}^{-3}$  and the wavelength of the radiation was 256 nm (where there is a maximum in the absorption). Calculate the molar absorption coefficient of benzene at this wavelength given that the transmission was 48 per cent. What will the transmittance be in a 4.0-mm cell at the same wavelength?

**13.6(b)** A 2.50-mm cell was filled with a solution of a dye. The concentration of the dye was  $15.5 \text{ mmol dm}^{-3}$ . Calculate the molar absorption coefficient of

benzene at this wavelength given that the transmission was 32 per cent. What will the transmittance be in a 4.50-mm cell at the same wavelength?

**13.7(a)** A swimmer enters a gloomier world (in one sense) on diving to greater depths. Given that the mean molar absorption coefficient of sea water in the visible region is  $6.2 \times 10^{-3} \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ , calculate the depth at which a diver will experience (a) half the surface intensity of light, (b) one-tenth the surface intensity.

**13.7(b)** Given that the maximum molar absorption coefficient of a molecule containing a carbonyl group is  $30 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$  near 280 nm, calculate the thickness of a sample that will result in (a) half the initial intensity of radiation, (b) one-tenth the initial intensity.

**13.8(a)** The electronic absorption bands of many molecules in solution have half-widths at half-height of about  $5000 \text{ cm}^{-1}$ . Estimate the integrated absorption coefficients of bands for which (a)  $\epsilon_{\text{max}} \approx 1 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ , (b)  $\epsilon_{\text{max}} \approx 5 \times 10^2 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ .

**13.8(b)** The electronic absorption band of a compound in solution had a Gaussian lineshape and a half-width at half-height of  $4233 \text{ cm}^{-1}$  and  $\epsilon_{\text{max}} = 1.54 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ . Estimate the integrated absorption coefficient.

**13.9(a)** The term symbol for one of the excited states of  $\text{H}_2$  is  $^3\Pi_u$ . Use the building-up principle to find the excited-state configuration to which this term symbol corresponds.

**13.9(b)** The term symbol for the ground state of  $\text{N}_2^+$  is  $^2\Pi_g$ . Use the building-up principle to find the excited-state configuration to which this term symbol corresponds.

**13.10(a)** One of the excited states of the  $\text{C}_2$  molecule has the valence electron configuration  $1\sigma_g^2 1\sigma_u^2 1\pi_u^2 1\pi_g^1$ . Give the multiplicity and parity of the term.

**13.10(b)** One of the excited states of the  $\text{C}_2$  molecule has the valence electron configuration  $1\sigma_g^2 1\sigma_u^2 1\pi_u^2 1\pi_g^2$ . Give the multiplicity and parity of the term.

**13.11(a)** Which of the following transitions are electric-dipole allowed? (a)  $^2\Pi \leftrightarrow ^2\Pi$ , (b)  $^1\Sigma \leftrightarrow ^1\Sigma$ , (c)  $\Sigma \leftrightarrow \Delta$ , (d)  $\Sigma^+ \leftrightarrow \Sigma^-$ , (e)  $\Sigma^+ \leftrightarrow \Sigma^+$ .

**13.11(b)** Which of the following transitions are electric-dipole allowed? (a)  $^1\Sigma_g^+ \leftrightarrow ^1\Sigma_u^+$ , (b)  $^3\Sigma_g^+ \leftrightarrow ^3\Sigma_u^+$ , (c)  $t_{2g} \leftrightarrow e_g$ , (d)  $\pi^* \leftrightarrow n$ .

**13.12(a)** The ground-state wavefunction of a certain molecule is described by the vibrational wavefunction  $\psi_0 = N_0 e^{-ax^2}$ . Calculate the Franck–Condon factor for a transition to a vibrational state described by the wavefunction  $\psi'_0 = N'_0 e^{-b(x-x_0)^2}$ , with  $b = a/2$ .

**13.12(b)** The ground-state wavefunction of a certain molecule is described by the vibrational wavefunction  $\psi_0 = N_0 e^{-ax^2}$ . Calculate the Franck–Condon factor for a transition to a vibrational state described by the wavefunction  $\psi'_1 = N'_1 x e^{-b(x-x_0)^2}$ , with  $b = a/2$ .

**13.13(a)** The following parameters describe the electronic ground state and an excited electronic state of  $\text{SnO}$ :  $\tilde{B} = 0.3540 \text{ cm}^{-1}$ ,  $\tilde{B}' = 0.3101 \text{ cm}^{-1}$ . Which branch of the transition between them shows a head? At what value of  $J$  will it occur?

**13.13(b)** The following parameters describe the electronic ground state and an excited electronic state of  $\text{BeH}$ :  $\tilde{B} = 10.308 \text{ cm}^{-1}$ ,  $\tilde{B}' = 10.470 \text{ cm}^{-1}$ . Which branch of the transition between them shows a head? At what value of  $J$  will it occur?

**13.14(a)** The R-branch of the  $^1\Pi_u \leftarrow ^1\Sigma_g^+$  transition of  $\text{H}_2$  shows a band head at the very low value of  $J = 1$ . The rotational constant of the ground state is  $60.80 \text{ cm}^{-1}$ . What is the rotational constant of the upper state? Has the bond length increased or decreased in the transition?

**13.14(b)** The P-branch of the  $^2\Pi \leftarrow ^2\Sigma^+$  transition of  $\text{CdH}$  shows a band head at  $J = 25$ . The rotational constant of the ground state is  $5.437 \text{ cm}^{-1}$ . What is the

rotational constant of the upper state? Has the bond length increased or decreased in the transition?

**13.15(a)** The two compounds 2,3-dimethyl-2-butene (7) and 2,5-dimethyl-2,4-hexadiene (8) are to be distinguished by their ultraviolet absorption spectra. The maximum absorption in one compound occurs at 192 nm and in the other at 243 nm. Match the maxima to the compounds and justify the assignment.

7 2,3-Dimethyl-2-butene

8 2,5-Dimethyl-2,4-hexadiene

**13.15(b)** 1,3,5-hexatriene (a kind of 'linear' benzene) was converted into benzene itself. On the basis of a free-electron molecular orbital model (in which hexatriene is treated as a linear box and benzene as a ring), would you expect the lowest energy absorption to rise or fall in energy?

**13.16(a)** The compound  $\text{CH}_3\text{CH}=\text{CHCHO}$  has a strong absorption in the ultraviolet at  $46\,950 \text{ cm}^{-1}$  and a weak absorption at  $30\,000 \text{ cm}^{-1}$ . Justify these features and assign the ultraviolet absorption transitions.

**13.16(b)** 3-Buten-2-one (9) has a strong absorption at 213 nm and a weaker absorption at 320 nm. Justify these features and assign the ultraviolet absorption transitions.

9 3-Buten-2-one

**13.17(a)** The complex ion  $[\text{Fe}(\text{OH}_2)_6]^{3+}$  has an electronic absorption spectrum with a maximum at 700 nm. Estimate a value of  $\Delta_O$  for the complex.

**13.17(b)** The complex ion  $[\text{Fe}(\text{CN})_6]^{3-}$  has an electronic absorption spectrum with a maximum at 305 nm. Estimate a value of  $\Delta_O$  for the complex.

**13.18(a)** The line marked A in Fig. 13.41 is the fluorescence spectrum of benzophenone in solid solution in ethanol at low temperatures observed when the sample is illuminated with 360 nm light. What can be said about the vibrational energy levels of the carbonyl group in (a) its ground electronic state and (b) its excited electronic state?

**13.18(b)** When naphthalene is illuminated with 360 nm light it does not absorb, but the line marked B in Fig 13.41 is the phosphorescence spectrum of a solid solution of a mixture of naphthalene and benzophenone in ethanol.

Fig. 13.41

Now a component of fluorescence from naphthalene can be detected. Account for this observation.

**13.19(a)** Consider a laser cavity of length 30 cm. What are the allowed wavelengths and frequencies of the resonant modes?

**13.19(b)** Consider a laser cavity of length 1.0 m. What are the allowed wavelengths and frequencies of the resonant modes?

**13.20(a)** A pulsed laser rated at 0.10 mJ can generate radiation with peak power output of 5.0 MW and average power output of 7.0 kW. What are the pulse duration and repetition rate?

**13.20(b)** A pulsed laser rated at 20.0  $\mu\text{J}$  can generate radiation with peak power output of 100 kW and average power output of 0.40 mW. What are the pulse duration and repetition rate?

**13.21(a)** Use mathematical software or an electronic spreadsheet to simulate the output of a mode-locked laser (that is, plots such as that shown in Fig. 13.33) for  $L = 30$  cm and  $N = 100$  and 1000.

**13.21(b)** Use mathematical software or an electronic spreadsheet to simulate the output of a mode-locked laser (that is, plots such as that shown in Fig. 13.33) for  $L = 1.0$  cm and  $N = 50$  and 500.

## Problems\*

### Numerical problems

**13.1** The vibrational wavenumber of the oxygen molecule in its electronic ground state is  $1580\text{ cm}^{-1}$ , whereas that in the first excited state ( $B\ ^3\Sigma_u^-$ ), to which there is an allowed electronic transition, is  $700\text{ cm}^{-1}$ . Given that the separation in energy between the minima in their respective potential energy curves of these two electronic states is 6.175 eV, what is the wavenumber of the lowest energy transition in the band of transitions originating from the  $v = 0$  vibrational state of the electronic ground state to this excited state? Ignore any rotational structure or anharmonicity.

**13.2** We are now ready to understand more deeply the features of photoelectron spectra (Section 10.4e). The highest kinetic energy electrons in the photoelectron spectrum of  $\text{H}_2\text{O}$  using 21.22 eV radiation are at about 12–13 eV and show a large vibrational spacing of 0.41 eV. The symmetric stretching mode of the neutral  $\text{H}_2\text{O}$  molecule lies at  $3652\text{ cm}^{-1}$ . (a) What conclusions can be drawn from the nature of the orbital from which the electron is ejected? (b) In the same spectrum of  $\text{H}_2\text{O}$ , the band near 7.0 eV shows a long vibrational series with spacing 0.125 eV. The bending mode of  $\text{H}_2\text{O}$  lies at  $1596\text{ cm}^{-1}$ . What conclusions can you draw about the characteristics of the orbital occupied by the photoelectron?

**13.3** The electronic spectrum of the IBr molecule shows two low-lying, well-defined convergence limits at  $14\,660$  and  $18\,345\text{ cm}^{-1}$ . Energy levels for the iodine and bromine atoms occur at  $0$ ,  $7598$ ; and  $0$ ,  $3685\text{ cm}^{-1}$ , respectively. Other atomic levels are at much higher energies. What possibilities exist for the numerical value of the dissociation energy of IBr? Decide which is the correct possibility by calculating this quantity from  $\Delta_f H^\circ(\text{IBr(g)}) = +40.79\text{ kJ mol}^{-1}$  and the dissociation energies of  $\text{I}_2(\text{g})$  and  $\text{Br}_2(\text{g})$  which are  $146$  and  $190\text{ kJ mol}^{-1}$ , respectively.

**13.4** In many cases it is possible to assume that an absorption band has a Gaussian lineshape (one proportional to  $e^{-x^2}$ ) centred on the band maximum. Assume such a lineshape, and show that  $\mathcal{A} \approx 1.0645 \epsilon_{\text{max}} \Delta \tilde{\nu}_{1/2}$ , where  $\Delta \tilde{\nu}_{1/2}$  is the width at half-height. The absorption spectrum of azoethane ( $\text{CH}_3\text{CH}_2\text{N}_2$ ) between  $24\,000\text{ cm}^{-1}$  and  $34\,000\text{ cm}^{-1}$  is shown in Fig. 13.42. First, estimate  $\mathcal{A}$  for the band by assuming that it is Gaussian. Then integrate the absorption band graphically. The latter can be done either by ruling and counting squares, or by tracing the line shape on to paper and weighing. A more sophisticated procedure would be to use mathematical software to fit a polynomial to the absorption band (or a Gaussian), and then to integrate the result analytically.

**13.5** A lot of information about the energy levels and wavefunctions of small inorganic molecules can be obtained from their ultraviolet spectra. An example of a spectrum with considerable vibrational structure, that of

Fig. 13.42

gaseous  $\text{SO}_2$  at  $25^\circ\text{C}$ , is shown in Fig. 13.6. Estimate the integrated absorption coefficient for the transition. What electronic states are accessible from the  $A_1$  ground state of this  $C_{2v}$  molecule by electric dipole transitions?

**13.6‡** J.G. Dojahn *et al.* (*J. Phys. Chem.* **100**, 9649 (1996)) characterized the potential energy curves of the ground and electronic states of homonuclear diatomic halogen anions. These anions have a  $^2\Sigma_u^+$  ground state and  $^2\Pi_g$ ,  $^2\Pi_u$ , and  $^2\Sigma_g^+$  excited states. To which of the excited states are transitions by absorption of photons allowed? Explain.

**13.7** A transition of particular importance in  $\text{O}_2$  gives rise to the ‘Schumann–Runge band’ in the ultraviolet region. The wavenumbers (in  $\text{cm}^{-1}$ ) of transitions from the ground state to the vibrational levels of the first excited state ( $^3\Sigma_u^-$ ) are  $50\,062.6$ ,  $50\,725.4$ ,  $51\,369.0$ ,  $51\,988.6$ ,  $52\,579.0$ ,  $53\,143.4$ ,  $53\,679.6$ ,  $54\,177.0$ ,  $54\,641.8$ ,  $55\,078.2$ ,  $55\,460.0$ ,  $55\,803.1$ ,  $56\,107.3$ ,  $56\,360.3$ ,  $56\,570.6$ . What is the dissociation energy of the upper electronic state? (Use a Birge–Sponer plot.) The same excited state is known to dissociate into one ground state O atom and one excited state atom with an energy  $190\text{ kJ mol}^{-1}$  above the ground state. (This excited atom is responsible for a great deal of photochemical mischief in the atmosphere.) Ground state  $\text{O}_2$  dissociates into two ground-state atoms. Use this information to calculate the dissociation energy of ground-state  $\text{O}_2$  from the Schumann–Runge data.

**13.8** Suppose that we can model a charge-transfer transition in a one-dimensional system as a process in which a rectangular wavefunction that is nonzero in the range  $0 \leq x \leq a$  makes a transition to another rectangular

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp and Carmen Giunta.

wavefunction that is nonzero in the range  $\frac{1}{2}a \leq x \leq b$ . Evaluate the transition moment  $\int \psi_0^* x \psi_1 dx$ .

**13.9** Aromatic hydrocarbons and  $I_2$  form complexes from which charge-transfer electronic transitions are observed. The hydrocarbon acts an electron donor and  $I_2$  as an electron acceptor. The energies  $h\nu_{\max}$  of the charge transfer transitions for a number of hydrocarbon– $I_2$  complexes are given below:

| Hydrocarbon             | benzene | biphenyl | naphthalene | phenanthrene | pyrene | anthracene |
|-------------------------|---------|----------|-------------|--------------|--------|------------|
| $h\nu_{\max}/\text{eV}$ | 4.184   | 3.654    | 3.452       | 3.288        | 2.989  | 2.890      |

Investigate the hypothesis that there is a correlation between the energy of the HOMO of the hydrocarbon (from which the electron comes in the charge-transfer transition) and  $h\nu_{\max}$ . Use one of the molecular electronic structure methods discussed in Chapter 10 to determine the energy of the HOMO of each hydrocarbon in the data set.

**13.10** A certain molecule fluoresces at a wavelength of 400 nm with a half-life of 1.0 ns. It phosphoresces at 500 nm. If the ratio of the transition probabilities for stimulated emission for the  $S^* \rightarrow S$  to the  $T \rightarrow S$  transitions is  $1.0 \times 10^5$ , what is the half-life of the phosphorescent state?

**13.11** The fluorescence spectrum of anthracene vapour shows a series of peaks of increasing intensity with individual maxima at 440 nm, 410 nm, 390 nm, and 370 nm followed by a sharp cut-off at shorter wavelengths. The absorption spectrum rises sharply from zero to a maximum at 360 nm with a trail of peaks of lessening intensity at 345 nm, 330 nm, and 305 nm. Account for these observations.

**13.12** Consider some of the precautions that must be taken when conducting fluorescence microscopy experiments with the aim of detecting single molecules. (a) What is the molar concentration of a solution in which there is, on average, one solute molecule in  $1.0 \mu\text{m}^3$  (1.0 fL) of solution? (b) It is important to use pure solvents in single-molecule spectroscopy because optical signals from fluorescent impurities in the solvent may mask optical signals from the solute. Suppose that water containing a fluorescent impurity of molar mass  $100 \text{ g mol}^{-1}$  is used as solvent and that analysis indicates the presence of 0.10 mg of impurity per 1.0 kg of solvent. On average, how many impurity molecules will be present in  $1.0 \mu\text{m}^3$  of solution? You may take the density of water as  $1.0 \text{ g cm}^{-3}$ . Comment on the suitability of this solvent for single-molecule spectroscopy experiments.

**13.13** Light-induced degradation of molecules, also called *photobleaching*, is a serious problem in fluorescence microscopy. A molecule of a fluorescent dye commonly used to label biopolymers can withstand about  $10^6$  excitations by photons before light-induced reactions destroy its  $\pi$  system and the molecule no longer fluoresces. For how long will a single dye molecule fluoresce while being excited by 1.0 mW of 488 nm radiation from a continuous-wave argon ion laser? You may assume that the dye has an absorption spectrum that peaks at 488 nm and that every photon delivered by the laser is absorbed by the molecule.

### Theoretical problems

**13.14** It is common to make measurements of absorbance at two wavelengths and use them to find the individual concentrations of two components A and B in a mixture. Show that the molar concentrations of A and B are

$$[A] = \frac{\epsilon_{B2}A_1 - \epsilon_{B1}A_2}{(\epsilon_{A1}\epsilon_{B2} - \epsilon_{A2}\epsilon_{B1})l} \quad [B] = \frac{\epsilon_{A1}A_2 - \epsilon_{A2}A_1}{(\epsilon_{A1}\epsilon_{B2} - \epsilon_{A2}\epsilon_{B1})l}$$

where  $A_1$  and  $A_2$  are absorbances of the mixture at wavelengths  $\lambda_1$  and  $\lambda_2$ , and the molar extinction coefficients of A (and B) at these wavelengths are  $\epsilon_{A1}$  and  $\epsilon_{A2}$  (and  $\epsilon_{B1}$  and  $\epsilon_{B2}$ ).

**13.15** When pyridine is added to a solution of iodine in carbon tetrachloride the 520 nm band of absorption shifts toward 450 nm. However, the absorbance of the solution at 490 nm remains constant: this feature is called

an *isosbestic point*. Show that an isosbestic point should occur when two absorbing species are in equilibrium.

**13.16** Spin angular momentum is conserved when a molecule dissociates into atoms. What atom multiplicities are permitted when (a) an  $O_2$  molecule, (b) an  $N_2$  molecule dissociates into atoms?

**13.17** Assume that the electronic states of the  $\pi$  electrons of a conjugated molecule can be approximated by the wavefunctions of a particle in a one-dimensional box, and that the dipole moment can be related to the displacement along this length by  $\mu = -ex$ . Show that the transition probability for the transition  $n = 1 \rightarrow n = 2$  is nonzero, whereas that for  $n = 1 \rightarrow n = 3$  is zero. *Hint.* The following relations will be useful:

$$\sin x \sin y = \frac{1}{2} \cos(x - y) - \frac{1}{2} \cos(x + y)$$

$$\int x \cos ax \, dx = \frac{1}{a^2} \cos ax + \frac{x}{a} \sin ax$$

**13.18** Use a group theoretical argument to decide which of the following transitions are electric-dipole allowed: (a) the  $\pi^* \leftarrow \pi$  transition in ethene, (b) the  $\pi^* \leftarrow n$  transition in a carbonyl group in a  $C_{2v}$  environment.

**13.19** Estimate the transition dipole moment of a charge-transfer transition modelled as the migration of an electron from a H1s orbital on one atom to another H1s orbital on an atom a distance  $R$  away. Approximate the transition moment by  $-eRS$  where  $S$  is the overlap integral of the two orbitals. Sketch the oscillator strength as a function of  $R$  using the curve for  $S$  given in Fig. 10.29. Why does the intensity fall to zero as  $R$  approaches zero and infinity?

**13.20** The Beer–Lambert law states that the absorbance of a sample at a wavenumber  $\tilde{\nu}$  is proportional to the molar concentration  $[J]$  of the absorbing species  $J$  and to the length  $L$  of the sample (eqn 13.4). In this problem you will show that the intensity of fluorescence emission from a sample of  $J$  is also proportional to  $[J]$  and  $L$ . Consider a sample of  $J$  that is illuminated with a beam of intensity  $I_0(\tilde{\nu})$  at the wavenumber  $\tilde{\nu}$ . Before fluorescence can occur, a fraction of  $I_0(\tilde{\nu})$  must be absorbed and an intensity  $I(\tilde{\nu})$  will be transmitted. However, not all of the absorbed intensity is emitted and the intensity of fluorescence depends on the fluorescence quantum yield,  $\phi_f$ , the efficiency of photon emission. The fluorescence quantum yield ranges from 0 to 1 and is proportional to the ratio of the integral of the fluorescence spectrum over the integrated absorption coefficient. Because of a Stokes shift of magnitude  $\Delta\tilde{\nu}_{\text{Stokes}}$ , fluorescence occurs at a wavenumber  $\tilde{\nu}_f$ , with  $\tilde{\nu}_f + \Delta\tilde{\nu}_{\text{Stokes}} = \tilde{\nu}$ . It follows that the fluorescence intensity at  $\tilde{\nu}_f$ ,  $I_f(\tilde{\nu}_f)$ , is proportional to  $\phi_f$  and to the intensity of exciting radiation that is absorbed by  $J$ ,  $I_{\text{abs}}(\tilde{\nu}) = I_0(\tilde{\nu}) - I(\tilde{\nu})$ . (a) Use the Beer–Lambert law to express  $I_{\text{abs}}(\tilde{\nu})$  in terms of  $I_0(\tilde{\nu})$ ,  $[J]$ ,  $L$ , and  $\epsilon(\tilde{\nu})$ , the molar absorption coefficient of  $J$  at  $\tilde{\nu}$ . (b) Use your result from part (a) to show that  $I_f(\tilde{\nu}_f) \propto I_0(\tilde{\nu})\epsilon(\tilde{\nu})\phi_f[J]L$ .

### Applications: to biochemistry, environmental science, and astrophysics

**13.21** The protein haemerythrin (Her) is responsible for binding and carrying  $O_2$  in some invertebrates. Each protein molecule has two  $Fe^{2+}$  ions that are in very close proximity and work together to bind one molecule of  $O_2$ . The  $Fe_2O_2$  group of oxygenated haemerythrin is coloured and has an electronic absorption band at 500 nm. Figure 13.43 shows the UV-visible absorption spectrum of a derivative of haemerythrin in the presence of different concentrations of  $CNS^-$  ions. What may be inferred from the spectrum?

**13.22** The flux of visible photons reaching Earth from the North Star is about  $4 \times 10^3 \text{ mm}^{-2} \text{ s}^{-1}$ . Of these photons, 30 per cent are absorbed or scattered by the atmosphere and 25 per cent of the surviving photons are scattered by the surface of the cornea of the eye. A further 9 per cent are absorbed inside the cornea. The area of the pupil at night is about  $40 \text{ mm}^2$  and the response time of the eye is about 0.1 s. Of the photons passing through the pupil, about 43 per cent are absorbed in the ocular medium. How many photons from the

Fig. 13.43

North Star are focused on to the retina in 0.1 s? For a continuation of this story, see R.W. Rodieck, *The first steps in seeing*, Sinauer, Sunderland (1998).

**13.23** Use molecule (10) as a model of the *trans* conformation of the chromophore found in rhodopsin. In this model, the methyl group bound to the nitrogen atom of the protonated Schiff's base replaces the protein. (a) Using molecular modelling software and the computational method of your instructor's choice, calculate the energy separation between the HOMO and LUMO of (10). (b) Repeat the calculation for the 11-*cis* form of (10). (c) Based on your results from parts (a) and (b), do you expect the experimental frequency for the  $\pi^* \leftarrow \pi$  visible absorption of the *trans* form of (10) to be higher or lower than that for the 11-*cis* form of (10)?

10

**13.24‡** Ozone absorbs ultraviolet radiation in a part of the electromagnetic spectrum energetic enough to disrupt DNA in biological organisms and that is absorbed by no other abundant atmospheric constituent. This spectral range, denoted UV-B, spans the wavelengths of about 290 nm to 320 nm. The molar extinction coefficient of ozone over this range is given in the table below (W.B. DeMore *et al.*, *Chemical kinetics and photochemical data for use in stratospheric modeling: Evaluation Number 11*, JPL Publication 94–26 (1994).)

| $\lambda/\text{nm}$                                       | 292.0 | 296.3 | 300.8 | 305.4 | 310.1 | 315.0 | 320.0 |
|-----------------------------------------------------------|-------|-------|-------|-------|-------|-------|-------|
| $\epsilon/(\text{dm}^3 \text{ mol}^{-1} \text{ cm}^{-1})$ | 1512  | 865   | 477   | 257   | 135.9 | 69.5  | 34.5  |

Compute the integrated absorption coefficient of ozone over the wavelength range 290–320 nm. (Hint:  $\epsilon(\tilde{\nu})$  can be fitted to an exponential function quite well.)

**13.25‡** The abundance of ozone is typically inferred from measurements of UV absorption and is often expressed in terms of *Dobson units* (DU): 1 DU is equivalent to a layer of pure ozone  $10^{-3}$  cm thick at 1 atm and 0°C. Compute the absorbance of UV radiation at 300 nm expected for an ozone abundance of 300 DU (a typical value) and 100 DU (a value reached during seasonal Antarctic ozone depletions) given a molar absorption coefficient of  $476 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ .

**13.26‡** G.C.G. Wachewsky *et al.* (*J. Phys. Chem.* **100**, 11559 (1996)) examined the UV absorption spectrum of  $\text{CH}_3\text{I}$ , a species of interest in connection with stratospheric ozone chemistry. They found the integrated absorption coefficient to be dependent on temperature and pressure to an extent inconsistent with internal structural changes in isolated  $\text{CH}_3\text{I}$  molecules; they explained the changes as due to dimerization of a substantial fraction of the  $\text{CH}_3\text{I}$ , a process which would naturally be pressure- and temperature-dependent. (a) Compute the integrated absorption coefficient over a triangular lineshape in the range  $31\,250$  to  $34\,483 \text{ cm}^{-1}$  and a maximal molar absorption coefficient of  $150 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$  at  $31\,250 \text{ cm}^{-1}$ . (b) Suppose 1 per cent of the  $\text{CH}_3\text{I}$  units in a sample at 2.4 Torr and 373 K exists as dimers. Compute the absorbance expected at  $31\,250 \text{ cm}^{-1}$  in a sample cell of length 12.0 cm. (c) Suppose 18 per cent of the  $\text{CH}_3\text{I}$  units in a sample at 100 Torr and 373 K exists as dimers. Compute the absorbance expected at  $31\,250 \text{ cm}^{-1}$  in a sample cell of length 12.0 cm; compute the molar absorption coefficient that would be inferred from this absorbance if dimerization was not considered.

**13.27‡** The molecule  $\text{Cl}_2\text{O}_2$  is believed to participate in the seasonal depletion of ozone over Antarctica. M. Schwell *et al.* (*J. Phys. Chem.* **100**, 10070 (1996)) measured the ionization energies of  $\text{Cl}_2\text{O}_2$  by photoelectron spectroscopy in which the ionized fragments were detected using a mass spectrometer. From their data, we can infer that the ionization enthalpy of  $\text{Cl}_2\text{O}_2$  is 11.05 eV and the enthalpy of the dissociative ionization  $\text{Cl}_2\text{O}_2 \rightarrow \text{Cl} + \text{OClO}^+ + e^-$  is 10.95 eV. They used this information to make some inferences about the structure of  $\text{Cl}_2\text{O}_2$ . Computational studies had suggested that the lowest energy isomer is  $\text{ClOOCl}$ , but that  $\text{ClClO}_2$  ( $C_{2v}$ ) and  $\text{ClOClO}$  are not very much higher in energy. The  $\text{Cl}_2\text{O}_2$  in the photoionization step is the lowest energy isomer, whatever its structure may be, and its enthalpy of formation had previously been reported as  $+133 \text{ kJ mol}^{-1}$ . The  $\text{Cl}_2\text{O}_2$  in the dissociative ionization step is unlikely to be  $\text{ClOOCl}$ , for the product can be derived from it only with substantial rearrangement. Given  $\Delta_f H^\circ(\text{OClO}^+) = +1096 \text{ kJ mol}^{-1}$  and  $\Delta_f H^\circ(e^-) = 0$ , determine whether the  $\text{Cl}_2\text{O}_2$  in the dissociative ionization is the same as that in the photoionization. If different, how much greater is its  $\Delta_f H^\circ$ ? Are these results consistent with or contradictory to the computational studies?

**13.28‡** One of the principal methods for obtaining the electronic spectra of unstable radicals is to study the spectra of comets, which are almost entirely due to radicals. Many radical spectra have been found in comets, including that due to CN. These radicals are produced in comets by the absorption of far ultraviolet solar radiation by their parent compounds. Subsequently, their fluorescence is excited by sunlight of longer wavelength. The spectra of comet Hale–Bopp (C/1995 O1) have been the subject of many recent studies. One such study is that of the fluorescence spectrum of CN in the comet at large heliocentric distances by R.M. Wagner and D.G. Schleicher (*Science* **275**, 1918 (1997)), in which the authors determine the spatial distribution and rate of production of CN in the coma. The (0–0) vibrational band is centred on 387.6 nm and the weaker (1–1) band with relative intensity 0.1 is centred on 386.4 nm. The band heads for (0–0) and (0–1) are known to be 388.3 and 421.6 nm, respectively. From these data, calculate the energy of the excited  $S_1$  state relative to the ground  $S_0$  state, the vibrational wavenumbers and the difference in the vibrational wavenumbers of the two states, and the relative populations of the  $v = 0$  and  $v = 1$  vibrational levels of the  $S_1$  state. Also estimate the effective temperature of the molecule in the excited  $S_1$  state. Only eight rotational levels of the  $S_1$  state are thought to be populated. Is that observation consistent with the effective temperature of the  $S_1$  state?

Problems

One of the most widely used spectroscopic procedures in chemistry makes use of the classical concept of resonance. The chapter begins with an account of conventional nuclear magnetic resonance, which shows how the resonance frequency of a magnetic nucleus is affected by its electronic environment and the presence of magnetic nuclei in its vicinity. Then we turn to the modern versions of NMR, which are based on the use of pulses of electromagnetic radiation and the processing of the resulting signal by Fourier transform techniques. The experimental techniques for electron paramagnetic resonance resemble those used in the early days of NMR. The information obtained is used to investigate species with unpaired electrons.

When two pendulums share a slightly flexible support and one is set in motion, the other is forced into oscillation by the motion of the common axle. As a result, energy flows between the two pendulums. The energy transfer occurs most efficiently when the frequencies of the two pendulums are identical. The condition of strong effective coupling when the frequencies of two oscillators are identical is called **resonance**. Resonance is the basis of a number of everyday phenomena, including the response of radios to the weak oscillations of the electromagnetic field generated by a distant transmitter. Historically, spectroscopic techniques that measure transitions between nuclear and electron spin states have carried the term ‘resonance’ in their names because they have depended on matching a set of energy levels to a source of monochromatic radiation and observing the strong absorption that occurs at resonance.

## The effect of magnetic fields on electrons and nuclei

The Stern–Gerlach experiment (Section 8.8) provided evidence for electron spin. It turns out that many nuclei also possess spin angular momentum. Orbital and spin angular momenta give rise to magnetic moments, and to say that electrons and nuclei have magnetic moments means that, to some extent, they behave like small bar magnets with energies that depend on their orientation in an applied magnetic field. First, we establish how the energies of electrons and nuclei depend on the applied field. Then we see how to use this dependence to study the structure and dynamics of complex molecules.

## 14.1 The energies of electrons in magnetic fields

**Key points** Electrons interact with magnetic fields, which remove the degeneracy of the quantized  $m_s$  states. The different energies can be represented on the vector model as vectors precessing at the Larmor frequency,  $\nu_L$ .

Classically, the energy of a magnetic moment  $\boldsymbol{\mu}$  in a magnetic field  $\mathcal{B}$  is equal to the scalar product

$$E = -\boldsymbol{\mu} \cdot \mathcal{B} \quad (14.1)$$

More formally,  $\mathcal{B}$  is the magnetic induction and is measured in tesla, T; 1 T = 1 kg s<sup>-2</sup>A<sup>-1</sup>. The (non-SI) unit gauss, G, is also occasionally used: 1 T = 10<sup>4</sup> G.

Quantum mechanically, we write the hamiltonian as

$$\hat{H} = -\hat{\boldsymbol{\mu}} \cdot \mathcal{B} \quad (14.2)$$

To write an expression for  $\hat{\boldsymbol{\mu}}$ , we recall from *Further information 9.2* (on spin–orbit coupling in atoms) that the magnetic moment of an electron is proportional to its angular momentum. For an electron possessing orbital angular momentum we write

$$\hat{\boldsymbol{\mu}} = \gamma_e \hat{\mathbf{I}} \quad \text{and} \quad \hat{H} = -\gamma_e \mathcal{B} \cdot \hat{\mathbf{I}} \quad (14.3)$$

where  $\hat{\mathbf{I}}$  is the orbital angular momentum operator and from classical electrodynamics

$$\gamma_e = -\frac{e}{2m_e} \quad \text{Definition of magnetogyric ratio of an electron} \quad [14.4]$$

$\gamma_e$  is called the **magnetogyric ratio** of the electron. Its negative sign (arising from the sign of the electron's charge) shows that the orbital moment is opposite in direction to the orbital angular momentum vector (as is depicted in Fig. 9.27).

For a magnetic field of magnitude  $\mathcal{B}_0$  along the  $z$ -direction, the hamiltonian in eqn 14.3 becomes

$$\hat{H} = -\gamma_e \mathcal{B}_0 \hat{I}_z \quad (14.5a)$$

Because the eigenvalues of the operator  $\hat{I}_z$  are  $m_l \hbar$  the eigenvalues of this hamiltonian are

$$E_{m_l} = -\gamma_e m_l \hbar \mathcal{B}_0 = \mu_B m_l \mathcal{B}_0 \quad (14.5b)$$

The combination  $-\gamma_e \hbar$  occurs widely and, as in this equation, is expressed as the **Bohr magneton**,  $\mu_B$ :

$$\mu_B = -\gamma_e \hbar = \frac{e\hbar}{2m_e} = 9.274 \times 10^{-24} \text{ J T}^{-1} \quad \text{Definition of the Bohr magneton} \quad [14.6]$$

The Bohr magneton, a positive quantity, is often regarded as the fundamental quantum of magnetic moment.

The spin magnetic moment of an electron, which has a spin quantum number  $s = \frac{1}{2}$  (Section 8.8), is also proportional to its spin angular momentum. However, instead of eqn 14.3, the spin magnetic moment and hamiltonian operators are, respectively,

$$\hat{\boldsymbol{\mu}} = g_e \gamma_e \hat{\mathbf{S}} \quad \text{and} \quad \hat{H} = -g_e \gamma_e \mathcal{B} \cdot \hat{\mathbf{S}} \quad (14.7)$$

where  $\hat{\mathbf{S}}$  is the spin angular momentum operator and the extra factor  $g_e$  is called the  **$g$ -value** of the electron:  $g_e = 2.002\,319 \dots$ . Dirac's relativistic theory (his modification of the Schrödinger equation to make it consistent with Einstein's special relativity) gives  $g_e = 2$ ; the additional  $0.002\,319 \dots$  arises from interactions of the electron with the electromagnetic fluctuations of the vacuum that surrounds the electron. For a magnetic field of magnitude  $\mathcal{B}_0$  in the  $z$ -direction

### A brief comment

Scalar products (or 'dot products') are explained in *Mathematical background 5* following Chapter 9.

**Fig. 14.1** The interactions between the  $m_s$  states of an electron and an external magnetic field may be visualized as the precession of the vectors representing the angular momentum.

$$\hat{H} = -g_e \gamma_e \mathcal{B}_0 \hat{s}_z \quad (14.8a)$$

Because the eigenvalues of the operator  $\hat{s}_z$  are  $m_s \hbar$  with  $m_s = +\frac{1}{2}$  ( $\alpha$ ) and  $m_s = -\frac{1}{2}$  ( $\beta$ ), it follows that the energies of an electron spin in a magnetic field are

$$E_{m_s} = -g_e \gamma_e m_s \hbar \mathcal{B}_0 = g_e \mu_B m_s \mathcal{B}_0 \quad (14.8b)$$

Energies of an electron spin in a magnetic field

In the absence of a magnetic field, the states with different values of  $m_s$  are degenerate. When a field is present, the degeneracy is removed: the state with  $m_s = +\frac{1}{2}$  moves up in energy by  $\frac{1}{2} g_e \mu_B \mathcal{B}_0$  and the state with  $m_s = -\frac{1}{2}$  moves down by  $\frac{1}{2} g_e \mu_B \mathcal{B}_0$ . The different energies arising from an interaction with an external field are sometimes represented on the vector model by picturing the vectors as **precessing**, or sweeping round their cones (Fig. 14.1), with the rate of precession equal to the **Larmor frequency**,  $\nu_L$ :

$$\nu_L = \frac{|\gamma_e \mathcal{B}_0|}{2\pi} \quad (14.9)$$

Definition of Larmor frequency

Equation 14.9 shows that the Larmor frequency increases with the strength of the magnetic field. For a field of 1 T, the Larmor frequency is 30 GHz.

## 14.2 The energies of nuclei in magnetic fields

**Key points** The spin quantum number,  $I$ , of a nucleus is either an integer or a half-integer. Nuclei interact with magnetic fields, which remove the degeneracy of the quantized  $m_I$  states.

The nuclear spin quantum number,  $I$ , is a fixed characteristic property of a nucleus and, depending on the nuclide, is either an integer or a half-integer (Table 14.1). A nucleus with spin quantum number  $I$  has the following properties:

1. An angular momentum of magnitude  $\{I(I+1)\}^{1/2} \hbar$ .
2. A component of angular momentum  $m_I \hbar$  on a specified axis ('the  $z$ -axis'), where  $m_I = I, I-1, \dots, -I$ .
3. If  $I > 0$ , a magnetic moment with a constant magnitude and an orientation that is determined by the value of  $m_I$ .

According to the second property, the spin, and hence the magnetic moment, of the nucleus may lie in  $2I+1$  different orientations relative to an axis. A proton has  $I = \frac{1}{2}$  and its spin may adopt either of two orientations; a  $^{14}\text{N}$  nucleus has  $I = 1$  and its spin may adopt any of three orientations; both  $^{12}\text{C}$  and  $^{16}\text{O}$  have  $I = 0$  and hence zero magnetic moment.

**Table 14.1** Nuclear constitution and the nuclear spin quantum number\*

| Number of protons | Number of neutrons | $I$                                                             |
|-------------------|--------------------|-----------------------------------------------------------------|
| even              | even               | 0                                                               |
| odd               | odd                | integer (1, 2, 3, ...)                                          |
| even              | odd                | half-integer ( $\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \dots$ ) |
| odd               | even               | half-integer ( $\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \dots$ ) |

\* The spin of a nucleus may be different if it is in an excited state; throughout this chapter we deal only with the ground state of nuclei.

**Table 14.2\*** Nuclear spin properties

\* More values are given in the *Data section*.

The energy of interaction between a nucleus with a magnetic moment  $\mu$  and an external magnetic field  $\mathcal{B}$  may be calculated by using operators analogous to those of eqn 14.3:

$$\hat{\mu} = \gamma \hat{I} \quad \text{and} \quad \hat{H} = -\gamma \mathcal{B} \cdot \hat{I} \quad (14.10a)$$

where  $\gamma$  is the magnetogyric ratio of the specified nucleus, an empirically determined characteristic arising from its internal structure (Table 14.2). The corresponding energies when the magnetic field of magnitude  $\mathcal{B}_0$  is applied along the  $z$ -axis are

$$E_{m_I} = -\gamma \hbar \mathcal{B}_0 m_I \quad \text{Energies of a nuclear spin in a magnetic field} \quad (14.10b)$$

As for electrons, the nuclear spin may be pictured as precessing around the direction of the applied field at a rate proportional to the applied field. For protons, a field of 1 T corresponds to a Larmor frequency (eqn 14.9, with  $\gamma_e$  replaced by  $\gamma$ ) of about 40 MHz.

The magnetic moment of a nucleus is sometimes expressed in terms of the **nuclear  $g$ -factor**,  $g_I$ , a characteristic of the nucleus, and the **nuclear magneton**,  $\mu_N$ , a quantity independent of the nucleus, by using

$$\gamma \hbar = g_I \mu_N \quad \mu_N = \frac{e \hbar}{2 m_p} = 5.051 \times 10^{-27} \text{ J T}^{-1} \quad \text{Definitions of nuclear } g\text{-factor and nuclear magneton} \quad [14.11]$$

where  $m_p$  is the mass of the proton. The nuclear magneton is about 2000 times smaller than the Bohr magneton, so nuclear magnetic moments—and consequently the energies of interaction with magnetic fields—are about 2000 times weaker than the electron spin magnetic moment. Nuclear  $g$ -factors vary between  $-6$  and  $+6$  (Table 14.2): positive values of  $g_I$  and  $\gamma$  denote a magnetic moment that lies in the same direction as the spin angular momentum vector; negative values indicate that the magnetic moment and spin lie in opposite directions. For the remainder of this chapter we shall assume that  $\gamma$  is positive, as is the case for the majority of nuclei. In such cases, it follows from eqn 14.10b that states with  $m_I < 0$  lie above states with  $m_I > 0$ .

### 14.3 Magnetic resonance spectroscopy

**Key points** Electron paramagnetic resonance (EPR), a microwave technique, is the observation of the frequency at which an electron spin comes into resonance with an electromagnetic field when the molecule is exposed to a strong magnetic field. Nuclear magnetic resonance (NMR), a radiofrequency technique, is the analogous observation for nuclei.

**Fig. 14.2** Electron spin levels in a magnetic field. Note that the  $\beta$  state is lower in energy than the  $\alpha$  state (because the magnetogyric ratio of an electron is negative). Resonance is achieved when the frequency of the incident radiation matches the frequency corresponding to the energy separation.

**Fig. 14.3** The nuclear spin energy levels of a spin- $\frac{1}{2}$  nucleus with positive magnetogyric ratio (for example,  $^1\text{H}$  or  $^{13}\text{C}$ ) in a magnetic field. Resonance occurs when the energy separation of the levels matches the energy of the photons in the electromagnetic field.

In its original form, the magnetic resonance experiment is the resonant absorption of radiation by nuclei or unpaired electrons in a magnetic field. From eqn 14.8b, the separation between the (upper)  $m_s = +\frac{1}{2}$  and (lower)  $m_s = -\frac{1}{2}$  levels of an electron spin in a magnetic field of magnitude  $\mathcal{B}_0$  in the  $z$ -direction is

$$\Delta E = E_{1/2} - E_{-1/2} = \frac{1}{2}g_e\mu_B\mathcal{B}_0 - (-\frac{1}{2}g_e\mu_B\mathcal{B}_0) = g_e\mu_B\mathcal{B}_0 \quad (14.12a)$$

If the sample is exposed to radiation of frequency  $\nu$ , the energy separations come into resonance with the radiation when the frequency satisfies the **resonance condition** (Fig. 14.2):

$$h\nu = g_e\mu_B\mathcal{B}_0$$

Resonance condition for electrons

 (14.12b)

At resonance there is strong coupling between the electron spins and the radiation, and strong absorption occurs as the spins make the transition  $\beta \rightarrow \alpha$ . **Electron paramagnetic resonance** (EPR), or **electron spin resonance** (ESR), is the study of molecules and ions containing unpaired electrons by observing the magnetic field at which they come into resonance with radiation of known frequency. Magnetic fields of about 0.3 T (the value used in most commercial EPR spectrometers) correspond to resonance with an electromagnetic field of frequency 10 GHz ( $10^{10}$  Hz) and wavelength 3 cm. Because 3 cm radiation falls in the microwave region of the electromagnetic spectrum, EPR is a microwave technique.

The energy separation between the (lower, for  $\gamma > 0$ )  $m_I = +\frac{1}{2}$  and (upper)  $m_I = -\frac{1}{2}$  states of a **spin- $\frac{1}{2}$  nucleus**, a nucleus with  $I = \frac{1}{2}$ , is

$$\Delta E = E_{-1/2} - E_{+1/2} = \frac{1}{2}\gamma\hbar\mathcal{B}_0 - (-\frac{1}{2}\gamma\hbar\mathcal{B}_0) = \gamma\hbar\mathcal{B}_0 \quad (14.13a)$$

and resonant absorption occurs when the resonance condition (Fig. 14.3)

$$h\nu = \gamma\hbar\mathcal{B}_0$$

Resonance condition for spin- $\frac{1}{2}$  nuclei

 (14.13b)

is fulfilled. Because  $\gamma\hbar\mathcal{B}_0/h$  is the Larmor frequency of the nucleus, this resonance occurs when the frequency of the electromagnetic field matches the Larmor frequency ( $\nu = \nu_L$ ). In its simplest form, **nuclear magnetic resonance** (NMR) is the study of the properties of molecules containing magnetic nuclei by applying a magnetic field and observing the frequency of the resonant electromagnetic field. Larmor frequencies of nuclei at the fields normally employed (about 12 T) typically lie in the radiofrequency region of the electromagnetic spectrum (close to 500 MHz), so NMR is a radiofrequency technique.

For much of this chapter we consider spin- $\frac{1}{2}$  nuclei, but NMR is applicable to nuclei with any nonzero spin. As well as protons, which are the most common nuclei studied by NMR, spin- $\frac{1}{2}$  nuclei include  $^{13}\text{C}$ ,  $^{19}\text{F}$ , and  $^{31}\text{P}$ . Nuclear magnetic resonance is far more important than EPR, and so we consider it first and at greater length.

## Nuclear magnetic resonance

Although the NMR technique is simple in concept, NMR spectra can be highly complex. However, they have proved invaluable in chemistry, for they reveal so much structural information. A magnetic nucleus is a very sensitive, non-invasive probe of the surrounding electronic structure.

## 14.4 The NMR spectrometer

**Key points** NMR spectrometers consist of a source of radiofrequency radiation and a superconducting magnet. The resonance absorption intensity increases with the strength of the applied magnetic field (as  $\mathcal{B}_0^2$ ).

An NMR spectrometer consists of the appropriate sources of radiofrequency radiation and a magnet that can produce a uniform, intense field. Most modern instruments use a superconducting magnet capable of producing fields of the order of 10 T and more (Fig. 14.4). The sample is rotated rapidly to average out magnetic inhomogeneities; however, although sample spinning is essential for the investigation of small molecules, for large molecules it can lead to irreproducible results and is often avoided. Although a superconducting magnet operates at the temperature of liquid helium (4 K), the sample itself is normally at room temperature or held in a variable temperature enclosure between, typically,  $-150$  to  $+100^\circ\text{C}$ .

The intensity of an NMR transition depends on a number of factors. We show in the following *Justification* that

$$\text{Intensity} \propto (N_\alpha - N_\beta)\mathcal{B}_0 \quad (14.14a)$$

where

$$N_\alpha - N_\beta \approx \frac{N\gamma\hbar\mathcal{B}_0}{2kT} \quad (14.14b)$$

with  $N$  the total number of spins ( $N = N_\alpha + N_\beta$ ). It follows that decreasing the temperature increases the intensity by increasing the population difference. By combining these two equations we see that the intensity is proportional to  $\mathcal{B}_0^2$ , so NMR transitions can be enhanced significantly by increasing the strength of the applied magnetic field. We shall also see (Section 14.6) that the use of high magnetic fields simplifies the appearance of spectra and so allows them to be interpreted more readily. We also conclude that absorptions of nuclei with large magnetogyric ratios ( $^1\text{H}$ , for instance) are more intense than those with small magnetogyric ratios ( $^{13}\text{C}$ , for instance)

**Fig. 14.4** The layout of a typical NMR spectrometer. The link from the transmitter to the detector indicates that the high frequency of the transmitter is subtracted from the high frequency signal detected to give a low frequency signal for processing.

### Justification 14.1 Intensities in NMR spectra

From the general considerations of transition intensities in *Justification 13.4*, we know that the rate of absorption of electromagnetic radiation is proportional to the population of the lower energy state ( $N_\alpha$  in the case of a proton NMR transition) and the rate of stimulated emission is proportional to the population of the upper state ( $N_\beta$ ). At the low frequencies typical of magnetic resonance, we can neglect spontaneous emission as it is very slow. Therefore, the net rate of absorption is proportional to the difference in populations, and we can write

$$\text{Rate of absorption} \propto N_\alpha - N_\beta$$

The intensity of absorption, the rate at which energy is absorbed, is proportional to the product of the rate of absorption (the rate at which photons are absorbed) and the energy of each photon, and the latter is proportional to the frequency  $\nu$  of the incident radiation (through  $E = h\nu$ ). At resonance, this frequency is proportional to the applied magnetic field (through  $\nu = \nu_L = \gamma\mathcal{B}_0/2\pi$ ), so we can write

$$\text{Intensity of absorption} \propto (N_\alpha - N_\beta)\mathcal{B}_0$$

as in eqn 14.14a. To write an expression for the population difference, we use the Boltzmann distribution (*Fundamentals F.5*) to write the ratio of populations as

$$\frac{N_{\beta}}{N_{\alpha}} = e^{-\Delta E/kT} \approx 1 - \frac{\Delta E}{kT} = 1 - \frac{\gamma \hbar B_0}{kT}$$

where we have used  $e^{-x} \approx 1 - x$  (which is valid for  $x \ll 1$ ) and  $\Delta E = E_{\beta} - E_{\alpha}$ . The expansion of the exponential term is appropriate for  $\Delta E \ll kT$ , a condition usually met for nuclear spins. It follows that

$$N_{\alpha} - N_{\beta} = N_{\alpha} \left( 1 - \frac{N_{\beta}}{N_{\alpha}} \right) \approx \frac{\gamma \hbar B_0 N_{\alpha}}{kT}$$

Because  $N_{\alpha} \approx \frac{1}{2}N$  (the two spin states are nearly equally populated),

$$N_{\alpha} - N_{\beta} = N_{\alpha} \left( 1 - \frac{N_{\beta}}{N_{\alpha}} \right) \approx \frac{\gamma \hbar B_0 N}{2kT}$$

which is eqn 14.14b.

## 14.5 The chemical shift

**Key points** (a) The chemical shift of a nucleus is the difference between its resonance frequency and that of a reference standard. (b) The shielding constant is the sum of a local contribution, a neighbouring group contribution, and a solvent contribution. (c) The local contribution is the sum of a diamagnetic contribution and a paramagnetic contribution. (d) The neighbouring group contribution arises from the currents induced in nearby groups of atoms. (e) The solvent contribution can arise from specific molecular interactions between the solute and the solvent.

Nuclear magnetic moments interact with the *local* magnetic field. The local field may differ from the applied field because the latter induces electronic orbital angular momentum (that is, the circulation of electronic currents) which gives rise to a small additional magnetic field  $\delta B$  at the nuclei. This additional field is proportional to the applied field, and it is conventional to write

$$\delta B = -\sigma B_0$$

Definition of  
shielding constant

[14.15]

where the dimensionless quantity  $\sigma$  is called the **shielding constant** of the nucleus ( $\sigma$  is usually positive but may be negative). The ability of the applied field to induce an electronic current in the molecule, and hence affect the strength of the resulting local magnetic field experienced by the nucleus, depends on the details of the electronic structure near the magnetic nucleus of interest, so nuclei in different chemical groups have different shielding constants. The calculation of reliable values of the shielding constant is very difficult, but trends in it are quite well understood and we concentrate on them.

### (a) The $\delta$ scale of chemical shifts

Because the total local field is

$$B_{\text{loc}} = B_0 + \delta B = (1 - \sigma) B_0 \quad (14.16)$$

the nuclear Larmor frequency is

$$\nu_L = \frac{\gamma B_{\text{loc}}}{2\pi} = (1 - \sigma) \frac{\gamma B_0}{2\pi} \quad (14.17)$$

This frequency is different for nuclei in different environments. Hence, different nuclei, even of the same element, come into resonance at different frequencies if they are in different molecular environments.

Resonance frequencies are expressed in terms of an empirical quantity called the **chemical shift**, which is related to the difference between the resonance frequency,  $\nu$ , of the nucleus in question and that of a reference standard,  $\nu^\circ$ :

$$\delta = \frac{\nu - \nu^\circ}{\nu^\circ} \times 10^6 \quad \text{Definition of chemical shift} \quad [14.18]$$

The standard for protons is the proton resonance in tetramethylsilane ( $\text{Si}(\text{CH}_3)_4$ , commonly referred to as TMS), which bristles with protons and dissolves without reaction in many liquids. Other references are used for other nuclei. For  $^{13}\text{C}$ , the reference frequency is the  $^{13}\text{C}$  resonance in TMS; for  $^{31}\text{P}$  it is the  $^{31}\text{P}$  resonance in 85 per cent  $\text{H}_3\text{PO}_4(\text{aq})$ . The advantage of the  $\delta$ -scale is that shifts reported on it are independent of the applied field (because both numerator and denominator are proportional to the applied field).

#### • A brief illustration

From eqn 14.18,

$$\nu - \nu^\circ = \nu^\circ \delta \times 10^{-6}$$

A nucleus with  $\delta = 1.00$  in a spectrometer operating at 500 MHz will have a shift relative to the reference equal to

$$\nu - \nu^\circ = (500 \text{ MHz}) \times 1.00 \times 10^{-6} = 500 \text{ Hz}$$

In a spectrometer operating at 100 MHz, the shift relative to the reference would be only 100 Hz. •

**A note on good practice** In much of the literature, chemical shifts are reported in ‘parts per million’, ppm, in recognition of the factor of  $10^6$  in the definition. This practice is unnecessary.

The relation between  $\delta$  and  $\sigma$  is obtained by substituting eqn 14.17 into eqn 14.18:

$$\begin{aligned} \delta &= \frac{(1 - \sigma)\mathcal{B}_0 - (1 - \sigma^\circ)\mathcal{B}_0}{(1 - \sigma^\circ)\mathcal{B}_0} \times 10^6 \\ &= \frac{\sigma^\circ - \sigma}{1 - \sigma^\circ} \times 10^6 \approx (\sigma^\circ - \sigma) \times 10^6 \end{aligned} \quad \text{Relation between } \delta \text{ and } \sigma \quad (14.19)$$

As the shielding  $\sigma$ , gets smaller,  $\delta$  increases. Therefore, we speak of nuclei with large chemical shift as being strongly **deshielded**. Some typical chemical shifts are given in Fig. 14.5. As can be seen from the illustration, the nuclei of different elements have very different ranges of chemical shifts. The ranges exhibit the variety of electronic environments of the nuclei in molecules: the higher the atomic number of the element, the greater the number of electrons around the nucleus and hence the greater the range of shieldings. By convention, NMR spectra are plotted with  $\delta$  increasing from right to left.

The existence of a chemical shift explains the general features of the spectrum of ethanol shown in Fig. 14.6. The  $\text{CH}_3$  protons form one group of nuclei with  $\delta \approx 1.2$ . The two  $\text{CH}_2$  protons are in a different part of the molecule, experience a different local magnetic field, and resonate at  $\delta \approx 3.6$ . Finally, the OH proton is in another environment, and has a chemical shift of  $\delta \approx 4$ . The increasing value of  $\delta$  (that is, the decrease in shielding) is consistent with the electron-withdrawing power of the O atom: it reduces the electron density of the OH proton most, and that proton is strongly deshielded. It reduces the electron density of the distant methyl protons least, and those nuclei are least deshielded.

**Fig. 14.5** The range of typical chemical shifts for (a)  $^1\text{H}$  resonances and (b)  $^{13}\text{C}$  resonances.

**Fig. 14.6** The  $^1\text{H}$ -NMR spectrum of ethanol. The bold letters denote the protons giving rise to the resonance peak, and the step-like curve is the integrated signal.

The relative intensities of the signals (the areas under the absorption lines) can be used to help distinguish which group of lines corresponds to which chemical group. The determination of the area under an absorption line is referred to as the **integration** of the signal (just as any area under a curve may be determined by mathematical integration). Data analysis software performs this integration and the values are represented as the height of step-like curves superimposed on the spectrum, as in Fig. 14.6. In ethanol the group intensities are in the ratio 3:2:1 because there are three  $\text{CH}_3$  protons, two  $\text{CH}_2$  protons, and one OH proton in each molecule. Counting the number of magnetic nuclei as well as noting their chemical shifts helps in the identification of the sample.

### (b) The origin of shielding constants

The calculation of shielding constants is difficult, even for small molecules, for it requires detailed information (using the techniques outlined in Chapter 10) about the distribution of electron density in the ground and excited states and the excitation energies of the molecule. Nevertheless, considerable success has been achieved with small molecules such as  $\text{H}_2\text{O}$  and  $\text{CH}_4$  and even large molecules, such as proteins, are within the scope of some types of calculation. However, it is easier to understand the different contributions to chemical shifts by studying the large body of empirical information now available for large molecules.

The empirical approach supposes that the observed shielding constant is the sum of three contributions:

$$\sigma = \sigma(\text{local}) + \sigma(\text{neighbour}) + \sigma(\text{solvent}) \quad (14.20)$$

The **local contribution**,  $\sigma(\text{local})$ , is essentially the contribution of the electrons of the atom that contains the nucleus in question. The **neighbouring group contribution**,  $\sigma(\text{neighbour})$ , is the contribution from the groups of atoms that form the rest of the molecule. The **solvent contribution**,  $\sigma(\text{solvent})$ , is the contribution from the solvent molecules.

### (c) The local contribution

It is convenient to regard the local contribution to the shielding constant as the sum of a **diamagnetic contribution**,  $\sigma_d$ , and a **paramagnetic contribution**,  $\sigma_p$ :

$$\sigma(\text{local}) = \sigma_d + \sigma_p \quad \text{Local contribution to the shielding constant} \quad (14.21)$$

A diamagnetic contribution to  $\sigma(\text{local})$  opposes the applied magnetic field and shields the nucleus in question. A paramagnetic contribution to  $\sigma(\text{local})$  reinforces the applied magnetic field and deshields the nucleus in question. Therefore,  $\sigma_d > 0$  and  $\sigma_p < 0$ . The total local contribution is positive if the diamagnetic contribution dominates, and is negative if the paramagnetic contribution dominates.

The diamagnetic contribution arises from the ability of the applied field to generate a circulation of charge in the ground-state electron distribution of the atom. The circulation generates a magnetic field that opposes the applied field and hence shields the nucleus. The magnitude of  $\sigma_d$  depends on the electron density close to the nucleus and can be calculated from the **Lamb formula**:<sup>1</sup>

$$\sigma_d = \frac{e^2 \mu_0}{12\pi m_e} \left\langle \frac{1}{r} \right\rangle \quad \text{Lamb formula} \quad (14.22)$$

where  $\mu_0$  is the vacuum permeability (a fundamental constant, see inside the front cover) and  $r$  is the electron–nucleus distance.

#### • A brief illustration

To calculate  $\sigma_d$  for the proton in a free H atom, we need to calculate the expectation value of  $1/r$  for a hydrogen 1s orbital. Wavefunctions are given in Table 9.1, and the integral we need is given in Example 7.4. Because  $d\tau = r^2 dr \sin\theta d\theta d\phi$ , we can write

$$\left\langle \frac{1}{r} \right\rangle = \int \frac{\psi^* \psi}{r} d\tau = \frac{1}{\pi a_0^3} \int_0^{2\pi} d\phi \int_0^\pi \sin\theta d\theta \int_0^\infty r e^{-2r/a_0} dr = \frac{4}{a_0^3} \int_0^\infty r e^{-2r/a_0} dr = \frac{1}{a_0}$$

Therefore,

$$\sigma_d = \frac{e^2 \mu_0}{12\pi m_e a_0}$$

With the values of the fundamental constants inside the front cover, this expression evaluates to  $1.78 \times 10^{-5}$ . •

The diamagnetic contribution is the only contribution in closed-shell free atoms. It is also the only contribution to the local shielding for electron distributions that have spherical or cylindrical symmetry. Thus, it is the only contribution to the local shielding from inner cores of atoms, for cores remain nearly spherical even though the atom may be a component of a molecule and its valence electron distribution highly distorted. The diamagnetic contribution is broadly proportional to the electron density of the atom containing the nucleus of interest. It follows that the shielding is decreased if the electron density on the atom is reduced by the influence of an electronegative atom nearby. That reduction in shielding as the electronegativity of a neighbouring atom increases translates into an increase in the chemical shift  $\delta$  (Fig. 14.7).

The local paramagnetic contribution,  $\sigma_p$ , arises from the ability of the applied field to force electrons to circulate through the molecule by making use of orbitals that are unoccupied in the ground state. It is zero in free atoms and around the axes of linear molecules (such as ethyne,  $\text{HC}\equiv\text{CH}$ ) where the electrons can circulate freely and a field applied along the internuclear axis is unable to force them into other orbitals. We can expect large paramagnetic contributions from small atoms (because the induced

**Fig. 14.7** The variation of chemical shielding with electronegativity. The shifts for the methylene protons agree with the trend expected with increasing electronegativity. However, to emphasize that chemical shifts are subtle phenomena, notice that the trend for the methyl protons is opposite to that expected. For these protons another contribution (the magnetic anisotropy of C–H and C–X bonds) is dominant.

<sup>1</sup> For a derivation, see our *Molecular quantum mechanics* (2005).

currents are then close to the nucleus) in molecules with low lying excited states (because an applied field can then induce significant currents). In fact, the paramagnetic contribution is the dominant local contribution for atoms other than hydrogen.

#### (d) Neighbouring group contributions

The neighbouring group contribution arises from the currents induced in nearby groups of atoms. Consider the influence of the neighbouring group X on the proton H in a molecule such as H–X. The applied field generates currents in the electron distribution of X and gives rise to an induced magnetic moment proportional to the applied field; the constant of proportionality is the magnetic susceptibility,  $\chi$  (chi), of the group X:  $\mu_{\text{induced}} = \chi \mathcal{B}_0$ . The susceptibility is negative for a diamagnetic group because the induced moment is opposite to the direction of the applied field. As we show in the following *Justification*, the induced moment gives rise to a magnetic field with a component parallel to the applied field and at a distance  $r$  and angle  $\theta$  (1) that has the form

$$\mathcal{B}_{\text{local}} \propto \frac{\mu_{\text{induced}}(1 - 3 \cos^2 \theta)}{r^3} \quad \text{Local dipolar field} \quad (14.23a)$$

We see that the strength of the additional magnetic field experienced by the proton is inversely proportional to the cube of the distance  $r$  between H and X. Second, if the magnetic susceptibility is independent of the orientation of the molecule (is ‘isotropic’), because  $1 - 3 \cos^2 \theta$  is zero when averaged over a sphere (see Problem 14.17), the local field averages to zero. To a good approximation, the shielding constant  $\sigma(\text{neighbour})$  depends on the distance  $r$  and the difference  $\chi_{\parallel} - \chi_{\perp}$  as

$$\sigma(\text{neighbour}) \propto (\chi_{\parallel} - \chi_{\perp}) \left( \frac{1 - 3 \cos^2 \Theta}{r^3} \right) \quad \text{Neighbouring group contribution to the shielding constant} \quad (14.23b)$$

where  $\Theta$  (upper-case theta) is the angle between the X–H axis and the symmetry axis of the neighbouring group (2). Equation 14.23 shows that the neighbouring group contribution may be positive or negative according to the relative magnitudes of the two magnetic susceptibilities and the relative orientation of the nucleus with respect to X. If  $54.7^\circ < \Theta < 125.3^\circ$ , then  $1 - 3 \cos^2 \Theta$  is positive, but it is negative otherwise (Figs. 14.8 and 14.9).

#### Justification 14.2 Dipolar fields

Standard electromagnetic theory gives the magnetic field at a point  $r$  from a point magnetic dipole  $\mu$  as

$$\mathcal{B} = \frac{\mu_0}{4\pi r^3} \left( \mu - \frac{3(\mu \cdot r)r}{r^2} \right)$$

where  $\mu_0$  is the vacuum permeability (a fundamental constant with the defined value  $4\pi \times 10^{-7} \text{ T}^2 \text{ J}^{-1} \text{ m}^3$ ). The electric field due to a point electric dipole is given by a similar expression:

$$\mathcal{E} = \frac{1}{4\pi\epsilon_0 r^3} \left( \mu - \frac{3(\mu \cdot r)r}{r^2} \right)$$

where  $\epsilon_0$  is the vacuum permittivity, which is related to  $\mu_0$  by  $\epsilon_0 = 1/\mu_0 c^2$ . The component of magnetic field in the  $z$ -direction is

**Fig. 14.8** A depiction of the field arising from a point magnetic dipole. The three shades of colour represent the strength of field declining with distance (as  $1/r^3$ ), and each surface shows the angle dependence of the  $z$ -component of the field for each distance.

$$\mathcal{B}_z = \frac{\mu_0}{4\pi r^3} \left( \mu_z - \frac{3(\boldsymbol{\mu} \cdot \mathbf{r})z}{r^2} \right)$$

with  $z = r \cos \theta$ , the  $z$ -component of the distance vector  $\mathbf{r}$ . If the magnetic dipole is also parallel to the  $z$ -direction,  $\mu_z = \mu$  and  $\boldsymbol{\mu} \cdot \mathbf{r} = \mu r \cos \theta$ . It follows that

$$\mathcal{B}_z = \frac{\mu_0}{4\pi r^3} \left( \mu - \frac{3(\mu r \cos \theta)(r \cos \theta)}{r^2} \right) = \frac{\mu\mu_0(1 - 3 \cos^2 \theta)}{4\pi r^3}$$

as in eqn 14.23a.

A special case of a neighbouring group effect is found in aromatic compounds. The strong anisotropy of the magnetic susceptibility of the benzene ring is ascribed to the ability of the field to induce a **ring current**, a circulation of electrons around the ring, when it is applied perpendicular to the molecular plane. Protons in the plane are deshielded (Fig. 14.10), but any that happen to lie above or below the plane (as members of substituents of the ring) are shielded.

### (e) The solvent contribution

A solvent can influence the local magnetic field experienced by a nucleus in a variety of ways. Some of these effects arise from specific interactions between the solute and the solvent (such as hydrogen-bond formation and other forms of Lewis acid–base complex formation). The anisotropy of the magnetic susceptibility of the solvent molecules, especially if they are aromatic, can also be the source of a local magnetic field. Moreover, if there are steric interactions that result in a loose but specific interaction between a solute molecule and a solvent molecule, then protons in the solute molecule may experience shielding or deshielding effects according to their location relative to the solvent molecule (Fig. 14.11). We shall see that the NMR spectra of species that contain protons with widely different chemical shifts are easier to interpret than those in which the shifts are similar, so the appropriate choice of solvent may help to simplify the appearance and interpretation of a spectrum.

**Fig. 14.10** The shielding and deshielding effects of the ring current induced in the benzene ring by the applied field. Protons attached to the ring are deshielded but a proton attached to a substituent that projects above the ring is shielded.

**Fig. 14.11** An aromatic solvent (benzene here) can give rise to local currents that shield or deshield a proton in a solute molecule. In this relative orientation of the solvent and solute, the proton on the solute molecule is shielded.

## 14.6 The fine structure

**Key points** (a) Spin–spin coupling is expressed in terms of the spin–spin coupling constant  $J$  and depends on the relative orientation of two nuclear spins. (b)  $N$  equivalent spin- $\frac{1}{2}$  nuclei split the resonance of a nearby spin or group of equivalent spins into  $N + 1$  lines with an intensity distribution given by Pascal’s triangle. (c) The coupling constant decreases as the number of bonds separating two nuclei increases. (d) Spin–spin coupling can be explained in terms of the polarization mechanism and the Fermi contact interaction. (e) Chemically and magnetically equivalent nuclei have the same chemical shifts. (f) In strongly coupled spectra, transitions cannot be allocated to definite groups.

The splitting of resonances into individual lines by spin–spin coupling in Fig. 14.6 is called the **fine structure** of the spectrum. It arises because each magnetic nucleus may contribute to the local field experienced by the other nuclei and so modify their resonance frequencies. The strength of the interaction is expressed in terms of the **scalar coupling constant**,  $J$ , and reported in hertz (Hz). The scalar coupling constant is so called because the energy of interaction it describes is proportional to the scalar product of the two interacting spins:  $E \propto I_1 \cdot I_2$ . As explained in *Mathematical background 5*, a scalar product depends on the angle between the two vectors, so writing the energy in this way is simply a way of saying that the energy of interaction between two spins depends on their relative orientation. The constant of proportionality in this expression is written  $hJ/\hbar^2$  (so  $E = (hJ/\hbar^2)I_1 \cdot I_2$ ); because each spin angular momentum is proportional to  $\hbar$ ,  $E$  is then proportional to  $hJ$  and  $J$  is a frequency (with units hertz). For nuclei that are constrained to align with the applied field in the  $z$ -direction, the only contribution to  $I_1 \cdot I_2$  is  $I_{1z}I_{2z}$ , with eigenvalues  $m_1m_2\hbar^2$ , so the energy due to spin–spin coupling is

$$E_{m_1m_2} = hJm_1m_2$$

Spin–spin coupling energy

 (14.24)

## (a) The energy levels of coupled systems

It will be useful for later discussions to consider an NMR spectrum in terms of the energy levels of the nuclei and the transitions between them. In NMR, letters far apart in the alphabet (typically A and X) are used to indicate nuclei with very different chemical shifts; letters close together (such as A and B) are used for nuclei with similar chemical shifts. We shall consider first an AX system, a molecule that contains two spin- $\frac{1}{2}$  nuclei A and X with very different chemical shifts in the sense that the difference in chemical shift corresponds to a frequency that is large compared to  $J$ .

For a spin- $\frac{1}{2}$  AX system there are four spin states:

$$\alpha_A\alpha_X \quad \alpha_A\beta_X \quad \beta_A\alpha_X \quad \beta_A\beta_X$$

The energy depends on the orientation of the spins in the external magnetic field, and if spin–spin coupling is neglected

$$E_{m_Am_X} = -\gamma\hbar(1 - \sigma_A)\mathcal{B}_0m_A - \gamma\hbar(1 - \sigma_X)\mathcal{B}_0m_X = -h\nu_Am_A - h\nu_Xm_X \quad (14.25a)$$

where  $\nu_A$  and  $\nu_X$  are the Larmor frequencies of A and X and  $m_A$  and  $m_X$  are their quantum numbers ( $m_A = \pm\frac{1}{2}$ ,  $m_X = \pm\frac{1}{2}$ ). This expression gives the four lines on the left of Fig. 14.12. When spin–spin coupling is included (by using eqn 14.24), the energy levels are

$$E_{m_Am_X} = -h\nu_Am_A - h\nu_Xm_X + hJm_Am_X \quad (14.25b)$$

If  $J > 0$ , a lower energy is obtained when  $m_Am_X < 0$ , which is the case if one spin is  $\alpha$  and the other is  $\beta$ . A higher energy is obtained if both spins are  $\alpha$  or both spins are  $\beta$ .

**Fig. 14.12** The energy levels of an AX system. The four levels on the left are those of the two spins in the absence of spin–spin coupling. The four levels on the right show how a positive spin–spin coupling constant affects the energies. The transitions shown are for  $\beta \leftarrow \alpha$  of A or X, the other nucleus (X or A, respectively) remaining unchanged. We have exaggerated the effect for clarity in practice, the splitting caused by spin–spin coupling is much smaller than that caused by the applied field.

The opposite is true if  $J < 0$ . The resulting energy level diagram (for  $J > 0$ ) is shown on the right of Fig. 14.12. We see that the  $\alpha\alpha$  and  $\beta\beta$  states are both raised by  $\frac{1}{4}hJ$  and that the  $\alpha\beta$  and  $\beta\alpha$  states are both lowered by  $\frac{1}{4}hJ$ .

When a transition of nucleus A occurs, nucleus X remains unchanged. Therefore, the A resonance is a transition for which  $\Delta m_A = +1$  and  $\Delta m_X = 0$ . There are two such transitions, one in which  $\beta_A \leftarrow \alpha_A$  occurs when the X nucleus is  $\alpha$ , and the other in which  $\beta_A \leftarrow \alpha_A$  occurs when the X nucleus is  $\beta$ . They are shown in Fig. 14.12 and in a slightly different form in Fig. 14.13. The energies of the transitions are

$$\Delta E = h\nu_A \pm \frac{1}{2}hJ \quad (14.26a)$$

Therefore, the A resonance consists of a doublet of separation  $J$  centred on the chemical shift of A (Fig. 14.14). Similar remarks apply to the X resonance, which consists of two transitions according to whether the A nucleus is  $\alpha$  or  $\beta$  (as shown in Fig. 14.13). The transition energies are

$$\Delta E = h\nu_X \pm \frac{1}{2}hJ \quad (14.26b)$$

It follows that the X resonance also consists of two lines of the same separation  $J$ , but they are centred on the chemical shift of X (as shown in Fig. 14.14).

### (b) Patterns of coupling

We have seen that, in an AX system, spin–spin coupling results in a doublet of lines for the A resonance and a doublet of lines for the X resonance of the same separation. The X resonance in an  $AX_n$  species (such as an  $AX_2$  or  $AX_3$  species) is also a doublet with splitting  $J$ . As we shall explain below, a group of equivalent nuclei resonates like a single nucleus. The only difference for the X resonance of an  $AX_n$  species is that the intensity is  $n$  times as great as that of an AX species (Fig. 14.15). The A resonance in an  $AX_n$  species, though, is quite different from the A resonance in an AX species. For example, consider an  $AX_2$  species with two equivalent X nuclei. The A resonance is split into a doublet of separation  $J$  by one X, and each line of that doublet is split again by the same amount by the second X (Fig. 14.16). This splitting results in three lines in

**Fig. 14.14** The effect of spin–spin coupling on an AX spectrum. Each resonance is split into two lines separated by  $J$ . The pairs of resonances are centred on the chemical shifts of the protons in the absence of spin–spin coupling.

**Fig. 14.15** The X resonance of an  $AX_2$  species is also a doublet, because the two equivalent X nuclei behave like a single nucleus; however, the overall absorption is twice as intense as that of an AX species.

**Fig. 14.13** An alternative depiction of the energy levels and transitions shown in Fig. 14.11. Once again, we have exaggerated the effect of spin–spin coupling.

**Fig. 14.16** The origin of the 1:2:1 triplet in the A resonance of an  $AX_2$  species. The resonance of A is split into two by coupling with one X nucleus (as shown in the inset), and then each of those two lines is split into two by coupling to the second X nucleus. Because each X nucleus causes the same splitting, the two central transitions are coincident and give rise to an absorption line of double the intensity of the outer lines.

**Fig. 14.17** The origin of the 1:3:3:1 quartet in the A resonance of an  $AX_3$  species. The third X nucleus splits each of the lines shown in Fig. 14.16 for an  $AX_2$  species into a doublet, and the intensity distribution reflects the number of transitions that have the same energy.

the intensity ratio 1:2:1 (because the central frequency can be obtained in two ways). The A resonance of an  $A_nX_2$  species would also be a 1:2:1 triplet of splitting  $J$ , the only difference being that the intensity of the A resonance would be  $n$  times as great as that of  $AX_2$ .

Three equivalent X nuclei (an  $AX_3$  species) split the resonance of A into four lines of intensity ratio 1:3:3:1 and separation  $J$  (Fig. 14.17). The X resonance, though, is still a doublet of separation  $J$ . In general,  $n$  equivalent spin- $\frac{1}{2}$  nuclei split the resonance of a nearby spin or group of equivalent spins into  $n + 1$  lines with an intensity distribution given by 'Pascal's triangle' in which each entry is the sum of the two entries immediately above (3). The easiest way of constructing the pattern of fine structure is to draw a diagram in which each successive row shows the splitting due to an additional proton. The procedure is illustrated in Fig. 14.18 and was used in Figs. 14.16 and 14.17. It is easily extended to molecules containing nuclei with  $I > \frac{1}{2}$  (Fig. 14.19).

#### Example 14.1 Accounting for the fine structure in a spectrum

Account for the fine structure in the NMR spectrum of the C–H protons of ethanol.

**Method** Consider how each group of equivalent protons (for instance, three methyl protons) split the resonances of the other groups of protons. There is no splitting within groups of equivalent protons. Each splitting pattern can be decided by referring to Pascal's triangle.

**Answer** The three protons of the  $CH_3$  group split the resonance of the  $CH_2$  protons into a 1:3:3:1 quartet with a splitting  $J$ . Likewise, the two protons of the  $CH_2$  group split the resonance of the  $CH_3$  protons into a 1:2:1 triplet with the same splitting  $J$ . The OH resonance is not split because the OH protons migrate rapidly from molecule to molecule (including molecules of impurities in the sample) and their effect averages to zero. In gaseous ethanol, where this migration does not occur, the OH resonance appears as a triplet, showing that the  $CH_2$  protons interact with the OH proton.

**Self-test 14.1** What fine-structure can be expected for the protons in  $^{14}NH_4^+$ ? The spin quantum number of nitrogen-14 is 1. [1:1:1 triplet from N]

#### (c) The magnitudes of coupling constants

The scalar coupling constant of two nuclei separated by  $N$  bonds is denoted  $^NJ$ , with subscripts for the types of nuclei involved. Thus,  $^1J_{CH}$  is the coupling constant for a proton joined directly to a  $^{13}C$  atom, and  $^2J_{CH}$  is the coupling constant when the same two nuclei are separated by two bonds (as in  $^{13}C-C-H$ ). A typical value of  $^1J_{CH}$  is in the range 120 to 250 Hz;  $^2J_{CH}$  is between  $-10$  and  $+20$  Hz. Both  $^3J$  and  $^4J$  can give detectable effects in a spectrum, but couplings over larger numbers of bonds can generally be ignored. One of the longest range couplings that has been detected is  $^9J_{HH} = 0.4$  Hz between the  $CH_3$  and  $CH_2$  protons in  $CH_3C\equiv C-C\equiv C-C\equiv C-CH_2OH$ .

As we have remarked (in the discussion following eqn 14.25b), the sign of  $J_{XY}$  indicates whether the energy of two spins is lower when they are parallel ( $J < 0$ ) or when they are antiparallel ( $J > 0$ ). It is found that  $^1J_{CH}$  is often positive,  $^2J_{HH}$  is often negative,  $^3J_{HH}$  is often positive, and so on. An additional point is that  $J$  varies with the angle between the bonds (Fig. 14.20). Thus, a  $^3J_{HH}$  coupling constant is often found to depend on the dihedral angle  $\phi$  (4) according to the Karplus equation:

**Fig. 14.18** The intensity distribution of the A resonance of an  $AX_n$  resonance can be constructed by considering the splitting caused by 1, 2, . . .  $n$  protons, as in Figs. 14.16 and 14.17. The resulting intensity distribution has a binomial distribution and is given by the integers in the corresponding row of Pascal's triangle. Note that, although the lines have been drawn side-by-side for clarity, the members of each group are coincident. Four protons, in  $AX_4$ , split the A resonance into a 1:4:6:4:1 quintet.

**Fig. 14.19** The intensity distribution arising from spin-spin interaction with nuclei with  $I = 1$  can be constructed similarly, but each successive nucleus splits the lines into three equal intensity components. Two equivalent spin-1 nuclei give rise to a 1:2:3:2:1 quintet.

$$^3J_{HH} = A + B \cos \phi + C \cos 2\phi \quad \text{Karplus equation} \quad (14.27)$$

with  $A$ ,  $B$ , and  $C$  empirical constants with values close to +7 Hz, −1 Hz, and +5 Hz, respectively, for an HCCH fragment. It follows that the measurement of  $^3J_{HH}$  in a series of related compounds can be used to determine their conformations. The coupling constant  $^1J_{CH}$  also depends on the hybridization of the C atom, as the following values indicate:

|                      | sp  | sp <sup>2</sup> | sp <sup>3</sup> |
|----------------------|-----|-----------------|-----------------|
| $^1J_{CH}/\text{Hz}$ | 250 | 160             | 125             |

#### (d) The origin of spin-spin coupling

Spin-spin coupling is a very subtle phenomenon and it is better to treat  $J$  as an empirical parameter than to use calculated values. However, we can get some insight into its origins, if not its precise magnitude—or always reliably its sign—by considering the magnetic interactions within molecules.

A nucleus with spin projection  $m_I$  gives rise to a magnetic field with  $z$ -component  $\mathcal{B}_{\text{nuc}}$  at a distance  $R$ , where, to a good approximation,

$$\mathcal{B}_{\text{nuc}} = -\frac{\gamma \hbar \mu_0}{4\pi R^3} (1 - 3 \cos^2 \theta) m_I \quad (14.28)$$

The angle  $\theta$  is defined in (5); we saw a version of this expression in eqn 14.23a. The magnitude of this field is about 0.1 mT when  $R = 0.3$  nm, corresponding to a splitting

**Fig. 14.20** The variation of the spin-spin coupling constant with angle predicted by the Karplus equation for an HCCH group and an HNCH group.

**interActivity** Draw a family of curves showing the variation of  $^3J_{HH}$  with  $\phi$  for which  $A = +7.0$  Hz,  $B = -1.0$  Hz, and  $C$  varies slightly from a typical value of +5.0 Hz. What is the effect of changing the value of the parameter  $C$  on the shape of the curve? In a similar fashion, explore the effect of the values of  $A$  and  $B$  on the shape of the curve.

**Fig. 14.21** The origin of the Fermi contact interaction. From far away, the magnetic field pattern arising from a ring of current (representing the rotating charge of the nucleus, the pale grey sphere) is that of a point dipole. However, if an electron can sample the field close to the region indicated by the sphere, the field distribution differs significantly from that of a point dipole. For example, if the electron can penetrate the sphere, then the spherical average of the field it experiences is not zero.

**Fig. 14.22** The polarization mechanism for spin–spin coupling ( $^1J_{HH}$ ). The two arrangements have slightly different energies. In this case,  $J$  is positive, corresponding to a lower energy when the nuclear spins are antiparallel.

of resonance signal of about  $10^4$  Hz, and is of the order of magnitude of the splitting observed in solid samples (see Section 14.13a).

In a liquid, the angle  $\theta$  sweeps over all values as the molecule tumbles, and the factor  $1 - 3 \cos^2 \theta$  averages to zero (see Problem 14.17). Hence the direct dipolar interaction between spins cannot account for the fine structure of the spectra of rapidly tumbling molecules. The direct interaction does make an important contribution to the spectra of solid samples and is a very useful indirect source of structure information through its involvement in spin relaxation (Section 14.11).

Spin–spin coupling in molecules in solution can be explained in terms of the **polarization mechanism**, in which the interaction is transmitted through the bonds. The simplest case to consider is that of  $^1J_{XY}$  where X and Y are spin- $\frac{1}{2}$  nuclei joined by an electron-pair bond. The coupling mechanism depends on the fact that the energy depends on the relative orientation of the bonding electron and nuclear spins. This electron–nucleus coupling is magnetic in origin, and may be either a dipolar interaction or a **Fermi contact interaction**. A pictorial description of the latter is as follows. First, we regard the magnetic moment of the nucleus as arising from the circulation of a current in a tiny loop with a radius similar to that of the nucleus (Fig. 14.21). Far from the nucleus the field generated by this loop is indistinguishable from the field generated by a point magnetic dipole. Close to the loop, however, the field differs from that of a point dipole. The magnetic interaction between this non-dipolar field and the electron's magnetic moment is the contact interaction. The contact interaction—essentially the failure of the point-dipole approximation—depends on the very close approach of an electron to the nucleus and hence can occur only if the electron occupies an s orbital (which is the reason why  $^1J_{CH}$  depends on the hybridization ratio). We shall suppose that it is energetically favourable for an electron spin and a nuclear spin to be antiparallel (as is the case for a proton and an electron in a hydrogen atom).

If the X nucleus is  $\alpha$ , a  $\beta$  electron of the bonding pair will tend to be found nearby, because that is an energetically favourable arrangement (Fig. 14.22). The second electron in the bond, which must have  $\alpha$  spin if the other is  $\beta$  (by the Pauli principle), will be found mainly at the far end of the bond because electrons tend to stay apart to reduce their mutual repulsion. Because it is energetically favourable for the spin of Y to be antiparallel to an electron spin, a Y nucleus with  $\beta$  spin has a lower energy than when it has  $\alpha$  spin. The opposite is true when X is  $\beta$ , for now the  $\alpha$  spin of Y has the lower energy. In other words, the antiparallel arrangement of nuclear spins lies lower in energy than the parallel arrangement as a result of their magnetic coupling with the bond electrons. That is,  $^1J_{CH}$  is positive.

To account for the value of  $^2J_{XY}$ , as in H–C–H, we need a mechanism that can transmit the spin alignments through the central C atom (which may be  $^{12}\text{C}$ , with no nuclear spin of its own). In this case (Fig. 14.23), an X nucleus with  $\alpha$  spin polarizes the electrons in its bond, and the  $\alpha$  electron is likely to be found closer to the C nucleus. The more favourable arrangement of two electrons on the same atom is with their spins parallel (Hund's rule, Section 9.4), so the more favourable arrangement is for the  $\alpha$  electron of the neighbouring bond to be close to the C nucleus. Consequently, the  $\beta$  electron of that bond is more likely to be found close to the Y nucleus, and therefore that nucleus will have a lower energy if it is  $\alpha$ . Hence, according to this mechanism, the lower energy will be obtained if the Y spin is parallel to that of X. That is,  $^2J_{HH}$  is negative.

The coupling of nuclear spin to electron spin by the Fermi contact interaction is most important for proton spins, but it is not necessarily the most important mechanism for other nuclei. These nuclei may also interact by a dipolar mechanism with the electron magnetic moments and with their orbital motion, and there is no simple way of specifying whether  $J$  will be positive or negative.

**(e) Equivalent nuclei**

A group of nuclei are **chemically equivalent** if they are related by a symmetry operation of the molecule and have the same chemical shifts. Chemically equivalent nuclei are nuclei that would be regarded as ‘equivalent’ according to ordinary chemical criteria. Nuclei are **magnetically equivalent** if, as well as being chemically equivalent, they also have identical spin–spin interactions with any other magnetic nuclei in the molecule.

The difference between chemical and magnetic equivalence is illustrated by  $\text{CH}_2\text{F}_2$  and  $\text{H}_2\text{C}=\text{CF}_2$ . In each of these molecules the protons are chemically equivalent: they are related by symmetry and undergo the same chemical reactions. However, although the protons in  $\text{CH}_2\text{F}_2$  are magnetically equivalent, those in  $\text{H}_2\text{C}=\text{CF}_2$  are not. One proton in the latter has a *cis* spin-coupling interaction with a given F nucleus whereas the other proton has a *trans* interaction with it. In contrast, in  $\text{CH}_2\text{F}_2$  both protons are connected to a given F nucleus by identical bonds, so there is no distinction between them. Strictly speaking, the  $\text{CH}_3$  protons in ethanol (and other compounds) are magnetically inequivalent on account of their different interactions with the  $\text{CH}_2$  protons in the next group. However, they are in practice made magnetically equivalent by the rapid rotation of the  $\text{CH}_3$  group, which averages out any differences. Magnetically inequivalent species can give very complicated spectra (for instance, the proton and  $^{19}\text{F}$  spectra of  $\text{H}_2\text{C}=\text{CF}_2$  each consist of 12 lines), and we shall not consider them further.

An important feature of chemically equivalent magnetic nuclei is that, although they do couple together, the coupling has no effect on the appearance of the spectrum. The reason for the invisibility of the coupling is set out in the following *Justification*, but qualitatively it is that all allowed nuclear spin transitions are *collective* reorientations of groups of equivalent nuclear spins that do not change the relative orientations of the spins within the group (Fig. 14.24). Then, because the relative orientations of nuclear spins are not changed in any transition, the magnitude of the coupling between them is undetectable. Hence, an isolated  $\text{CH}_3$  group gives a single, unsplit line because all the allowed transitions of the group of three protons occur without change of their relative orientations.

**Justification 14.3** *The energy levels of an  $A_2$  system*

Consider an  $A_2$  system of two spin- $\frac{1}{2}$  nuclei. First, consider the energy levels in the absence of spin–spin coupling. There are four spin states that (just as for two electrons) can be classified according to their total spin  $I$  (the analogue of  $S$  for two electrons) and their total projection  $M_I$  on the  $z$ -axis. The states are analogous to those we developed for two electrons in singlet and triplet states (eqn 9.41):

|                           |            |                                            |
|---------------------------|------------|--------------------------------------------|
| Spins parallel, $I = 1$ : | $M_I = +1$ | $\alpha\alpha$                             |
|                           | $M_I = 0$  | $(1/2^{1/2})\{\alpha\beta + \beta\alpha\}$ |
|                           | $M_I = -1$ | $\beta\beta$                               |
| Spins paired, $I = 0$ :   | $M_I = 0$  | $(1/2^{1/2})\{\alpha\beta - \beta\alpha\}$ |

The sign in  $\alpha\beta + \beta\alpha$  signifies an in-phase alignment of spins and  $I = 1$ ; the  $-$  sign in  $\alpha\beta - \beta\alpha$  signifies an alignment out of phase by  $\pi$ , and hence  $I = 0$  (see Fig. 9.18). The effect of a magnetic field on these four states is shown in Fig. 14.25: the energies of the two states with  $M_I = 0$  are unchanged by the field because they are composed of equal proportions of  $\alpha$  and  $\beta$  spins.

As remarked in Section 14.6, the spin–spin coupling energy is proportional to the scalar product of the vectors representing the spins,  $E = (hJ/\hbar^2)I_1 \cdot I_2$ . The scalar product can be expressed in terms of the total nuclear spin by noting that

**Fig. 14.23** The polarization mechanism for  $^2J_{\text{HH}}$  spin–spin coupling. The spin information is transmitted from one bond to the next by a version of the mechanism that accounts for the lower energy of electrons with parallel spins in different atomic orbitals (Hund's rule of maximum multiplicity). In this case,  $J < 0$ , corresponding to a lower energy when the nuclear spins are parallel.

**Fig. 14.24** (a) A group of two equivalent nuclei realigns as a group, without change of angle between the spins, when a resonant absorption occurs. Hence it behaves like a single nucleus and the spin–spin coupling between the individual spins of the group is undetectable. (b) Three equivalent nuclei also realign as a group without change of their relative orientations.

**Fig. 14.25** The energy levels of an  $A_2$  system in the absence of spin–spin coupling are shown on the left. When spin–spin coupling is taken into account, the energy levels on the right are obtained. Note that the three states with total nuclear spin  $I = 1$  correspond to parallel spins and give rise to the same increase in energy ( $J$  is positive); the one state with  $I = 0$  (antiparallel nuclear spins) has a lower energy in the presence of spin–spin coupling. The only allowed transitions are those that preserve the angle between the spins, and so take place between the three states with  $I = 1$ . They occur at the same resonance frequency as they would have in the absence of spin–spin coupling.

$$I^2 = (I_1 + I_2) \cdot (I_1 + I_2) = I_1^2 + I_2^2 + 2I_1 \cdot I_2$$

rearranging this expression to

$$I_1 \cdot I_2 = \frac{1}{2} \{I^2 - I_1^2 - I_2^2\}$$

and replacing the magnitudes by their quantum mechanical values:

$$I_1 \cdot I_2 = \frac{1}{2} \{I(I+1) - I_1(I_1+1) - I_2(I_2+1)\} \hbar^2$$

Then, because  $I_1 = I_2 = \frac{1}{2}$ , it follows that

$$E = \frac{1}{2} hJ \{I(I+1) - \frac{3}{2}\}$$

For parallel spins,  $I = 1$  and  $E = +\frac{1}{4} hJ$ ; for antiparallel spins  $I = 0$  and  $E = -\frac{3}{4} hJ$ , as in Fig. 14.25. We see that three of the states move in energy in one direction and the fourth (the one with antiparallel spins) moves three times as much in the opposite direction. The resulting energy levels are shown on the right in Fig. 14.25.

The NMR spectrum of the  $A_2$  species arises from transitions between the levels. However, the radiofrequency field affects the two equivalent protons equally, so it cannot change the orientation of one proton relative to the other; therefore, the transitions take place within the set of states that correspond to parallel spin (those labelled  $I = 1$ ), and no spin-parallel state can change to a spin-antiparallel state (the state with  $I = 0$ ). Put another way, the allowed transitions are subject to the selection rule  $\Delta I = 0$ . This selection rule is in addition to the rule  $\Delta M_I = \pm 1$  that arises from the conservation of angular momentum and the unit spin of the photon. The allowed transitions are shown in Fig. 14.25: we see that there are only two transitions, and that they occur at the same resonance frequency that the nuclei would have in the absence of spin–spin coupling. Hence, the spin–spin coupling interaction does not affect the appearance of the spectrum.

#### (f) Strongly coupled nuclei

NMR spectra are usually much more complex than the foregoing simple analysis suggests. We have described the extreme case in which the differences in chemical shifts are much greater than the spin–spin coupling constants. In such cases it is simple to identify groups of magnetically equivalent nuclei and to think of the groups of nuclear spins as reorientating relative to each other. The spectra that result are called **first-order spectra**.

Transitions cannot be allocated to definite groups when the differences in their chemical shifts are comparable to their spin–spin coupling interactions. The complicated spectra that are then obtained are called **strongly coupled spectra** (or ‘second-order spectra’) and are much more difficult to analyse (Fig. 14.26). Because the difference in resonance frequencies increases with field, but spin–spin coupling constants are independent of it, a second-order spectrum may become simpler (and first-order) at high fields and individual groups of nuclei become identifiable again.

A clue to the type of analysis that is appropriate is given by the notation for the types of spins involved. Thus, an AX spin system (which consists of two nuclei with a large chemical shift difference) has a first-order spectrum. An AB system, on the other hand (with two nuclei of similar chemical shifts), gives a spectrum typical of a strongly coupled system. An AX system may have widely different Larmor frequencies because A and X are nuclei of different elements (such as  $^{13}\text{C}$  and  $^1\text{H}$ ), in which case they form a **heteronuclear spin system**. AX may also denote a **homonuclear spin system** in which the nuclei are of the same element but in markedly different environments.

## 14.7 Conformational conversion and exchange processes

**Key point** Coalescence of two NMR lines occurs when a conformational interchange or chemical exchange of nuclei is fast; the spectrum shows a single line at the mean of the two chemical shifts.

The appearance of an NMR spectrum is changed if magnetic nuclei can jump rapidly between different environments. Consider a molecule, such as *N,N*-dimethylformamide, that can jump between conformations; in its case, the methyl shifts depend on whether they are *cis* or *trans* to the carbonyl group (Fig. 14.27). When the jumping rate is low, the spectrum shows two sets of lines, one each from molecules in each conformation. When the interconversion is fast, the spectrum shows a single line at the mean of the two chemical shifts. At intermediate inversion rates, the line is very broad. This maximum broadening occurs when the lifetime,  $\tau$ , of a conformation gives rise to a linewidth that is comparable to the difference of resonance frequencies,  $\delta\nu$  and both broadened lines blend together into a very broad line. Coalescence of the two lines occurs when

$$\tau = \frac{\sqrt{2}}{\pi\delta\nu} \quad \text{Condition for coalescence of two NMR lines} \quad (14.29)$$

### • A brief illustration

The NO group in *N,N*-dimethylnitrosamine,  $(\text{CH}_3)_2\text{N}-\text{NO}$  (**6**), rotates about the N–N bond and, as a result, the magnetic environments of the two  $\text{CH}_3$  groups are interchanged. The two  $\text{CH}_3$  resonances are separated by 390 Hz in a 600 MHz spectrometer. According to eqn 14.29,

$$\tau = \frac{\sqrt{2}}{\pi \times (390 \text{ s}^{-1})} = 1.2 \text{ ms}$$

It follows that the signal will collapse to a single line when the interconversion rate exceeds about  $1/\tau = 830 \text{ s}^{-1}$ . •

**Self-test 14.2** What would you deduce from the observation of a single line from the same molecule in a 300 MHz spectrometer?

[Conformation lifetime less than 2.3 ms]

A similar explanation accounts for the loss of fine structure in solvents able to exchange protons with the sample. For example, hydroxyl protons are able to exchange with water protons. When this **chemical exchange** occurs, a molecule  $\text{ROH}$  with an  $\alpha$ -spin proton (we write this  $\text{ROH}_\alpha$ ) rapidly converts to  $\text{ROH}_\beta$  and then perhaps to  $\text{ROH}_\alpha$  again because the protons provided by the solvent molecules in successive exchanges have random spin orientations. Therefore, instead of seeing a spectrum composed of contributions from both  $\text{ROH}_\alpha$  and  $\text{ROH}_\beta$  molecules (that is, a spectrum showing a doublet structure due to the OH proton) we see a spectrum that shows no splitting caused by coupling of the OH proton (as in Fig. 14.6). The effect is observed when the lifetime of a molecule due to this chemical exchange is so short that the lifetime broadening is greater than the doublet splitting. Because this splitting is often very small (a few hertz), a proton must remain attached to the same molecule for longer than about 0.1 s for the splitting to be observable. In water, the exchange rate is much faster than that, so alcohols show no splitting from the OH protons. In dry dimethylsulfoxide (DMSO), the exchange rate may be slow enough for the splitting to be detected.

**Fig. 14.26** The NMR spectra of an  $A_2$  system (top) and an  $AX$  system (bottom) are simple ‘first-order’ spectra. At intermediate relative values of the chemical shift difference and the spin–spin coupling, complex ‘strongly coupled’ spectra are obtained. Note how the inner two lines of the bottom spectrum move together, grow in intensity, and form the single central line of the top spectrum. The two outer lines diminish in intensity and are absent in the top spectrum.

**6**  $(\text{CH}_3)_2\text{NNO}$

**Fig. 14.27** When a molecule changes from one conformation to another, the positions of its protons are interchanged and jump between magnetically distinct environments.

**Fig. 14.28** The vector model of angular momentum for a single spin- $\frac{1}{2}$  nucleus. The angle around the  $z$ -axis is indeterminate.

**Fig. 14.29** The magnetization of a sample of spin- $\frac{1}{2}$  nuclei is the resultant of all their magnetic moments. (a) In the absence of an externally applied field, there are equal numbers of  $\alpha$  and  $\beta$  spins at random angles around the  $z$ -axis (the field direction) and the magnetization is zero. (b) In the presence of a field, the spins precess around their cones (that is, there is an energy difference between the  $\alpha$  and  $\beta$  states) and there are slightly more  $\alpha$  spins than  $\beta$  spins. As a result, there is a net magnetization along the  $z$ -axis.

## Pulse techniques in NMR

The common method of detecting the energy separation between nuclear spin states is more sophisticated than simply looking for the frequency at which resonance occurs. One of the best analogies that has been suggested to illustrate the preferred way of observing an NMR spectrum is that of detecting the spectrum of vibrations of a bell. We could stimulate the bell with a gentle vibration at a gradually increasing frequency, and note the frequencies at which it resonated with the stimulation. A lot of time would be spent getting zero response when the stimulating frequency was between the bell's vibrational modes. However, if we were simply to hit the bell with a hammer, we would immediately obtain a clang composed of all the frequencies that the bell can produce. The equivalent in NMR is to monitor the radiation nuclear spins emit as they return to equilibrium after the appropriate stimulation. The resulting **Fourier-transform NMR** gives greatly increased sensitivity, so opening up much of the periodic table to the technique. Moreover, multiple-pulse FTNMR gives chemists unparalleled control over the information content and display of spectra. We need to understand how the equivalent of the hammer blow is delivered and how the signal is monitored and interpreted. These features are generally expressed in terms of the vector model of angular momentum introduced in Section 8.7d; the mathematical basis of Fourier transform techniques in general is discussed in *Mathematical background 7* following Chapter 19.

### 14.8 The magnetization vector

**Key points** (a) In the presence of a magnetic field, the magnetization vector grows in magnitude and precesses at the Larmor frequency. (b) When a radiofrequency pulse is applied, the magnetization vector tips and rotates in a different plane. Free-induction decay (FID) is the decay of the magnetization after the pulse. (c) Fourier transformation of the FID curve gives the NMR spectrum.

Consider a sample composed of many identical spin- $\frac{1}{2}$  nuclei. By analogy with the discussion of angular momenta in Section 8.7d, a nuclear spin can be represented by a vector of length  $\{I(I+1)\}^{1/2}$  units with a component of length  $m_I$  units along the  $z$ -axis. As the uncertainty principle does not allow us to specify the  $x$ - and  $y$ -components of the angular momentum, all we know is that the vector lies somewhere on a cone around the  $z$ -axis. For  $I = \frac{1}{2}$ , the length of the vector is  $\frac{1}{2}\sqrt{3}$  and it makes an angle of  $55^\circ$  to the  $z$ -axis (Fig. 14.28).

In the absence of a magnetic field, the sample consists of equal numbers of  $\alpha$  and  $\beta$  nuclear spins with their vectors lying at random angles on the cones. These angles are unpredictable, and at this stage we picture the spin vectors as stationary. The **magnetization**,  $M$ , of the sample, its net nuclear magnetic moment, is zero (Fig. 14.29a).

#### (a) The effect of the static field

Two changes occur in the magnetization when a magnetic field of magnitude  $\mathcal{B}_0$  is present and aligned in the  $z$ -direction. First, the energies of the two orientations change, the  $\alpha$  spins moving to low energy and the  $\beta$  spins to high energy (provided  $\gamma > 0$ ). At 10 T, the Larmor frequency for protons is 427 MHz, and in the vector model the individual vectors are pictured as precessing at this rate. This motion is a pictorial representation of the difference in energy of the spin states (it is not an actual representation of reality but is inspired by the actual motion of a classical bar magnet in a magnetic field). As the field is increased, the Larmor frequency increases and the precession becomes faster. Secondly, the populations of the two spin states (the numbers of  $\alpha$  and  $\beta$  spins) at thermal equilibrium change, and there will be more  $\alpha$  spins than

$\beta$  spins. Because  $h\nu_L/kT \approx 7 \times 10^{-5}$  for protons at 300 K and 10 T, it follows from the Boltzmann distribution that  $N_\beta/N_\alpha = e^{-h\nu_L/kT}$  is only slightly less than 1. That is, there is only a tiny imbalance of populations, and it is even smaller for other nuclei with their smaller magnetogyric ratios. However, despite its smallness, the imbalance means that there is a net magnetization that we can represent by a vector  $M$  pointing in the  $z$ -direction and with a length proportional to the population difference (Fig. 14.29b).

### (b) The effect of the radiofrequency field

We now consider the effect of a radiofrequency field circularly polarized in the  $xy$ -plane, so that the magnetic component of the electromagnetic field (the only component we need to consider) is rotating around the  $z$ -direction in the same sense as the Larmor precession of the nuclei. The strength of the rotating magnetic field is  $\mathcal{B}_1$ .

To interpret the effects of radiofrequency pulses on the magnetization, it is useful to imagine stepping on to a platform, a so-called **rotating frame**, that rotates around the direction of the applied field. Suppose we choose the frequency of the radiofrequency field to be equal to the Larmor frequency of the spins,  $\nu_L = \gamma\mathcal{B}_0/2\pi$ ; this choice is equivalent to selecting the resonance condition in the conventional experiment. The rotating magnetic field is in step with the precessing spins, the nuclei experience a steady  $\mathcal{B}_1$  field, and precess about it at a frequency  $\gamma\mathcal{B}_1/2\pi$  (Fig. 14.30). Now suppose that the  $\mathcal{B}_1$  field is applied in a pulse of duration  $\frac{1}{4} \times (2\pi/\gamma\mathcal{B}_1)$ , the magnetization tips through an angle of  $\frac{1}{4} \times 2\pi = \pi/2$  ( $90^\circ$ ) in the rotating frame and we say that we have applied a  **$90^\circ$  pulse**, or a ' $\pi/2$  pulse' (Fig. 14.31a). The duration of the pulse depends on the strength of the  $\mathcal{B}_1$  field, but is typically of the order of microseconds.

Now imagine stepping out of the rotating frame. To a fixed external observer (the role played by a radiofrequency coil), the magnetization vector is rotating at the Larmor frequency in the  $xy$ -plane (Fig. 14.31b). The rotating magnetization induces in the coil a signal that oscillates at the Larmor frequency and that can be amplified and processed. In practice, the processing takes place after subtraction of a constant high frequency component (the radiofrequency used for  $\mathcal{B}_1$ ), so that all the signal manipulation takes place at frequencies of a few kilohertz.

As time passes, the individual spins move out of step (partly because they are precessing at slightly different rates, as we shall explain later), so the magnetization vector shrinks exponentially with a time constant  $T_2$  and induces an ever weaker signal in the detector coil. The form of the signal that we can expect is therefore the oscillating-decaying **free-induction decay** (FID) shown in Fig. 14.32. The  $y$ -component of the magnetization varies as

$$M_y(t) = M_0 \cos(2\pi\nu_L t) e^{-t/T_2} \quad \text{Free induction decay} \quad (14.30)$$

We have considered the effect of a pulse applied at exactly the Larmor frequency. However, virtually the same effect is obtained off resonance, provided that the pulse is applied close to  $\nu_L$ . If the difference in frequency is small compared to the inverse of the duration of the  $90^\circ$  pulse, the magnetization will end up in the  $xy$ -plane. Note that we do not need to know the Larmor frequency beforehand: the short pulse is the analogue of the hammer blow on the bell, exciting a range of frequencies. The detected signal shows that a particular resonant frequency is present.

### (c) Time- and frequency-domain signals

We can think of the magnetization vector of a homonuclear AX spin system with  $J=0$  as consisting of two parts, one formed by the A spins and the other by the X spins. When the  $90^\circ$  pulse is applied, both magnetization vectors are rotated into the  $xy$ -plane. However, because the A and X nuclei precess at different frequencies, they

**Fig. 14.30** (a) In a resonance experiment, a circularly polarized radiofrequency magnetic field  $\mathcal{B}_1$  is applied in the  $xy$ -plane (the magnetization vector lies along the  $z$ -axis). (b) If we step into a frame rotating at the radiofrequency,  $\mathcal{B}_1$  appears to be stationary, as does the magnetization  $M$  if the Larmor frequency is equal to the radiofrequency. When the two frequencies coincide, the magnetization vector of the sample rotates around the direction of the  $\mathcal{B}_1$  field.

**Fig. 14.31** (a) If the radiofrequency field is applied for a certain time, the magnetization vector is rotated into the  $xy$ -plane. (b) To an external stationary observer (the coil), the magnetization vector is rotating at the Larmor frequency, and can induce a signal in the coil.

**Fig. 14.34** A free induction decay signal of a sample of ethanol. Its Fourier transform is the frequency-domain spectrum shown in Fig. 14.6. The total length of the image corresponds to about 1 s.

**Fig. 14.32** A simple free-induction decay of a sample of spins with a single resonance frequency.

**Fig. 14.33** (a) A free induction decay signal of a sample of AX species and (b) its analysis into its frequency components.

**interActivity** The *Living graphs* section of the text's web site has an applet that allows you to calculate and display the FID curve from an AX system. Explore the effect on the shape of the FID curve of changing the chemical shifts (and therefore the Larmor frequencies) of the A and X nuclei.

induce two signals in the detector coils, and the overall FID curve may resemble that in Fig. 14.33a. The composite FID curve is the analogue of the struck bell emitting a rich tone composed of all the frequencies (in this case, just the two resonance frequencies of the uncoupled A and X nuclei) at which it can vibrate.

The problem we must address is how to recover the resonance frequencies present in a free-induction decay. We know that the FID curve is a sum of decaying oscillating functions, so the problem is to analyse it into its components by carrying out a Fourier transformation (*Further information 14.1* and *Mathematical background 7*). When the signal in Fig. 14.33a is transformed in this way, we get the frequency-domain spectrum shown in Fig. 14.33b. One line represents the Larmor frequency of the A nuclei and the other that of the X nuclei.

The FID curve in Fig. 14.34 is obtained from a sample of ethanol. The frequency-domain spectrum obtained from it by Fourier transformation is the one that we have already discussed (Fig. 14.6). We can now see why the FID curve in Fig. 14.34 is so complex: it arises from the precession of a magnetization vector that is composed of eight components, each with a characteristic frequency.

## 14.9 Spin relaxation

**Key points** Spin relaxation is the return of a spin system to equilibrium. (a) During longitudinal (or spin–lattice) relaxation,  $\beta$  spins revert to  $\alpha$  spins. Transverse (or spin–spin) relaxation is the randomization of spin directions. (b) The longitudinal relaxation time  $T_1$  can be measured by the inversion recovery technique. (c) The transverse relaxation time  $T_2$  can be measured by observing spin echoes.

There are two reasons why the component of the magnetization vector in the  $xy$ -plane shrinks. Both reflect the fact that the nuclear spins are not in thermal equilibrium with their surroundings (for then  $M$  lies parallel to  $z$ ). At thermal equilibrium the spins have a Boltzmann distribution, with more  $\alpha$  spins than  $\beta$  spins. The return to equilibrium is the process called **spin relaxation**.

### (a) Longitudinal and transverse relaxation

Consider the effect of a  $180^\circ$  pulse, which may be visualized in the rotating frame as a flip of the net magnetization vector from one direction along the  $z$ -axis (with more  $\alpha$  spins than  $\beta$  spins) to the opposite direction (with more  $\beta$  spins than  $\alpha$  spins). After the pulse, the populations revert to their thermal equilibrium values exponentially. As they do so, the  $z$ -component of magnetization reverts to its equilibrium value  $M_0$  with a time constant called the **longitudinal relaxation time**,  $T_1$  (Fig. 14.35):

$$M_z(t) - M_0 \propto e^{-t/T_1} \quad \text{Definition of longitudinal relaxation time} \quad (14.31)$$

Because this relaxation process involves giving up energy to the surroundings (the 'lattice') as  $\beta$  spins revert to  $\alpha$  spins, the time constant  $T_1$  is also called the **spin-lattice relaxation time**. Spin-lattice relaxation is caused by local magnetic fields that fluctuate at a frequency close to the resonance frequency of the  $\beta \rightarrow \alpha$  transition. Such fields can arise from the tumbling motion of molecules in a fluid sample. If molecular tumbling is too slow or too fast compared to the resonance frequency, it will give rise to a fluctuating magnetic field with a frequency that is either too low or too high to stimulate a spin change from  $\beta$  to  $\alpha$ , so  $T_1$  will be long. Only if the molecule tumbles at about the resonance frequency will the fluctuating magnetic field be able to induce spin changes effectively, and only then will  $T_1$  be short. The rate of molecular tumbling increases with temperature and with reducing viscosity of the solvent, so we can expect a dependence like that shown in Fig. 14.36. The quantitative treatment of relaxation times depends on setting up models of molecular motion and using, for instance, the diffusion equation (Section 20.9).

Now consider the events following a  $90^\circ$  pulse. The magnetization vector in the  $xy$ -plane is large when the spins are bunched together immediately after the pulse. However, this orderly bunching of spins is not at equilibrium and, even if there were no spin-lattice relaxation, we would expect the individual spins to spread out until they were uniformly distributed with all possible angles around the  $z$ -axis (Fig. 14.37). At that stage, the component of magnetization vector in the plane would be zero. The randomization of the spin directions occurs exponentially with a time constant called the **transverse relaxation time**,  $T_2$ :

$$M_y(t) \propto e^{-t/T_2} \quad \text{Definition of transverse relaxation time} \quad (14.32)$$

Because the relaxation involves the relative orientation of the spins around their respective cones,  $T_2$  is also known as the **spin-spin relaxation time**. Any relaxation process that changes the balance between  $\alpha$  and  $\beta$  spins will also contribute to this randomization, so the time constant  $T_2$  is almost always less than or equal to  $T_1$ .

Local magnetic fields also affect spin-spin relaxation. When the fluctuations are slow, each molecule lingers in its local magnetic environment and the spin orientations randomize quickly around their cones. If the molecules move rapidly from one magnetic environment to another, the effects of differences in local magnetic field average to zero: individual spins do not precess at very different rates, they can remain bunched for longer, and spin-spin relaxation does not take place as quickly. In other words, slow molecular motion corresponds to short  $T_2$  and fast motion corresponds

**Fig. 14.35** In longitudinal relaxation the spins relax back towards their thermal equilibrium populations. On the left we see the precessional cones representing spin- $\frac{1}{2}$  angular momenta, and they do not have their thermal equilibrium populations (there are more  $\beta$ -spins than  $\alpha$ -spins). On the right, which represents the sample a long time after a time  $T_1$  has elapsed, the populations are those characteristic of a Boltzmann distribution. In actuality,  $T_1$  is the time constant for relaxation to the arrangement on the right and  $T_1 \ln 2$  is the half-life of the arrangement on the left.

**Fig. 14.36** The variation of the two relaxation times with the rate at which the molecules move (either by tumbling or migrating through the solution). The horizontal axis can be interpreted as representing temperature or viscosity. Note that, at rapid rates of motion, the two relaxation times coincide.

**Fig. 14.37** The transverse relaxation time,  $T_2$ , is the time constant for the phases of the spins to become randomized (another condition for equilibrium) and to change from the orderly arrangement shown on the left to the disorderly arrangement on the right (long after a time  $T_2$  has elapsed). Note that the populations of the states remain the same; only the relative phase of the spins relaxes. In actuality,  $T_2$  is the time constant for relaxation to the arrangement on the right and  $T_2 \ln 2$  is the half-life of the arrangement on the left.

to long  $T_2$  (as shown in Fig. 14.36). Calculations show that, when the motion is fast, the main randomizing effect arises from  $\beta \rightarrow \alpha$  transitions rather than different precession rates on the cones, and then  $T_2 \approx T_1$ .

If the  $y$ -component of magnetization decays with a time constant  $T_2$ , the spectral line is broadened (Fig. 14.38), and its width at half-height becomes

$$\Delta\nu_{1/2} = \frac{1}{\pi T_2} \quad \text{Width at half-height of an NMR line} \quad (14.33)$$

This connection between decay rate and spectral width emerges naturally from a Fourier analysis (*Mathematical background 7*). Typical values of  $T_2$  in proton NMR are of the order of seconds, so linewidths of around 0.1 Hz can be anticipated, in broad agreement with observation.

So far, we have assumed that the equipment, and in particular the magnet, is perfect, and that the differences in Larmor frequencies arise solely from interactions within the sample. In practice, the magnet is not perfect, and the field is different at different locations in the sample. The inhomogeneity broadens the resonance, and in most cases this **inhomogeneous broadening** dominates the broadening we have discussed so far. It is common to express the extent of inhomogeneous broadening in terms of an **effective transverse relaxation time**,  $T_2^*$ , by using a relation like eqn 14.33, but writing

$$T_2^* = \frac{1}{\pi \Delta\nu_{1/2}} \quad \text{Definition of effective transverse relaxation time} \quad [14.34]$$

where  $\Delta\nu_{1/2}$  is the observed width at half-height of a line with a Lorentzian shape of the form  $I \propto 1/(1 + \nu^2)$ .

#### • A brief illustration

Consider a line in a spectrum with a width of 10 Hz. It follows from eqn 14.34 that the effective transverse relaxation time is

$$T_2^* = \frac{1}{\pi \times (10 \text{ s}^{-1})} = 32 \text{ ms} \quad \bullet$$

#### (b) The measurement of $T_1$

The longitudinal relaxation time  $T_1$  can be measured by the **inversion recovery technique**. The first step is to apply a  $180^\circ$  pulse to the sample. A  $180^\circ$  pulse is achieved by applying the  $\mathcal{B}_1$  field for twice as long as for a  $90^\circ$  pulse, so the magnetization vector precesses through  $180^\circ$  and points in the  $z$ -direction (Fig. 14.39). No signal can be seen at this stage because there is no component of magnetization in the  $xy$ -plane (where the coil can detect it). The  $\beta$  spins begin to relax back into  $\alpha$  spins, and the magnetization vector first shrinks exponentially, falling through zero to its thermal equilibrium value,  $M_0$ . After an interval  $\tau$ , a  $90^\circ$  pulse is applied that rotates the remaining magnetization into the  $xy$ -plane, where it generates an FID signal. The frequency-domain spectrum is then obtained by Fourier transformation.

The intensity of the spectrum obtained in this way depends on the length of the magnetization vector that is rotated into the  $xy$ -plane. The length of that vector changes exponentially as the interval between the two pulses is increased, so the intensity of the spectrum also changes exponentially with increasing  $\tau$ . We can therefore measure  $T_1$  by fitting an exponential curve to the series of spectra obtained with different values of  $\tau$ .

**Fig. 14.38** A Lorentzian absorption line. The width at half-height is inversely proportional to the parameter  $T_2$  and, the longer the transverse relaxation time, the narrower the line.

 **InterActivity** The *Living graphs* section of the text's web site has an applet that allows you to calculate and display Lorentzian absorption lines. Explore the effect of the parameter  $T_2$  on the width and the maximal intensity of a Lorentzian line. Rationalize your observations.

### (c) Spin echoes

The measurement of  $T_2$  (as distinct from  $T_2^*$ ) depends on being able to eliminate the effects of inhomogeneous broadening. The cunning required is at the root of some of the most important advances that have been made in NMR since its introduction.

A **spin echo** is the magnetic analogue of an audible echo: transverse magnetization is created by a radiofrequency pulse, decays away, is reflected by a second pulse, and grows back to form an echo. The sequence of events is shown in Fig. 14.40. We can consider the overall magnetization as being made up of a number of different magnetizations, each of which arises from a **spin packet** of nuclei with very similar precession frequencies. The spread in these frequencies arises because the applied field  $\mathcal{B}_0$  is inhomogeneous, so different parts of the sample experience different fields. The precession frequencies also differ if there is more than one chemical shift present. As will be seen, the importance of a spin echo is that it can suppress the effects of both field inhomogeneities and chemical shifts.

First, a  $90^\circ$  pulse is applied to the sample. We follow events by using the rotating frame, in which  $\mathcal{B}_1$  is stationary along the  $x$ -axis and causes the magnetization to rotate into the  $xy$ -plane. The spin packets now begin to fan out because they have different Larmor frequencies, with some above the radiofrequency and some below. The detected signal depends on the resultant of the spin-packet magnetization vectors, and decays with a time-constant  $T_2^*$  because of the combined effects of field inhomogeneity and spin-spin relaxation.

**Fig. 14.39** The result of applying a  $180^\circ$  pulse to the magnetization in the rotating frame and the effect of a subsequent  $90^\circ$  pulse. The amplitude of the frequency-domain spectrum varies with the interval between the two pulses because spin-lattice relaxation has time to occur.

**Fig. 14.40** The sequence of pulses leading to the observation of a spin echo.

**Fig. 14.41** The exponential decay of spin echoes can be used to determine the transverse relaxation time.

**Fig. 14.42** In a magnetic field that varies linearly over a sample, all the protons within a given slice (that is, at a given field value) come into resonance and give a signal of the corresponding intensity. The resulting intensity pattern is a map of the numbers in all the slices, and portrays the shape of the sample. Changing the orientation of the field shows the shape along the corresponding direction, and computer manipulation can be used to build up the three-dimensional shape of the sample.

After an evolution period  $\tau$ , a  $180^\circ$  pulse is applied to the sample—this time about the  $y$ -axis of the rotating frame (the axis of the pulse is changed from  $x$  to  $y$  by a  $90^\circ$  phase shift of the radiofrequency radiation). The pulse rotates the magnetization vectors of the faster spin packets into the positions previously occupied by the slower spin packets, and vice versa. Thus, as the vectors continue to precess, the fast vectors are now behind the slow; the fan begins to close up again, and the resultant signal begins to grow back into an echo. After another interval of length  $\tau$ , all the vectors will once more be aligned along the  $y$ -axis, and the fanning out caused by the field inhomogeneity is said to have been **refocused**: the spin echo has reached its maximum.

The important feature of the technique is that the size of the echo is independent of any local fields that remain constant during the two  $\tau$  intervals. If a spin packet is ‘fast’ because it happens to be composed of spins in a region of the sample that experiences higher than average fields, then it remains fast throughout both intervals, and what it gains on the first interval it loses on the second interval. Hence, the size of the echo is independent of inhomogeneities in the magnetic field, for these remain constant. The true transverse relaxation arises from fields that vary on a molecular distance scale, and there is no guarantee that an individual ‘fast’ spin will remain ‘fast’ in the refocusing phase: the spins within the packets therefore spread with a time constant  $T_2$ . Hence, the effects of the true relaxation are not refocused, and the size of the echo decays with the time constant  $T_2$  (Fig. 14.41).

#### IMPACT ON MEDICINE

##### 114.1 Magnetic resonance imaging

One of the most striking applications of nuclear magnetic resonance is in medicine. *Magnetic resonance imaging* (MRI) is a portrayal of the concentrations of protons in a solid object. The technique relies on the application of specific pulse sequences to an object in an inhomogeneous magnetic field.

If an object containing hydrogen nuclei (a tube of water or a human body) is placed in an NMR spectrometer and exposed to a *homogeneous* magnetic field, then a single resonance signal will be detected. Now consider a flask of water in a magnetic field that varies linearly in the  $z$ -direction according to  $\mathcal{B}_0 + G_z z$ , where  $G_z$  is the field gradient along the  $z$ -direction (Fig. 14.42). Then the water protons will be resonant at the frequencies

$$\nu_L(z) = \frac{\gamma}{2\pi} (\mathcal{B}_0 + G_z z) \quad (14.35)$$

(Similar equations may be written for gradients along the  $x$ - and  $y$ -directions.) Application of a  $90^\circ$  radiofrequency pulse with  $\nu = \nu_L(z)$  will result in a signal with an intensity that is proportional to the numbers of protons at the position  $z$ . This is an example of *slice selection*, the application of a selective  $90^\circ$  pulse that excites nuclei in a specific region, or slice, of the sample. It follows that the intensity of the NMR signal will be a projection of the numbers of protons on a line parallel to the field gradient. The image of a three-dimensional object such as a flask of water can be obtained if the slice selection technique is applied at different orientations (see Fig. 14.43). In *projection reconstruction*, the projections can be analysed on a computer to reconstruct the three-dimensional distribution of protons in the object.

In practice, the NMR signal is not obtained by direct analysis of the FID curve after application of a single  $90^\circ$  pulse. Instead, spin echoes are often detected with several variations of the  $90^\circ$ – $\tau$ – $180^\circ$  pulse sequence (Section 14.9c). In *phase encoding*, field gradients are applied during the evolution period and the detection period of a

spin-echo pulse sequence. The first step consists of a  $90^\circ$  pulse that results in slice selection along the  $z$ -direction. The second step consists of application of a *phase gradient*, a field gradient along the  $y$ -direction, during the evolution period. At each position along the gradient, a spin packet will precess at a different Larmor frequency due to chemical shift effects and the field inhomogeneity, so each packet will dephase to a different extent by the end of the evolution period. We can control the extent of dephasing by changing the duration of the evolution period, so Fourier transformation on  $\tau$  gives information about the location of a proton along the  $y$ -direction.<sup>2</sup> For each value of  $\tau$ , the next steps are application of the  $180^\circ$  pulse and then of a *read gradient*, a field gradient along the  $x$ -direction, during detection of the echo. Protons at different positions along  $x$  experience different fields and will resonate at different frequencies. Therefore Fourier transformation of the FID gives different signals for protons at different positions along  $x$ .

A common problem with the techniques described above is image contrast, which must be optimized in order to show spatial variations in water content in the sample. One strategy for solving this problem takes advantage of the fact that the relaxation times of water protons are shorter for water in biological tissues than for the pure liquid. Furthermore, relaxation times from water protons are also different in healthy and diseased tissues. A  $T_1$ -weighted image is obtained by repeating the spin-echo sequence before spin-lattice relaxation can return the spins in the sample to equilibrium. Under these conditions, differences in signal intensities are directly related to differences in  $T_1$ . A  $T_2$ -weighted image is obtained by using an evolution period  $\tau$  that is relatively long. Each point on the image is an echo signal that behaves in the manner shown in Fig. 14.41, so signal intensities are strongly dependent on variations in  $T_2$ . However, allowing so much of the decay to occur leads to weak signals even for those protons with long spin-spin relaxation times. Another strategy involves the use of *contrast agents*, paramagnetic compounds that shorten the relaxation times of nearby protons. The technique is particularly useful in enhancing image contrast and in diagnosing disease if the contrast agent is distributed differently in healthy and diseased tissues.

The MRI technique is used widely to detect physiological abnormalities and to observe metabolic processes. With *functional MRI*, blood flow in different regions of the brain can be studied and related to the mental activities of the subject. The technique is based on differences in the magnetic properties of deoxygenated and oxygenated haemoglobin, the iron-containing protein that transports  $O_2$  in red blood cells. The more paramagnetic deoxygenated haemoglobin affects the proton resonances of tissue differently from the oxygenated protein. Because there is greater blood flow in active regions of the brain than in inactive regions, changes in the intensities of proton resonances due to changes in levels of oxygenated haemoglobin can be related to brain activity.

The special advantage of MRI is that it can image *soft tissues* (Fig. 14.43), whereas X-rays are largely used for imaging hard, bony structures and abnormally dense regions, such as tumours. In fact, the invisibility of hard structures in MRI is an advantage, as it allows the imaging of structures encased by bone, such as the brain and the spinal cord. X-rays are known to be dangerous on account of the ionization they cause; the high magnetic fields used in MRI may also be dangerous but, apart from anecdotes about the extraction of loose fillings from teeth, there is no convincing evidence of their harmfulness, and the technique is considered safe.

**Fig. 14.43** The great advantage of MRI is that it can display soft tissue, such as in this cross-section through a patient's head. (Courtesy of the University of Manitoba.)

<sup>2</sup> For technical reasons, it is more common to vary the magnitude of the phase gradient.

## 14.10 Spin decoupling

**Key point** In proton decoupling of  $^{13}\text{C}$ -NMR spectra, protons are made to undergo rapid spin reorientations and the  $^{13}\text{C}$  nucleus senses an average orientation. As a result, its resonance is a single line and not a group of lines.

Carbon-13 is a **dilute-spin species** in the sense that it is unlikely that more than one  $^{13}\text{C}$  nucleus will be found in any given small molecule (provided the sample has not been enriched with that isotope; the natural abundance of  $^{13}\text{C}$  is only 1.1 per cent). Even in large molecules, although more than one  $^{13}\text{C}$  nucleus may be present, it is unlikely that they will be close enough to give an observable splitting. Hence, it is not normally necessary to take into account  $^{13}\text{C}$ – $^{13}\text{C}$  spin–spin coupling within a molecule.

Protons are **abundant-spin species** in the sense that a molecule is likely to contain many of them. If we were observing a  $^{13}\text{C}$ -NMR spectrum, we would obtain a very complex spectrum on account of the coupling of the one  $^{13}\text{C}$  nucleus with many of the protons that are present. To avoid this difficulty,  $^{13}\text{C}$ -NMR spectra are normally observed using the technique of **proton decoupling**. Thus, if the  $\text{CH}_3$  protons of ethanol are irradiated with a second, strong, resonant radiofrequency pulse, they undergo rapid spin reorientations and the  $^{13}\text{C}$  nucleus senses an average orientation. As a result, its resonance is a single line and not a 1:3:3:1 quartet. Proton decoupling has the additional advantage of enhancing sensitivity, because the intensity is concentrated into a single transition frequency instead of being spread over several transition frequencies (see Section 14.11). If care is taken to ensure that the other parameters on which the strength of the signal depends are kept constant, the intensities of proton-decoupled spectra are proportional to the number of  $^{13}\text{C}$  nuclei present. The technique is widely used to characterize synthetic polymers.

## 14.11 The nuclear Overhauser effect

**Key point** The nuclear Overhauser effect is the modification of one resonance by the saturation of another.

We have seen already that one advantage of protons in NMR is their high magnetogyric ratio, which results in relatively large Boltzmann population differences and hence greater resonance intensities than for most other nuclei. In the steady-state **nuclear Overhauser effect** (NOE), spin relaxation processes involving internuclear dipole–dipole interactions are used to transfer this population advantage to another nucleus (such as  $^{13}\text{C}$  or another proton), so that the latter's resonances are modified.

To understand the effect, we consider the populations of the four levels of a homonuclear (for instance, proton) AX system; these levels were shown in Fig. 14.13. At thermal equilibrium, the population of the  $\alpha_A\alpha_X$  level is the greatest, and that of the  $\beta_A\beta_X$  level is the least; the other two levels have the same energy and an intermediate population. The thermal equilibrium absorption intensities reflect these populations as shown in Fig. 14.44. Now consider the combined effect of spin relaxation and keeping the X spins saturated (that is, their populations equalized). When we saturate the X transition, the populations of the X levels are equalized ( $N_{\alpha_X} = N_{\beta_X}$ ) and all transitions involving  $\alpha_X \leftrightarrow \beta_X$  spin flips are no longer observed. At this stage there is no change in the populations of the A levels. If that were all there were to happen, all we would see would be the loss of the X resonance and no effect on the A resonance.

Now consider the effect of spin relaxation. Relaxation can occur in a variety of ways if there is a dipolar interaction between the A and X spins. One possibility is for the magnetic field acting between the two spins to cause them *both* to flop simultaneously

**Fig. 14.44** The energy levels of an AX system and an indication of their relative populations. Each grey square above the line represents an excess population and each white square below the line represents a population deficit. The transitions of A and X are marked.

**Fig. 14.45** (a) When the X transition is saturated, the populations of its two states are equalized and the population excess and deficit become as shown (using the same symbols as in Fig. 14.44). (b) Dipole–dipole relaxation relaxes the populations of the highest and lowest states, and they regain their original populations. (c) The A transitions reflect the difference in populations resulting from the preceding changes, and are enhanced compared with those shown in Fig. 14.44.

from  $\beta$  to  $\alpha$ , so the  $\alpha_A\alpha_X$  and  $\beta_A\beta_X$  states regain their thermal equilibrium populations. However, the populations of the  $\alpha_A\beta_X$  and  $\beta_A\alpha_X$  levels remain unchanged at the values characteristic of saturation. As we see from Fig. 14.45, the population difference between the states joined by transitions of A is now greater than at equilibrium, so the resonance absorption is enhanced. Another possibility is for the dipolar interaction between the two spins to cause  $\alpha_A$  to flip to  $\beta_A$  and simultaneously  $\beta_X$  to flop to  $\alpha_X$  (or vice versa). This transition equilibrates the populations of  $\alpha_A\beta_X$  and  $\beta_A\alpha_X$  but leaves the  $\alpha_A\alpha_X$  and  $\beta_A\beta_X$  populations unchanged. Now we see from the illustration that the population differences in the states involved in the A transitions are decreased, so the resonance absorption is diminished.

Which effect wins? Does the NOE enhance the A absorption or does it diminish it? As in the discussion of relaxation times in Section 14.9, the efficiency of the intensity-enhancing  $\beta_A\beta_X \leftrightarrow \alpha_A\alpha_X$  relaxation is high if the dipole field oscillates at a frequency close to the transition frequency, which in this case is about  $2\nu$ ; likewise, the efficiency of the intensity-diminishing  $\alpha_A\beta_X \leftrightarrow \beta_A\alpha_X$  relaxation is high if the dipole field is stationary (as there is no frequency difference between the initial and final states). A large molecule rotates so slowly that there is very little motion at  $2\nu$ , so we expect an intensity decrease (Fig. 14.46). A small molecule rotating rapidly can be expected to have substantial motion at  $2\nu$ , and a consequent enhancement of the signal. In

**Fig. 14.46** (a) When the X transition is saturated, just as in Fig. 14.45 the populations of its two states are equalized and the population excess and deficit become as shown. (b) Dipole–dipole relaxation relaxes the populations of the two intermediate states, and they regain their original populations. (c) The A transitions reflect the difference in populations resulting from the preceding changes, and are diminished compared with those shown in Fig. 14.44.

practice, the enhancement lies somewhere between the two extremes and is reported in terms of the parameter  $\eta$  (eta), where

$$\eta = \frac{I_A - I_A^\circ}{I_A^\circ} \quad \text{Definition of the NOE enhancement parameter} \quad [14.36]$$

Here  $I_A^\circ$  and  $I_A$  are the intensities of the NMR signals due to nucleus A before and after application of the long ( $>T_1$ ) radiofrequency pulse that saturates transitions due to the X nucleus. When A and X are nuclei of the same species, such as protons,  $\eta$  lies between  $-1$  (diminution) and  $+\frac{1}{2}$  (enhancement). However,  $\eta$  also depends on the values of the magnetogyric ratios of A and X. In the case of maximal enhancement it is possible to show that

$$\eta = \frac{\gamma_X}{2\gamma_A} \quad (14.37)$$

where  $\gamma_A$  and  $\gamma_X$  are the magnetogyric ratios of nuclei A and X, respectively. For  $^{13}\text{C}$  close to a saturated proton, the ratio evaluates to 1.99, which shows that an enhancement of about a factor of 2 can be achieved.

The NOE is also used to determine interproton distances. The Overhauser enhancement of a proton A generated by saturating a spin X depends on the fraction of A's spin-lattice relaxation that is caused by its dipolar interaction with X. Because the dipolar field is proportional to  $r^{-3}$ , where  $r$  is the internuclear distance, and the relaxation effect is proportional to the square of the field, and therefore to  $r^{-6}$ , the NOE may be used to determine the geometries of molecules in solution. The determination of the structure of a small protein in solution involves the use of several hundred NOE measurements, effectively casting a net over the protons present. The enormous importance of this procedure is that we can determine the conformation of biological macromolecules in an aqueous environment and do not need to try to make the single crystals that are essential for an X-ray diffraction investigation (Chapter 19).

## 14.12 Two-dimensional NMR

**Key points** In two-dimensional NMR, spectra are displayed in two axes, with resonances belonging to different groups lying at different locations on the second axis. In correlation spectroscopy (COSY), all spin-spin couplings in a molecule are determined. In nuclear Overhauser effect spectroscopy (NOESY), internuclear distances up to about 0.5 nm are determined.

**Fig. 14.47** An idealization of the COSY spectrum of an AX spin system.

An NMR spectrum contains a great deal of information and, if many protons are present, is very complex. Even a first-order spectrum is complex, for the fine structure of different groups of lines can overlap. The complexity would be reduced if we could use two axes to display the data, with resonances belonging to different groups lying at different locations on the second axis. This separation is essentially what is achieved in **two-dimensional NMR**.

Much modern NMR work makes use of **correlation spectroscopy** (COSY) in which a clever choice of pulses and Fourier transformation techniques makes it possible to determine all spin-spin couplings in a molecule. A typical outcome for an AX system is shown in Fig. 14.47. The diagram shows contours of equal signal intensity on a plot of intensity against the frequency coordinates  $\nu_1$  and  $\nu_2$ . The **diagonal peaks** are signals centred on  $(\delta_A, \delta_A)$  and  $(\delta_X, \delta_X)$  and lie along the diagonal where  $\nu_1 = \nu_2$ . That is, the spectrum along the diagonal is equivalent to the one-dimensional spectrum obtained with the conventional NMR technique (Fig. 14.14). The **cross-peaks** (or **off-diagonal peaks**) are signals centred on  $(\delta_A, \delta_X)$  and  $(\delta_X, \delta_A)$  and owe their existence to the coupling between the A and X nuclei.

Although information from two-dimensional NMR spectroscopy is trivial in an AX system, it can be of enormous help in the interpretation of more complex spectra, leading to a map of the couplings between spins and to the determination of the bonding network in complex molecules. Indeed, the spectrum of a synthetic or biological polymer that would be impossible to interpret in one-dimensional NMR can often be interpreted reasonably rapidly by two-dimensional NMR.

#### • A brief illustration

Figure 14.48 is a portion of the COSY spectrum of the amino acid isoleucine (7), showing the resonances associated with the protons bound to the carbon atoms. From the molecular structure, we expect that: (i) the  $C_\alpha$ -H proton is coupled only to the  $C_\beta$ -H proton, (ii) the  $C_\beta$ -H protons are coupled to the  $C_\alpha$ -H,  $C_\gamma$ -H, and  $C_\delta$ -H protons, and (iii) the inequivalent  $C_\delta$ -H protons are coupled to the  $C_\beta$ -H and  $C_\gamma$ -H protons. We now note that:

- The resonance with  $\delta = 3.6$  shares a cross-peak with only one other resonance at  $\delta = 1.9$ , which in turn shares cross-peaks with resonances at  $\delta = 1.4$ , 1.2, and 0.9. We conclude that the resonances at  $\delta = 3.6$  and 1.9 correspond to the  $C_\alpha$ -H and  $C_\beta$ -H protons, respectively.
- The proton with resonance at  $\delta = 0.8$  is not coupled to the  $C_\beta$ -H protons, so we assign the resonance at  $\delta = 0.8$  to the  $C_\gamma$ -H protons.
- The resonances at  $\delta = 1.4$  and 1.2 do not share cross-peaks with the resonance at  $\delta = 0.9$ .
- In the light of the expected couplings, we assign the resonance at  $\delta = 0.9$  to the  $C_\gamma$ -H protons and the resonances at  $\delta = 1.4$  and 1.2 to the inequivalent  $C_\delta$ -H protons. •

We have seen that the nuclear Overhauser effect can provide information about internuclear distances through analysis of enhancement patterns in the NMR spectrum before and after saturation of selected resonances. In **nuclear Overhauser effect spectroscopy** (NOESY) a map of all possible NOE interactions is obtained by again using a proper choice of radiofrequency pulses and Fourier transformation techniques. Like a COSY spectrum, a NOESY spectrum consists of a series of diagonal peaks that correspond to the one-dimensional NMR spectrum of the sample. The off-diagonal peaks indicate which nuclei are close enough to each other to give rise to a nuclear Overhauser effect. NOESY data reveal internuclear distances up to about 0.5 nm.

### 14.13 Solid-state NMR

**Key points** (a) Broad NMR linewidths in solid samples are determined by magnetic interactions between nuclear spins and chemical shift anisotropy. (b) Magic-angle spinning (MAS) is a technique in which the NMR linewidths in a solid sample are reduced by spinning at an angle of  $54.74^\circ$  to the applied magnetic field.

The principal difficulty with the application of NMR to solids is the low resolution characteristic of solid samples. Nevertheless, there are good reasons for seeking to overcome these difficulties. They include the possibility that a compound of interest is unstable in solution or that it is insoluble, so conventional solution NMR cannot be employed. Moreover, many species are intrinsically interesting as solids, and it is important to determine their structures and dynamics. Synthetic polymers are particularly interesting in this regard, and information can be obtained about the arrangement of molecules, their conformations, and the motion of different parts of the chain. This kind of information is crucial to an interpretation of the bulk properties of the

**Fig. 14.48** Proton COSY spectrum of isoleucine. (The *brief illustration* and corresponding spectrum are adapted from K.E. van Holde, *et al.*, *Principles of physical biochemistry*, Prentice Hall, Upper Saddle River (1998).)

**7** Isoleucine

polymer in terms of its molecular characteristics. Similarly, inorganic substances, such as the zeolites that are used as molecular sieves and shape-selective catalysts, can be studied using solid-state NMR, and structural problems can be resolved that cannot be tackled by X-ray diffraction. The recent surge of interest in inorganic nanomaterials has also contributed to the development of solid-state NMR studies.

Problems of resolution and linewidth are not the only features that plague NMR studies of solids, but the rewards are so great that considerable efforts have been made to overcome them and have achieved notable success. Because molecular rotation has almost ceased (except in special cases, including ‘plastic crystals’ in which the molecules continue to tumble), spin–lattice relaxation times are very long but spin–spin relaxation times are very short. Hence, in a pulse experiment, there is a need for lengthy delays—of several seconds—between successive pulses so that the spin system has time to revert to equilibrium. Even gathering the murky information may therefore be a lengthy process. Moreover, because lines are so broad, very high powers of radiofrequency radiation may be required to achieve saturation. Whereas solution pulse NMR uses transmitters of a few tens of watts, solid-state NMR may require transmitters rated at several hundreds of watts.

#### (a) The origins of linewidths in solids

There are three principal contributions to the linewidths of solids. One is the direct magnetic dipolar interaction between nuclear spins. As we saw in the discussion of spin–spin coupling, a nuclear magnetic moment will give rise to a local magnetic field, which points in different directions at different locations around the nucleus. If we are interested only in the component parallel to the direction of the applied magnetic field (because only this component has a significant effect), then we can use a classical expression in *Justification 14.2* to write the magnitude of the local magnetic field as

$$\mathcal{B}_{\text{loc}} = -\frac{\gamma\hbar\mu_0 m_I}{4\pi R^3}(1 - 3\cos^2\theta) \quad (14.38)$$

Unlike in solution, this field is not motionally averaged to zero. Many nuclei may contribute to the total local field experienced by a nucleus of interest, and different nuclei in a sample may experience a wide range of fields. Typical dipole fields are of the order of 1 mT, which corresponds to splittings and linewidths of the order of 10 kHz.

A second source of linewidth is the anisotropy of the chemical shift. We have seen that chemical shifts arise from the ability of the applied field to generate electron currents in molecules. In general, this ability depends on the orientation of the molecule relative to the applied field. In solution, when the molecule is tumbling rapidly, only the average value of the chemical shift is relevant. However, the anisotropy is not averaged to zero for stationary molecules in a solid, and molecules in different orientations have resonances at different frequencies. The chemical shift anisotropy also varies with the angle between the applied field and the principal axis of the molecule as  $1 - 3\cos^2\theta$ .

The third contribution is the electric quadrupole interaction. Nuclei with  $I > \frac{1}{2}$  have a distribution of charge that gives rise to an electric quadrupole moment (for instance, the positive charge may be concentrated around the equator or at the poles). An electric quadrupole interacts with an electric field gradient, such as may arise from a non-spherical distribution of charge around the nucleus. This interaction also varies as  $1 - 3\cos^2\theta$ .

#### (b) The reduction of linewidths

Fortunately, there are techniques available for reducing the linewidths of solid samples. One technique, **magic-angle spinning (MAS)**, takes note of the  $1 - 3\cos^2\theta$

dependence of the dipole–dipole interaction, the chemical shift anisotropy, and the electric quadrupole interaction. The ‘magic angle’ is the angle at which  $1 - 3 \cos^2 \theta = 0$ , and corresponds to  $54.74^\circ$ . In the technique, the sample is spun at high speed at the magic angle to the applied field (Fig. 14.49). All the dipolar interactions and the anisotropies average to the value they would have at the magic angle, but at that angle they are zero. The difficulty with MAS is that the spinning frequency must not be less than the width of the spectrum, which is of the order of kilohertz. However, gas-driven sample spinners that can be rotated at up to 25 kHz are now routinely available, and a considerable body of work has been done.

Pulsed techniques similar to those described in the previous section may also be used to reduce linewidths. The dipolar field of protons, for instance, may be reduced by a decoupling procedure. However, because the range of coupling strengths is so large, radiofrequency power of the order of 1 kW is required. Elaborate pulse sequences have also been devised that reduce linewidths by averaging procedures that make use of twisting the magnetization vector through an elaborate series of angles.

## Electron paramagnetic resonance

Electron paramagnetic resonance (EPR) is less widely applicable than NMR because it cannot be detected in normal, spin-paired molecules and the sample must possess unpaired electron spins. It is used to study radicals formed during chemical reactions or by radiation, radicals that act as probes of biological structure, many d-metal complexes, and molecules in triplet states (such as those involved in phosphorescence, Section 13.4). The sample may be a gas, a liquid, or a solid, but the free rotation of molecules in the gas phase gives rise to complications.

### 14.14 The EPR spectrometer

**Key point** EPR spectrometers consist of a microwave source, a cavity in which the sample is inserted, a microwave detector, and an electromagnet.

Both Fourier-transform (FT) and continuous wave (CW) EPR spectrometers are available. The FT-EPR instrument is based on the concepts developed in Section 14.8, except that pulses of microwaves are used to excite electron spins in the sample. The layout of the more common CW-EPR spectrometer is shown in Fig. 14.50. It consists of a microwave source (a klystron or a Gunn oscillator), a cavity in which the sample is inserted in a glass or quartz container, a microwave detector, and an electromagnet with a field that can be varied in the region of 0.3 T. The EPR spectrum is obtained by monitoring the microwave absorption as the field is changed, and a typical spectrum (of the benzene radical anion,  $\text{C}_6\text{H}_6^-$ ) is shown in Fig. 14.51. The peculiar appearance of the spectrum, which is in fact the first derivative of the absorption, arises from the detection technique, which is sensitive to the slope of the absorption curve (Fig. 14.52).

### 14.15 The g-value

**Key point** The EPR resonance condition is written in terms of the g-value of the radical,  $g$ ; the deviation of  $g$  from  $g_e = 2.0023$  depends on the ability of the applied field to induce local electron currents in the radical.

**Fig. 14.49** In magic angle spinning, the sample spins at  $54.74^\circ$  (that is,  $\arccos 1/3^{1/2}$ ) to the applied magnetic field. Rapid motion at this angle averages dipole–dipole interactions and chemical shift anisotropies to zero.

**Fig. 14.50** The layout of a continuous-wave EPR spectrometer. A typical magnetic field is 0.3 T, which requires 9 GHz (3 cm) microwaves for resonance.

**Fig. 14.51** The EPR spectrum of the benzene radical anion,  $\text{C}_6\text{H}_6\dot{-}$ , in fluid solution.  $a$  is the hyperfine splitting of the spectrum; the centre of the spectrum is determined by the  $g$ -value of the radical.

**Fig. 14.52** When phase-sensitive detection is used, the signal is the first derivative of the absorption intensity. Note that the peak of the absorption corresponds to the point where the derivative passes through zero.

Equation 14.12b gives the resonance frequency for a transition between the  $m_s = -\frac{1}{2}$  and the  $m_s = +\frac{1}{2}$  levels of a ‘free’ electron in terms of the  $g$ -value  $g_e \approx 2.0023$ . The magnetic moment of an unpaired electron in a radical also interacts with an external field, but the  $g$ -value is different from that for a free electron because of local magnetic fields induced by the molecular framework of the radical. Consequently, the resonance condition is normally written as

$$h\nu = g\mu_B B_0$$

EPR resonance condition

 (14.39)

where  $g$  is the  $g$ -value of the radical.

#### • A brief illustration

The centre of the EPR spectrum of the methyl radical occurred at 329.40 mT in a spectrometer operating at 9.2330 GHz (radiation belonging to the X band of the microwave region). Its  $g$ -value is therefore

$$g = \frac{h\nu}{\mu_B B_0} = \frac{(6.626\,08 \times 10^{-34} \text{ J s}) \times (9.2330 \times 10^9 \text{ s}^{-1})}{(9.2740 \times 10^{-24} \text{ J T}^{-1}) \times (0.329\,40 \text{ T})} = 2.0027$$

**Self-test 14.3** At what magnetic field would the methyl radical come into resonance in a spectrometer operating at 34.000 GHz (radiation belonging to the Q band of the microwave region)? [1.213 T]

The  $g$ -value in a molecular environment (a radical or a d-metal complex) is related to the ease with which the applied field can stir up currents through the molecular framework and the strength of the magnetic field the currents generate. Therefore, the  $g$ -value gives some information about electronic structure and plays a similar role in EPR to that played by shielding constants in NMR.

Electrons can migrate through the molecular framework by making use of excited states (Fig. 14.53). This additional path for circulation of electrons gives rise to a local magnetic field that adds to the applied field. Therefore, we expect the ease of stirring up currents to be inversely proportional to the separation of energy levels,  $\Delta E$ , in the molecule. As we saw in Section 9.9, the strength of the field generated by electronic currents in atoms (and analogously in molecules) is related to the extent of coupling between spin and orbital angular momenta. That is, the local field strength is proportional to the molecular spin–orbit coupling constant,  $\xi$ .

We can conclude from the discussion above that the  $g$ -value of a radical or d-metal complex differs from  $g_e$ , the ‘free-electron’  $g$ -value, by an amount that is proportional to  $\xi/\Delta E$ . This proportionality is widely observed. Many organic radicals have  $g$ -values close to 2.0027 and inorganic radicals have  $g$ -values typically in the range 1.9 to 2.1. The  $g$ -values of paramagnetic d-metal complexes often differ considerably from  $g_e$ , varying from 0 to 6, because in them  $\Delta E$  is small (on account of the splitting of d orbitals brought about by interactions with ligands, as we saw in Section 13.3).

Just as in the case of the chemical shift in NMR spectroscopy, the  $g$ -value is anisotropic, that is, its magnitude depends on the orientation of the radical with respect to the applied field. In solution, when the molecule is tumbling rapidly, only the average value of the  $g$ -value is observed. Therefore, anisotropy of the  $g$ -value is observed only for radicals trapped in solids.

## 14.16 Hyperfine structure

**Key points** The hyperfine structure of an EPR spectrum is its splitting of individual resonance lines into components by the magnetic interaction between the electron and nuclei with spin. (a) If a radical contains  $N$  equivalent nuclei with spin quantum number  $I$ , then there are  $2NI + 1$  hyperfine lines with an intensity distribution given by a modified version of Pascal's triangle. (b) Hyperfine structure can be explained by dipole–dipole interactions, Fermi contact interactions, and the polarization mechanism.

The most important feature of EPR spectra is their **hyperfine structure**, the splitting of individual resonance lines into components. In general in spectroscopy, the term ‘hyperfine structure’ means the structure of a spectrum that can be traced to interactions of the electrons with nuclei other than as a result of the latter’s point electric charge. The source of the hyperfine structure in EPR is the magnetic interaction between the electron spin and the magnetic dipole moments of the nuclei present in the radical.

### (a) The effects of nuclear spin

Consider the effect on the EPR spectrum of a single H nucleus located somewhere in a radical. The proton spin is a source of magnetic field and, depending on the orientation of the nuclear spin, the field it generates adds to or subtracts from the applied field. The total local field is therefore

$$\mathcal{B}_{\text{loc}} = \mathcal{B} + am_I \quad m_I = \pm \frac{1}{2} \quad (14.40)$$

where  $a$  is the **hyperfine coupling constant**. Half the radicals in a sample have  $m_I = +\frac{1}{2}$ , so half resonate when the applied field satisfies the condition

$$h\nu = g\mu_B(\mathcal{B} + \frac{1}{2}a), \quad \text{or} \quad \mathcal{B} = \frac{h\nu}{g\mu_B} - \frac{1}{2}a \quad (14.41a)$$

The other half (which have  $m_I = -\frac{1}{2}$ ) resonate when

$$h\nu = g\mu_B(\mathcal{B} - \frac{1}{2}a), \quad \text{or} \quad \mathcal{B} = \frac{h\nu}{g\mu_B} + \frac{1}{2}a \quad (14.41b)$$

Therefore, instead of a single line, the spectrum shows two lines of half the original intensity separated by  $a$  and centred on the field determined by  $g$  (Fig. 14.54).

If the radical contains an  $^{14}\text{N}$  atom ( $I = 1$ ), its EPR spectrum consists of three lines of equal intensity, because the  $^{14}\text{N}$  nucleus has three possible spin orientations, and each spin orientation is possessed by one-third of all the radicals in the sample. In general, a spin- $I$  nucleus splits the spectrum into  $2I + 1$  hyperfine lines of equal intensity.

When there are several magnetic nuclei present in the radical, each one contributes to the hyperfine structure. In the case of equivalent protons (for example, the two  $\text{CH}_2$  protons in the radical  $\text{CH}_3\text{CH}_2\cdot$ ) some of the hyperfine lines are coincident. It is not hard to show that, if the radical contains  $N$  equivalent protons, then there are  $N + 1$  hyperfine lines with a binomial intensity distribution (the intensity distribution given by Pascal’s triangle). The spectrum of the benzene radical anion in Fig. 14.51, which has seven lines with intensity ratio 1:6:15:20:15:6:1, is consistent with a radical containing six equivalent protons. More generally, if the radical contains  $N$  equivalent nuclei with spin quantum number  $I$ , then there are  $2NI + 1$  hyperfine lines with an intensity distribution based on a modified version of Pascal’s triangle as shown in the following *Example*.

**Fig. 14.53** An applied magnetic field can induce circulation of electrons that makes use of excited state orbitals.

**Fig. 14.54** The hyperfine interaction between an electron and a spin- $\frac{1}{2}$  nucleus results in four energy levels in place of the original two. As a result, the spectrum consists of two lines (of equal intensity) instead of one. The intensity distribution can be summarized by a simple stick diagram. The diagonal lines show the energies of the states as the applied field is increased, and resonance occurs when the separation of states matches the fixed energy of the microwave photon.

**Fig. 14.55** The analysis of the hyperfine structure of radicals containing one  $^{14}\text{N}$  nucleus ( $I = 1$ ) and two equivalent protons.

**Fig. 14.56** The analysis of the hyperfine structure of radicals containing three equivalent  $^{14}\text{N}$  nuclei.

#### Example 14.2 Predicting the hyperfine structure of an EPR spectrum

A radical contains one  $^{14}\text{N}$  nucleus ( $I = 1$ ) with hyperfine constant 1.61 mT and two equivalent protons ( $I = \frac{1}{2}$ ) with hyperfine constant 0.35 mT. Predict the form of the EPR spectrum.

**Method** We should consider the hyperfine structure that arises from each type of nucleus or group of equivalent nuclei in succession. So, split a line with one nucleus, then each of those lines is split by a second nucleus (or group of nuclei), and so on. It is best to start with the nucleus with the largest hyperfine splitting; however, any choice could be made, and the order in which nuclei are considered does not affect the conclusion.

**Answer** The  $^{14}\text{N}$  nucleus gives three hyperfine lines of equal intensity separated by 1.61 mT. Each line is split into doublets of spacing 0.35 mT by the first proton, and each line of these doublets is split into doublets with the same 0.35 mT splitting (Fig. 14.55). The central lines of each split doublet coincide, so the proton splitting gives 1:2:1 triplets of internal splitting 0.35 mT. Therefore, the spectrum consists of three equivalent 1:2:1 triplets.

**Self-test 14.4** Predict the form of the EPR spectrum of a radical containing three equivalent  $^{14}\text{N}$  nuclei. [Fig. 14.56]

The hyperfine structure of an EPR spectrum is a kind of fingerprint that helps to identify the radicals present in a sample. Moreover, because the magnitude of the splitting depends on the distribution of the unpaired electron near the magnetic nuclei present, the spectrum can be used to map the molecular orbital occupied by the unpaired electron. For example, because the hyperfine splitting in  $\text{C}_6\text{H}_6^-$  is 0.375 mT, and one proton is close to a C atom with one-sixth the unpaired electron spin density (because the electron is spread uniformly around the ring), the hyperfine splitting caused by a proton in the electron spin entirely confined to a single adjacent C atom should be  $6 \times 0.375 \text{ mT} = 2.25 \text{ mT}$ . If in another aromatic radical we find a hyperfine splitting constant  $a$ , then the **spin density**,  $\rho$ , the probability that an unpaired electron is on the atom, can be calculated from the **McConnell equation**:

$$a = Q\rho$$

McConnell equation

 (14.42)

with  $Q = 2.25 \text{ mT}$ . In this equation,  $\rho$  is the spin density on a C atom and  $a$  is the hyperfine splitting observed for the H atom to which it is attached.

#### • A brief illustration

The hyperfine structure of the EPR spectrum of the radical anion (naphthalene) $^-$  can be interpreted as arising from two groups of four equivalent protons. Those at the 1, 4, 5, and 8 positions in the ring have  $a = 0.490 \text{ mT}$  and those in the 2, 3, 6, and 7 positions have  $a = 0.183 \text{ mT}$ . The densities obtained by using the McConnell equation are 0.22 and 0.08, respectively (8). •

**Self-test 14.5** The spin density in (anthracene) $^-$  is shown in (9). Predict the form of its EPR spectrum.

[A 1:2:1 triplet of splitting 0.43 mT split into a 1:4:6:4:1 quintet of splitting 0.22 mT, split into a 1:4:6:4:1 quintet of splitting 0.11 mT,  $3 \times 5 \times 5 = 75$  lines in all]

**(b) The origin of the hyperfine interaction**

The hyperfine interaction is an interaction between the magnetic moments of the unpaired electron and the nuclei. There are two contributions to the interaction.

An electron in a p orbital does not approach the nucleus very closely, so it experiences a field that appears to arise from a point magnetic dipole. The resulting interaction is called the **dipole–dipole interaction**. The contribution of a magnetic nucleus to the local field experienced by the unpaired electron is given by an expression like that in eqn 14.28. A characteristic of this type of interaction is that it is anisotropic. Furthermore, just as in the case of NMR, the dipole–dipole interaction averages to zero when the radical is free to tumble. Therefore, hyperfine structure due to the dipole–dipole interaction is observed only for radicals trapped in solids.

An s electron is spherically distributed around a nucleus and so has zero average dipole–dipole interaction with the nucleus even in a solid sample. However, because an s electron has a nonzero probability of being at the nucleus, it is incorrect to treat the interaction as one between two point dipoles. An s electron has a Fermi contact interaction with the nucleus, which as we saw in Section 14.6d is a magnetic interaction that occurs when the point dipole approximation fails. The contact interaction is isotropic (that is, independent of the radical's orientation), and consequently is shown even by rapidly tumbling molecules in fluids (provided the spin density has some s character).

The dipole–dipole interactions of p electrons and the Fermi contact interaction of s electrons can be quite large. For example, a 2p electron in a nitrogen atom experiences an average field of about 4.8 mT from the  $^{14}\text{N}$  nucleus. A 1s electron in a hydrogen atom experiences a field of about 50 mT as a result of its Fermi contact interaction with the central proton. More values are listed in Table 14.3. The magnitudes of the contact interactions in radicals can be interpreted in terms of the s orbital character of the molecular orbital occupied by the unpaired electron, and the dipole–dipole interaction can be interpreted in terms of the p character. The analysis of hyperfine structure therefore gives information about the composition of the orbital, and especially the hybridization of the atomic orbitals (see Problem 14.13).

We still have the source of the hyperfine structure of the  $\text{C}_6\text{H}_6^-$  anion and other aromatic radical anions to explain. The sample is fluid, and as the radicals are tumbling the hyperfine structure cannot be due to the dipole–dipole interaction. Moreover, the protons lie in the nodal plane of the  $\pi$  orbital occupied by the unpaired electron, so the structure cannot be due to a Fermi contact interaction. The explanation lies in a **polarization mechanism** similar to the one responsible for spin–spin coupling in NMR. There is a magnetic interaction between a proton and the  $\alpha$  electrons ( $m_s = +\frac{1}{2}$ ) which results in one of the electrons tending to be found with a greater probability nearby (Fig. 14.57). The electron with opposite spin is therefore more likely to be close to the C atom at the other end of the bond. The unpaired electron on the C atom has a lower energy if it is parallel to that electron (Hund's rule favours parallel electrons on atoms), so the unpaired electron can detect the spin of the proton indirectly. Calculation using this model leads to a hyperfine interaction in agreement with the observed value of 2.25 mT.

**IMPACT ON BIOCHEMISTRY AND NANOSCIENCE****114.2 Spin probes**

We saw in Sections 14.15 and 14.16 that anisotropy of the g-value and of the nuclear hyperfine interactions can be observed when a radical is immobilized in a solid. Figure 14.58 shows the variation of the lineshape of the EPR spectrum of the di-*tert*-butyl nitroxide radical (10) with temperature. At 292 K, the radical tumbles freely and isotropic hyperfine coupling to the  $^{14}\text{N}$  nucleus gives rise to three sharp peaks. At

**Table 14.3\*** Hyperfine coupling constants for atoms, a/mT

| Nuclide         | Isotropic coupling | Anisotropic coupling |
|-----------------|--------------------|----------------------|
| $^1\text{H}$    | 50.8 (1s)          |                      |
| $^2\text{H}$    | 7.8 (1s)           |                      |
| $^{14}\text{N}$ | 55.2 (2s)          | 4.8 (2p)             |
| $^{19}\text{F}$ | 1720 (2s)          | 108.4 (2p)           |

\* More values are given in the Data section.

**Fig. 14.57** The polarization mechanism for the hyperfine interaction in  $\pi$ -electron radicals. The arrangement in (a) is lower in energy than that in (b), so there is an effective coupling between the unpaired electron and the proton.

**Fig. 14.58** EPR spectra of the di-*tert*-butyl nitroxide radical at 292 K and 77 K. Adapted from J.R. Bolton, in *Biological applications of electron spin resonance*, H.M. Swartz, J.R. Bolton, and D.C. Borg (ed.), Wiley, New York (1972).

**Fig. 14.59** The EPR spectra of dibenzyl nitroxide in water with different concentrations of  $\beta$ -cyclodextrin. Based on P. Franchi *et al.*, *Current Organic Chemistry*, 1831, 8 (2004).

77 K, motion of the radical is restricted. Both isotropic and anisotropic hyperfine couplings determine the appearance of the spectrum, which now consists of three broad peaks.

A *spin probe* (or *spin label*) is a radical that interacts with a molecular assembly (a biopolymer or a nanostructure) and with an EPR spectrum that reports on the structural and dynamical properties of the assembly. The ideal spin probe is one with a spectrum that broadens significantly as its motion is restricted to a relatively small extent. Nitroxide spin probes have been used to show that the hydrophobic interiors of biological membranes, once thought to be rigid, are in fact very fluid and individual lipid molecules move laterally through the sheet-like structure of the membrane. The EPR spectrum also can reveal whether a nitroxide spin probe is free in solution, positioned as a guest within a macromolecular host, or intercalated within micelles (see Chapter 18). For example, hyperfine coupling constants to the  $^{14}\text{N}$  nucleus can change if the N–O group is exposed to the solvent or buried in the assembly.

Benzyl *tert*-butyl nitroxide (11) and dibenzyl nitroxide (12) are particularly well-suited spin probes for supramolecular systems, such as those formed with the host  $\beta$ -cyclodextrin (13). As the concentration of the host system is increased, the EPR spectrum shifts from that of the free nitroxide to that of the 1:1 complexed radical (Fig. 14.59). The variations in the nitrogen hyperfine coupling are attributed to the extent of exposure of the N–O group to water, with the lowest value for  $\beta$ -cyclodextrin and its hydrophobic cavity. The hyperfine coupling constant for the benzyl hydrogens two bonds from the unpaired electron reflects the conformation of the nitroxide radical in the various macromolecular host systems, particularly with regard to rotation of the benzyl group about the C–N bond. The symmetric nitroxide spin probe in (12) can be incorporated into two  $\beta$ -cyclodextrin cavities. This 1:2 inclusion complex exhibits reduced nitrogen hyperfine splitting, which is consistent with the less polar environment achieved by the complete shielding of the nitroxide from solvent.

## Checklist of key equations

## Further information

### Further information 14.1 *Fourier transformation of the FID curve*

The analysis of the FID curve is achieved by the standard mathematical technique of Fourier transformation, which is explained more fully in *Mathematical background 7* following Chapter 19). We start by noting that the signal  $S(t)$  in the time domain, the total FID curve, is the sum (more precisely, the integral) over all the contributing frequencies

$$S(t) = \int_{-\infty}^{\infty} I(\nu) e^{2\pi i \nu t} d\nu \quad (14.43)$$

Because  $e^{2\pi i \nu t} = \cos(2\pi \nu t) + i \sin(2\pi \nu t)$ , the expression above is a sum over harmonically oscillating functions, with each one weighted by the intensity  $I(\nu)$ .

We need  $I(\nu)$ , the spectrum in the frequency domain; it is obtained by evaluating the integral

$$I(\nu) = 2 \operatorname{Re} \int_0^{\infty} S(t) e^{-2\pi i \nu t} dt \quad (14.44)$$

where Re means take the real part of the following expression. This integral is very much like an overlap integral: it gives a nonzero value if  $S(t)$  contains a component that matches the oscillating function  $e^{2\pi i \nu t}$ . The integration is carried out at a series of frequencies  $\nu$  on a computer that is built into the spectrometer.

## Discussion questions

**14.1** To what extent are all spectroscopic techniques resonance techniques, and are magnetic resonance techniques best so-called?

**14.2** Discuss in detail the origins of the local, neighbouring group, and solvent contributions to the shielding constant.

**14.3** Describe the significance of the chemical shift in relation to the terms 'high-field' and 'low-field'.

**14.4** Explain why groups of equivalent protons do not exhibit the spin-spin coupling that exists between them.

**14.5** Explain the difference between magnetically equivalent and chemically equivalent nuclei, and give two examples of each.

**14.6** Discuss in detail the effects of a  $90^\circ$  pulse and of a  $180^\circ$  pulse on a system of spin- $\frac{1}{2}$  nuclei in a static magnetic field.

**14.7** Suggest a reason why the relaxation times of  $^{13}\text{C}$  nuclei are typically much longer than those of  $^1\text{H}$  nuclei.

**14.8** Discuss how the Fermi contact interaction and the polarization mechanism contribute to spin–spin couplings in NMR and hyperfine interactions in EPR.

**14.9** Suggest how spin probes could be used to estimate the depth of a crevice in a biopolymer, such as the active site of an enzyme.

## Exercises

**14.1(a)** Calculate the Larmor frequency of an electron in a magnetic field of 1.0 T.

**14.1(b)** Calculate the Larmor frequency of a proton in a magnetic field of 1.0 T.

**14.2(a)** For how long must a magnetic field of 1.0 T be applied to rotate the angular momentum vector of an electron through  $90^\circ$ ?

**14.2(b)** For how long must a magnetic field of 1.0 T be applied to rotate the angular momentum vector of a proton through  $90^\circ$ ?

**14.3(a)** What is the resonance frequency of a proton in a magnetic field of 14.1 T?

**14.3(b)** What is the resonance frequency of a  $^{19}\text{F}$  nucleus in a magnetic field of 16.2 T?

**14.4(a)** Calculate the frequency separation of the nuclear spin levels of a  $^{13}\text{C}$  nucleus in a magnetic field of 14.4 T given that the magnetogyric ratio is  $6.73 \times 10^7 \text{ T}^{-1} \text{ s}^{-1}$ .

**14.4(b)** Calculate the frequency separation of the nuclear spin levels of a  $^{14}\text{N}$  nucleus in a magnetic field of 15.4 T given that the magnetogyric ratio is  $1.93 \times 10^7 \text{ T}^{-1} \text{ s}^{-1}$ .

**14.5(a)** Which has the greater energy level separation in a 600 MHz NMR spectrometer, a proton or a deuteron?

**14.5(b)** Which has the greater energy level separation, a  $^{14}\text{N}$  nucleus in an NMR spectrometer operating at 14 T or an electron in an EPR spectrometer operating at 0.30 T?

**14.6(a)** Use Table 14.2 to predict the magnetic fields at which (a)  $^1\text{H}$ , (b)  $^2\text{H}$ , (c)  $^{13}\text{C}$  come into resonance at (i) 250 MHz, (ii) 500 MHz.

**14.6(b)** Use Table 14.2 to predict the magnetic fields at which (a)  $^{14}\text{N}$ , (b)  $^{19}\text{F}$ , and (c)  $^{31}\text{P}$  come into resonance at (i) 300 MHz, (ii) 750 MHz.

**14.7(a)** Calculate the relative population differences ( $\delta N/N$ ) for protons in fields of (a) 0.30 T, (b) 1.5 T, and (c) 10 T at  $25^\circ\text{C}$ .

**14.7(b)** Calculate the relative population differences ( $\delta N/N$ ) for  $^{13}\text{C}$  nuclei in fields of (a) 0.50 T, (b) 2.5 T, and (c) 15.5 T at  $25^\circ\text{C}$ .

**14.8(a)** Evaluate the strength of the  $z$ -component of a magnetic field at 100 pm from an electron spin when  $\theta$  is (a) 0, (b)  $90^\circ$ .

**14.8(b)** Evaluate the strength of the  $z$ -component of a magnetic field at 100 pm from a proton spin when  $\theta$  is (a) 0, (b)  $90^\circ$ .

**14.9(a)** The first generally available NMR spectrometers operated at a frequency of 60 MHz; today it is not uncommon to use a spectrometer that operates at 800 MHz. What are the relative population differences ( $\delta N/N$ ) of  $^{13}\text{C}$  spin states in these two spectrometers at  $25^\circ\text{C}$ ?

**14.9(b)** What are the relative population differences ( $\delta N/N$ ) of electron spins in an EPR spectrometer operating at 0.33 T at (a)  $25^\circ\text{C}$ , (b) 77 K?

**14.10(a)** The chemical shift of the  $\text{CH}_3$  protons in acetaldehyde (ethanal) is  $\delta = 2.20$  and that of the CHO proton is 9.80. What is the difference in local magnetic field between the two regions of the molecule when the applied field is (a) 1.5 T, (b) 15 T?

**14.10(b)** The chemical shift of the  $\text{CH}_3$  protons in diethyl ether is  $\delta = 1.16$  and that of the  $\text{CH}_2$  protons is 3.36. What is the difference in local magnetic field between the two regions of the molecule when the applied field is (a) 1.9 T, (b) 16.5 T?

**14.11(a)** Sketch the appearance of the  $^1\text{H}$ -NMR spectrum of acetaldehyde (ethanal) using  $J = 2.90 \text{ Hz}$  and the data in Exercise 14.10a in a spectrometer operating at (a) 250 MHz, (b) 500 MHz.

**14.11(b)** Sketch the appearance of the  $^1\text{H}$ -NMR spectrum of diethyl ether using  $J = 6.97 \text{ Hz}$  and the data in Exercise 14.10b in a spectrometer operating at (a) 350 MHz, (b) 650 MHz.

**14.12(a)** Construct a version of Pascal's triangle to show the fine structure that might arise from spin–spin coupling to a group of four spin- $\frac{3}{2}$  nuclei.

**14.12(b)** Construct a version of Pascal's triangle to show the fine structure that might arise from spin–spin coupling to a group of three spin- $\frac{5}{2}$  nuclei.

**14.13(a)** Two groups of protons are made equivalent by the isomerization of a fluxional molecule. At low temperatures, where the interconversion is slow, one group has  $\delta = 4.0$  and the other has  $\delta = 5.2$ . At what rate of interconversion will the two signals merge in a spectrometer operating at 250 MHz?

**14.13(b)** Two groups of protons are made equivalent by the isomerization of a fluxional molecule. At low temperatures, where the interconversion is slow, one group has  $\delta = 5.5$  and the other has  $\delta = 6.8$ . At what rate of interconversion will the two signals merge in a spectrometer operating at 350 MHz?

**14.14(a)** Sketch the form of the  $^{19}\text{F}$ -NMR spectra of a natural sample of tetrafluoroborate ions,  $\text{BF}_4^-$ , allowing for the relative abundances of  $^{10}\text{B}$  and  $^{11}\text{B}$ .

**14.14(b)** From the data in Table 14.2, predict the frequency needed for  $^{31}\text{P}$ -NMR in an NMR spectrometer designed to observe proton resonance at 500 MHz. Sketch the proton and  $^{31}\text{P}$  resonances in the NMR spectrum of  $\text{PH}_4^+$ .

**14.15(a)** Sketch the form of an  $\text{A}_3\text{M}_2\text{X}_4$  spectrum, where A, M, and X are protons with distinctly different chemical shifts and  $J_{\text{AM}} > J_{\text{AX}} > J_{\text{MX}}$ .

**14.15(b)** Sketch the form of an  $\text{A}_2\text{M}_2\text{X}_5$  spectrum, where A, M, and X are protons with distinctly different chemical shifts and  $J_{\text{AM}} > J_{\text{AX}} > J_{\text{MX}}$ .

**14.16(a)** Which of the following molecules have sets of nuclei that are chemically but not magnetically equivalent? (a)  $\text{CH}_3\text{CH}_3$ , (b)  $\text{CH}_2=\text{CH}_2$ .

**14.16(b)** Which of the following molecules have sets of nuclei that are chemically but not magnetically equivalent? (a)  $\text{CH}_2=\text{C}=\text{CF}_2$ , (b) *cis*- and *trans*- $[\text{Mo}(\text{CO})_4(\text{PH}_3)_2]$ .

**14.17(a)** What is the effective transverse relaxation time when the width of a resonance line is 1.5 Hz?

**14.17(b)** What is the effective transverse relaxation time when the width of a resonance line is 12 Hz?

**14.18(a)** Predict the maximum enhancement (as the value of  $\eta$ ) that could be obtained in a NOE observation in which  $^{31}\text{P}$  is coupled to protons.

**14.18(b)** Predict the maximum enhancement (as the value of  $\eta$ ) that could be obtained in a NOE observation in which  $^{19}\text{F}$  is coupled to protons.

**14.19(a)** The duration of a  $90^\circ$  or  $180^\circ$  pulse depends on the strength of the  $B_1$  field. If a  $90^\circ$  pulse requires 10  $\mu\text{s}$ , what is the strength of the  $B_1$  field? How long would the corresponding  $180^\circ$  pulse require?

**14.19(b)** The duration of a  $90^\circ$  or  $180^\circ$  pulse depends on the strength of the  $B_1$  field. If a  $180^\circ$  pulse requires 12.5  $\mu\text{s}$ , what is the strength of the  $B_1$  field? How long would the corresponding  $90^\circ$  pulse require?

**14.20(a)** What magnetic field would be required in order to use an EPR X-band spectrometer (9 GHz) to observe  $^1\text{H}$ -NMR and a 300 MHz spectrometer to observe EPR?

**14.20(b)** Some commercial EPR spectrometers use 8 mm microwave radiation (the Q band). What magnetic field is needed to satisfy the resonance condition?

**14.21(a)** The centre of the EPR spectrum of atomic hydrogen lies at 329.12 mT in a spectrometer operating at 9.2231 GHz. What is the  $g$ -value of the electron in the atom?

**14.21(b)** The centre of the EPR spectrum of atomic deuterium lies at 330.02 mT in a spectrometer operating at 9.2482 GHz. What is the  $g$ -value of the electron in the atom?

**14.22(a)** A radical containing two equivalent protons shows a three-line spectrum with an intensity distribution 1:2:1. The lines occur at 330.2 mT, 332.5 mT, and 334.8 mT. What is the hyperfine coupling constant for each proton? What is the  $g$ -value of the radical given that the spectrometer is operating at 9.319 GHz?

**14.22(b)** A radical containing three equivalent protons shows a four-line spectrum with an intensity distribution 1:3:3:1. The lines occur at 331.4 mT, 333.6 mT, 335.8 mT, and 338.0 mT. What is the hyperfine coupling constant for each proton? What is the  $g$ -value of the radical given that the spectrometer is operating at 9.332 GHz?

**14.23(a)** A radical containing two inequivalent protons with hyperfine constants 2.0 mT and 2.6 mT gives a spectrum centred on 332.5 mT. At what fields do the hyperfine lines occur and what are their relative intensities?

**14.23(b)** A radical containing three inequivalent protons with hyperfine constants 2.11 mT, 2.87 mT, and 2.89 mT gives a spectrum centred on 332.8 mT. At what fields do the hyperfine lines occur and what are their relative intensities?

**14.24(a)** Predict the intensity distribution in the hyperfine lines of the EPR spectra of (a)  $\cdot\text{CH}_3$ , (b)  $\cdot\text{CD}_3$ .

**14.24(b)** Predict the intensity distribution in the hyperfine lines of the EPR spectra of (a)  $\cdot\text{CH}_2\text{CH}_3$ , (b)  $\cdot\text{CD}_2\text{CD}_3$ .

**14.25(a)** The benzene radical anion has  $g = 2.0025$ . At what field should you search for resonance in a spectrometer operating at (a) 9.302 GHz, (b) 33.67 GHz?

**14.25(b)** The naphthalene radical anion has  $g = 2.0024$ . At what field should you search for resonance in a spectrometer operating at (a) 9.312 GHz, (b) 33.88 GHz?

**14.26(a)** The EPR spectrum of a radical with a single magnetic nucleus is split into four lines of equal intensity. What is the nuclear spin of the nucleus?

**14.26(b)** The EPR spectrum of a radical with two equivalent nuclei of a particular kind is split into five lines of intensity ratio 1:2:3:2:1. What is the spin of the nuclei?

**14.27(a)** Sketch the form of the hyperfine structures of radicals  $\text{XH}_2$  and  $\text{XD}_2$ , where the nucleus X has  $I = \frac{5}{2}$ .

**14.27(b)** Sketch the form of the hyperfine structures of radicals  $\text{XH}_3$  and  $\text{XD}_3$ , where the nucleus X has  $I = \frac{3}{2}$ .

**14.28(a)** A fluxional radical has EPR resonances at  $g_{\parallel} = 2.012$  and  $g_{\perp} = 2.032$  parallel and perpendicular to its molecular axis, respectively. At what tumbling rate (in rotations per second) would the two resonances merge in a spectrometer operating at 0.30 T?

**14.28(b)** A fluxional radical has EPR resonances at  $g_{\parallel} = 2.022$  and  $g_{\perp} = 2.023$  parallel and perpendicular to its molecular axis, respectively. At what tumbling rate (in rotations per second) would the two resonances merge in a spectrometer operating at 1.0 T?

## Problems\*

### Numerical problems

**14.1** A scientist investigates the possibility of neutron spin resonance, and has available a commercial NMR spectrometer operating at 300 MHz. What field is required for resonance? What is the relative population difference at room temperature? Which is the lower energy spin state of the neutron?

**14.2** Two groups of protons have  $\delta = 4.0$  and  $\delta = 5.2$  and are interconverted by a conformational change of a fluxional molecule. In a 60 MHz spectrometer the spectrum collapsed into a single line at 280 K but at 300 MHz the collapse did not occur until the temperature had been raised to 300 K. What is the activation energy of the interconversion?

**14.3‡** Suppose that the FID in Fig. 14.32 was recorded in a 300 MHz spectrometer, and that the interval between maxima in the oscillations in the

FID is 0.10 s. What is the Larmor frequency of the nuclei and the spin-spin relaxation time?

**14.4** Use mathematical software to construct the FID curve for a set of three nuclei with resonances at  $\delta = 3.2$ , 4.1, and 5.0 in a spectrometer operating at 800 MHz. Suppose that  $T_2 = 1.0$  s. Go on to plot FID curves that show how they vary as the frequency of the spectrometer is changed from 200 MHz to 800 MHz.

**14.5‡** In a classic study of the application of NMR to the measurement of rotational barriers in molecules, P.M. Nair and J.D. Roberts (*J. Am. Chem. Soc.* 79, 4565 (1957)) obtained the 40 MHz  $^{19}\text{F}$ -NMR spectrum of  $\text{F}_2\text{BrCCBrCl}_2$ . Their spectra are reproduced in Fig. 14.60. At 193 K the spectrum shows five resonance peaks. Peaks I and III are separated by 160 Hz, as are IV and V. The ratio of the integrated intensities of peak II to peaks I, III, IV, and V is approximately 10 to 1. At 273 K, the five peaks have collapsed into one.

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp and Carmen Giunta.

Fig. 14.60

Explain the spectrum and its change with temperature. At what rate of interconversion will the spectrum collapse to a single line? Calculate the rotational energy barrier between the rotational isomers on the assumption that it is related to the rate of interconversion between the isomers.

**14.6‡** Various versions of the Karplus equation (eqn 14.27) have been used to correlate data on vicinal proton coupling constants in systems of the type  $R_1R_2CHCHR_3R_4$ . The original version (M. Karplus, *J. Am. Chem. Soc.* 85, 2870 (1963)) is  $^3J_{HH} = A \cos^2 \phi_{HH} + B$ . When  $R_3 = R_4 = H$ ,  $^3J_{HH} = 7.3$  Hz; when  $R_3 = CH_3$  and  $R_4 = H$ ,  $^3J_{HH} = 8.0$  Hz; when  $R_3 = R_4 = CH_3$ ,  $^3J_{HH} = 11.2$  Hz. Assume that only staggered conformations are important and determine which version of the Karplus equation fits the data better.

**14.7‡** It might be unexpected that the Karplus equation, which was first derived for  $^3J_{HH}$  coupling constants, should also apply to vicinal coupling between the nuclei of metals such as tin. T.N. Mitchell and B. Kowall (*Magn. Reson. Chem.* 33, 325 (1995)) have studied the relation between  $^3J_{HH}$  and  $^3J_{SnSn}$  in compounds of the type  $Me_3SnCH_2CHRSnMe_3$  and find that  $^3J_{SnSn} = 78.86^3J_{HH} + 27.84$  Hz. (a) Does this result support a Karplus-type equation for tin? Explain your reasoning. (b) Obtain the Karplus equation for  $^3J_{SnSn}$  and plot it as a function of the dihedral angle. (c) Draw the preferred conformation.

**14.8** Figure 14.61 shows the proton COSY spectrum of 1-nitropropane ( $NO_2CH_2CH_2CH_3$ ). The circles show enhanced views of the spectral features. Account for the appearance of off-diagonal peaks in the spectrum. (Spectrum provided by Prof. G. Morris.)

**14.9** The z-component of the magnetic field at a distance  $R$  from a magnetic moment parallel to the z-axis is given by eqn 14.28. In a solid, a proton at a

Fig. 14.61

distance  $R$  from another can experience such a field and the measurement of the splitting it causes in the spectrum can be used to calculate  $R$ . In gypsum, for instance, the splitting in the  $H_2O$  resonance can be interpreted in terms of a magnetic field of 0.715 mT generated by one proton and experienced by the other. What is the separation of the protons in the  $H_2O$  molecule?

**14.10** The angular  $NO_2$  molecule has a single unpaired electron and can be trapped in a solid matrix or prepared inside a nitrite crystal by radiation damage of  $NO_2^-$  ions. When the applied field is parallel to the OO direction the centre of the spectrum lies at 333.64 mT in a spectrometer operating at 9.302 GHz. When the field lies along the bisector of the  $ONO$  angle, the resonance lies at 331.94 mT. What are the  $g$ -values in the two orientations?

**14.11** The hyperfine coupling constant in  $\cdot CH_3$  is 2.3 mT. Use the information in Table 14.3 to predict the splitting between the hyperfine lines of the spectrum of  $\cdot CD_3$ . What are the overall widths of the hyperfine spectra in each case?

**14.12** The  $p$ -dinitrobenzene radical anion can be prepared by reduction of  $p$ -dinitrobenzene. The radical anion has two equivalent N nuclei ( $I = 1$ ) and four equivalent protons. Predict the form of the EPR spectrum using  $a(N) = 0.148$  mT and  $a(H) = 0.112$  mT.

**14.13** When an electron occupies a 2s orbital on an N atom it has a hyperfine interaction of 55.2 mT with the nucleus. The spectrum of  $NO_2$  shows an isotropic hyperfine interaction of 5.7 mT. For what proportion of its time is the unpaired electron of  $NO_2$  occupying a 2s orbital? The hyperfine coupling constant for an electron in a 2p orbital of an N atom is 4.8 mT. In  $NO_2$  the anisotropic part of the hyperfine coupling is 1.3 mT. What proportion of its time does the unpaired electron spend in the 2p orbital of the N atom in  $NO_2$ ? What is the total probability that the electron will be found on (a) the N atoms, (b) the O atoms? What is the hybridization ratio of the N atom? Does the hybridization support the view that  $NO_2$  is angular?

**14.14** The hyperfine coupling constants observed in the radical anions (14), (15), and (16) are shown (in millitesla, mT). Use the value for the benzene radical anion to map the probability of finding the unpaired electron in the  $\pi$  orbital on each C atom.

### Theoretical problems

**14.15** Derive an expression for the diamagnetic shielding arising from (a) an electron in the 1s orbital of a hydrogenic atom of atomic number  $Z$ , (b) an electron in a  $H2s$  orbital. *Hint.* Use eqn 14.22 and the information in the brief illustration that follows it.

**14.16** In this problem you will use the molecular electronic structure methods described in Chapter 10 to investigate the hypothesis that the magnitude of the  $^{13}C$  chemical shift correlates with the net charge on a  $^{13}C$  atom. (a) Using molecular modelling software<sup>3</sup> and the computational method of your choice, calculate the net charge at the C atom *para* to the substituents in this series of molecules: benzene, phenol, toluene, trifluorotoluene, benzonitrile, and nitrobenzene. (b) The  $^{13}C$  chemical shifts of the *para* C atoms in each of the molecules that you examined in part (a) are given below:

<sup>3</sup> The web site contains links to molecular modelling freeware and to other sites where you may perform molecular orbital calculations directly from your web browser.

| Substituent | OH    | CH <sub>3</sub> | H     | CF <sub>3</sub> | CN    | NO <sub>2</sub> |
|-------------|-------|-----------------|-------|-----------------|-------|-----------------|
| $\delta$    | 130.1 | 128.4           | 128.5 | 128.9           | 129.1 | 129.4           |

Is there a linear correlation between net charge and  $^{13}\text{C}$  chemical shift of the *para* C atom in this series of molecules? (c) If you did find a correlation in part (b), use the concepts developed in this chapter to explain the physical origins of the correlation.

**14.17** In a liquid, the dipolar magnetic field averages to zero: show this result by evaluating the average of the field given in eqn 14.28. *Hint.* The volume element in polar coordinates is  $\sin \theta \, d\theta \cdot d\phi$ .

**14.18** When interacting with a large biopolymer or even larger organelle, a small molecule might not rotate freely in all directions and the dipolar interaction might not average to zero. Suppose a molecule is bound so that, although the vector separating two protons may rotate freely around the *z*-axis, the colatitude may vary only between 0 and  $\theta'$ . Average the dipolar field over this restricted range of orientations and confirm that the average vanishes when  $\theta' = \pi$  (corresponding to rotation over an entire sphere). What is the average value of the local dipolar field for the  $\text{H}_2\text{O}$  molecule in Problem 14.9 if it is bound to a biopolymer that enables it to rotate up to  $\theta' = 30^\circ$ ?

**14.19** The shape of a spectral line,  $I(\omega)$ , is related to the free induction decay signal  $S(t)$  by eqn 14.44, where 'Re' means take the real part of what follows. Calculate the lineshape corresponding to an oscillating, decaying function  $S(t) = \cos \omega_0 t e^{-t/\tau}$ .

**14.20** In the language of Problem 14.19, show that, if  $S(t) = (a \cos \omega_1 t + b \cos \omega_2 t) e^{-t/\tau}$ , then the spectrum consists of two lines with intensities proportional to  $a$  and  $b$  and located at  $\omega = \omega_1$  and  $\omega_2$ , respectively.

**14.21** Suppose that a signal is (a) a decaying exponential function proportional to  $e^{-t/\tau}$ , (b) a Gaussian function proportional to  $e^{-t^2/\tau^2}$ . To what linewidth (at half-height) does each process lead?

### Applications: to biochemistry and medicine

**14.22** Interpret the following features of the NMR spectra of hen lysozyme: (a) saturation of a proton resonance assigned to the side chain of methionine-105 changes the intensities of proton resonances assigned to the side chains of tryptophan-28 and tyrosine-23; (b) saturation of proton resonances assigned to tryptophan-28 did not affect the spectrum of tyrosine-23.

**14.23** Suggest a reason why the spin-lattice relaxation time of benzene (a small molecule) in a mobile, deuterated hydrocarbon solvent increases with temperature, whereas that of an oligonucleotide (a large molecule) decreases.

**14.24** NMR spectroscopy may be used to determine the equilibrium constant for dissociation of a complex between a small molecule, such as an enzyme inhibitor I, and a protein, such as an enzyme E:

In the limit of slow chemical exchange, the NMR spectrum of a proton in I would consist of two resonances: one at  $\nu_I$  for free I and another at  $\nu_{\text{EI}}$  for bound I. When chemical exchange is fast, the NMR spectrum of the same proton in I consists of a single peak with a resonance frequency  $\nu$  given by  $\nu = f_I \nu_I + f_{\text{EI}} \nu_{\text{EI}}$ , where  $f_I = [\text{I}]/([\text{I}] + [\text{EI}])$  and  $f_{\text{EI}} = [\text{EI}]/([\text{I}] + [\text{EI}])$  are, respectively, the fractions of free I and bound I. For the purposes of analysing the data, it is also useful to define the frequency differences  $\delta\nu = \nu - \nu_I$  and  $\delta\nu = \nu_{\text{EI}} - \nu_I$ . Show that, when the initial concentration of I,  $[\text{I}]_0$ , is much greater than the initial concentration of E,  $[\text{E}]_0$ , a plot of  $[\text{I}]_0$  against  $\delta\nu^{-1}$  is a straight line with slope  $[\text{E}]_0 \Delta\nu$  and *y*-intercept  $K$ .

**14.25** The molecular electronic structure methods described in Chapter 10 may be used to predict the spin density distribution in a radical. Recent EPR studies have shown that the amino acid tyrosine participates in a number of biological electron-transfer reactions, including the processes of water oxidation to  $\text{O}_2$  in plant photosystem II (*Impact 121.1*). During the course of these electron-transfer reactions, a tyrosine radical forms, with spin density delocalized over the side chain of the amino acid. (a) The phenoxy radical shown in (17) is a suitable model of the tyrosine radical. Using molecular modelling software and the computational method of your choice (semi-empirical or *ab initio* methods), calculate the spin densities at the O atom and at all of the C atoms in (17). (b) Predict the form of the EPR spectrum of (17).

**14.26** Sketch the EPR spectra of the di-*tert*-butyl nitroxide radical (10) at 292 K in the limits of very low concentration (at which electron exchange is negligible), moderate concentration (at which electron exchange effects begin to be observed), and high concentration (at which electron exchange effects predominate). Discuss how the observation of electron exchange between nitroxide spin probes can inform the study of lateral mobility of lipids in a biological membrane.

**14.27** You are designing an MRI spectrometer. What field gradient (in microtesla per metre,  $\mu\text{T m}^{-1}$ ) is required to produce a separation of 100 Hz between two protons separated by the long diameter of a human kidney (taken as 8 cm) given that they are in environments with  $\delta = 3.4$ ? The radiofrequency field of the spectrometer is at 400 MHz and the applied field is 9.4 T.

**14.28** Suppose a uniform disc-shaped organ is in a linear field gradient, and that the MRI signal is proportional to the number of protons in a slice of width  $\delta x$  at each horizontal distance  $x$  from the centre of the disc. Sketch the shape of the absorption intensity for the MRI image of the disc before any computer manipulation has been carried out.

Problems

Statistical thermodynamics provides the link between the microscopic properties of matter and its bulk properties. Two key ideas are introduced in this chapter. The first is the Boltzmann distribution, which is used to predict the populations of states in systems at thermal equilibrium. In this chapter we see its derivation in terms of the distribution of particles over available states. The derivation leads naturally to the introduction of the partition function, which is the central mathematical concept of this and the next chapter. We see how to interpret the partition function and how to calculate it in a number of simple cases. We then see how to extract thermodynamic information from the partition function. In the final part of the chapter, we generalize the discussion to include systems that are composed of assemblies of interacting particles. Very similar equations are developed to those in the first part of the chapter, but they are much more widely applicable.

The preceding chapters of this part of the text have shown how the energy levels of molecules can be calculated, determined spectroscopically, and related to their structures. The next major step is to see how knowledge of these energy levels can be used to account for the properties of matter in bulk. To do so, we now introduce the concepts of **statistical thermodynamics**, the link between individual molecular properties and bulk thermodynamic properties.

The crucial step in going from the quantum mechanics of individual molecules to the thermodynamics of bulk samples is to recognize that the latter deals with the *average* behaviour of large numbers of molecules. For example, the pressure of a gas depends on the average force exerted by its molecules, and there is no need to specify which molecules happen to be striking the wall at any instant. Nor is it necessary to consider the fluctuations in the pressure as different numbers of molecules collide with the wall at different moments. The fluctuations in pressure are very small compared with the steady pressure: it is highly improbable that there will be a sudden lull in the number of collisions, or a sudden surge. Fluctuations in other thermodynamic properties also occur, but for large numbers of particles they are negligible compared to the mean values.

This chapter introduces statistical thermodynamics in two stages. The first, the derivation of the Boltzmann distribution for individual particles, is of restricted applicability, but it has the advantage of taking us directly to a result of central importance in a straightforward and elementary way. We can *use* statistical thermodynamics once we have deduced the Boltzmann distribution. Then (in Section 15.5) we extend the arguments to systems composed of interacting particles.

## The distribution of molecular states

We consider a closed system composed of  $N$  molecules. Although the total energy is constant at  $E$ , it is not possible to be definite about how that energy is shared between the molecules. Collisions result in the ceaseless redistribution of energy not only between the molecules but also among their different modes of motion. The closest we can come to a description of the distribution of energy is to report the **population** of a state, the average number of molecules that occupy it, and to say that on average there are  $n_i$  molecules in a state of energy  $\epsilon_i$ . The populations of the states remain almost constant, but the precise identities of the molecules in each state may change at every collision.

The problem we address in this section is the calculation of the populations of states for any type of molecule in any mode of motion at any temperature. The only restriction is that the molecules should be independent, in the sense that the total energy of the system is a sum of their individual energies. We are discounting (at this stage) the possibility that in a real system a contribution to the total energy may arise from interactions between molecules. We also adopt the **principle of equal *a priori* probabilities**, the assumption that all possibilities for the distribution of energy are equally probable. *A priori* means in this context loosely ‘as far as one knows’. We have no reason to presume otherwise than that, for a collection of molecules at thermal equilibrium, vibrational states of a certain energy, for instance, are as likely to be populated as rotational states of the same energy.

One very important conclusion that will emerge from the following analysis is that the populations of states depend on a single parameter, the ‘temperature’. That is, statistical thermodynamics provides a molecular justification for the concept of temperature and some insight into this crucially important quantity.

### 15.1 Configurations and weights

**Key points** (a) The weight of a configuration is the number of ways that molecules can be distributed over the available states. (b) The most probable distribution, that of the greatest weight, is the Boltzmann distribution.

Any individual molecule may exist in states with energies  $\epsilon_0, \epsilon_1 \dots$ . We shall always take  $\epsilon_0$ , the lowest state, as the zero of energy ( $\epsilon_0 = 0$ ), and measure all other energies relative to that state. To obtain the actual internal energy,  $U$ , we may have to add a constant to the calculated energy of the system. For example, if we are considering the vibrational contribution to the internal energy, then we must add the total zero-point energy of any oscillators in the sample.

#### (a) Instantaneous configurations

At any instant there will be  $N_0$  molecules in the state with energy  $\epsilon_0$ ,  $N_1$  with  $\epsilon_1$ , and so on. The specification of the set of populations  $N_0, N_1, \dots$  in the form  $\{N_0, N_1, \dots\}$  is a statement of the instantaneous **configuration** of the system. The instantaneous configuration fluctuates with time because the populations change. We can picture a large number of different instantaneous configurations. One, for example, might be  $\{N, 0, 0, \dots\}$ , corresponding to every molecule being in its ground state. Another might be  $\{N - 2, 2, 0, 0, \dots\}$ , in which two of the molecules are in the first excited state. The latter configuration is intrinsically more likely to be found than the former because it can be achieved in more ways:  $\{N, 0, 0, \dots\}$  can be achieved in only one way, but  $\{N - 2, 2, \dots\}$  can be achieved in  $\frac{1}{2}N(N - 1)$  different ways (Fig. 15.1; see the

**Fig. 15.1** Whereas a configuration  $\{5, 0, 0, \dots\}$  can be achieved in only one way, a configuration  $\{3, 2, 0, \dots\}$  can be achieved in the ten different ways shown here, where the tinted blocks represent different molecules.

following *Justification*). At this stage in the argument, we are ignoring the requirement that the total energy of the system must be constant (the second configuration has a higher energy than the first); the constraint of total energy will be imposed later in this section.

If, as a result of collisions, the system were to fluctuate between the configurations  $\{N, 0, 0, \dots\}$  and  $\{N - 2, 2, 0, \dots\}$ , it would almost always be found in the second, more likely state (especially if  $N$  were large). In other words, a system free to switch between the two configurations would show properties characteristic almost exclusively of the second configuration. A general configuration  $\{N_0, N_1, \dots\}$  can be achieved in  $\mathcal{W}$  different ways, where  $\mathcal{W}$  is called the **weight** of the configuration. The weight of the configuration  $\{N_0, N_1, \dots\}$  is given by the expression

$$\mathcal{W} = \frac{N!}{N_0! N_1! N_2! \dots} \quad \text{The weight of a configuration} \quad (15.1)$$

Equation 15.1 is a generalization of the formula in  $\mathcal{W} = \frac{1}{2}N(N-1)$ , and reduces to it for the configuration  $\{N-2, 2, 0, \dots\}$ .

#### A brief comment

More formally,  $\mathcal{W}$  is called the *multinomial coefficient*. In eqn 15.1,  $x!$ ,  $x$  factorial, denotes  $x(x-1)(x-2)\dots 1$  and, by definition,  $0! = 1$ .

#### • A brief illustration

To calculate the number of ways of distributing 20 identical objects with the arrangement 1, 0, 3, 5, 10, 1, we note that the configuration is  $\{1, 0, 3, 5, 10, 1\}$  with  $N = 20$ ; therefore the weight is

$$\mathcal{W} = \frac{20!}{1!0!3!5!10!1!} = 9.31 \times 10^8 \quad \bullet$$

**Self-test 15.1** Calculate the weight of the configuration in which 20 objects are distributed in the arrangement 0, 1, 5, 0, 8, 0, 3, 2, 0, 1. [ $4.19 \times 10^{10}$ ]

**Fig. 15.2** The 18 molecules shown here can be distributed into four receptacles (distinguished by the three vertical lines) in  $18!$  different ways. However,  $3!$  of the selections that put three molecules in the first receptacle are equivalent,  $6!$  that put six molecules into the second receptacle are equivalent, and so on. Hence the number of distinguishable arrangements is  $18!/3!6!5!4!$ .

#### Justification 15.1 The weight of a configuration

First, consider the weight of the configuration  $\{N-2, 2, 0, 0, \dots\}$ . One candidate for promotion to an upper state can be selected in  $N$  ways. There are  $N-1$  candidates for the second choice, so the total number of choices is  $N(N-1)$ . However, we should not distinguish the choice (Jack, Jill) from the choice (Jill, Jack) because they lead to the same configurations. Therefore, only half the choices lead to distinguishable configurations, and the total number of distinguishable choices is  $\frac{1}{2}N(N-1)$ .

Now we generalize this remark. Consider the number of ways of distributing  $N$  balls into bins. The first ball can be selected in  $N$  different ways, the next ball in  $N-1$  different ways for the balls remaining, and so on. Therefore, there are  $N(N-1)\dots 1 = N!$  ways of selecting the balls for distribution over the bins. However, if there are  $N_0$  balls in the bin labelled  $\epsilon_0$ , there would be  $N_0!$  different ways in which the same balls could have been chosen (Fig. 15.2). Similarly, there are  $N_1!$  ways in which the  $N_1$  balls in the bin labelled  $\epsilon_1$  can be chosen, and so on. Therefore, the total number of distinguishable ways of distributing the balls so that there are  $N_0$  in bin  $\epsilon_0$ ,  $N_1$  in bin  $\epsilon_1$ , etc. regardless of the order in which the balls were chosen is  $N!/N_0!N_1!\dots$ , which is the content of eqn 15.1.

It will turn out to be more convenient to deal with the natural logarithm of the weight,  $\ln \mathcal{W}$ , rather than with the weight itself. We shall therefore need the expression

$$\begin{aligned}
\ln \mathcal{W} &= \ln \frac{N!}{N_0! N_1! N_2! \dots !} = \ln N! - \ln(N_0! N_1! N_2! \dots !) \\
&= \ln N! - (\ln N_0! + \ln N_1! + \ln N_2! + \dots) \\
&= \ln N! - \sum_i \ln N_i!
\end{aligned}$$

where in the first line we have used  $\ln(x/y) = \ln x - \ln y$  and in the second  $\ln xy = \ln x + \ln y$ . One reason for introducing  $\ln \mathcal{W}$  is that it is easier to make approximations. In particular, we can simplify the factorials by using **Stirling's approximation** in the form

$$\ln x! \approx x \ln x - x$$

Stirling's  
approximation

(15.2)

Then the approximate expression for the weight is

$$\ln \mathcal{W} = (N \ln N - N) - \sum_i (N_i \ln N_i - N_i) = N \ln N - \sum_i N_i \ln N_i \quad (15.3)$$

The final form of eqn 15.3 is derived by noting that the sum of  $N_i$  is equal to  $N$ , so the second and fourth terms in the second expression cancel.

#### A brief comment

A more accurate form of Stirling's approximation is

$$x! \approx (2\pi)^{1/2} x^{x+1/2} e^{-x}$$

and is in error by less than 1 per cent when  $x$  is greater than about 10. We deal with far larger values of  $x$ , and the simplified version in eqn 15.2 is adequate.

### (b) The Boltzmann distribution

We have seen that the configuration  $\{N - 2, 2, 0, \dots\}$  dominates  $\{N, 0, 0, \dots\}$ , and it should be easy to believe that there may be other configurations that have a much greater weight than both. We shall see, in fact, that there is a configuration with so great a weight that it overwhelms all the rest in importance to such an extent that the system will almost always be found in it. The properties of the system will therefore be characteristic of that particular dominating configuration. This dominating configuration can be found by looking for the values of  $N_i$  that lead to a maximum value of  $\mathcal{W}$ . Because  $\mathcal{W}$  is a function of all the  $N_i$ , we can do this search by varying the  $N_i$  and looking for the values that correspond to  $d\mathcal{W} = 0$  (just as in the search for the maximum of any function), or equivalently a maximum value of  $\ln \mathcal{W}$ . However, there are two difficulties with this procedure.

The first difficulty is that the only permitted configurations are those corresponding to the specified, constant, total energy of the system. This requirement rules out many configurations;  $\{N, 0, 0, \dots\}$  and  $\{N - 2, 2, 0, \dots\}$ , for instance, have different energies, so both cannot occur in the same isolated system. It follows that, in looking for the configuration with the greatest weight, we must ensure that the configuration also satisfies the condition

$$\text{Constant total energy:} \quad \sum_i N_i \epsilon_i = E \quad (15.4)$$

where  $E$  is the total energy of the system.

The second constraint is that, because the total number of molecules present is also fixed (at  $N$ ), we cannot arbitrarily vary all the populations simultaneously. Thus, increasing the population of one state by 1 demands that the population of another state must be reduced by 1. Therefore, the search for the maximum value of  $\mathcal{W}$  is also subject to the condition

$$\text{Constant total number of molecules:} \quad \sum_i N_i = N \quad (15.5)$$

We show in *Further information 15.1* that the populations in the configuration of greatest weight, subject to the two constraints in eqns 15.4 and 15.5, depend on the energy of the state according to the **Boltzmann distribution**:

$$\frac{N_i}{N} = \frac{e^{-\beta\epsilon_i}}{\sum_i e^{-\beta\epsilon_i}} \quad \text{Boltzmann distribution} \quad (15.6a)$$

where  $\epsilon_0 \leq \epsilon_1 \leq \epsilon_2 \dots$ . Equation 15.6a is the justification of the remark that a single parameter, here denoted  $\beta$ , determines the most probable populations of the states of the system. We shall see in Section 15.3b that

$$\beta = \frac{1}{kT} \quad (15.6b)$$

where  $T$  is the thermodynamic temperature and  $k$  is Boltzmann's constant. In other words, *the thermodynamic temperature is the unique parameter that governs the most probable populations of states of a system at thermal equilibrium*. In *Further information 15.1*, moreover, we see that  $\beta$  is a more natural measure of temperature than  $T$  itself.

## 15.2 The molecular partition function

**Key points** (a) The molecular partition function indicates the number of thermally accessible states of a collection of molecules at a temperature  $T$ . (b) The translational partition function is calculated by noting that translational states form a near continuum. When the energy is a sum of contributions from independent modes of motion, the partition function is a product of partition functions for each mode of motion.

The Boltzmann distribution is hugely important throughout physical chemistry (and science in general). From now on we write it as

$$p_i = \frac{e^{-\beta\epsilon_i}}{q} \quad \text{Population of a state} \quad (15.7)$$

where  $p_i$  is the fraction of molecules in the state  $i$ ,  $p_i = N_i/N$ , and  $q$  is the **molecular partition function**:

$$q = \sum_i e^{-\beta\epsilon_i} \quad \text{Definition of the molecular partition function} \quad [15.8]$$

The sum in  $q$  is sometimes expressed slightly differently. It may happen that several states have the same energy, and so give the same contribution to the sum. If, for example,  $g_i$  states have the same energy  $\epsilon_i$  (so the level is  $g_i$ -fold degenerate), we could write

$$q = \sum_{\text{levels } I} g_I e^{-\beta\epsilon_I} \quad (15.9)$$

where the sum is now over energy levels (sets of states with the same energy), not individual states. We use the letter  $i$  to label individual states and  $I$  to label levels; when appropriate, we replace these labels by the appropriate quantum numbers.

**Example 15.1** Writing a partition function

Write an expression for the partition function of a linear molecule (such as HCl) treated as a rigid rotor.

**Method** To use eqn 15.9 we need to know (a) the energies of the levels, (b) the degeneracies, the number of states that belong to each level. Whenever calculating a partition function, the energies of the levels are expressed relative to 0 for the state of lowest energy. The energy levels of a rigid linear rotor were derived in Section 12.4c.

**Answer** From eqn 12.14, the energy levels of a linear rotor are  $hc\tilde{B}J(J+1)$ , with  $J = 0, 1, 2, \dots$ . Therefore label the levels with this quantum number. The state of lowest energy has zero energy, so no adjustment need be made to the energies given by this expression. Each level consists of  $2J+1$  degenerate states. Therefore,

$$q = \sum_{J=0}^{\infty} \overbrace{(2J+1)}^{g_J} \overbrace{e^{-\beta hc\tilde{B}J(J+1)}}^{\epsilon_J}$$

The sum can be evaluated numerically by supplying the value of  $\tilde{B}$  (from spectroscopy or calculation) and the temperature. For reasons explained in Section 16.2b, this expression applies only to unsymmetrical linear rotors (for instance, HCl, not  $\text{CO}_2$ ).

**Self-test 15.2** Write the partition function for a two-level system, the lower state (at energy 0) being nondegenerate, and the upper state (at an energy  $\epsilon$ ) doubly degenerate.

$$[q = 1 + 2e^{-\beta\epsilon}]$$

**(a) An interpretation of the partition function**

Some insight into the significance of a partition function can be obtained by considering how  $q$  depends on the temperature. When  $T$  is close to zero, the parameter  $\beta = 1/kT$  is close to infinity. Then every term except one in the sum defining  $q$  is zero because each one has the form  $e^{-x}$  with  $x \rightarrow \infty$ . The exception is the term with  $\epsilon_0 \equiv 0$  (or the  $g_0$  terms at zero energy if the ground state is  $g_0$ -fold degenerate), because then  $\epsilon_0/kT \equiv 0$  whatever the temperature, including zero. As there is only one surviving term when  $T = 0$ , and its value is  $g_0$ , it follows that

$$\lim_{T \rightarrow 0} q = g_0 \quad (15.10)$$

That is, at  $T = 0$ , the partition function is equal to the degeneracy of the ground state.

Now consider the case when  $T$  is so high that for each term in the sum  $\epsilon_j/kT \approx 0$ . Because  $e^{-x} = 1$  when  $x = 0$  each term in the sum now contributes 1. It follows that the sum is equal to the number of molecular states, which in general is infinite:

$$\lim_{T \rightarrow \infty} q = \infty \quad (15.11)$$

In some idealized cases, the molecule may have only a finite number of states; then the upper limit of  $q$  is equal to the number of states. For example, if we were considering only the spin energy levels of a doublet ( $S = \frac{1}{2}$ ) radical in a magnetic field, then there would be only two states ( $M_S = \pm \frac{1}{2}$ ). The partition function for such a system can therefore be expected to rise towards 2 as  $T$  is increased towards infinity.

We see that the molecular partition function gives an indication of the number of states that are thermally accessible to a molecule at the temperature of the system.

**Fig. 15.3** The equally spaced infinite array of energy levels used in the calculation of the partition function. A harmonic oscillator has the same spectrum of levels.

#### A brief comment

The sum of the infinite series  $S = 1 + x + x^2 + \dots$  is obtained by multiplying both sides by  $x$ , which gives  $xS = x + x^2 + x^3 + \dots = S - 1$  and hence  $S = 1/(1 - x)$ .

**Fig. 15.4** The partition function for the system shown in Fig. 15.3 (a harmonic oscillator) as a function of temperature.

**interActivity** Plot the partition function of a harmonic oscillator against temperature for several values of the energy separation  $\epsilon$ . How does  $q$  vary with temperature when  $T$  is high, in the sense that  $kT \gg \epsilon$  (or  $\beta\epsilon \ll 1$ )?

At  $T = 0$ , only the ground level is accessible and  $q = g_0$ . At very high temperatures, virtually all states are accessible, and  $q$  is correspondingly large.

#### Example 15.2 Evaluating the partition function for a uniform ladder of energy levels

Evaluate the partition function for a molecule with an infinite number of equally spaced nondegenerate energy levels (Fig. 15.3). These levels can be thought of as the vibrational energy levels of a diatomic molecule in the harmonic approximation.

**Method** We expect the partition function to increase from 1 at  $T = 0$  and approach infinity as  $T$  goes to  $\infty$ . To evaluate eqn 15.8 explicitly, note that

$$1 + x + x^2 + \dots = \frac{1}{1 - x}$$

**Answer** If the separation of neighbouring levels is  $\epsilon$ , the partition function is

$$q = 1 + e^{-\beta\epsilon} + e^{-2\beta\epsilon} + \dots = 1 + e^{-\beta\epsilon} + (e^{-\beta\epsilon})^2 + \dots = \frac{1}{1 - e^{-\beta\epsilon}}$$

This expression is plotted in Fig. 15.4: notice that, as anticipated,  $q$  rises from 1 to infinity as the temperature is raised.

**Self-test 15.3** Find and plot an expression for the partition function of a system with one state at zero energy and another state at the energy  $\epsilon$ .

$$[q = 1 + e^{-\beta\epsilon}, \text{ Fig. 15.5}]$$

It follows from eqn 15.7 and the expression for  $q$  derived in Example 15.2 for a uniform ladder of states of spacing  $\epsilon$ ,

$$q = \frac{1}{1 - e^{-\beta\epsilon}} \quad \text{Partition function for a uniform array of states} \quad (15.12)$$

**Fig. 15.5** The partition function for a two-level system as a function of temperature. The two graphs differ in the scale of the temperature axis to show the approach to 1 as  $T \rightarrow 0$  and the slow approach to 2 as  $T \rightarrow \infty$ .

**interActivity** Consider a three-level system with levels 0,  $\epsilon$ , and  $2\epsilon$ . Plot the partition function against  $kT/\epsilon$ .

that the fraction of molecules in the state with energy  $\epsilon_i$  is

$$p_i = \frac{e^{-\beta\epsilon_i}}{q} = (1 - e^{-\beta\epsilon})e^{-\beta\epsilon_i} \quad (15.13)$$

Figure 15.6 shows how  $p_i$  varies with temperature. At very low temperatures, where  $q$  is close to 1, only the lowest state is significantly populated. As the temperature is raised, the population breaks out of the lowest state, and the upper states become progressively more highly populated. At the same time, the partition function rises from 1 and its value gives an indication of the range of states populated. The name ‘partition function’ reflects the sense in which  $q$  measures how the total number of molecules is distributed—partitioned—over the available states.

The corresponding expressions for a two-level system derived in Self-test 15.3 are

$$p_0 = \frac{1}{1 + e^{-\beta\epsilon}} \quad p_1 = \frac{e^{-\beta\epsilon}}{1 + e^{-\beta\epsilon}} \quad \text{Populations of a two-state system} \quad (15.14)$$

These functions are plotted in Fig. 15.7. Notice how the populations tend towards equality ( $p_0 = \frac{1}{2}$ ,  $p_1 = \frac{1}{2}$ ) as  $T \rightarrow \infty$ . A common error is to suppose that all the molecules in the system will be found in the upper energy state when  $T = \infty$ ; however, we see from eqn 15.14 that, as  $T \rightarrow \infty$  the populations of states become equal. The same conclusion is true of multi-level systems too: as  $T \rightarrow \infty$ , all states become equally populated.

### Example 15.3 Using the partition function to calculate a population

Calculate the proportion of  $\text{I}_2$  molecules in their ground, first excited, and second excited vibrational states at  $25^\circ\text{C}$ . The vibrational wavenumber is  $214.6\text{ cm}^{-1}$ .

**Method** Vibrational energy levels have a constant separation (in the harmonic approximation, Section 12.8), so the partition function is given by eqn 15.12 and the populations by eqn 15.13. To use the latter equation, we identify the index  $i$  with the quantum number  $v$ , and calculate  $p_v$  for  $v = 0, 1$ , and  $2$ . At  $298.15\text{ K}$ ,  $kT/hc = 207.226\text{ cm}^{-1}$ .

**Answer** First, we note that

$$\beta\epsilon = \frac{hc\tilde{\nu}}{kT} = \frac{214.6\text{ cm}^{-1}}{207.226\text{ cm}^{-1}} = 1.036$$

**Fig. 15.6** The populations of the energy levels of the system shown in Fig. 15.3 at different temperatures, and the corresponding values of the partition function calculated in Example 15.2. Note that  $\beta = 1/kT$ .

**interActivity** To visualize the content of Fig. 15.6 in a different way, plot the functions  $p_0$ ,  $p_1$ ,  $p_2$ , and  $p_3$  against  $kT/\epsilon$ .

**Fig. 15.7** The fraction of populations of the two states of a two-level system as a function of temperature (eqn 15.14). Note that, as the temperature approaches infinity, the populations of the two states become equal (and the fractions both approach 0.5).

**interActivity** Consider a three-level system with levels 0,  $\epsilon$ , and  $2\epsilon$ . Plot the functions  $p_0$ ,  $p_1$ , and  $p_2$  against  $kT/\epsilon$ .

Then it follows from eqn 15.13 that the populations are

$$p_v = (1 - e^{-\beta\epsilon})e^{-v\beta\epsilon} = 0.645e^{-1.036v}$$

Therefore,  $p_0 = 0.645$ ,  $p_1 = 0.229$ ,  $p_2 = 0.081$ . The I–I bond is not stiff and the atoms are heavy: as a result, the vibrational energy separations are small and at room temperature several vibrational levels are significantly populated. The value of the partition function,  $q = 1.55$ , reflects this small but significant spread of populations.

**Self-test 15.4** At what temperature would the  $v = 1$  level of  $I_2$  have (a) half the population of the ground state, (b) the same population as the ground state?

[(a) 445 K, (b) infinite]

### (b) Approximations and factorizations

In general, exact analytical expressions for partition functions cannot be obtained. However, closed approximate expressions can often be found and prove to be very important in a number of chemical applications. For instance, the expression for the partition function for a particle of mass  $m$  free to move in a one-dimensional container of length  $X$  can be evaluated by making use of the fact that the separation of energy levels is very small and that large numbers of states are accessible at normal temperatures. As shown in the following *Justification*, in this case

$$q_X = \left( \frac{2\pi m}{h^2\beta} \right)^{1/2} X = \left( \frac{2\pi mkT}{h^2} \right)^{1/2} X \quad \text{Partition function for translation in one dimension} \quad (15.15)$$

This expression shows that the partition function for translational motion increases with the length of the box and the mass of the particle, for in each case the separation of the energy levels becomes smaller and more levels become thermally accessible. For a given mass and length of the box, the partition function also increases with increasing temperature, because more states become accessible.

**Justification 15.2** *The partition function for a particle in a one-dimensional box*

The energy levels of a molecule of mass  $m$  in a container of length  $X$  are given by eqn 8.4a with  $L = X$ :

$$E_n = \frac{n^2 h^2}{8mX^2} \quad n = 1, 2, \dots$$

The lowest level ( $n = 1$ ) has energy  $h^2/8mX^2$ , so the energies relative to that level are

$$\epsilon_n = (n^2 - 1)\epsilon \quad \epsilon = h^2/8mX^2$$

The sum to evaluate is therefore

$$q_X = \sum_{n=1}^{\infty} e^{-(n^2-1)\beta\epsilon}$$

The translational energy levels are very close together in a container the size of a typical laboratory vessel; therefore, the sum can be approximated by an integral:

$$q_X = \int_1^{\infty} e^{-(n^2-1)\beta\epsilon} dn = \int_0^{\infty} e^{-n^2\beta\epsilon} dn$$

The extension of the lower limit to  $n = 0$  and the replacement of  $n^2 - 1$  by  $n^2$  introduces negligible error but turns the integral into standard form. We make the substitution  $x^2 = n^2 \beta \epsilon$ , implying  $dn = dx/(\beta \epsilon)^{1/2}$ , and therefore that

$$q_X = \left( \frac{1}{\beta \epsilon} \right)^{1/2} \int_0^{\infty} e^{-x^2} dx = \left( \frac{1}{\beta \epsilon} \right)^{1/2} \left( \frac{\pi^{1/2}}{2} \right) = \left( \frac{2\pi m}{h^2 \beta} \right)^{1/2} X$$

Another useful feature of partition functions is used to derive expressions when the energy of a molecule arises from several different, independent sources: if the energy is a sum of contributions from independent modes of motion, then the partition function is a product of partition functions for each mode of motion. For instance, suppose the molecule we are considering is free to move in three dimensions. We take the length of the container in the  $y$ -direction to be  $Y$  and that in the  $z$ -direction to be  $Z$ . The total energy of a molecule  $\epsilon$  is the sum of its translational energies in all three directions:

$$\epsilon_{n_1 n_2 n_3} = \epsilon_{n_1}^{(X)} + \epsilon_{n_2}^{(Y)} + \epsilon_{n_3}^{(Z)} \quad (15.16)$$

where  $n_1$ ,  $n_2$ , and  $n_3$  are the quantum numbers for motion in the  $x$ -,  $y$ -, and  $z$ -directions, respectively. Therefore, because  $e^{a+b+c} = e^a e^b e^c$ , the partition function factorizes as follows:

$$\begin{aligned} q &= \sum_{\text{all } n} e^{-\beta \epsilon_{n_1}^{(X)} - \beta \epsilon_{n_2}^{(Y)} - \beta \epsilon_{n_3}^{(Z)}} = \sum_{\text{all } n} e^{-\beta \epsilon_{n_1}^{(X)}} e^{-\beta \epsilon_{n_2}^{(Y)}} e^{-\beta \epsilon_{n_3}^{(Z)}} \\ &= \left( \sum_{n_1} e^{-\beta \epsilon_{n_1}^{(X)}} \right) \left( \sum_{n_2} e^{-\beta \epsilon_{n_2}^{(Y)}} \right) \left( \sum_{n_3} e^{-\beta \epsilon_{n_3}^{(Z)}} \right) = q_X q_Y q_Z \end{aligned} \quad (15.17)$$

It is generally true that, if the energy of a molecule can be written as the sum of independent terms, then the partition function is the corresponding product of individual contributions.

Equation 15.15 gives the partition function for translational motion in the  $x$ -direction. The only change for the other two directions is to replace the length  $X$  by the lengths  $Y$  or  $Z$ . Hence the partition function for motion in three dimensions is

$$q = \left( \frac{2\pi m}{h^2 \beta} \right)^{3/2} XYZ \quad (15.18)$$

The product of lengths  $XYZ$  is the volume,  $V$ , of the container, so we can write

$$q = \frac{V}{\Lambda^3} \quad \Lambda = h \left( \frac{\beta}{2\pi m} \right)^{1/2} = \frac{h}{(2\pi m k T)^{1/2}} \quad \text{Partition function for translation in three dimensions} \quad (15.19)$$

The quantity  $\Lambda$  has the dimensions of length and is called the **thermal wavelength** (sometimes the *thermal de Broglie wavelength*) of the molecule. The thermal wavelength decreases with increasing mass and temperature. As in the one-dimensional case, the partition function increases with the mass of the particle (as  $m^{3/2}$ ) and the volume of the container (as  $V$ ); for a given mass and volume, the partition function increases with temperature (as  $T^{3/2}$ ).

• **A brief illustration**

To calculate the translational partition function of an  $\text{H}_2$  molecule confined to a  $100 \text{ cm}^3$  vessel at  $25^\circ\text{C}$  we use  $m = 2.016m_{\text{u}}$ ; then

$$\Lambda = \frac{6.626 \times 10^{-34} \text{ J s}}{\{2\pi \times (2.016 \times 1.6605 \times 10^{-27} \text{ kg}) \times (1.38 \times 10^{-23} \text{ J K}^{-1}) \times (298 \text{ K})\}^{1/2}}$$

$$= 7.12 \times 10^{-11} \text{ m}$$

where we have used  $1 \text{ J} = 1 \text{ kg m}^2 \text{ s}^{-2}$ . Therefore,

$$q = \frac{1.00 \times 10^{-4} \text{ m}^3}{(7.12 \times 10^{-11} \text{ m})^3} = 2.77 \times 10^{26}$$

About  $10^{26}$  quantum states are thermally accessible, even at room temperature and for this light molecule. Many states are occupied if the thermal wavelength (which in this case is  $71.2 \text{ pm}$ ) is small compared with the linear dimensions of the container. •

**Self-test 15.5** Calculate the translational partition function for a  $\text{D}_2$  molecule under the same conditions. [ $q = 7.8 \times 10^{26}$ ,  $2^{3/2}$  times larger]

The validity of the approximations that led to eqn 15.19 can be expressed in terms of the average separation of the particles in the container,  $d$ . We do not have to worry about the role of the Pauli principle in the occupation of states if there are many states available for each molecule. Because  $q$  is the total number of accessible states, the average number of states per molecule is  $q/N$ . For this quantity to be large,  $q \gg 1$ , we require  $V/N\Lambda^3 \gg 1$ . However,  $V/N$  is the volume occupied by a single particle, and therefore the average separation of the particles is  $d = (V/N)^{1/3}$ . The condition for there being many states available per molecule is therefore  $d^3/\Lambda^3 \gg 1$ , and therefore  $d \gg \Lambda$ . That is, for eqn 15.19 to be valid, *the average separation of the particles must be much greater than their thermal wavelength*. For  $\text{H}_2$  molecules at 1 bar and 298 K, the average separation is  $3 \text{ nm}$ , which is significantly larger than their thermal wavelength ( $71.2 \text{ pm}$ ).

## The internal energy and the entropy

The importance of the molecular partition function is that it contains all the information needed to calculate the thermodynamic properties of a system of independent particles. In this respect,  $q$  plays a role in statistical thermodynamics very similar to that played by the wavefunction in quantum mechanics:  $q$  is a kind of thermal wavefunction. Here we start to see how this information can be extracted.

### 15.3 The internal energy

**Key points** (a) The internal energy is proportional to the derivative of the partition function with respect to temperature. (b) The parameter  $\beta = 1/kT$ .

We shall begin to unfold the importance of  $q$  by showing how to derive an expression for the internal energy of the system.

**(a) The relation between  $U$  and  $q$** 

The total energy of the system relative to the energy of the lowest state is

$$E(T) = \sum_i N_i \varepsilon_i \quad (15.20)$$

The energy depends on the temperature because the populations of the states depend on the temperature. Because the most probable configuration is so strongly dominating, we can use the Boltzmann distribution for the populations and write

$$E(T) = \frac{N}{q} \sum_i \varepsilon_i e^{-\beta \varepsilon_i} \quad (15.21)$$

To manipulate this expression into a form involving only  $q$  we note that

$$\varepsilon_i e^{-\beta \varepsilon_i} = - \frac{d}{d\beta} e^{-\beta \varepsilon_i}$$

It follows that

$$E(T) = - \frac{N}{q} \sum_i \frac{d}{d\beta} e^{-\beta \varepsilon_i} = - \frac{N}{q} \frac{d}{d\beta} \sum_i e^{-\beta \varepsilon_i} = - \frac{N}{q} \frac{dq}{d\beta} \quad (15.22)$$

• **A brief illustration**

From the two-level partition function  $q = 1 + e^{-\beta \varepsilon}$  we can deduce that the total energy of  $N$  two-level systems is

$$E(T) = - \left( \frac{N}{1 + e^{-\beta \varepsilon}} \right) \frac{d}{d\beta} (1 + e^{-\beta \varepsilon}) = \frac{N \varepsilon e^{-\beta \varepsilon}}{1 + e^{-\beta \varepsilon}} = \frac{N \varepsilon}{1 + e^{\beta \varepsilon}}$$

This function is plotted in Fig. 15.8. Notice how the energy is zero at  $T=0$ , when only the lower state (at the zero of energy) is occupied, and rises to  $\frac{1}{2}N\varepsilon$  as  $T \rightarrow \infty$ , when the two levels become equally populated. •

There are several points in relation to eqn 15.22 that need to be made. Because  $\varepsilon_0 = 0$  (remember that we measure all energies from the lowest available level),  $E(T)$  should be interpreted as the value of the internal energy relative to its value at  $T=0$ ,  $U(0)$ . Therefore, to obtain the conventional internal energy  $U$ , we must add the internal energy at  $T=0$ :

$$U(T) = U(0) + E(T) \quad (15.23)$$

Secondly, because the partition function may depend on variables other than the temperature (for example, the volume), the derivative with respect to  $\beta$  in eqn 15.22 is actually a *partial* derivative with these other variables held constant. The complete expression relating the molecular partition function to the thermodynamic internal energy of a system of independent molecules is therefore

$$U(T) = U(0) - \frac{N}{q} \left( \frac{\partial q}{\partial \beta} \right)_V \quad \text{Internal energy in terms of the partition function . . .} \quad (15.24a)$$

An equivalent form is obtained by noting that  $dx/x = d \ln x$ :

$$U(T) = U(0) - N \left( \frac{\partial \ln q}{\partial \beta} \right)_V \quad \text{. . . and an alternative version} \quad (15.24b)$$

These two equations confirm that we need know only the partition function (as a function of temperature) to calculate the internal energy relative to its value at  $T=0$ .

**Fig. 15.8** The total energy of a two-level system (expressed as a multiple of  $N\varepsilon$ ) as a function of temperature, on two temperature scales. The graph at the top shows the slow rise away from zero energy at low temperatures; the slope of the graph at  $T=0$  is 0 (that is, the heat capacity is zero at  $T=0$ ). The graph below shows the slow rise to 0.5 as  $T \rightarrow \infty$  as both states become equally populated (see Fig. 15.7).

**interActivity** Draw graphs similar to those in Fig. 15.8 for a three-level system with levels 0,  $\varepsilon$ , and  $2\varepsilon$ .

**(b) The value of  $\beta$** 

We now confirm that the parameter  $\beta$ , which we have anticipated is equal to  $1/kT$ , does indeed have that value. To do so, we compare the equipartition expression for the internal energy of a monatomic perfect gas, which from *Fundamentals F.5* we know to be

$$U(T) = U(0) + \frac{3}{2}nRT \quad (15.25a)$$

with the value calculated from the translational partition function (see the following *Justification*), which is

$$U(T) = U(0) + \frac{3N}{2\beta} \quad (15.25b)$$

It follows by comparing these two expressions that

$$\beta = \frac{N}{nRT} = \frac{nN_A}{nN_A kT} = \frac{1}{kT} \quad (15.26)$$

We have used  $N = nN_A$ , where  $n$  is the amount of gas molecules,  $N_A$  is Avogadro's constant, and  $R = N_A k$ . Although we have proved that  $\beta = 1/kT$  by examining a very specific example, the translational motion of a perfect monatomic gas, the result is general.

---

**Justification 15.3** *The internal energy of a perfect gas*

To use eqn 15.24, we introduce the translational partition function from eqn 15.19:

$$\left( \frac{\partial q}{\partial \beta} \right)_V = \left( \frac{\partial}{\partial \beta} \frac{V}{\Lambda^3} \right)_V = V \frac{d}{d\beta} \frac{1}{\Lambda^3} = -3 \frac{V}{\Lambda^4} \frac{d\Lambda}{d\beta}$$

Then we note from the formula for  $\Lambda$  in eqn 15.19 that

$$\frac{d\Lambda}{d\beta} = \frac{d}{d\beta} \left\{ \frac{h\beta^{1/2}}{(2\pi m)^{1/2}} \right\} = \frac{1}{2\beta^{1/2}} \times \frac{h}{(2\pi m)^{1/2}} = \frac{\Lambda}{2\beta}$$

and so obtain

$$\left( \frac{\partial q}{\partial \beta} \right)_V = -\frac{3V}{2\beta\Lambda^3}$$

By eqn 15.24a,

$$U(T) = U(0) - N \left( \frac{\Lambda^3}{V} \right) \left( -\frac{3V}{2\beta\Lambda^3} \right) = U(0) + \frac{3N}{2\beta}$$

as in eqn 15.25b.

---

## 15.4 The statistical entropy

---

**Key point** The statistical entropy is defined by the Boltzmann formula but may be expressed in terms of the molecular partition function.

---

If it is true that the partition function contains all thermodynamic information, then it must be possible to use it to calculate the entropy as well as the internal energy. Because we know (from Section 3.2) that entropy is related to the dispersal of energy

and that the partition function is a measure of the number of thermally accessible states, we can be confident that the two are indeed related.

We shall develop the relation between the entropy and the partition function in two stages. In *Further information 15.2*, we justify one of the most celebrated equations in statistical thermodynamics, the **Boltzmann formula** for the entropy:

$$S = k \ln \mathcal{W}$$

Boltzmann formula  
for the entropy

[15.27]

In this expression,  $\mathcal{W}$  is the weight of the most probable configuration of the system. In the second stage, we express  $\mathcal{W}$  in terms of the partition function.

The statistical entropy behaves in exactly the same way as the thermodynamic entropy. Thus, as the temperature is lowered, the value of  $\mathcal{W}$ , and hence of  $S$ , decreases because fewer configurations are consistent with the total energy. In the limit  $T \rightarrow 0$ ,  $\mathcal{W} = 1$ , so  $\ln \mathcal{W} = 0$ , because only one configuration (every molecule in the lowest level) is compatible with  $E = 0$ . It follows that  $S \rightarrow 0$  as  $T \rightarrow 0$ , which is compatible with the Third Law of thermodynamics, that the entropies of all perfect crystals approach the same value as  $T \rightarrow 0$  (Section 3.4).

Now we relate the Boltzmann formula for the entropy to the partition function. To do so, we substitute the expression for  $\ln \mathcal{W}$  given in eqn 15.3 into eqn 15.27 and, as shown in the following *Justification*, obtain

$$S(T) = \frac{U(T) - U(0)}{T} + Nk \ln q$$

Entropy in terms of  
the partition function

(15.28)

#### Justification 15.4 The statistical entropy

The first stage is to use eqn 15.3 ( $\ln \mathcal{W} = N \ln N - \sum_i N_i \ln N_i$ ) and  $N = \sum_i N_i$  to write

$$\begin{aligned} S(T) &= k \left\{ N \ln N - \sum_i N_i \ln N_i \right\} = k \left\{ \left( \sum_i N_i \right) \ln N - \sum_i N_i \ln N_i \right\} \\ &= k \sum_i N_i \{ \ln N - \ln N_i \} \end{aligned}$$

Next, we use  $\ln x - \ln y = \ln(x/y) = -\ln(y/x)$  to write this expression as

$$S(T) = -k \sum_i N_i \ln \frac{N_i}{N} = -Nk \sum_i p_i \ln p_i$$

where  $p_i = N_i/N$ , the fraction of molecules in state  $i$ . It follows from eqn 15.7 that

$$\ln p_i = -\beta \epsilon_i - \ln q$$

and therefore that

$$S(T) = -Nk \left( -\beta \sum_i p_i \epsilon_i - \sum_i p_i \ln q \right) = k\beta \{ U(T) - U(0) \} + Nk \ln q$$

We have used the fact that the sum over the  $p_i$  is equal to 1 and that (from eqns 15.20 and 15.23)

$$N \sum_i p_i \epsilon_i = \sum_i N_i p_i \epsilon_i = \sum_i N_i \epsilon_i = E(T) = U(T) - U(0)$$

We have already established that  $\beta = 1/kT$ , so eqn 15.28 immediately follows.

**Fig. 15.9** The temperature variation of the entropy of the system shown in Fig. 15.3 (expressed here as a multiple of  $Nk$ ). The entropy approaches zero as  $T \rightarrow 0$ , and increases without limit as  $T \rightarrow \infty$ .

**InterActivity** Plot the function  $dS/dT$ , the temperature coefficient of the entropy, against  $kT/\epsilon$ . Is there a temperature at which this coefficient passes through a maximum? If you find a maximum, explain its physical origins.

#### Example 15.4 Calculating the entropy of a collection of oscillators

Calculate the entropy of a collection of  $N$  independent harmonic oscillators, and evaluate it using vibrational data for  $\text{I}_2$  vapour at  $25^\circ\text{C}$  (Example 15.3).

**Method** To use eqn 15.28, we use the partition function for a molecule with evenly spaced vibrational energy levels, eqn 15.12. With the partition function available, the internal energy can be found by differentiation (as in eqn 15.24a), and the two expressions then combined to give  $S$ .

**Answer** The molecular partition function as given in eqn 15.12 is

$$q = \frac{1}{1 - e^{-\beta\epsilon}}$$

The internal energy is obtained by using eqn 15.24a:

$$U(T) - U(0) = -\frac{N}{q} \left( \frac{\partial q}{\partial \beta} \right)_V = \frac{N\epsilon e^{-\beta\epsilon}}{1 - e^{-\beta\epsilon}} = \frac{N\epsilon}{e^{\beta\epsilon} - 1}$$

The entropy is therefore

$$S(T) = Nk \left\{ \frac{\beta\epsilon}{e^{\beta\epsilon} - 1} - \ln(1 - e^{-\beta\epsilon}) \right\}$$

This function is plotted in Fig. 15.9. For  $\text{I}_2$  at  $25^\circ\text{C}$ ,  $\beta\epsilon = 1.036$  (Example 15.3), so  $S_m = 8.38 \text{ J K}^{-1} \text{ mol}^{-1}$ .

**Self-test 15.6** Evaluate the molar entropy of  $N$  two-level systems and plot the resulting expression. What is the entropy when the two states are equally thermally accessible? [ $S(T)/Nk = \beta\epsilon/(1 + e^{\beta\epsilon}) + \ln(1 + e^{-\beta\epsilon})$ ; see Fig. 15.10;  $S = Nk \ln 2$ ]

#### IMPACT ON TECHNOLOGY

##### 15.1 Reaching very low temperatures

Common refrigerators do not need to reach temperatures too far below the melting point of water, but the study of physical and chemical phenomena at very low temperatures requires more sophisticated technology. The world record low temperature stands at about 100 pK for solids and at about 500 pK for gases, where molecules move so slowly it takes them about 10 s to travel 1 cm. Gases may be cooled by Joule–Thomson expansion below their inversion temperature (Section 2.12), and temperatures lower than 4 K (the boiling point of helium) can be reached by the evaporation of liquid helium by pumping rapidly through large diameter pipes. Temperatures as low as about 1 K can be reached in this way, but at lower temperatures helium is insufficiently volatile for this procedure to be effective; moreover, the superfluid phase begins to interfere with the cooling process by creeping round the apparatus.

Common methods used to reach very low temperatures include *laser cooling* and *adiabatic demagnetization*. In laser cooling, also called *optical trapping*, atoms in the gas phase are cooled by inelastic collisions with photons from intense laser beams, which act as walls of a very small container. For example, the technique can be used to cool a group of 2000 rubidium atoms to 20 nK. Adiabatic demagnetization relies on the fact that, in the absence of a magnetic field, the unpaired electrons of a paramagnetic material are orientated at random, but in the presence of a magnetic field there are more  $\beta$  spins ( $m_s = -\frac{1}{2}$ ) than  $\alpha$  spins ( $m_s = +\frac{1}{2}$ ). In thermodynamic terms, the

application of a magnetic field lowers the entropy of a sample (Fig. 15.11), and at a given temperature, the entropy of a sample is lower when the field is on than when it is off.

A sample of paramagnetic material, such as a d- or f-metal complex, is cooled to about 1 K by using helium. Gadolinium(III) sulfate octahydrate,  $\text{Gd}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$ , has been used because each gadolinium ion carries several unpaired electrons but is separated from its neighbours by a coordination sphere of hydrating  $\text{H}_2\text{O}$  molecules. The sample is then exposed to a strong magnetic field while it is surrounded by helium, which provides thermal contact with the cold reservoir. This magnetization step is isothermal, and heat leaves the sample as the electron spins adopt the lower energy state (AB in Fig. 15.11). Thermal contact between the sample and the surroundings is now broken by pumping away the helium and the magnetic field is reduced to zero. This step is adiabatic and effectively reversible, so the state of the sample changes from B to C. At the end of this step the sample is the same as it was at A except that it now has a lower entropy. That lower entropy in the absence of a magnetic field corresponds to a lower temperature. That is, adiabatic demagnetization has cooled the sample.

Even lower temperatures can be reached if nuclear spins (which also behave like small magnets) are used instead of electron spins in the technique of *adiabatic nuclear demagnetization*. This technique was used to reach the current world record (in silver) of 280 pK.

## The canonical partition function

In this section we see how to generalize our conclusions to include systems composed of interacting molecules. We shall also see how to obtain the molecular partition function from the more general form of the partition function developed here.

### 15.5 The canonical ensemble

**Key points** (a) A canonical ensemble is an imaginary collection of replications of the actual system with a common temperature. It is used to extend statistical thermodynamics to include interacting molecules. (b) The thermodynamic limit is reached when the number of replications becomes infinite. (c) Most members of the ensemble have an energy very close to the mean value.

The crucial new concept we need when treating systems of interacting particles is the ‘ensemble’. Like so many scientific terms, the term has basically its normal meaning of ‘collection’, but it has been sharpened and refined into a precise significance.

#### (a) The concept of ensemble

To set up an ensemble, we take a closed system of specified volume, composition, and temperature, and think of it as replicated  $\tilde{N}$  times (Fig. 15.12). All the identical closed systems are regarded as being in thermal contact with one another, so they can exchange energy. The total energy of all the systems is  $\tilde{E}$  and, because they are in thermal equilibrium with one another, they all have the same temperature,  $T$ . This imaginary collection of replications of the actual system with a common temperature is called the **canonical ensemble**. The word ‘canon’ means ‘according to a rule’.

There are two other important ensembles. In the **microcanonical ensemble** the condition of constant temperature is replaced by the requirement that all the systems should have exactly the same energy: each system is individually isolated. In the **grand canonical ensemble** the volume and temperature of each system is the same, but they

**Fig. 15.10** The temperature variation of the entropy of a two-level system (expressed as a multiple of  $Nk$ ). As  $T \rightarrow \infty$  the two states become equally populated and  $S$  approaches  $Nk \ln 2$ .

 **interActivity** Draw graphs similar to those in Fig. 15.10 for a three-level system with levels 0,  $\epsilon$ , and  $2\epsilon$ .

**Fig. 15.11** The technique of adiabatic demagnetization is used to attain very low temperatures. The upper curve shows the variation in the entropy of a paramagnetic system in the absence of an applied field. The lower curve shows the variation in entropy when a field is applied and has made the electron spins more orderly. The isothermal magnetization step is from A to B; the adiabatic demagnetization step (at constant entropy) is from B to C.

**Fig. 15.12** A representation of the canonical ensemble, in this case for  $\tilde{N} = 20$ . The individual replications of the actual system all have the same composition and volume. They are all in mutual thermal contact, and so all have the same temperature. Energy may be transferred between them as heat, and so they do not all have the same energy. The total energy  $\tilde{E}$  of all 20 replications is a constant because the ensemble is isolated overall.

are open, which means that matter can be imagined as able to pass between the systems; the composition of each one may fluctuate, but now the chemical potential is the same in each system:

Microcanonical ensemble:  $N, V, E$  common

Canonical ensemble:  $N, V, T$  common

Grand canonical ensemble:  $\mu, V, T$  common

Definitions of ensembles

The important point about an ensemble is that it is a collection of *imaginary* replications of the system, so we are free to let the number of members be as large as we like; when appropriate, we can let  $\tilde{N}$  become infinite. The number of members of the ensemble in a state with energy  $E_i$  is denoted  $\tilde{N}_i$ , and we can speak of the configuration of the ensemble (by analogy with the configuration of the system used in Section 15.1) and its weight,  $\tilde{W}$ . Note that  $\tilde{N}$  is unrelated to  $N$ , the number of molecules in the actual system;  $\tilde{N}$  is the number of imaginary replications of that system.

### (b) Dominating configurations

Just as in Section 15.1, some of the configurations of the ensemble will be very much more probable than others. For instance, it is very unlikely that the whole of the total energy,  $\tilde{E}$ , will accumulate in one system. By analogy with the earlier discussion, we can anticipate that there will be a dominating configuration, and that we can evaluate

the thermodynamic properties by taking the average over the ensemble using that single, most probable, configuration. In the **thermodynamic limit** of  $\tilde{N} \rightarrow \infty$ , this dominating configuration is overwhelmingly the most probable, and it dominates the properties of the system virtually completely.

The quantitative discussion follows the argument in Section 15.1 with the modification that  $N$  and  $N_i$  are replaced by  $\tilde{N}$  and  $\tilde{N}_i$ . The weight of a configuration  $\{\tilde{N}_0, \tilde{N}_1, \dots\}$  is

$$\tilde{\mathcal{W}} = \frac{\tilde{N}!}{\tilde{N}_0! \tilde{N}_1! \dots} \quad (15.29)$$

The configuration of greatest weight, subject to the constraints that the total energy of the ensemble is constant at  $\tilde{E}$  and that the total number of members is fixed at  $\tilde{N}$ , is given by the **canonical distribution**:

$$\frac{\tilde{N}_i}{\tilde{N}} = \frac{e^{-\beta E_i}}{Q} \quad Q = \sum_i e^{-\beta E_i} \quad \text{Definition of canonical partition function} \quad (15.30)$$

The quantity  $Q$ , which is a function of the temperature, is called the **canonical partition function**.

### (c) Fluctuations from the most probable distribution

The canonical distribution in eqn 15.30 is only apparently an exponentially decreasing function of the energy of the system. We must appreciate that eqn 15.30 gives the probability of occurrence of members in a single state  $i$  of the entire system of energy  $E_i$ . There may in fact be numerous states with almost identical energies. For example, in a gas the identities of the molecules moving slowly or quickly can change without necessarily affecting the total energy. The density of states, the number of states in an energy range divided by the width of the range (Fig. 15.13), is a very sharply increasing function of energy. It follows that the probability of a member of an ensemble having a specified energy (as distinct from being in a specified state) is given by eqn 15.30, a sharply decreasing function, multiplied by a sharply increasing function (Fig. 15.14). Therefore, the overall distribution is a sharply peaked function. We conclude that most members of the ensemble have an energy very close to the mean value.

## 15.6 The thermodynamic information in the partition function

**Key points** (a) The internal energy of a system composed of interacting molecules is proportional to the derivative of the canonical partition function with respect to temperature. (b) The entropy of an interacting system can be calculated from the canonical partition function.

Like the molecular partition function, the canonical partition function carries all the thermodynamic information about a system. However,  $Q$  is more general than  $q$  because it does not assume that the molecules are independent. We can therefore use  $Q$  to discuss the properties of condensed phases and real gases where molecular interactions are important.

### (a) The internal energy

If the total energy of the ensemble is  $\tilde{E}$ , and there are  $\tilde{N}$  members, the average energy of a member is  $E = \tilde{E}/\tilde{N}$ . We use this quantity to calculate the internal energy of the system in the thermodynamic limit of  $\tilde{N}$  (and  $\tilde{E}$ ) approaching infinity:

$$U(T) = U(0) + E(T) = U(0) + \tilde{E}(T)/\tilde{N} \quad \text{as} \quad \tilde{N} \rightarrow \infty \quad (15.31)$$

**Fig. 15.13** The energy density of states is the number of states in an energy range divided by the width of the range.

**Fig. 15.14** To construct the form of the distribution of members of the canonical ensemble in terms of their energies, we multiply the probability that any one is in a state of given energy, eqn 15.32, by the density of states corresponding to that energy (a steeply rising function). The product is a sharply peaked function at the mean energy, which shows that almost all the members of the ensemble have that energy.

The fraction,  $\tilde{p}_i$ , of members of the ensemble in a state  $i$  with energy  $E_i$  is given by the analogue of eqn 15.7 as

$$\tilde{p}_i = \frac{e^{-\beta E_i}}{Q} \quad (15.32)$$

It follows that the internal energy is given by

$$U(T) = U(0) + \sum_i \tilde{p}_i E_i = U(0) + \frac{1}{Q} \sum_i E_i e^{-\beta E_i} \quad (15.33)$$

By the same argument that led to eqn 15.24,

$$U(T) = U(0) - \frac{1}{Q} \left( \frac{\partial Q}{\partial \beta} \right)_V = U(0) - \left( \frac{\partial \ln Q}{\partial \beta} \right)_V \quad (15.34)$$

Internal energy in terms of the canonical partition function

### (b) The entropy

The total weight,  $\tilde{\mathcal{W}}$ , of a configuration of the ensemble is the product of the average weight  $\mathcal{W}$  of each member of the ensemble,  $\tilde{\mathcal{W}} = \mathcal{W}^N$ . Hence, we can calculate  $S$  from

$$S = k \ln \mathcal{W} = k \ln \tilde{\mathcal{W}}^{1/N} = \frac{k}{N} \ln \tilde{\mathcal{W}} \quad (15.35)$$

It follows, by the same argument used in Section 15.4, that

$$S(T) = \frac{U(T) - U(0)}{T} + k \ln Q \quad (15.36)$$

Entropy in terms of the canonical partition function

## 15.7 Independent molecules

**Key points** (a) For distinguishable independent molecules,  $Q = q^N$ ; for indistinguishable independent molecules,  $Q = q^N/N!$ . (b) The entropy of a perfect gas is given by the Sackur–Tetrode equation.

We shall now see how to recover the molecular partition function from the more general canonical partition function when the molecules are independent. When the molecules are independent and distinguishable (in the sense to be described), we show in the following *Justification* that the relation between  $Q$  and  $q$  is

$$Q = q^N \quad (15.37)$$

### Justification 15.5 The relation between $Q$ and $q$

The total energy of a collection of  $N$  independent molecules is the sum of the energies of the molecules. Therefore, we can write the total energy of a state  $i$  of the system as

$$E_i = \varepsilon_i(1) + \varepsilon_i(2) + \cdots + \varepsilon_i(N)$$

In this expression,  $\varepsilon_i(1)$  is the energy of molecule 1 when the system is in the state  $i$ ,  $\varepsilon_i(2)$  the energy of molecule 2 when the system is in the same state  $i$ , and so on. The canonical partition function is then

$$Q = \sum_i e^{-\beta \varepsilon_i(1) - \beta \varepsilon_i(2) - \cdots - \beta \varepsilon_i(N)}$$

The sum over the states of the system can be reproduced by letting each molecule enter all its own individual states (although we meet an important proviso shortly). Therefore, instead of summing over the states  $i$  of the system, we can sum over all the individual states  $i$  of molecule 1, all the states  $i$  of molecule 2, and so on. This rewriting of the original expression leads to

$$Q = \left( \sum_i e^{-\beta \epsilon_i} \right) \left( \sum_i e^{-\beta \epsilon_i} \right) \cdots \left( \sum_i e^{-\beta \epsilon_i} \right) = \left( \sum_i e^{-\beta \epsilon_i} \right)^N = q^N$$

### (a) Distinguishable and indistinguishable molecules

If all the molecules are identical and free to move through space, we cannot distinguish them and the relation  $Q = q^N$  is not valid. Suppose that molecule 1 is in some state  $a$ , molecule 2 is in  $b$ , and molecule 3 is in  $c$ , then one member of the ensemble has an energy  $E = \epsilon_a + \epsilon_b + \epsilon_c$ . This member, however, is indistinguishable from one formed by putting molecule 1 in state  $b$ , molecule 2 in state  $c$ , and molecule 3 in state  $a$ , or some other permutation. There are six such permutations in all, and  $N!$  in general. In the case of indistinguishable molecules, it follows that we have counted too many states in going from the sum over system states to the sum over molecular states, so writing  $Q = q^N$  overestimates the value of  $Q$ . The detailed argument is quite involved, but at all except very low temperatures it turns out that the correction factor is  $1/N!$ . Therefore:

- For indistinguishable independent molecules:  $Q = q^N/N!$  (15.38a)
- For distinguishable independent molecules:  $Q = q^N$  (15.38b)

 Relation  
between  
 $Q$  and  $q$ 

For molecules to be indistinguishable, they must be of the same kind: an Ar atom is never indistinguishable from a Ne atom. Their identity, however, is not the only criterion. Each identical molecule in a crystal lattice, for instance, can be 'named' with a set of coordinates. Identical molecules in a lattice can therefore be treated as distinguishable because their sites are distinguishable, and we use eqn 15.38b. On the other hand, identical molecules in a gas are free to move to different locations, and there is no way of keeping track of the identity of a given molecule; we therefore use eqn 15.38a.

### (b) The entropy of a monatomic gas

An important application of the previous material is the derivation (as shown in the following *Justification*) of the **Sackur–Tetrode equation** for the entropy of a monatomic gas:

$$S(T) = nR \ln \left( \frac{e^{5/2} V}{n N_A \Lambda^3} \right) \quad \Lambda = \frac{h}{(2\pi m k T)^{1/2}} \quad \text{Sackur–Tetrode equation . . .} \quad (15.39a)$$

This equation implies that the molar entropy of a perfect gas of high molar mass is greater than one of low molar mass under the same conditions (because the former has more thermally accessible translational states). Because the gas is perfect, we can use the relation  $V = nRT/p$  to express the entropy in terms of the pressure as

$$S(T) = nR \ln \left( \frac{e^{5/2} k T}{p \Lambda^3} \right) \quad \text{. . . in terms of pressure} \quad (15.39b)$$

**Justification 15.6** *The Sackur–Tetrode equation*

For a gas of independent molecules,  $Q$  may be replaced by  $q^N/N!$ , with the result that eqn 15.36 becomes

$$S(T) = \frac{U(T) - U(0)}{T} + Nk \ln q - k \ln N!$$

Because the number of molecules ( $N = nN_A$ ) in a typical sample is large, we can use Stirling's approximation (eqn 15.2) to write

$$S(T) = \frac{U(T) - U(0)}{T} + nR \ln q - nR \ln N + nR$$

The only mode of motion for a gas of atoms is translation, and the partition function is  $q = V/\Lambda^3$  (eqn 15.19), where  $\Lambda$  is the thermal wavelength. The internal energy is given by eqn 15.25a, so the entropy is

$$S(T) = \frac{3}{2}nR + nR \left( \ln \frac{V}{\Lambda^3} - \ln nN_A + 1 \right) = nR \left( \ln e^{3/2} + \ln \frac{V}{\Lambda^3} - \ln nN_A + \ln e \right)$$

which rearranges into eqn 15.39.

**Example 15.5** *Using the Sackur–Tetrode equation*

Calculate the standard molar entropy of gaseous argon at 25°C.

**Method** To calculate the molar entropy,  $S_m$ , from eqn 15.39b, divide both sides by  $n$ . To calculate the standard molar entropy,  $S_m^\ominus$ , set  $p = p^\ominus$  in the expression for  $S_m$ :

$$S_m^\ominus = R \ln \left( \frac{e^{5/2} k T}{p^\ominus \Lambda^3} \right)$$

**Answer** The mass of an Ar atom is  $m = 39.95m_u$ . At 25°C, its thermal wavelength is 16.0 pm (by the same kind of calculation as in the *brief illustration* in Section 15.2b). Therefore,

$$S_m^\ominus = R \ln \left\{ \frac{e^{5/2} \times (4.12 \times 10^{-21} \text{ J})}{(10^5 \text{ N m}^{-2}) \times (1.60 \times 10^{-11} \text{ m})^3} \right\} = 18.6R = 155 \text{ J K}^{-1} \text{ mol}^{-1}$$

We can anticipate, on the basis of the number of accessible states for a lighter molecule, that the standard molar entropy of Ne is likely to be smaller than for Ar; its actual value is  $17.60R$  at 298 K.

**Self-test 15.7** Calculate the translational contribution to the standard molar entropy of  $\text{H}_2$  at 25°C. [14.2R]

**Fig. 15.15** As the width of a container is increased (going from (a) to (b)), the energy levels become closer together (as  $1/L^2$ ), and as a result more are thermally accessible at a given temperature. Consequently, the entropy of the system rises as the container expands.

The Sackur–Tetrode equation implies that, when a monatomic perfect gas expands isothermally from  $V_i$  to  $V_f$ , its entropy changes by

$$\Delta S = nR \ln(aV_f) - nR \ln(aV_i) = nR \ln \frac{V_f}{V_i} \quad (15.40)$$

where  $aV$  is the collection of quantities inside the logarithm of eqn 15.39a. This is exactly the expression we obtained by using classical thermodynamics (Example 3.1). Now, though, we see that that classical expression is in fact a consequence of the increase in the number of accessible translational states when the volume of the container is increased (Fig. 15.15).

## Checklist of key equations

## Further information

### Further information 15.1 The Boltzmann distribution

We remarked in Section 15.1 that  $\ln \mathcal{W}$  is easier to handle than  $\mathcal{W}$ . Therefore, to find the form of the Boltzmann distribution, we look for the condition for  $\ln \mathcal{W}$  being a maximum rather than dealing directly with  $\mathcal{W}$ . If you are interested in the outline of the derivation, you need go no further than Section FI15.1a. However, if you wish to learn about some of the mathematical details of the calculation, go on to Section FI15.1b.

#### (a) The derivation

Because  $\ln \mathcal{W}$  depends on all the  $N_i$ , when a configuration changes and the  $N_i$  change to  $N_i + dN_i$ , the function  $\ln \mathcal{W}$  changes to  $\ln \mathcal{W} + d \ln \mathcal{W}$ , where

$$d \ln \mathcal{W} = \sum_i \left( \frac{\partial \ln \mathcal{W}}{\partial N_i} \right) dN_i$$

All this expression states is that a change in  $\ln \mathcal{W}$  is the sum of contributions arising from changes in each value of  $N_i$ . At a maximum,  $d \ln \mathcal{W} = 0$ . However, when the  $N_i$  change, they do so subject to the two constraints

$$\sum_i \epsilon_i dN_i = 0 \quad \sum_i dN_i = 0 \quad (15.41)$$

The first constraint recognizes that the total energy must not change, and the second recognizes that the total number of molecules must not change. These two constraints prevent us from solving  $d \ln \mathcal{W} = 0$  simply by setting all  $(\partial \ln \mathcal{W} / \partial N_i) = 0$  because the  $dN_i$  are not all independent.

The way to take constraints into account was devised by the French mathematician Lagrange, and is called the **method of undetermined multipliers** (see below). All we need here is the rule that a constraint should be multiplied by a constant and then added to the main variation equation. The variables are then treated as though they were all independent, and the constants are evaluated at the end of the calculation.

We employ the technique as follows. The two constraints in eqn 15.41 are multiplied by the constants  $-\beta$  and  $\alpha$ , respectively (the minus sign in  $-\beta$  has been included for future convenience), and then added to the expression for  $d \ln \mathcal{W}$ :

$$\begin{aligned} d \ln \mathcal{W} &= \sum_i \left( \frac{\partial \ln \mathcal{W}}{\partial N_i} \right) dN_i + \alpha \sum_i dN_i - \beta \sum_i \epsilon_i dN_i \\ &= \sum_i \left\{ \left( \frac{\partial \ln \mathcal{W}}{\partial N_i} \right) + \alpha - \beta \epsilon_i \right\} dN_i \end{aligned}$$

All the  $dN_i$  are now treated as independent. Hence the only way of satisfying  $\ln \mathcal{W} = 0$  is to require that, for each  $i$ ,

$$\frac{\partial \ln \mathcal{W}}{\partial N_i} + \alpha - \beta \epsilon_i = 0 \quad (15.42)$$

when the  $N_i$  have their most probable values.

Differentiation of  $\ln \mathcal{W}$  as given in eqn 15.3 with respect to  $N_i$  gives

$$\frac{\partial \ln \mathcal{W}}{\partial N_i} = \frac{\partial(N \ln N)}{\partial N_i} - \sum_j \frac{\partial(N_j \ln N_j)}{\partial N_i}$$

Note that we have had to change the summation index (from  $i$  to  $j$ ) to avoid confusion with the index on  $N_i$ . The derivative of the first term is obtained as follows:

$$\begin{aligned} \frac{\partial(N \ln N)}{\partial N_i} &= \left( \frac{\partial N}{\partial N_i} \right) \ln N + N \left( \frac{\partial \ln N}{\partial N_i} \right) \\ &= \ln N + \frac{\partial N}{\partial N_i} = \ln N + 1 \end{aligned}$$

The  $\ln N$  in the first term on the right in the second line arises because  $N = N_1 + N_2 + \dots$  and so the derivative of  $N$  with respect to any of the  $N_i$  is 1: that is,  $\partial N / \partial N_i = 1$ . The second term on the right in the second line arises because  $\partial(\ln N) / \partial N_i = (1/N) \partial N / \partial N_i$ . The final 1 is then obtained in the same way as in the preceding remark, by using  $\partial N / \partial N_i = 1$ .

For the derivative of the second term we first note that

$$\frac{\partial \ln N_j}{\partial N_i} = \frac{1}{N_j} \left( \frac{\partial N_j}{\partial N_i} \right)$$

If  $i \neq j$ ,  $N_j$  is independent of  $N_i$ , so  $\partial N_j / \partial N_i = 0$ . However, if  $i = j$ ,

$$\frac{\partial N_j}{\partial N_i} = \frac{\partial N_j}{\partial N_j} = 1$$

Therefore,

$$\frac{\partial N_j}{\partial N_i} = \delta_{ij}$$

with  $\delta_{ij}$  the Kronecker delta ( $\delta_{ij} = 1$  if  $i = j$ ;  $\delta_{ij} = 0$  otherwise). Then

$$\begin{aligned} \sum_j \frac{\partial(N_j \ln N_j)}{\partial N_i} &= \sum_j \left\{ \left( \frac{\partial N_j}{\partial N_i} \right) \ln N_j + N_j \left( \frac{\partial \ln N_j}{\partial N_i} \right) \right\} \\ &= \sum_j \left\{ \left( \frac{\partial N_j}{\partial N_i} \right) \ln N_j + \left( \frac{\partial N_j}{\partial N_i} \right) \right\} \\ &= \sum_j \left( \frac{\partial N_j}{\partial N_i} \right) (\ln N_j + 1) \\ &= \sum_j \delta_{ij} (\ln N_j + 1) = \ln N_i + 1 \end{aligned}$$

and therefore

$$\frac{\partial \ln \mathcal{W}}{\partial N_i} = -(\ln N_i + 1) + (\ln N + 1) = -\ln \frac{N_i}{N}$$

It follows from eqn 15.42 that

$$-\ln \frac{N_i}{N} + \alpha - \beta \epsilon_i = 0$$

and therefore that

$$\frac{N_i}{N} = e^{\alpha - \beta \epsilon_i}$$

At this stage we note that

$$N = \sum_i N_i = \sum_i N e^{\alpha - \beta \epsilon_i} = N e^{\alpha} \sum_i e^{-\beta \epsilon_i}$$

Because the  $N$  cancels on each side of this equality, it follows that

$$e^{\alpha} = \frac{1}{\sum_j e^{-\beta \epsilon_j}} \quad (15.43)$$

and

$$\frac{N_i}{N} = e^{\alpha - \beta \epsilon_i} = e^{\alpha} e^{-\beta \epsilon_i} = \frac{1}{\sum_j e^{-\beta \epsilon_j}} e^{-\beta \epsilon_i}$$

which is eqn 15.6a (because at this stage we are free to replace the summation index  $j$  by  $i$ ).

### (b) The method of undetermined multipliers

To understand the derivation above more fully we need to see how we take constraints into account. Suppose we need to find the maximum (or minimum) value of some function  $f$  that depends on several variables  $x_1, x_2, \dots, x_n$ . When the variables undergo a small change from  $x_i$  to  $x_i + \delta x_i$  the function changes from  $f$  to  $f + \delta f$ , where

$$\delta f = \sum_i^n \left( \frac{\partial f}{\partial x_i} \right) \delta x_i \quad (15.44)$$

At a minimum or maximum,  $\delta f = 0$ , so then

$$\sum_i^n \left( \frac{\partial f}{\partial x_i} \right) \delta x_i = 0 \quad (15.45)$$

If the  $x_i$  were all independent, all the  $\delta x_i$  would be arbitrary, and this equation could be solved by setting each  $(\partial f / \partial x_i) = 0$  individually. When the  $x_i$  are not all independent, the  $\delta x_i$  are not all independent, and the simple solution is no longer valid. We proceed as follows.

Let the constraint connecting the variables be an equation of the form  $g = 0$ . For example, in the preceding section one constraint was  $n_0 + n_1 + \dots = N$ , which can be written

$$g = 0, \text{ with } g = (n_0 + n_1 + \dots) - N$$

The constraint  $g = 0$  is always valid, so  $g$  remains unchanged when the  $x_i$  are varied:

$$\delta g = \sum_i \left( \frac{\partial g}{\partial x_i} \right) \delta x_i = 0 \quad (15.46)$$

Because  $\delta g$  is zero, we can multiply it by a parameter,  $\lambda$ , and add it to eqn 15.45:

$$\sum_i^n \left\{ \left( \frac{\partial f}{\partial x_i} \right) + \lambda \left( \frac{\partial g}{\partial x_i} \right) \right\} \delta x_i = 0 \quad (15.47)$$

This equation can be solved for one of the  $\delta x$ ,  $\delta x_n$  for instance, in terms of all the other  $\delta x_i$ . All those other  $\delta x_i$  ( $i = 1, 2, \dots, n-1$ ) are independent, because there is only one constraint on the system. But here is the trick:  $\lambda$  is arbitrary; therefore we can choose it so that the coefficient of  $\delta x_n$  in eqn 15.47 is zero. That is, we choose  $\lambda$  so that

$$\left(\frac{\partial f}{\partial x_n}\right) + \lambda \left(\frac{\partial g}{\partial x_n}\right) = 0 \quad (15.48)$$

Then eqn 15.47 becomes

$$\sum_i^{n-1} \left\{ \left(\frac{\partial f}{\partial x_i}\right) + \lambda \left(\frac{\partial g}{\partial x_i}\right) \right\} \delta x_i = 0 \quad (15.49)$$

Now the  $n-1$  variations  $\delta x_i$  are independent, so the solution of this equation is

$$\left(\frac{\partial f}{\partial x_i}\right) + \lambda \left(\frac{\partial g}{\partial x_i}\right) = 0 \quad i = 1, 2, \dots, n-1 \quad (15.50)$$

However, eqn 15.48 has exactly the same form as this equation, so the maximum or minimum of  $f$  can be found by solving

$$\left(\frac{\partial f}{\partial x_i}\right) + \lambda \left(\frac{\partial g}{\partial x_i}\right) = 0 \quad i = 1, 2, \dots, n \quad (15.51)$$

The use of this approach was illustrated in Section FI15.1a for two constraints and therefore two undetermined multipliers  $\lambda_1$  and  $\lambda_2$  ( $\alpha$  and  $-\beta$ ).

The multipliers  $\lambda$  cannot always remain undetermined. One approach is to solve eqn 15.48 instead of incorporating it into the minimization scheme. In Section FI15.1a we used the alternative procedure of keeping  $\lambda$  undetermined until a property was calculated for which the value was already known. Thus, we found that  $\beta = 1/kT$  by calculating the internal energy of a perfect gas.

### Further information 15.2 The Boltzmann formula

A change in the internal energy

$$U(T) = U(0) + \sum_i N_i \varepsilon_i \quad (15.52)$$

may arise from either a modification of the energy levels of a system (when  $\varepsilon_i$  changes to  $\varepsilon_i + d\varepsilon$ ) or from a modification of the populations (when  $N_i$  changes to  $N_i + dN_i$ ). The most general change is therefore

$$dU = dU(0) + \sum_i N_i d\varepsilon_i + \sum_i \varepsilon_i dN_i \quad (15.53)$$

Because the energy levels do not change when a system is heated at constant volume (Fig. 15.16), in the absence of all changes other than heating

$$dU = \sum_i \varepsilon_i dN_i$$

We know from thermodynamics (and specifically from eqn 3.46) that under the same conditions

$$dU = dq_{\text{rev}} = T dS$$

**Fig. 15.16** (a) When a system is heated, the energy levels are unchanged but their populations are changed. (b) When work is done on a system, the energy levels themselves are changed. The levels in this case are the one-dimensional particle-in-a-box energy levels of Chapter 8: they depend on the size of the container and move apart as its length is decreased.

Therefore,

$$dS = \frac{dU}{T} = k\beta \sum_i \varepsilon_i dN_i \quad (15.54)$$

For changes in the most probable configuration (the only one we need consider), we rearrange eqn 15.42 to

$$\beta \varepsilon_i = \frac{\partial \ln \mathcal{W}}{\partial N_i} + \alpha$$

and find that

$$dS = k \sum_i \left( \frac{\partial \ln \mathcal{W}}{\partial N_i} \right) dN_i + k\alpha \sum_i dN_i$$

Because the number of molecules is constant, the sum over the  $dN_i$  is zero. Hence

$$dS = k \sum_i \left( \frac{\partial \ln \mathcal{W}}{\partial N_i} \right) dN_i = k(d \ln \mathcal{W})$$

This relation strongly suggests the definition  $S = k \ln \mathcal{W}$ , as in eqn 15.27.

## Discussion questions

**15.1** Describe the physical significance of the partition function.

**15.2** Explain how the internal energy and entropy of a system composed of two levels vary with temperature.

**15.3** Discuss the relationship between ‘population’, ‘configuration’, and ‘weight’. What is the significance of the most probable configuration?

**15.4** What is temperature?

**15.5** What is the difference between a ‘state’ and an ‘energy level’? Why is it important to make this distinction?

**15.6** Explain what is meant by an *ensemble* and why it is useful in statistical thermodynamics.

**15.7** Under what circumstances may identical particles be regarded as distinguishable?

## Exercises

**15.1(a)** Calculate the weight of the configuration in which 16 objects are distributed in the arrangement 0, 1, 2, 3, 8, 0, 0, 0, 2.

**15.1(b)** Calculate the weight of the configuration in which 21 objects are distributed in the arrangement 6, 0, 5, 0, 4, 0, 3, 0, 2, 0, 0, 1.

**15.2(a)** What are the relative populations of the states of a two-level system when the temperature is infinite?

**15.2(b)** What are the relative populations of the states of a two-level system as the temperature approaches zero?

**15.3(a)** What is the temperature of a two-level system of energy separation equivalent to  $400\text{ cm}^{-1}$  when the population of the upper state is one-third that of the lower state?

**15.3(b)** What is the temperature of a two-level system of energy separation equivalent to  $300\text{ cm}^{-1}$  when the population of the upper state is one-half that of the lower state?

**15.4(a)** A certain molecule has a nondegenerate excited state lying at  $540\text{ cm}^{-1}$  above the nondegenerate ground state. At what temperature will 10 per cent of the molecules be in the upper state?

**15.4(b)** A certain molecule has a doubly degenerate excited state lying at  $360\text{ cm}^{-1}$  above the nondegenerate ground state. At what temperature will 15 per cent of the molecules be in the upper level?

**15.5(a)** Calculate (a) the thermal wavelength, (b) the translational partition function at (i) 300 K and (ii) 3000 K of a molecule of molar mass  $150\text{ g mol}^{-1}$  in a container of volume  $1.00\text{ cm}^3$ .

**15.5(b)** Calculate (a) the thermal wavelength, (b) the translational partition function of a Ne atom in a cubic box of side  $1.00\text{ cm}$  at (i) 300 K and (ii) 3000 K.

**15.6(a)** Calculate the ratio of the translational partition functions of  $\text{D}_2$  and  $\text{H}_2$  at the same temperature and volume.

**15.6(b)** Calculate the ratio of the translational partition functions of xenon and helium at the same temperature and volume.

**15.7(a)** By what factor does the number of available configurations increase when 100 J of energy is added to a system containing 1.00 mol of particles at constant volume at 298 K?

**15.7(b)** By what factor does the number of available configurations increase when  $20\text{ m}^3$  of air at 1.00 atm and 300 K is allowed to expand by 0.0010 per cent at constant temperature?

**15.8(a)** The bond length of  $\text{O}_2$  is 120.75 pm. Use the high-temperature approximation to calculate the rotational partition function of the molecule at 300 K.

**15.8(b)** The bond length of  $\text{N}_2$  is 109.75 pm. Use the high-temperature approximation to calculate the rotational partition function of the molecule at 300 K.

**15.9(a)** The NOF molecule is an asymmetric rotor with rotational constants  $3.1752\text{ cm}^{-1}$ ,  $0.3951\text{ cm}^{-1}$ , and  $0.3505\text{ cm}^{-1}$ . Calculate the rotational partition function of the molecule at (a)  $25^\circ\text{C}$ , (b)  $100^\circ\text{C}$ .

**15.9(b)** The  $\text{H}_2\text{O}$  molecule is an asymmetric rotor with rotational constants  $27.877\text{ cm}^{-1}$ ,  $14.512\text{ cm}^{-1}$ , and  $9.285\text{ cm}^{-1}$ . Calculate the rotational partition function of the molecule at (a)  $25^\circ\text{C}$ , (b)  $100^\circ\text{C}$ .

**15.10(a)** The rotational constant of CO is  $1.931\text{ cm}^{-1}$ . Evaluate the rotational partition function explicitly (without approximation) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.10(b)** The rotational constant of HI is  $6.511\text{ cm}^{-1}$ . Evaluate the rotational partition function explicitly (without approximation) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.11(a)** The rotational constant of  $\text{CH}_4$  is  $5.241\text{ cm}^{-1}$ . Evaluate the rotational partition function explicitly (without approximation but ignoring the role of nuclear statistics) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.11(b)** The rotational constant of  $\text{CCl}_4$  is  $0.0572\text{ cm}^{-1}$ . Evaluate the rotational partition function explicitly (without approximation but ignoring the role of nuclear statistics) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.12(a)** The rotational constants of  $\text{CH}_3\text{Cl}$  are  $\tilde{A} = 5.097\text{ cm}^{-1}$  and  $\tilde{B} = 0.443\text{ cm}^{-1}$ . Evaluate the rotational partition function explicitly (without approximation but ignoring the role of nuclear statistics) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.12(b)** The rotational constants of  $\text{NH}_3$  are  $\tilde{A} = 6.196\text{ cm}^{-1}$  and  $\tilde{B} = 9.444\text{ cm}^{-1}$ . Evaluate the rotational partition function explicitly (without approximation but ignoring the role of nuclear statistics) and plot its value as

a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.13(a)** Give the symmetry number for each of the following molecules: (a) CO, (b) O<sub>2</sub>, (c) H<sub>2</sub>S, (d) SiH<sub>4</sub>, and (e) CHCl<sub>3</sub>.

**15.13(b)** Give the symmetry number for each of the following molecules: (a) CO<sub>2</sub>, (b) O<sub>3</sub>, (c) SO<sub>3</sub>, (d) SF<sub>6</sub>, and (e) Al<sub>2</sub>Cl<sub>6</sub>.

**15.14(a)** Estimate the rotational partition function of ethene at 25°C given that  $\bar{A} = 4.828 \text{ cm}^{-1}$ ,  $\bar{B} = 1.0012 \text{ cm}^{-1}$ , and  $\bar{C} = 0.8282 \text{ cm}^{-1}$ . Take the symmetry number into account.

**15.14(b)** Evaluate the rotational partition function of pyridine, C<sub>5</sub>H<sub>5</sub>N, at room temperature given that  $\bar{A} = 0.2014 \text{ cm}^{-1}$ ,  $\bar{B} = 0.1936 \text{ cm}^{-1}$ , and  $\bar{C} = 0.0987 \text{ cm}^{-1}$ . Take the symmetry number into account.

**15.15(a)** The vibrational wavenumber of Br<sub>2</sub> is 323.2 cm<sup>-1</sup>. Evaluate the vibrational partition function explicitly (without approximation) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.15(b)** The vibrational wavenumber of I<sub>2</sub> is 214.5 cm<sup>-1</sup>. Evaluate the vibrational partition function explicitly (without approximation) and plot its value as a function of temperature. At what temperature is the value within 5 per cent of the value calculated from the approximate formula?

**15.16(a)** Calculate the vibrational partition function of CS<sub>2</sub> at 500 K given the wavenumbers 658 cm<sup>-1</sup> (symmetric stretch), 397 cm<sup>-1</sup> (bend; two modes), and 1535 cm<sup>-1</sup> (asymmetric stretch).

**15.16(b)** Calculate the vibrational partition function of HCN at 900 K given the wavenumbers 3311 cm<sup>-1</sup> (symmetric stretch), 712 cm<sup>-1</sup> (bend; two modes), and 2097 cm<sup>-1</sup> (asymmetric stretch).

**15.17(a)** Calculate the vibrational partition function of CCl<sub>4</sub> at 500 K given the wavenumbers 459 cm<sup>-1</sup> (symmetric stretch, A), 217 cm<sup>-1</sup> (deformation, E), 776 cm<sup>-1</sup> (deformation, T), and 314 cm<sup>-1</sup> (deformation, T).

**15.17(b)** Calculate the vibrational partition function of Cl<sub>4</sub> at 500 K given the wavenumbers 178 cm<sup>-1</sup> (symmetric stretch, A), 90 cm<sup>-1</sup> (deformation, E), 555 cm<sup>-1</sup> (deformation, T), and 125 cm<sup>-1</sup> (deformation, T).

**15.18(a)** A certain atom has a threefold degenerate ground level, a nondegenerate electronically excited level at 3500 cm<sup>-1</sup>, and a threefold degenerate level at 4700 cm<sup>-1</sup>. Calculate the partition function of these electronic states at 1900 K.

**15.18(b)** A certain atom has a doubly degenerate ground level, a triply degenerate electronically excited level at 1250 cm<sup>-1</sup>, and a doubly degenerate level at 1300 cm<sup>-1</sup>. Calculate the partition function of these electronic states at 2000 K.

**15.19(a)** Calculate the electronic contribution to the molar internal energy at 1900 K for a sample composed of the atoms specified in Exercise 15.18a.

**15.19(b)** Calculate the electronic contribution to the molar internal energy at 2000 K for a sample composed of the atoms specified in Exercise 15.18b.

**15.20(a)** An electron spin can adopt either of two orientations in a magnetic field, and its energies are  $\pm\mu_B\mathcal{B}$ , where  $\mu_B$  is the Bohr magneton. Deduce an expression for the partition function and mean energy of the electron and sketch the variation of the functions with  $\mathcal{B}$ . Calculate the relative populations of the spin states at (a) 4.0 K, (b) 298 K when  $\mathcal{B} = 1.0 \text{ T}$ .

**15.20(b)** A nitrogen nucleus spin can adopt any of three orientations in a magnetic field, and its energies are  $0, \pm\gamma_N\hbar\mathcal{B}$ , where  $\gamma_N$  is the magnetogyric ratio of the nucleus. Deduce an expression for the partition function and mean energy of the nucleus and sketch the variation of the functions with  $\mathcal{B}$ . Calculate the relative populations of the spin states at (a) 1.0 K, (b) 298 K when  $\mathcal{B} = 20.0 \text{ T}$ .

**15.21(a)** Consider a system of distinguishable particles having only two nondegenerate energy levels separated by an energy that is equal to the value of  $kT$  at 10 K. Calculate (a) the ratio of populations in the two states at (1) 1.0 K, (2) 10 K, and (3) 100 K, (b) the molecular partition function at 10 K, (c) the molar energy at 10 K, (d) the molar heat capacity at 10 K, (e) the molar entropy at 10 K.

**15.21(b)** Consider a system of distinguishable particles having only three nondegenerate energy levels separated by an energy that is equal to the value of  $kT$  at 25.0 K. Calculate (a) the ratio of populations in the states at (1) 1.00 K, (2) 25.0 K, and (3) 100 K, (b) the molecular partition function at 25.0 K, (c) the molar energy at 25.0 K, (d) the molar heat capacity at 25.0 K, (e) the molar entropy at 25.0 K.

**15.22(a)** At what temperature would the population of the first excited vibrational state of HCl be 1/e times its population of the ground state?

**15.22(b)** At what temperature would the population of the first excited rotational level of HCl be 1/e times its population of the ground state?

**15.23(a)** Calculate the standard molar entropy of neon gas at (a) 200 K, (b) 298.15 K.

**15.23(b)** Calculate the standard molar entropy of xenon gas at (a) 100 K, (b) 298.15 K.

**15.24(a)** Calculate the vibrational contribution to the entropy of Cl<sub>2</sub> at 500 K given that the wavenumber of the vibration is 560 cm<sup>-1</sup>.

**15.24(b)** Calculate the vibrational contribution to the entropy of Br<sub>2</sub> at 600 K given that the wavenumber of the vibration is 321 cm<sup>-1</sup>.

**15.25(a)** Identify the systems for which it is essential to include a factor of  $1/N!$  on going from  $Q$  to  $q$ : (a) a sample of helium gas, (b) a sample of carbon monoxide gas, (c) a solid sample of carbon monoxide, (d) water vapour.

**15.25(b)** Identify the systems for which it is essential to include a factor of  $1/N!$  on going from  $Q$  to  $q$ : (a) a sample of carbon dioxide gas, (b) a sample of graphite, (c) a sample of diamond, (d) ice.

## Problems\*

## Numerical problems

**15.1** Use mathematical software to evaluate  $\mathcal{W}$  for  $N = 20$  for a series of distributions over a uniform ladder of energy levels, ensuring that the total energy is constant. Identify the configuration of greatest weight and compare it to the distribution predicted by the Boltzmann expression. Explore what happens as the value of the total energy is changed.

**15.2†** Consider a system A consisting of subsystems  $A_1$  and  $A_2$ , for which  $\mathcal{W}_1 = 1 \times 10^{20}$  and  $\mathcal{W}_2 = 2 \times 10^{20}$ . What is the number of configurations available to the combined system? Also, compute the entropies  $S$ ,  $S_1$ , and  $S_2$ . What is the significance of this result?

**15.3†** Consider  $1.00 \times 10^{22}$   $^4\text{He}$  atoms in a box of dimensions  $1.0 \text{ cm} \times 1.0 \text{ cm} \times 1.0 \text{ cm}$ . Calculate the occupancy of the first excited level at 1.0 mK, 2.0 K, and 4.0 K. Do the same for  $^3\text{He}$ . What conclusions might you draw from the results of your calculations?

**15.4** This problem is also best done using mathematical software. Equation 15.12 is the partition function for a harmonic oscillator. Consider a Morse oscillator (Section 12.10) in which the energy levels are given by eqn 12.38.

$$E_v = (v + \frac{1}{2})hc\tilde{\nu} - (v + \frac{1}{2})^2hc x_e \tilde{\nu}$$

Evaluate the partition function for this oscillator, remembering (1) to measure energies from the lowest level and (2) to note that there is only a finite number of levels. Plot the partition function against temperature for a variety of values of  $x_e$ , and—on the same graph—compare your results with that for a harmonic oscillator.

**15.5** Explore the conditions under which the ‘integral’ approximation for the translational partition function is not valid by considering the translational partition function of an Ar atom in a cubic box of side 1.00 cm. Estimate the temperature at which, according to the integral approximation,  $q = 10$  and evaluate the exact partition function at that temperature.

**15.6** A certain atom has a doubly degenerate ground level pair and an upper level of four degenerate states at  $450 \text{ cm}^{-1}$  above the ground level. In an atomic beam study of the atoms it was observed that 30 per cent of the atoms were in the upper level, and the translational temperature of the beam was 300 K. Are the electronic states of the atoms in thermal equilibrium with the translational states?

**15.7** (a) Calculate the electronic partition function of a tellurium atom at (i) 298 K, (ii) 5000 K by direct summation using the following data:

| Term   | Degeneracy | Wavenumber/ $\text{cm}^{-1}$ |
|--------|------------|------------------------------|
| Ground | 5          | 0                            |
| 1      | 1          | 4 707                        |
| 2      | 3          | 4 751                        |
| 3      | 5          | 10 559                       |

(b) What proportion of the Te atoms are in the ground term and in the term labelled 2 at the two temperatures? (c) Calculate the electronic contribution to the standard molar entropy of gaseous Te atoms.

**15.8** The four lowest electronic levels of a Ti atom are:  $^3\text{F}_2$ ,  $^3\text{F}_3$ ,  $^3\text{F}_4$ , and  $^5\text{F}_1$ , at 0, 170, 387, and  $6557 \text{ cm}^{-1}$ , respectively. There are many other electronic states at higher energies. The boiling point of titanium is  $3287^\circ\text{C}$ . What are the relative populations of these levels at the boiling point? (*Hint*. The degeneracies of the levels are  $2J + 1$ .)

**15.9** The NO molecule has a doubly degenerate excited electronic level  $121.1 \text{ cm}^{-1}$  above the doubly degenerate electronic ground term. Calculate and plot the electronic partition function of NO from  $T = 0$  to 1000 K. Evaluate (a) the term populations and (b) the electronic contribution to the molar internal energy at 300 K. Calculate the electronic contribution to the molar entropy of the NO molecule at 300 K and 500 K.

**15.10†** J. Sugar and A. Musgrove (*J. Phys. Chem. Ref. Data* 22, 1213 (1993)) have published tables of energy levels for germanium atoms and cations from  $\text{Ge}^+$  to  $\text{Ge}^{+31}$ . The lowest-lying energy levels in neutral Ge are as follows:

|                         | $^3\text{P}_0$ | $^3\text{P}_1$ | $^3\text{P}_2$ | $^1\text{D}_2$ | $^1\text{S}_0$ |
|-------------------------|----------------|----------------|----------------|----------------|----------------|
| $(E/hc)/\text{cm}^{-1}$ | 0              | 557.1          | 1410.0         | 7125.3         | 16 367.3       |

Calculate the electronic partition function at 298 K and 1000 K by direct summation. *Hint*. The degeneracy of a level is  $2J + 1$ .

**15.11** Calculate, by explicit summation, the vibrational partition function and the vibrational contribution to the molar internal energy of  $\text{I}_2$  molecules at (a) 100 K, (b) 298 K given that its vibrational energy levels lie at the following wavenumbers above the zero-point energy level: 0, 213.30, 425.39, 636.27,  $845.93 \text{ cm}^{-1}$ . What proportion of  $\text{I}_2$  molecules are in the ground and first two excited levels at the two temperatures? Calculate the vibrational contribution to the molar entropy of  $\text{I}_2$  at the two temperatures.

**15.12†** (a) The standard molar entropy of graphite at 298, 410, and 498 K is 5.69, 9.03, and  $11.63 \text{ J K}^{-1} \text{ mol}^{-1}$ , respectively. If 1.00 mol C(graphite) at 298 K is surrounded by thermal insulation and placed next to 1.00 mol C(graphite) at 498 K, also insulated, how many configurations are there altogether for the combined but independent systems? (b) If the same two samples are now placed in thermal contact and brought to thermal equilibrium, the final temperature will be 410 K. (Why might the final temperature not be the average? It isn't.) How many configurations are there now in the combined system? Neglect any volume changes. (c) Demonstrate that this process is spontaneous.

## Theoretical problems

**15.13** Explore the consequences of using the full version of Stirling's approximation,  $x! \approx (2\pi)^{1/2} x^{x+1/2} e^{-x}$ , in the development of the expression for the configuration of greatest weight. Does the more accurate approximation have a significant effect on the form of the Boltzmann distribution?

**15.14** A sample consisting of five molecules has a total energy  $5\epsilon$ . Each molecule is able to occupy states of energy  $j\epsilon$ , with  $j = 0, 1, 2, \dots$  (a) Calculate the weight of the configuration in which the molecules are distributed evenly over the available states. (b) Draw up a table with columns headed by the energy of the states and write beneath them all configurations that are consistent with the total energy. Calculate the weights of each configuration and identify the most probable configurations.

**15.15** A sample of nine molecules is numerically tractable but on the verge of being thermodynamically significant. Draw up a table of configurations for  $N = 9$ , total energy  $9\epsilon$  in a system with energy levels  $j\epsilon$  (as in Problem 15.14). Before evaluating the weights of the configurations, guess (by looking for the most ‘exponential’ distribution of populations) which of the configurations will turn out to be the most probable. Go on to calculate the weights and identify the most probable configuration.

\* Problems denoted with the symbol † were supplied by Charles Trapp and Carmen Giunta.

**15.16** The most probable configuration is characterized by a parameter we know as the ‘temperature’. The temperatures of the system specified in Problems 15.14 and 15.15 must be such as to give a mean value of  $\epsilon$  for the energy of each molecule and a total energy  $N\epsilon$  for the system. (a) Show that the temperature can be obtained by plotting  $p_j$  against  $j$ , where  $p_j$  is the (most probable) fraction of molecules in the state with energy  $j\epsilon$ . Apply the procedure to the system in Problem 15.15. What is the temperature of the system when  $\epsilon$  corresponds to  $50 \text{ cm}^{-1}$ ? (b) Choose configurations other than the most probable, and show that the same procedure gives a worse straight line, indicating that a temperature is not well-defined for them.

**15.17** A certain molecule can exist in either a nondegenerate singlet state or a triplet state (with degeneracy 3). The energy of the triplet exceeds that of the singlet by  $\epsilon$ . Assuming that the molecules are distinguishable (localized) and independent, (a) obtain the expression for the molecular partition function. (b) Find expressions in terms of  $\epsilon$  for the molar energy, molar heat capacity, and molar entropy of such molecules and calculate their values at  $T = \epsilon/k$ .

**15.18** Consider a system with energy levels  $\epsilon_j = j\epsilon$  and  $N$  molecules. (a) Show that, if the mean energy per molecule is  $a\epsilon$ , then the temperature is given by

$$\beta = \frac{1}{\epsilon} \ln \left( 1 + \frac{1}{a} \right)$$

Evaluate the temperature for a system in which the mean energy is  $\epsilon$ , taking  $\epsilon$  equivalent to  $50 \text{ cm}^{-1}$ . (b) Calculate the molecular partition function  $q$  for the system when its mean energy is  $a\epsilon$ . (c) Show that the entropy of the system is

$$S/k = (1+a) \ln(1+a) - a \ln a$$

and evaluate this expression for a mean energy  $\epsilon$ .

**15.19‡** For gases, the canonical partition function,  $Q$ , is related to the molecular partition function  $q$  by  $Q = q^N/N!$ . Use the expression for  $q$  and general thermodynamic relations to derive the perfect gas law  $pV = nRT$ .

**15.20** In the following pair of problems we explore the concept of negative absolute temperature ( $T < 0$ ). Show that for a two-level system (energy separation  $\epsilon$ ) that the temperature is formally negative when the population of the upper state exceeds that of the lower state. Use the partition function for this system to derive and plot expressions for the internal energy and the entropy (and the partition function itself) as a function of (a)  $kT/\epsilon$ , (b)  $\epsilon\beta$  from  $-10$  to  $+10$  in each case.

**15.21** The thermodynamic relation  $(\partial U/\partial S)_V = T$  applies formally to  $T < 0$  as well as to  $T > 0$ . Plot the  $U$  calculated in Problem 15.20 against  $S$  and confirm that  $(\partial U/\partial S)_V < 0$  and  $(\partial U/\partial S)_V > 0$  over the appropriate ranges of temperature.

### Applications: to atmospheric science and astrophysics

**15.22‡** The variation of the atmospheric pressure  $p$  with altitude  $h$  is predicted by the *barometric formula* to be  $p = p_0 e^{-h/H}$  where  $p_0$  is the pressure at sea level and  $H = RT/Mg$  with  $M$  the average molar mass of air and  $T$  the average temperature. Obtain the barometric formula from the Boltzmann distribution. Recall that the potential energy of a particle at height  $h$  above the surface of the Earth is  $mgh$ . Convert the barometric formula from pressure to number density,  $\mathcal{N}$ . Compare the relative number densities,  $\mathcal{N}(h)/\mathcal{N}(0)$ , for  $\text{O}_2$  and  $\text{H}_2\text{O}$  at  $h = 8.0 \text{ km}$ , a typical cruising altitude for commercial aircraft.

**15.23‡** Planets lose their atmospheres over time unless they are replenished. A complete analysis of the overall process is very complicated and depends upon the radius of the planet, temperature, atmospheric composition, and other factors. Prove that the atmosphere of planets cannot be in an equilibrium state by demonstrating that the Boltzmann distribution leads to a uniform finite number density as  $r \rightarrow \infty$ . *Hint.* Recall that in a gravitational field the potential energy is  $V(r) = -GMm/r$ , where  $G$  is the gravitational constant,  $M$  is the mass of the planet, and  $m$  the mass of the particle.

**15.24‡** Consider the electronic partition function of a perfect atomic hydrogen gas at a density of  $1.99 \times 10^{-4} \text{ kg m}^{-3}$  and  $5780 \text{ K}$ . These are the mean conditions within the Sun’s photosphere, the surface layer of the Sun that is about  $190 \text{ km}$  thick. (a) Show that this partition function, which involves a sum over an infinite number of quantum states that are solutions to the Schrödinger equation for an isolated atomic hydrogen atom, is infinite. (b) Develop a theoretical argument for truncating the sum and estimate the maximum number of quantum states that contribute to the sum. (c) Calculate the equilibrium probability that an atomic hydrogen electron is in each quantum state. Are there any general implications concerning electronic states that will be observed for other atoms and molecules? Is it wise to apply these calculations in the study of the Sun’s photosphere?

Problems

In this chapter we apply the concepts of statistical thermodynamics to the calculation of chemically significant quantities. First, we establish the relations between thermodynamic functions and partition functions. Next, we show that the molecular partition function can be factorized into contributions from each mode of motion and establish the formulas for the partition functions for translational, rotational, and vibrational modes of motion and the contribution of electronic excitation. These contributions can be calculated from spectroscopic data. Finally, we turn to specific applications, which include the mean energies of modes of motion, the heat capacities of substances, and residual entropies. In the final section, we see how to calculate the equilibrium constant of a reaction and through that calculation understand some of the molecular features that determine the magnitudes of equilibrium constants and their variation with temperature.

A partition function is the bridge between thermodynamics, spectroscopy, and quantum mechanics. Once it is known, a partition function can be used to calculate thermodynamic functions, heat capacities, entropies, and equilibrium constants. It also sheds light on the significance of these properties.

## Fundamental relations

In this section we see how to obtain any thermodynamic function once we know the partition function. Then we see how to calculate the molecular partition function, and through that the thermodynamic functions, from spectroscopic data.

### 16.1 The thermodynamic functions

---

**Key point** The following functions are written in terms of the canonical partition function: (a) the Helmholtz energy, (b) the pressure, (c) the enthalpy, (d) the Gibbs energy.

---

We have already derived (in Chapter 15) the two expressions for calculating the internal energy and the entropy of a system from its canonical partition function,  $Q$ :

$$U - U(0) = - \left( \frac{\partial \ln Q}{\partial \beta} \right)_V \quad S = \frac{U - U(0)}{T} + k \ln Q \quad (16.1)$$

where  $\beta = 1/kT$ . If the molecules are independent, we can go on to make the substitutions  $Q = q^N$  (for distinguishable molecules, as in a solid) or  $Q = q^N/N!$  (for indistinguishable molecules, as in a gas). All the thermodynamic functions introduced in Part 1 are related to  $U$  and  $S$ , so we have a route to their calculation from  $Q$ .

**(a) Helmholtz energy**

The Helmholtz energy,  $A$ , is defined as  $A = U - TS$ . This relation implies that  $A(0) = U(0)$ , so substitution for  $U$  and  $S$  by using eqn 16.1 leads to the very simple expression

$$A - A(0) = -kT \ln Q \quad \text{Helmholtz energy in terms of } Q \quad (16.2)$$

**(b) The pressure**

By an argument like that leading to eqn 3.35, it follows from  $A = U - TS$  that  $dA = -pdV - SdT$ . Therefore, on imposing constant temperature, the pressure and the Helmholtz energy are related by  $p = -(\partial A / \partial V)_T$ . It then follows from eqn 16.2 that

$$p = kT \left( \frac{\partial \ln Q}{\partial V} \right)_T \quad \text{Pressure in terms of } Q \quad (16.3)$$

This relation is entirely general, and may be used for any type of substance, including perfect gases, real gases, and liquids. Because  $Q$  is in general a function of the volume, temperature, and amount of substance, eqn 16.3 is an equation of state.

**Example 16.1** *Deriving an equation of state*

Derive an expression for the pressure of a gas of independent particles.

**Method** We should suspect that the pressure is that given by the perfect gas law. To proceed systematically, substitute the explicit formula for  $Q$  for a gas of independent, indistinguishable molecules (see eqn 15.38 and the *Checklist of key equations* at the end of Chapter 15) into eqn 16.3.

**Answer** For a gas of independent molecules,  $Q = q^N / N!$  with  $q = V/\Lambda^3$ :

$$\begin{aligned} p &= kT \left( \frac{\partial \ln Q}{\partial V} \right)_T = \frac{kT}{Q} \left( \frac{\partial Q}{\partial V} \right)_T = \frac{NkT}{q} \left( \frac{\partial q}{\partial V} \right)_T \\ &= \frac{NkT\Lambda^3}{V} \times \frac{1}{\Lambda^3} = \frac{NkT}{V} = \frac{nRT}{V} \end{aligned}$$

To derive this relation, we have used

$$\left( \frac{\partial q}{\partial V} \right)_T = \left( \frac{\partial (V/\Lambda^3)}{\partial V} \right)_T = \frac{1}{\Lambda^3}$$

and  $NkT = nN_A kT = nRT$ . The calculation shows that the equation of state of a gas of independent particles is indeed the perfect gas law.

**Self-test 16.1** Derive the equation of state of a sample for which  $Q = q^N f / N!$ , with  $q = V/\Lambda^3$ , where  $f$  depends on the volume.  $[p = nRT/V + kT(\partial \ln f / \partial V)_T]$

**(c) The enthalpy**

At this stage we can use the expressions for  $U$  and  $p$  in the definition  $H = U + pV$  to obtain an expression for the enthalpy,  $H$ , of any substance:

$$H - H(0) = - \left( \frac{\partial \ln Q}{\partial \beta} \right)_V + kTV \left( \frac{\partial \ln Q}{\partial V} \right)_T \quad \text{Enthalpy in terms of } Q \quad (16.4)$$

We have already seen that  $U - U(0) = \frac{3}{2}nRT$  for a gas of independent particles (eqn 15.25a), and have just shown that  $pV = nRT$ . Therefore, for such a gas,

$$H - H(0) = \frac{5}{2}nRT \quad (16.5)$$

#### (d) The Gibbs energy

One of the most important thermodynamic functions for chemistry is the Gibbs energy,  $G = H - TS = A + pV$ . We can now express this function in terms of the partition function by combining the expressions for  $A$  and  $p$ :

$$G - G(0) = -kT \ln Q + kTV \left( \frac{\partial \ln Q}{\partial V} \right)_T \quad \text{Gibbs energy in terms of } Q \quad (16.6)$$

This expression takes a simple form for a gas of independent molecules because  $pV$  in the expression  $G = A + pV$  can be replaced by  $nRT$ :

$$G - G(0) = -kT \ln Q + nRT \quad (16.7)^\circ$$

Furthermore, because  $Q = q^N/N!$ , and therefore  $\ln Q = N \ln q - \ln N!$ , it follows by using Stirling's approximation ( $\ln N! = N \ln N - N$ ) that we can write

$$\begin{aligned} G - G(0) &= -NkT \ln q + kT \ln N! + nRT \\ &= -nRT \ln q + kT(N \ln N - N) + nRT \\ &= -nRT \ln \frac{q}{N} \end{aligned} \quad (16.8)^\circ$$

with  $N = nN_A$ . Now we see another interpretation of the Gibbs energy: it is proportional to the logarithm of the average number of thermally accessible states per molecule.

It will turn out to be convenient to define the **molar partition function**,  $q_m = q/n$  (with units  $\text{mol}^{-1}$ ), for then

$$G - G(0) = -nRT \ln \frac{q_m}{N_A} \quad \text{Gibbs energy of independent molecules} \quad (16.9)^\circ$$

## 16.2 The molecular partition function

**Key points** The molecular partition function factorizes into a product of: (a) translational, (b) rotational, (c) vibrational, and (d) electronic contributions. (e) The contributions to the overall partition function are summarized in the *Checklist of key equations*.

The energy of a molecule is the sum of contributions from its different modes of motion:

$$\epsilon_i = \epsilon_i^T + \epsilon_i^R + \epsilon_i^V + \epsilon_i^E \quad (16.10)$$

where T denotes translation, R rotation, V vibration, and E the electronic contribution. The electronic contribution is not actually a 'mode of motion', but it is convenient to include it here. The separation of terms in eqn 16.10 is only approximate (except for translation) because the modes are not completely independent, but in most cases it is satisfactory. The separation of the electronic and vibrational motions is justified provided only the ground electronic state is occupied (for otherwise the vibrational characteristics depend on the electronic state) and, for the electronic ground state, that the Born–Oppenheimer approximation is valid (Chapter 10). The separation of the vibrational and rotational modes is justified to the extent that the rotational constant is independent of the vibrational state.

Given that the energy is a sum of independent contributions, the partition function factorizes into a product of contributions (recall Section 15.2b):

$$\begin{aligned}
 q &= \sum_i e^{-\beta \epsilon_i} = \sum_{i \text{ (all states)}} e^{-\beta \epsilon_i^T - \beta \epsilon_i^R - \beta \epsilon_i^V - \beta \epsilon_i^E} \\
 &= \sum_{i \text{ (translational)}} \sum_{i \text{ (rotational)}} \sum_{i \text{ (vibrational)}} \sum_{i \text{ (electronic)}} e^{-\beta \epsilon_i^T - \beta \epsilon_i^R - \beta \epsilon_i^V - \beta \epsilon_i^E} \\
 &= \left( \sum_{i \text{ (translational)}} e^{-\beta \epsilon_i^T} \right) \left( \sum_{i \text{ (rotational)}} e^{-\beta \epsilon_i^R} \right) \left( \sum_{i \text{ (vibrational)}} e^{-\beta \epsilon_i^V} \right) \left( \sum_{i \text{ (electronic)}} e^{-\beta \epsilon_i^E} \right) \\
 &= q^T q^R q^V q^E
 \end{aligned}
 \tag{16.11}$$

Factorization of the partition function

This factorization allows us to investigate each contribution separately.

### (a) The translational contribution

The translational partition function of a molecule of mass  $m$  in a container of volume  $V$  was derived in Section 15.2:

$$q^T = \frac{V}{\Lambda^3} \quad \Lambda = h \left( \frac{\beta}{2\pi m} \right)^{1/2} = \frac{h}{(2\pi m k T)^{1/2}} \tag{16.12}$$

Translational contribution to  $q$

Notice that  $q^T \rightarrow \infty$  as  $T \rightarrow \infty$  because an infinite number of states becomes accessible as the temperature is raised. Even at room temperature  $q^T \approx 2 \times 10^{28}$  for an  $O_2$  molecule in a vessel of volume  $100 \text{ cm}^3$ .

The thermal wavelength,  $\Lambda$ , lets us judge whether the approximations that led to the expression for  $q^T$  are valid. The approximations are valid if many states are occupied, which requires  $V/\Lambda^3$  to be large. That will be so if  $\Lambda$  is small compared with the linear dimensions of the container. For  $H_2$  at  $25^\circ\text{C}$ ,  $\Lambda = 71 \text{ pm}$ , which is far smaller than any conventional container is likely to be (but comparable to pores in zeolites or cavities in clathrates). For  $O_2$ , a heavier molecule,  $\Lambda = 18 \text{ pm}$ . We saw in Section 15.2 that an equivalent criterion of validity is that  $\Lambda$  should be much less than the average separation of the molecules in the sample.

### (b) The rotational contribution

As demonstrated in Example 15.1, the partition function of a nonsymmetrical (AB) linear rotor is

$$q^R = \sum_J (2J+1) e^{-\beta h c \tilde{B} J(J+1)} \tag{16.13}$$

The direct method of calculating  $q^R$  is to substitute the experimental values of the rotational energy levels into this expression and to sum the series numerically.

#### Example 16.2 Evaluating the rotational partition function explicitly

Evaluate the rotational partition function of  $^1\text{H}^{35}\text{Cl}$  at  $25^\circ\text{C}$ , given that  $\tilde{B} = 10.591 \text{ cm}^{-1}$ .

**Method** We use eqn 16.13 and evaluate it term by term. A useful relation is  $kT/hc = 207.22 \text{ cm}^{-1}$  at  $298.15 \text{ K}$ . The sum is readily evaluated by using mathematical software.

**Answer** To show how successive terms contribute, we draw up the following table by using  $hc\tilde{B}/kT = 0.05111$  (Fig. 16.1):

**Fig. 16.1** The contributions to the rotational partition function of an HCl molecule at  $25^\circ\text{C}$ . The vertical axis is the value of  $(2J+1)e^{-\beta h c \tilde{B} J(J+1)}$ . Successive terms (which are proportional to the populations of the levels) pass through a maximum because the population of individual states decreases exponentially, but the degeneracy of the levels increases with  $J$ .

|                            |   |      |      |      |      |     |      |
|----------------------------|---|------|------|------|------|-----|------|
| $J$                        | 0 | 1    | 2    | 3    | 4    | ... | 10   |
| $(2J+1)e^{-0.05111J(J+1)}$ | 1 | 2.71 | 3.68 | 3.79 | 3.24 | ... | 0.08 |

The sum required by eqn 16.13 (the sum of the numbers in the second row of the table) is 19.9; hence  $q^R = 19.9$  at this temperature. Taking  $J$  up to 50 gives  $q^R = 19.902$ . Notice that about ten  $J$ -levels are significantly populated but the number of populated *states* is larger on account of the  $(2J+1)$ -fold degeneracy of each level. We shall shortly encounter the approximation that  $q^R \approx kT/hc\tilde{B}$ , which in the present case gives  $q^R = 19.6$ , in good agreement with the exact value and with much less work.

**Self-test 16.2** Evaluate the rotational partition function for HCl at 0°C. [18.26]

At room temperature  $kT/hc \approx 200 \text{ cm}^{-1}$ . The rotational constants of many molecules are close to  $1 \text{ cm}^{-1}$  (Table 12.2) and often smaller (though the very light  $\text{H}_2$  molecule, for which  $\tilde{B} = 60.9 \text{ cm}^{-1}$ , is one exception). It follows that many rotational levels are populated at normal temperatures. When this is the case, we show in the following *Justification* that the partition function may be approximated by

$$q^R = \frac{kT}{hc\tilde{B}} \quad \text{for linear rotors} \quad (16.14a)$$

$$q^R = \left( \frac{kT}{hc} \right)^{3/2} \left( \frac{\pi}{\tilde{A}\tilde{B}\tilde{C}} \right)^{1/2} \quad \text{for non-linear rotors} \quad (16.14b)$$

where  $\tilde{A}$ ,  $\tilde{B}$ , and  $\tilde{C}$  are the rotational constants of the molecule. However, before using these expressions, read on (to eqns 16.15 and 16.16).

**Justification 16.1** *The rotational contribution to the molecular partition function*

When many rotational states are occupied and  $kT$  is much larger than the separation between neighbouring states, the sum in the partition function can be approximated by an integral, much as we did for translational motion in *Justification 15.2*:

$$q^R = \int_0^\infty (2J+1)e^{-\beta hc\tilde{B}J(J+1)} dJ$$

Although this integral looks complicated, it can be evaluated without much effort by noticing that because

$$\frac{d}{dJ} e^{aJ(J+1)} = \left\{ \frac{d}{dJ} aJ(J+1) \right\} e^{aJ(J+1)} = a(2J+1)e^{aJ(J+1)}$$

it can also be written as

$$q^R = -\frac{1}{\beta hc\tilde{B}} \int_0^\infty \left( \frac{d}{dJ} e^{-\beta hc\tilde{B}J(J+1)} \right) dJ$$

Then, because the integral of a derivative of a function is the function itself, we obtain

$$q^R = -\frac{1}{\beta hc\tilde{B}} e^{-\beta hc\tilde{B}J(J+1)} \bigg|_0^\infty = \frac{1}{\beta hc\tilde{B}}$$

which (because  $\beta = 1/kT$ ) is eqn 16.14a. The calculation for a nonlinear molecule is along the same lines, but slightly trickier: it is presented in *Further information 16.1*.

A useful way of expressing the temperature above which the rotational approximation is valid is to introduce the **characteristic rotational temperature**,  $\theta_R = hc\tilde{B}/k$ . Then ‘high temperature’ means  $T \gg \theta_R$  and under these conditions the rotational partition function of a linear molecule is simply  $T/\theta_R$ . Some typical values of  $\theta_R$  are shown in Table 16.1. The value for  $H_2$  is abnormally high and we must be careful with the approximation for this molecule.

The general conclusion at this stage is that molecules with large moments of inertia (and hence small rotational constants and low characteristic rotational temperatures) have large rotational partition functions. The large value of  $q^R$  reflects the closeness in energy (compared with  $kT$ ) of the rotational states in large, heavy molecules, and the large number of them that are accessible at normal temperatures.

We must take care, however, not to include too many rotational states in the sum. For a homonuclear diatomic molecule or a symmetrical linear molecule (such as  $CO_2$  or  $HC\equiv CH$ ), a rotation through  $180^\circ$  results in an indistinguishable state of the molecule. Hence, the number of thermally accessible states is only half the number that can be occupied by a heteronuclear diatomic molecule, where rotation through  $180^\circ$  does result in a distinguishable state. Therefore, for a symmetrical linear molecule

$$q^R = \frac{kT}{2hc\tilde{B}} = \frac{T}{2\theta_R} \quad (16.15a)$$

The equations for symmetrical and nonsymmetrical molecules can be combined into a single expression by introducing the **symmetry number**,  $\sigma$ , which is the number of indistinguishable orientations of the molecule. Then

$$q^R = \frac{kT}{\sigma hc\tilde{B}} = \frac{T}{\sigma\theta_R} \quad (16.15b)$$

 Rotational contribution to  $q$  in the high temperature limit (linear rotors)

For a heteronuclear diatomic molecule  $\sigma = 1$ ; for a homonuclear diatomic molecule or a symmetrical linear molecule,  $\sigma = 2$ .

#### Justification 16.2 The origin of the symmetry number

The quantum mechanical origin of the symmetry number is the Pauli principle, which forbids the occupation of certain states. We saw in Section 12.7, for example, that  $H_2$  may occupy rotational states with even  $J$  only if its nuclear spins are paired (*para*-hydrogen), and odd  $J$  states only if its nuclear spins are parallel (*ortho*-hydrogen). There are three states of *ortho*- $H_2$  to each value of  $J$  (because there are three parallel spin states of the two nuclei).

To set up the rotational partition function we note that ‘ordinary’ molecular hydrogen is a mixture of one part *para*- $H_2$  (with only its even- $J$  rotational states occupied) and three parts *ortho*- $H_2$  (with only its odd- $J$  rotational states occupied). Therefore, the average partition function per molecule is

$$q^R = \frac{1}{4} \sum_{\text{even } J} (2J+1)e^{-\beta hc\tilde{B}J(J+1)} + \frac{3}{4} \sum_{\text{odd } J} (2J+1)e^{-\beta hc\tilde{B}J(J+1)}$$

The odd- $J$  states are more heavily weighted than the even- $J$  states (Fig. 16.2). From the illustration we see that we would obtain approximately the same answer for the partition function (the sum of all the populations) if each  $J$  term contributed half its normal value to the sum. That is, the last equation can be approximated as

$$q^R = \frac{1}{2} \sum_J (2J+1)e^{-\beta hc\tilde{B}J(J+1)}$$

This approximation is very good when many terms contribute (at high temperatures).

**Table 16.1\*** Rotational and vibrational temperatures

| Molecule | Mode    | $\theta_v/K$ | $\theta_R/K$ |
|----------|---------|--------------|--------------|
| $H_2$    |         | 6330         | 88           |
| HCl      |         | 4300         | 15.2         |
| $I_2$    |         | 39           | 0.053        |
| $CO_2$   | $\nu_1$ | 1997         | 0.561        |
|          | $\nu_2$ | 3380         |              |
|          | $\nu_3$ | 960          |              |

\* For more values, see Table 12.2 in the *Data section* and use  $hc/k = 1.439 \text{ K cm}$ .

**Fig. 16.2** The values of the individual terms  $(2J+1)e^{-\beta hc\tilde{B}J(J+1)}$  contributing to the mean partition function of a 3:1 mixture of *ortho*- and *para*- $H_2$ . The partition function is the sum of all these terms. At high temperatures, the sum is approximately equal to the sum of the terms over all values of  $J$ , each with a weight of  $\frac{1}{2}$ . This is the sum of the contributions indicated by the curve.

**Fig. 16.3** The relative populations of the rotational energy levels of  $\text{CO}_2$ . Only states with even  $J$  values are occupied. The full line shows the smoothed, averaged population of levels.

**Table 16.2\*** Symmetry numbers

| Molecule               | $\sigma$ |
|------------------------|----------|
| $\text{H}_2\text{O}$   | 2        |
| $\text{NH}_3$          | 3        |
| $\text{CH}_4$          | 12       |
| $\text{C}_6\text{H}_6$ | 12       |

\* For more values, see Table 12.2 in the Data section.

The same type of argument may be used for linear symmetrical molecules in which identical bosons are interchanged by rotation (such as  $\text{CO}_2$ ). As pointed out in Section 12.7, if the nuclear spin of the bosons is 0, then only even- $J$  states are admissible. Because only half the rotational states are occupied, the rotational partition function is only half the value of the sum obtained by allowing all values of  $J$  to contribute (Fig. 16.3).

The same care must be exercised for other types of symmetrical molecule, and for a nonlinear molecule we write

$$q^R = \frac{1}{\sigma} \left( \frac{kT}{hc} \right)^{3/2} \left( \frac{\pi}{\tilde{A}\tilde{B}\tilde{C}} \right)^{1/2} \quad \text{Rotational contribution to } q \text{ in the high temperature limit (nonlinear molecules)} \quad (16.16)$$

Some typical values of the symmetry numbers required are given in Table 16.2. The value  $\sigma(\text{H}_2\text{O}) = 2$  reflects the fact that a  $180^\circ$  rotation about the bisector of the H–O–H angle interchanges two indistinguishable atoms. In  $\text{NH}_3$ , there are three indistinguishable orientations around the axis shown in (1). For  $\text{CH}_4$ , any of three  $120^\circ$  rotations about any of its four C–H bonds leaves the molecule in an indistinguishable state, so the symmetry number is  $3 \times 4 = 12$ . For benzene, any of six orientations around the axis perpendicular to the plane of the molecule leaves it apparently unchanged, as does a rotation of  $180^\circ$  around any of six axes in the plane of the molecule (three of which pass along each C–H bond and the remaining three pass through each C–C bond in the plane of the molecule). For the way that group theory is used to identify the value of the symmetry number, see Problem 16.18.

### (c) The vibrational contribution

The vibrational partition function of a molecule is calculated by substituting the measured vibrational energy levels into the exponentials appearing in the definition of  $q^V$ , and summing them numerically. In a polyatomic molecule each normal mode (Section 12.13) has its own partition function (provided the anharmonicities are so small that the modes are independent). The overall vibrational partition function is the product of the individual partition functions, and we can write  $q^V = q^V(1)q^V(2) \dots$ , where  $q^V(K)$  is the partition function for the  $K$ th normal mode and is calculated by direct summation of the observed spectroscopic levels.

If the vibrational excitation is not too great, the harmonic approximation may be made, and the vibrational energy levels written as

$$E_v = \left(v + \frac{1}{2}\right)hc\tilde{\nu} \quad v = 0, 1, 2, \dots \quad (16.17)$$

If, as usual, we measure energies from the zero-point level, then the permitted values are  $\epsilon_v = vhc\tilde{\nu}$  and the partition function is

$$q^V = \sum_v e^{-\beta vhc\tilde{\nu}} = \sum_v (e^{-\beta hc\tilde{\nu}})^v \quad (16.18)$$

(because  $e^{ax} = (e^x)^a$ ). We met this sum in Example 15.2 (which is no accident: the ladder-like array of levels in Fig. 15.3 is exactly the same as that of a harmonic oscillator). The series can be summed in the same way, and gives

$$q^V = \frac{1}{1 - e^{-\beta hc\tilde{\nu}}} \quad \text{Vibrational contribution to } q \quad (16.19)$$

This function is plotted in Fig. 16.4. In a polyatomic molecule, each normal mode gives rise to a partition function of this form.

**Example 16.3** Calculating a vibrational partition function

The wavenumbers of the three normal modes of  $\text{H}_2\text{O}$  are  $3656.7\text{ cm}^{-1}$ ,  $1594.8\text{ cm}^{-1}$ , and  $3755.8\text{ cm}^{-1}$ . Evaluate the vibrational partition function at 1500 K.

**Method** Use eqn 16.19 for each mode, and then form the product of the three contributions. At 1500 K,  $kT/hc = 1042.6\text{ cm}^{-1}$ .

**Answer** We draw up the following table displaying the contributions of each mode:

|                              |        |        |        |
|------------------------------|--------|--------|--------|
| Mode:                        | 1      | 2      | 3      |
| $\tilde{\nu}/\text{cm}^{-1}$ | 3656.7 | 1594.8 | 3755.8 |
| $hc\tilde{\nu}/kT$           | 3.507  | 1.530  | 3.602  |
| $q^V$                        | 1.031  | 1.276  | 1.028  |

The overall vibrational partition function is therefore

$$q^V = 1.031 \times 1.276 \times 1.028 = 1.353$$

The three normal modes of  $\text{H}_2\text{O}$  are at such high wavenumbers that even at 1500 K most of the molecules are in their vibrational ground state. However, there may be so many normal modes in a large molecule that their excitation may be significant even though each mode is not appreciably excited. For example, a nonlinear molecule containing 10 atoms has  $3N - 6 = 24$  normal modes (Section 12.13). If we assume a value of about 1.1 for the vibrational partition function of one normal mode, the overall vibrational partition function is about  $q^V \approx (1.1)^{24} = 9.8$ , which indicates significant vibrational excitation relative to a smaller molecule, such as  $\text{H}_2\text{O}$ .

**Self-test 16.3** Repeat the calculation for  $\text{CO}_2$ , where the vibrational wavenumbers are  $1388\text{ cm}^{-1}$ ,  $667.4\text{ cm}^{-1}$ , and  $2349\text{ cm}^{-1}$ , the second being the doubly degenerate bending mode. [6.79]

In many molecules the vibrational wavenumbers are so great that  $\beta hc\tilde{\nu} > 1$ . For example, the lowest vibrational wavenumber of  $\text{CH}_4$  is  $1306\text{ cm}^{-1}$ , so  $\beta hc\tilde{\nu} = 6.3$  at room temperature. C–H stretches normally lie in the range  $2850$  to  $2960\text{ cm}^{-1}$ , so for them  $\beta hc\tilde{\nu} \approx 14$ . In these cases,  $e^{-\beta hc\tilde{\nu}}$  in the denominator of  $q^V$  is very close to zero (for example,  $e^{-6.3} = 0.002$ ), and the vibrational partition function for a single mode is very close to 1 ( $q^V = 1.002$  when  $\beta hc\tilde{\nu} = 6.3$ , implying that only the zero-point level is significantly occupied).

Now consider the case of bonds so weak that  $\beta hc\tilde{\nu} \ll kT$ . When this condition is satisfied, the partition function may be approximated by expanding the exponential ( $e^x = 1 + x + \dots$ ):

$$q^V = \frac{1}{1 - (1 - \beta hc\tilde{\nu} + \dots)} \quad (16.20)$$

That is, for weak bonds at high temperatures,

$$q^V = \frac{1}{\beta hc\tilde{\nu}} = \frac{kT}{hc\tilde{\nu}} \quad (16.21)$$

Vibrational contribution to  $q$   
in the high temperature limit

The temperatures for which eqn 16.21 is valid can be expressed in terms of the **characteristic vibrational temperature**,  $\theta_V = hc\tilde{\nu}/k$  (Table 16.1). The value for  $\text{H}_2$  is abnormally high because the atoms are so light and the vibrational frequency is correspondingly high. In terms of the vibrational temperature, ‘high temperature’ means

**Fig. 16.4** The vibrational partition function of a molecule in the harmonic approximation. Note that the partition function is linearly proportional to the temperature when the temperature is high ( $T \gg \theta_V$ ).

**InterActivity** Plot the temperature dependence of the vibrational contribution to the molecular partition function for several values of the vibrational wavenumber. Estimate from your plots the temperature above which the harmonic oscillator is in the ‘high temperature’ limit.

**Fig. 16.5** The doubly degenerate ground electronic level of NO (with the spin and orbital angular momentum around the axis in opposite directions) and the doubly degenerate first excited level (with the spin and orbital momenta parallel). The upper level is thermally accessible at room temperature.

$T \gg \theta_V$  and, when this condition is satisfied,  $q^V = T/\theta_V$  (the analogue of the rotational expression).

#### (d) The electronic contribution

Electronic energy separations from the ground state are usually very large, so for most cases  $q^E = 1$ . An important exception arises in the case of atoms and molecules having electronically degenerate ground states, in which case  $q^E = g^E$ , where  $g^E$  is the degeneracy of the electronic ground state. Alkali metal atoms, for example, have doubly degenerate ground states (corresponding to the two orientations of their electron spin), so  $q^E = 2$ .

Some atoms and molecules have low-lying electronically excited states. (At high enough temperatures, all atoms and molecules have thermally accessible excited states.) An example is NO, which has the configuration  $\dots \pi^1$ . The orbital angular momentum may take two orientations with respect to the molecular axis (corresponding to circulation clockwise or counterclockwise around the axis), and the spin angular momentum may also take two orientations with respect to the axis, giving four states in all (Fig. 16.5). The energy of the two states in which the orbital and spin momenta are parallel (giving the  ${}^2\Pi_{3/2}$  term) is slightly greater than that of the two other states in which they are antiparallel (giving the  ${}^2\Pi_{1/2}$  term). The separation, which arises from spin–orbit coupling (Section 9.9), is only  $121\text{ cm}^{-1}$ . Hence, at normal temperatures, all four states are thermally accessible. If we denote the energies of the two levels as  $E_{1/2} = 0$  and  $E_{3/2} = \epsilon$ , the partition function is

$$q^E = \sum_{\text{energy levels}} g_j e^{-\beta \epsilon_j} = 2 + 2e^{-\beta \epsilon} \quad (16.22)$$

Figure 16.6 shows the variation of this function with temperature. At  $T = 0$ ,  $q^E = 2$ , because only the doubly degenerate ground state is accessible. At high temperatures,  $q^E \rightarrow 4$  because all four states are accessible. At  $25^\circ\text{C}$ ,  $q^E = 3.1$ .

#### (e) The overall partition function

The partition functions for each mode of motion of a molecule are collected in the *Checklist* at the end of the chapter. The overall partition function is the product of each contribution. For a diatomic molecule with no low-lying electronically excited states and  $T \gg \theta_R$

$$q = g^E \left( \frac{V}{\Lambda^3} \right) \left( \frac{T}{\sigma \theta_R} \right) \left( \frac{1}{1 - e^{-\theta_V/T}} \right) \quad (16.23)$$

#### Example 16.4 Calculating a thermodynamic function from spectroscopic data

Calculate the value of  $G_m^\circ - G_m^\circ(0)$  for  $\text{H}_2\text{O}(\text{g})$  at  $1500\text{ K}$  given that  $\tilde{A} = 27.8778\text{ cm}^{-1}$ ,  $\tilde{B} = 14.5092\text{ cm}^{-1}$ , and  $\tilde{C} = 9.2869\text{ cm}^{-1}$  and the information in Example 16.3.

**Method** The starting point is eqn 16.9. For the standard value, we evaluate the translational partition function at  $p^\circ$  (that is, at  $10^5\text{ Pa}$  exactly). The vibrational partition function was calculated in Example 16.3. Use the expressions in the *Checklist* for the other contributions.

**Answer** Because  $m = 18.015m_u$ , it follows that  $q_m^{\text{tr}}/N_A = 1.729 \times 10^8$ . For the vibrational contribution we have already found that  $q^V = 1.353$ . From Table 16.2 we see that  $\sigma = 2$ , so the rotational contribution is  $q^R = 486.7$ . Therefore,

$$\begin{aligned} G_m^\circ - G_m^\circ(0) &= -(8.3145\text{ J K}^{-1}\text{ mol}^{-1}) \times (1500\text{ K}) \times \ln\{(1.706 \times 10^8) \times 486.7 \times 1.352\} \\ &= -317.5\text{ kJ mol}^{-1} \end{aligned}$$

**Self-test 16.4** Repeat the calculation for  $\text{CO}_2$ . The vibrational data are given in Self-test 16.3;  $\tilde{B} = 0.3902 \text{ cm}^{-1}$ . [ $-366.9 \text{ kJ mol}^{-1}$ ]

Overall partition functions obtained from eqn 16.23 are approximate because they assume that the rotational levels are very close together and that the vibrational levels are harmonic. These approximations are avoided by using the energy levels identified spectroscopically and evaluating the sums explicitly.

## Using statistical thermodynamics

We can now calculate partition functions and, from them, any thermodynamic quantity, so gaining insight into a variety of physical, chemical, and biological processes. In this section, we indicate how to do the calculations for four important properties.

### 16.3 Mean energies

**Key points** The mean energy of a mode of motion can be calculated from the contribution of that mode to the molecular partition function. The mean energy is the sum of contributions from: (a) translation, (b) rotation, and (c) vibration.

It is often useful to know the mean energy,  $\langle \epsilon \rangle$ , of various modes of motion. When the molecular partition function can be factorized into contributions from each mode, the mean energy of each mode  $M$  (from eqn 15.22) is

$$\langle \epsilon^M \rangle = -\frac{1}{q^M} \left( \frac{\partial q^M}{\partial \beta} \right)_V \quad M = T, R, V, \text{ or } E \quad \text{Mean energy of a mode of motion} \quad (16.24)$$

#### (a) The mean translational energy

To see a pattern emerging, we consider first a one-dimensional system of length  $X$ , for which  $q^T = X/\Lambda$ , with  $\Lambda = h(\beta/2\pi m)^{1/2}$ . Then, if we note that  $\Lambda$  is a constant times  $\beta^{1/2}$ ,

$$\langle \epsilon^T \rangle = -\frac{\Lambda}{X} \left( \frac{\partial}{\partial \beta} \frac{X}{\Lambda} \right)_V = -\beta^{1/2} \frac{d}{d\beta} \left( \frac{1}{\beta^{1/2}} \right) = \frac{1}{2\beta} = \frac{1}{2} kT \quad (16.25a)$$

For a molecule free to move in three dimensions, the analogous calculation leads to

$$\langle \epsilon^T \rangle = \frac{3}{2} kT \quad \text{Mean translational energy} \quad (16.25b)$$

Both conclusions are in agreement with the classical equipartition theorem (see *Fundamentals F.5*) that the mean energy of each quadratic contribution to the energy is  $\frac{1}{2} kT$ . Furthermore, the fact that the mean energy is independent of the size of the container is consistent with the thermodynamic result that the internal energy of a perfect gas is independent of its volume (Section 2.11).

#### (b) The mean rotational energy

The mean rotational energy of a linear molecule is obtained from the partition function given in eqn 16.13:

$$q^R = 1 + 3e^{-2\beta h c \tilde{B}} + 5e^{-6\beta h c \tilde{B}} + \dots$$

**Fig. 16.6** The variation with temperature of the electronic partition function of an NO molecule. Note that the curve resembles that for a two-level system (Fig. 15.5), but rises from 2 (the degeneracy of the lower level) and approaches 4 (the total number of states) at high temperatures.

**interActivity** Plot the temperature dependence of the electronic partition function for several values of the energy separation  $\epsilon$  between two doubly degenerate levels. From your plots, estimate the temperature at which the population of the excited level begins to increase sharply.

**Fig. 16.7** The mean rotational energy of a nonsymmetrical linear rotor as a function of temperature. At high temperatures ( $T \gg \theta_R$ ), the energy is linearly proportional to the temperature, in accord with the equipartition theorem.

**InterActivity** Plot the temperature dependence of the mean rotational energy for several values of the rotational constant (for reasonable values of the rotational constant, see the *Data section*). From your plots, estimate the temperature at which the mean rotational energy begins to increase sharply.

Hence

$$\langle \epsilon^R \rangle = \frac{hc\tilde{B}(6e^{-2\beta hc\tilde{B}} + 30e^{-6\beta hc\tilde{B}} + \dots)}{1 + 3e^{-2\beta hc\tilde{B}} + 5e^{-6\beta hc\tilde{B}} + \dots} \quad \text{Mean rotational energy} \quad (16.26a)$$

This function is plotted in Fig. 16.7. At high temperatures ( $T \gg \theta_R$ ),  $q^R$  is given by eqn 16.15, and

$$\langle \epsilon^R \rangle = -\frac{1}{q^R} \frac{dq^R}{d\beta} = -\sigma hc\beta\tilde{B} \frac{d}{d\beta} \frac{1}{\sigma hc\beta\tilde{B}} = \frac{1}{\beta} = kT \quad \text{Mean rotational energy (high temperature limit)} \quad (16.26b)$$

( $q^R$  is independent of  $V$ , so the partial derivatives have been replaced by complete derivatives.) The high-temperature result is also in agreement with the equipartition theorem, for the classical expression for the energy of a linear rotor is  $E_k = \frac{1}{2}I_\perp\omega_a^2 + \frac{1}{2}I_\perp\omega_b^2$ . (There is no rotation around the line of atoms.) It follows from the equipartition theorem that the mean rotational energy is  $2 \times \frac{1}{2}kT = kT$ .

### (c) The mean vibrational energy

The vibrational partition function in the harmonic approximation is given in eqn 16.19. Because  $q^V$  is independent of the volume, it follows that

$$\frac{dq^V}{d\beta} = \frac{d}{d\beta} \left( \frac{1}{1 - e^{-\beta hc\tilde{\nu}}} \right) = -\frac{hc\tilde{\nu}e^{-\beta hc\tilde{\nu}}}{(1 - e^{-\beta hc\tilde{\nu}})^2} \quad (16.27)$$

and hence from

$$\langle \epsilon^V \rangle = -\frac{1}{q^V} \frac{dq^V}{d\beta} = -(1 - e^{-\beta hc\tilde{\nu}}) \left\{ -\frac{hc\tilde{\nu}e^{-\beta hc\tilde{\nu}}}{(1 - e^{-\beta hc\tilde{\nu}})^2} \right\} = \frac{hc\tilde{\nu}e^{-\beta hc\tilde{\nu}}}{1 - e^{-\beta hc\tilde{\nu}}}$$

that

$$\langle \epsilon^V \rangle = \frac{hc\tilde{\nu}}{e^{\beta hc\tilde{\nu}} - 1} \quad \text{Mean vibrational energy} \quad (16.28)$$

The zero-point energy,  $\frac{1}{2}hc\tilde{\nu}$ , can be added to the right-hand side if the mean energy is to be measured from 0 rather than the lowest attainable level (the zero-point level). The variation of the mean energy with temperature is illustrated in Fig. 16.8. At high temperatures, when  $T \gg \theta_V$ , or  $\beta hc\tilde{\nu} \ll 1$ , the exponential functions can be expanded ( $e^x = 1 + x + \dots$ ) and all but the leading terms discarded. This approximation leads to

$$\langle \epsilon^V \rangle = \frac{hc\tilde{\nu}}{(1 + \beta hc\tilde{\nu} + \dots) - 1} \approx \frac{1}{\beta} = kT \quad \text{Mean vibrational energy (high temperature limit)} \quad (16.29)$$

This result is in agreement with the value predicted by the classical equipartition theorem, because the energy of a one-dimensional oscillator is  $E = \frac{1}{2}mv_x^2 + \frac{1}{2}k_f x^2$  and the mean energy of each quadratic term is  $\frac{1}{2}kT$ .

## 16.4 Heat capacities

**Key points** (a) The constant-volume heat capacity can be calculated from the molecular partition function. (b) The total heat capacity of a molecular substance is the sum of the contributions of each mode.

The constant-volume heat capacity is defined as  $C_V = (\partial U / \partial T)_V$ . The derivative with respect to  $T$  is converted into a derivative with respect to  $\beta$  by using

$$\frac{d}{dT} = \frac{d\beta}{dT} \frac{d}{d\beta} = -\frac{1}{kT^2} \frac{d}{d\beta} = -k\beta^2 \frac{d}{d\beta} \quad (16.30)$$

It follows that

$$C_V = -k\beta^2 \left( \frac{\partial U}{\partial \beta} \right)_V \quad (16.31a)$$

Because the internal energy of a perfect gas is a sum of contributions, the heat capacity is also a sum of contributions from each mode. The contribution of mode M is

$$C_V^M = N \left( \frac{\partial \langle \epsilon^M \rangle}{\partial T} \right)_V = -Nk\beta^2 \left( \frac{\partial \langle \epsilon^M \rangle}{\partial \beta} \right)_V \quad (16.31b)$$

Contribution of a mode to the constant-volume heat capacity

### (a) The individual contributions

The temperature is always high enough (provided the gas is above its condensation temperature) for the mean translational energy to be  $\frac{3}{2}kT$ , the equipartition value. Therefore, the translational contribution to the molar constant-volume heat capacity is

$$C_{V,m}^T = N_A \frac{d(\frac{3}{2}kT)}{dT} = \frac{3}{2}R \quad (16.32)$$

Translational contribution to  $C_V$

Translation is the only mode of motion for a monatomic gas, so for such a gas  $C_{V,m} = \frac{3}{2}R = 12.47 \text{ J K}^{-1} \text{ mol}^{-1}$ . This result is very reliable: helium, for example, has this value over a range of 2000 K. We saw in Section 2.5c that  $C_{p,m} - C_{V,m} = R$ , so for a monatomic perfect gas  $C_{p,m} = \frac{5}{2}R$  and therefore

$$\gamma = \frac{C_p}{C_V} = \frac{5}{3} \quad (16.33)^\circ$$

Heat capacity ratio for a monatomic gas

When the temperature is high enough for the rotations of the molecules to be highly excited (when  $T \gg \theta_R$ ), we can use the equipartition value  $kT$  for the mean rotational energy (for a linear rotor) to obtain  $C_{V,m} = R$ . For nonlinear molecules, the mean rotational energy rises to  $\frac{3}{2}kT$ , so the molar rotational heat capacity rises to  $\frac{3}{2}R$  when  $T \gg \theta_R$ . Only the lowest rotational state is occupied when the temperature is very low, and then rotation does not contribute to the heat capacity. We can calculate the rotational heat capacity at intermediate temperatures by differentiating the equation for the mean rotational energy (eqn 16.26a). The resulting (untidy) expression, which is plotted in Fig. 16.9, shows that the contribution rises from zero (when  $T = 0$ ) to the equipartition value (when  $T \gg \theta_R$ ). Because the translational contribution is always present, we can expect the molar heat capacity of a gas of diatomic molecules  $C_{V,m}^T + C_{V,m}^R$  to rise from  $\frac{3}{2}R$  to  $\frac{5}{2}R$  as the temperature is increased above  $\theta_R$ . Problem 16.20 explores how the overall shape of the curve can be traced to the sum of thermal excitations between all the available rotational energy levels (Fig. 16.10).

Molecular vibrations contribute to the heat capacity, but only when the temperature is high enough for them to be significantly excited. The equipartition mean energy is  $kT$  for each mode, so the maximum contribution to the molar heat capacity is  $R$ . However, it is very unusual for the vibrations to be so highly excited that equipartition is valid, and it is more appropriate to use the full expression for the vibrational heat capacity, which is obtained by differentiating eqn 16.28:

$$C_{V,m}^V = Rf(T) \quad f(T) = \left( \frac{\theta_V}{T} \right)^2 \left( \frac{e^{-\theta_V/2T}}{1 - e^{-\theta_V/T}} \right)^2 \quad (16.34)$$

Vibrational contribution to  $C_V$

**Fig. 16.8** The mean vibrational energy of a molecule in the harmonic approximation as a function of temperature. At high temperatures ( $T \gg \theta_V$ ), the energy is linearly proportional to the temperature, in accord with the equipartition theorem.

**InterActivity** Plot the temperature dependence of the mean vibrational energy for several values of the vibrational wavenumber (for reasonable values of the vibrational wavenumber, see the *Data section*). From your plots, estimate the temperature at which the mean vibrational energy begins to increase sharply.

### A brief comment

Equation 16.34 is essentially the same as the Einstein formula for the heat capacity of a solid (eqn 7.11) with  $\theta_V$  the Einstein temperature,  $\theta_E$ . The only difference is that vibrations can take place in three dimensions in a solid.

**Fig. 16.9** The temperature dependence of the rotational contribution to the heat capacity of a linear molecule.

 **interActivity** The *Living graphs* section of the text's web site has applets for the calculation of the temperature dependence of the rotational contribution to the heat capacity. Explore the effect of the rotational constant on the plot of  $C_{V,m}^R$  against  $T$ .

**Fig. 16.10** The rotational heat capacity of a linear molecule can be regarded as the sum of contributions from a collection of two-level systems, in which the rise in temperature stimulates transitions between  $J$  levels, some of which are shown here. The calculation on which this illustration is based is sketched in Problem 16.20.

**Fig. 16.11** The temperature dependence of the vibrational heat capacity of a molecule in the harmonic approximation calculated by using eqn 16.34. Note that the heat capacity is within 10 per cent of its classical value for temperatures greater than  $\theta_V$ .

 **interActivity** The *Living graphs* section of the text's web site has applets for the calculation of the temperature dependence of the vibrational contribution to the heat capacity. Explore the effect of the vibrational wavenumber on the plot of  $C_{V,m}^V$  against  $T$ .

where  $\theta_V = hc\tilde{\nu}/k$  is the characteristic vibrational temperature. The curve in Fig. 16.11 shows how the vibrational heat capacity depends on temperature. Note that, even when the temperature is only slightly above  $\theta_V$ , the heat capacity is close to its equipartition value.

### (b) The overall heat capacity

The total heat capacity of a molecular substance is the sum of each contribution (Fig. 16.12). When equipartition is valid (when the temperature is well above the characteristic temperature of the mode,  $T \gg \theta_M$ ) we can estimate the heat capacity by counting the numbers of modes that are active. In gases, all three translational modes are always active and contribute  $\frac{3}{2}R$  to the molar heat capacity. If we denote the number of active rotational modes by  $\nu_R^*$  (so for most molecules at normal temperatures  $\nu_R^* = 2$  for linear molecules, and 3 for nonlinear molecules), then the rotational contribution is  $\frac{1}{2}\nu_R^*R$ . If the temperature is high enough for  $\nu_V^*$  vibrational modes to be active, the vibrational contribution to the molar heat capacity is  $\nu_V^*R$ . In most cases  $\nu_V^* \approx 0$ . It follows that the total molar heat capacity is

$$C_{V,m} = \frac{1}{2}(3 + \nu_R^* + 2\nu_V^*)R$$

Total heat capacity (at high temperatures)

(16.35)

### • A brief illustration

The characteristic temperatures (in round numbers) of the vibrations of  $\text{H}_2\text{O}$  are 5300 K, 2300 K, and 5400 K; the vibrations are therefore not excited at 373 K. The three rotational modes of  $\text{H}_2\text{O}$  have characteristic temperatures 40 K, 21 K, and 13 K, so they are fully excited, like the three translational modes. The translational contribution is  $\frac{3}{2}R = 12.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . Fully excited rotations contribute a further  $12.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . Therefore, a value close to  $25 \text{ J K}^{-1} \text{ mol}^{-1}$  is predicted. The experimental value is  $26.1 \text{ J K}^{-1} \text{ mol}^{-1}$ . The discrepancy is probably due to deviations from perfect gas behaviour. •

**Self-test 16.5** Estimate the molar constant-volume heat capacity of gaseous  $\text{I}_2$  at  $25^\circ\text{C}$  ( $B = 0.037 \text{ cm}^{-1}$ ;  $\tilde{\nu} = 214.5 \text{ cm}^{-1}$ ). [29  $\text{J K}^{-1} \text{ mol}^{-1}$ ]

## 16.5 Equations of state

**Key point** The canonical partition function of a gas factorizes into a part arising from the kinetic energy and a configuration integral,  $Z$ , which depends on the intermolecular interactions.

The relation between  $p$  and  $Q$  in eqn 16.3 is a very important route to the equations of state of real gases in terms of intermolecular forces, for the latter can be built into  $Q$ . We have already seen (Example 16.1) that the partition function for a gas of independent particles leads to the perfect gas equation of state,  $pV = nRT$ . Real gases differ from perfect gases in their equations of state and we saw in Section 1.3 that their equations of state may be written

$$\frac{pV_m}{RT} = 1 + \frac{B}{V_m} + \frac{C}{V_m^2} + \dots \quad (16.36)$$

where  $B$  is the second virial coefficient and  $C$  is the third virial coefficient.

The total kinetic energy of a gas is the sum of the kinetic energies of the individual molecules. Therefore, even in a real gas the canonical partition function factorizes into a part arising from the kinetic energy, which is the same as for the perfect gas, and a factor called the **configuration integral**,  $Z$ , which depends on the intermolecular potentials. We therefore write

$$Q = \frac{Z}{\Lambda^{3N}} \quad \begin{array}{l} Q \text{ in terms of the} \\ \text{configuration integral} \end{array} \quad (16.37)$$

By comparing this equation with eqn 15.38 ( $Q = q^N/N!$ , with  $q = V/\Lambda^3$ ), we see that for a perfect gas of atoms (with no contributions from rotational or vibrational modes)

$$Z = \frac{V^N}{N!} \quad \begin{array}{l} \text{Configuration integral} \\ \text{(perfect monatomic gas)} \end{array} \quad (16.38)^\circ$$

For a real monatomic gas (for which the intermolecular interactions are isotropic),  $Z$  is related to the total potential energy  $E_p$  of interaction of all the particles by

$$Z = \frac{1}{N!} \int e^{-\beta E_p} d\tau_1 d\tau_2 \cdots d\tau_N \quad \begin{array}{l} \text{Configuration integral} \\ \text{(real monatomic gas)} \end{array} \quad (16.39)$$

where  $d\tau_i$  is the volume element for atom  $i$ . The physical origin of this term is that the probability of occurrence of each arrangement of molecules possible in the sample is given by a Boltzmann distribution in which the exponent is given by the potential energy corresponding to that arrangement.

**Fig. 16.12** The general features of the temperature dependence of the heat capacity of diatomic molecules are as shown here. Each mode becomes active when its characteristic temperature is exceeded. The heat capacity becomes very large when the molecule dissociates because the energy is used to cause dissociation and not to raise the temperature. Then it falls back to the translation-only value of the atoms.

• **A brief illustration**

When the molecules do not interact with one another,  $E_p = 0$  and hence  $e^{-\beta E_p} = 1$ . Then

$$Z = \frac{1}{N!} \int d\tau_1 d\tau_2 \cdots d\tau_N = \frac{V^N}{N!}$$

because  $\int d\tau = V$ , where  $V$  is the volume of the container. This result coincides with eqn 16.38. •

When interactions between pairs of particles are significant and we can ignore three-body interactions, etc., the configuration integral simplifies to

$$Z = \frac{V^{N-2}}{N!} \int e^{-\beta E_p} d\tau_1 d\tau_2 \quad (16.40)$$

The second virial coefficient then turns out to be

$$B = -\frac{N_A}{2V} \int f d\tau_1 d\tau_2 \quad \text{Second virial coefficient} \quad (16.41)$$

The quantity  $f$  is the **Mayer  $f$ -function**: it goes to zero when the two particles are so far apart that  $E_p = 0$ . When the intermolecular interaction depends only on the separation  $r$  of the particles and not on their relative orientation or their absolute position in space, as in the interaction of closed-shell atoms in a uniform sample, the volume element simplifies to  $4\pi r^2 dr$  (because the integrals over the angular variables in  $d\tau = r^2 dr \sin \theta d\theta d\phi$  give a factor of  $4\pi$ ) and eqn 16.41 becomes

$$B = -2\pi N_A \int_0^\infty f r^2 dr \quad f = e^{-\beta E_p} - 1 \quad (16.42)$$

The integral can be evaluated (usually numerically) by substituting an expression for the intermolecular potential energy.

Intermolecular potential energies are discussed in more detail in Chapter 17, where several expressions are developed for them. At this stage, we can illustrate how eqn 16.42 is used by considering the **hard-sphere potential**, which is infinite when the separation of the two molecules,  $r$ , is less than or equal to a certain value  $\sigma$ , and is zero for greater separations. Then

$$e^{-\beta E_p} = 0 \quad f = -1 \quad \text{when } r \leq \sigma \quad (\text{and } E_p = \infty) \quad (16.43a)$$

$$e^{-\beta E_p} = 1 \quad f = 0 \quad \text{when } r > \sigma \quad (\text{and } E_p = 0) \quad (16.43b)$$

It follows from eqn 16.42 that the second virial coefficient is

$$B = 2\pi N_A \int_0^\sigma r^2 dr = \frac{2}{3} \pi N_A \sigma^3 \quad (16.44)$$

This calculation of  $B$  raises the question as to whether a potential can be found that, when the virial coefficients are evaluated, gives the van der Waals equation of state. Such a potential can be found for weak attractive interactions ( $a \ll RT$ ): it consists of a hard-sphere repulsive core and a long-range, shallow attractive region (see Problem 16.22). A further point is that, once a second virial coefficient has been calculated for a given intermolecular potential, it is possible to calculate other thermodynamic properties that depend on the form of the potential. For example, it is possible to calculate the isothermal Joule–Thomson coefficient,  $\mu_T$  (Section 2.12a), from the thermodynamic relation

$$\lim_{p \rightarrow 0} \mu_T = B - T \frac{dB}{dT} \quad (16.45)$$

(see Problem 16.17) and from the result calculate the Joule–Thomson coefficient itself by using eqn 2.53.

## 16.6 Molecular interactions in liquids

**Key points** (a) The radial distribution function,  $g(r)$ , is the probability that a molecule will be found in the range  $dr$  at a distance  $r$  from another molecule. (b) The radial distribution function may be calculated with Monte Carlo and molecular dynamics techniques. (c) The internal energy and pressure of a fluid may be expressed in terms of the radial distribution function.

The starting point for the discussion of solids is the well ordered structure of a perfect crystal, which will be discussed in Chapter 19. The starting point for the discussion of gases is the completely disordered distribution of the molecules of a perfect gas, as we saw in Chapter 1. Liquids lie between these two extremes. We shall see that the structural and thermodynamic properties of liquids depend on the nature of intermolecular interactions and that an equation of state can be built in a similar way to that just demonstrated for real gases.

### (a) The radial distribution function

The average relative locations of the particles of a liquid are expressed in terms of the **radial distribution function**,  $g(r)$ . This function is defined so that  $g(r)r^2dr$  is the probability that a molecule will be found in the range  $dr$  at a distance  $r$  from another molecule. In a perfect crystal,  $g(r)$  is a periodic array of sharp spikes, representing the certainty (in the absence of defects and thermal motion) that molecules (or ions) lie at definite locations. This regularity continues out to the edges of the crystal, so we say that crystals have **long-range order**. When the crystal melts, the long-range order is lost and, wherever we look at long distances from a given molecule, there is equal probability of finding a second molecule. Close to the first molecule, though, the nearest neighbours might still adopt approximately their original relative positions and, even if they are displaced by newcomers, the new particles might adopt their vacated positions. It is still possible to detect a sphere of nearest neighbours at a distance  $r_1$ , and perhaps beyond them a sphere of next-nearest neighbours at  $r_2$ . The existence of this **short-range order** means that the radial distribution function can be expected to oscillate at short distances, with a peak at  $r_1$ , a smaller peak at  $r_2$ , and perhaps some more structure beyond that.

The radial distribution function of the oxygen atoms in liquid water is shown in Fig. 16.13. Closer analysis shows that any given  $\text{H}_2\text{O}$  molecule is surrounded by other molecules at the corners of a tetrahedron. The form of  $g(r)$  at  $100^\circ\text{C}$  shows that the intermolecular interactions (in this case, principally by hydrogen bonds) are strong enough to affect the local structure right up to the boiling point. Raman spectra indicate that in liquid water most molecules participate in either three or four hydrogen bonds. Infrared spectra show that about 90 per cent of hydrogen bonds are intact at the melting point of ice, falling to about 20 per cent at the boiling point.

The formal expression for the radial distribution function for molecules 1 and 2 in a fluid consisting of  $N$  particles is the somewhat fearsome equation

$$g(r_{12}) = \frac{\int \int \cdots \int e^{-\beta V_N} d\tau_3 d\tau_4 \cdots d\tau_N}{N^2 \int \int \cdots \int e^{-\beta V_N} d\tau_1 d\tau_2 \cdots d\tau_N} \quad \text{Radial distribution function} \quad (16.46)$$

**Fig. 16.13** The radial distribution function of the oxygen atoms in liquid water at three temperatures. Note the expansion as the temperature is raised. (Based on A.H. Narten, M.D. Danford, and H.A. Levy, *Discuss. Faraday. Soc.* 43, 97 (1967).)

**Fig. 16.14** The radial distribution function for a simulation of a liquid using impenetrable hard spheres (ball bearings) of diameter  $d$ .

**Fig. 16.15** In a two-dimensional simulation of a liquid that uses periodic boundary conditions, when one particle leaves the cell its mirror image enters through the opposite face.

where  $\beta = 1/kT$  and  $V_N$  is the  $N$ -particle potential energy. Although fearsome, this expression is nothing more than the Boltzmann distribution for the relative locations of two molecules in a field provided by all the other molecules in the system.

### (b) The calculation of $g(r)$

Because the radial distribution function can be calculated by making assumptions about the intermolecular interactions, it can be used to test theories of liquid structure. However, even a fluid of hard spheres without attractive interactions (a collection of ball-bearings in a container) gives a function that oscillates near the origin (Fig. 16.14), and one of the factors influencing, and sometimes dominating, the structure of a liquid is the geometrical problem of stacking together reasonably hard spheres. Indeed, the radial distribution function of a liquid of hard spheres shows more pronounced oscillations at a given temperature than that of any other type of liquid. The attractive part of the potential modifies this basic structure, but sometimes only quite weakly. One of the reasons behind the difficulty of describing liquids theoretically is the similar importance of both the attractive and repulsive (hard core) components of the potential.

There are several ways of building the intermolecular potential into the calculation of  $g(r)$ . Numerical methods take a box of about  $10^3$  particles (the number increases as computers grow more powerful), and the rest of the liquid is simulated by surrounding the box with replications of the original box (Fig. 16.15). Then, whenever a particle leaves the box through one of its faces, its image arrives through the opposite face. When calculating the interactions of a molecule in a box, it interacts with all the molecules in the box and all the periodic replications of those molecules and itself in the other boxes.

In the **Monte Carlo method**, the particles in the box are moved through small but otherwise random distances, and the change in total potential energy of the  $N$  particles in the box,  $\Delta V_N$ , is calculated using one of the intermolecular potentials discussed in Section 17.5. Whether or not this new configuration is accepted is then judged from the following rules:

- 1 If the potential energy is not greater than before the change, then the configuration is accepted.

If the potential energy is greater than before the change, then it is necessary to check if the new configuration is reasonable and can exist in equilibrium with configurations of lower potential energy at a given temperature. To make progress, we use the result that, at equilibrium, the ratio of populations of two states with energy separation  $\Delta V_N$  is  $e^{-\Delta V_N/kT}$ . Because we are testing the viability of a configuration with a higher potential energy than the previous configuration in the calculation,  $\Delta V_N > 0$  and the exponential factor varies between 0 and 1. In the Monte Carlo method, the second rule, therefore, is:

- 2 The exponential factor is compared with a random number between 0 and 1; if the factor is larger than the random number, then the configuration is accepted; if the factor is not larger, the configuration is rejected.

The configurations generated with Monte Carlo calculations can be used to construct  $g(r)$  simply by counting the number of pairs of particles with a separation  $r$  and averaging the result over the whole collection of configurations.

In the **molecular dynamics** approach, the history of an initial arrangement is followed by calculating the trajectories of all the particles under the influence of the intermolecular potentials and the forces they exert. The calculation gives a series of snapshots of the liquid, and  $g(r)$  can be calculated as before. The temperature of the

system is inferred by computing the mean kinetic energy of the particles and using the equipartition result that

$$\langle \frac{1}{2}mv_q^2 \rangle = \frac{1}{2}kT \quad (16.47)$$

for each coordinate  $q$ .

### (c) The thermodynamic properties of liquids

Once  $g(r)$  is known it can be used to calculate the thermodynamic properties of liquids. For example, the contribution of the pairwise additive intermolecular potential,  $V_2$ , to the internal energy is given by the integral

$$U_{\text{interaction}}(T) = \frac{2\pi N^2}{V} \int_0^\infty g(r) V_2 r^2 dr \quad \text{Contribution of pairwise interactions to the internal energy} \quad (16.48)$$

That is,  $U_{\text{interaction}}$  is essentially the average two-particle potential energy weighted by  $g(r)r^2 dr$ , which is the probability that the pair of particles have a separation between  $r$  and  $r + dr$ . Likewise, the contribution that pairwise interactions make to the pressure is

$$\frac{pV}{nRT} = 1 - \frac{2\pi N}{3kTV} \int_0^\infty g(r) v_2 r^2 dr \quad v_2 = r \frac{dV_2}{dr} \quad (16.49a)$$

The quantity  $v_2$  is called the **virial** (hence the term ‘virial equation of state’). To understand the physical content of this expression, we rewrite it as

$$p = \frac{nRT}{V} - \frac{2\pi}{3} \left( \frac{N}{V} \right)^2 \int_0^\infty g(r) v_2 r^2 dr \quad \text{Pressure in terms of } g(r) \quad (16.49b)$$

The first term on the right is the **kinetic pressure**, the contribution to the pressure from the impact of the molecules in free flight. The second term is essentially the internal pressure,  $\pi_T = (\partial U / \partial V)_T$  (Section 2.11), representing the contribution to the pressure from the intermolecular forces. To see the connection, we should recognize  $-dV_2/dr$  (in  $v_2$ ) as the force required to move two molecules apart, and therefore  $-r(dV_2/dr)$  as the work required to separate the molecules through a distance  $r$ . The second term is therefore the average of this work over the range of pairwise separations in the liquid as represented by the probability of finding two molecules at separations between  $r$  and  $r + dr$ , which is  $g(r)r^2 dr$ . In brief, the integral, when multiplied by the square of the number density, is the change in internal energy of the system as it expands, and therefore is equal to the internal pressure.

## 16.7 Residual entropies

**Key point** The residual entropy is a nonzero entropy at  $T = 0$  arising from molecular disorder.

Entropies may be calculated from spectroscopic data; they may also be measured experimentally (Section 3.3d). In many cases there is good agreement, but in some the experimental entropy is less than the calculated value. One possibility is that the experimental determination failed to take a phase transition into account and a contribution of the form  $\Delta_{\text{trs}} H / T_{\text{trs}}$  was incorrectly omitted from the sum. Another possibility is that some disorder is present in the solid even at  $T = 0$ . The entropy at  $T = 0$  is then greater than zero and is called the **residual entropy**.

The origin and magnitude of the residual entropy can be explained by considering a crystal composed of AB molecules, where A and B are similar atoms (such as CO, with its very small electric dipole moment). There may be so little energy difference between ... AB AB AB AB ..., ... AB BA BA AB ..., and other arrangements that

**Fig. 16.16** The possible locations of H atoms around a central O atom in an ice crystal are shown by the white spheres. Only one of the locations on each bond may be occupied by an atom, and two H atoms must be close to the O atom and two H atoms must be distant from it.

**Fig. 16.17** The six possible arrangements of H atoms in the locations identified in Fig. 16.16. Occupied locations are denoted by grey spheres and unoccupied locations by white spheres.

the molecules adopt the orientations AB and BA at random in the solid. We can readily calculate the entropy arising from residual disorder by using the Boltzmann formula  $S = k \ln \mathcal{W}$ . To do so, we suppose that two orientations are equally probable, and that the sample consists of  $N$  molecules. Because the same energy can be achieved in  $2^N$  different ways (because each molecule can take either of two orientations), the total number of ways of achieving the same energy is  $\mathcal{W} = 2^N$ . It follows that

$$S = k \ln 2^N = Nk \ln 2 = nR \ln 2 \quad (16.50a)$$

We can therefore expect a residual molar entropy of  $R \ln 2 = 5.8 \text{ J K}^{-1} \text{ mol}^{-1}$  for solids composed of molecules that can adopt either of two orientations at  $T = 0$ . If  $s$  orientations are possible, the residual molar entropy will be

$$S_m(0) = R \ln s \quad \text{Residual entropy} \quad (16.50b)$$

An  $\text{FCIO}_3$  molecule, for example, can adopt four orientations with about the same energy (with the F atom at any of the four corners of a tetrahedron), and the calculated residual molar entropy of  $R \ln 4 = 11.5 \text{ J K}^{-1} \text{ mol}^{-1}$  is in good agreement with the experimental value ( $10.1 \text{ J K}^{-1} \text{ mol}^{-1}$ ). For CO, the measured residual entropy is  $5 \text{ J K}^{-1} \text{ mol}^{-1}$ , which is close to  $R \ln 2$ , the value expected for a random structure of the form  $\dots \text{CO CO OC CO OC OC} \dots$ .

#### • A brief illustration

Consider a sample of ice with  $N \text{ H}_2\text{O}$  molecules. Each O atom is surrounded tetrahedrally by four H atoms, two of which are attached by short  $\sigma$  bonds, the other two being attached by long hydrogen bonds (Fig. 16.16). It follows that each of the  $2N$  H atoms can be in one of two positions (either close to or far from an O atom as shown in Fig. 16.17), resulting in  $2^{2N}$  possible arrangements. However, not all these arrangements are acceptable. Indeed, of the  $2^4 = 16$  ways of arranging four H atoms around one O atom, only 6 have two short and two long OH distances and hence are acceptable. Therefore, the number of permitted arrangements is

$$\mathcal{W} = 2^{2N} \left(\frac{6}{16}\right)^N = \left(\frac{3}{2}\right)^N$$

It then follows that the residual molar entropy is

$$S_m(0) \approx k \ln \left(\frac{3}{2}\right)^{N_A} = N_A k \ln \left(\frac{3}{2}\right) = R \ln \left(\frac{3}{2}\right) = 3.4 \text{ J K}^{-1} \text{ mol}^{-1}$$

which is in good agreement with the experimental value of  $3.4 \text{ J K}^{-1} \text{ mol}^{-1}$ . The model, however, is not exact because it ignores the possibility that next-nearest neighbours and those beyond can influence the local arrangement of bonds. •

## 16.8 Equilibrium constants

**Key points** (a) The equilibrium constant can be written in terms of the partition function. (b) The equilibrium constant for dissociation of a diatomic molecule in the gas phase may be calculated from spectroscopic data. (c) The physical basis of equilibrium can be understood by using the principles of statistical thermodynamics.

The Gibbs energy of a gas of independent molecules is given by eqn 16.9 in terms of the molar partition function,  $q_m = q/n$ . The equilibrium constant  $K$  of a reaction is related to the standard Gibbs energy of reaction by  $\Delta_r G^\ominus = -RT \ln K$ . To calculate the equilibrium constant, we need to combine these two equations. We shall consider gas phase reactions in which the equilibrium constant is expressed in terms of the partial pressures of the reactants and products.

**(a) The relation between  $K$  and the partition function**

To find an expression for the standard reaction Gibbs energy we need expressions for the standard molar Gibbs energies,  $G^\ominus/n$ , of each species. For these expressions, we need the value of the molar partition function when  $p = p^\ominus$  (where  $p^\ominus = 1$  bar): we denote this **standard molar partition function**  $q_m^\ominus$ . Because only the translational component depends on the pressure, we can find  $q_m^\ominus$  by evaluating the partition function with  $V$  replaced by  $V_m^\ominus$ , where  $V_m^\ominus = RT/p^\ominus$ . For a species  $J$  it follows that

$$G_m^\ominus(J) = G_m^\ominus(J, 0) - RT \ln \frac{q_{J,m}^\ominus}{N_A} \quad (16.51)^\circ$$

where  $q_{J,m}^\ominus$  is the standard molar partition function of  $J$ . By combining expressions like this one (as shown in the following *Justification*), the equilibrium constant for the reaction  $aA + bB \rightarrow cC + dD$  is given by the expression

$$K = \frac{(q_{C,m}^\ominus/N_A)^c (q_{D,m}^\ominus/N_A)^d}{(q_{A,m}^\ominus/N_A)^a (q_{B,m}^\ominus/N_A)^b} e^{-\Delta_r E_0/RT} \quad (16.52a)$$

where  $\Delta_r E_0$  is the difference in molar energies of the ground states of the products and reactants (this term is defined more precisely in the *Justification*), and is calculated from the bond dissociation energies of the species (Fig. 16.18). In terms of the stoichiometric numbers introduced in Section 2.8a, we would write

$$K = \left\{ \prod_J \left( \frac{q_{J,m}^\ominus}{N_A} \right)^{v_J} \right\} e^{-\Delta_r E_0/RT} \quad \text{Equilibrium constant in terms of partition functions} \quad (16.52b)$$

**Fig. 16.18** The definition of  $\Delta_r E_0$  for the calculation of equilibrium constants.

**Justification 16.3** The equilibrium constant in terms of the partition function 1

The standard molar reaction Gibbs energy for the reaction is

$$\begin{aligned} \Delta_r G^\ominus &= cG_m^\ominus(C) + dG_m^\ominus(D) - aG_m^\ominus(A) - bG_m^\ominus(B) \\ &= cG_m^\ominus(C, 0) + dG_m^\ominus(D, 0) - aG_m^\ominus(A, 0) - bG_m^\ominus(B, 0) \\ &\quad - RT \left\{ c \ln \frac{q_{C,m}^\ominus}{N_A} + d \ln \frac{q_{D,m}^\ominus}{N_A} - a \ln \frac{q_{A,m}^\ominus}{N_A} - b \ln \frac{q_{B,m}^\ominus}{N_A} \right\} \end{aligned}$$

Because  $G(0) = U(0)$ , the first term on the right is

$$\Delta_r E_0 = cU_m^\ominus(C, 0) + dU_m^\ominus(D, 0) - aU_m^\ominus(A, 0) - bU_m^\ominus(B, 0) \quad (16.53)$$

the reaction internal energy at  $T = 0$  (a molar quantity).

Now we can write

$$\begin{aligned} \Delta_r G^\ominus &= \Delta_r E_0 - RT \left\{ \ln \left( \frac{q_{C,m}^\ominus}{N_A} \right)^c + \ln \left( \frac{q_{D,m}^\ominus}{N_A} \right)^d - \ln \left( \frac{q_{A,m}^\ominus}{N_A} \right)^a - \ln \left( \frac{q_{B,m}^\ominus}{N_A} \right)^b \right\} \\ &= \Delta_r E_0 - RT \ln \frac{(q_{C,m}^\ominus/N_A)^c (q_{D,m}^\ominus/N_A)^d}{(q_{A,m}^\ominus/N_A)^a (q_{B,m}^\ominus/N_A)^b} \\ &= -RT \left\{ -\frac{\Delta_r E_0}{RT} + \ln \frac{(q_{C,m}^\ominus/N_A)^c (q_{D,m}^\ominus/N_A)^d}{(q_{A,m}^\ominus/N_A)^a (q_{B,m}^\ominus/N_A)^b} \right\} \end{aligned}$$

At this stage we can pick out an expression for  $K$  by comparing this equation with  $\Delta_r G^\ominus = -RT \ln K$ , which gives

$$\ln K = -\frac{\Delta_r E_0}{RT} + \ln \frac{(q_{C,m}^\ominus/N_A)^c (q_{D,m}^\ominus/N_A)^d}{(q_{A,m}^\ominus/N_A)^a (q_{B,m}^\ominus/N_A)^b}$$

This expression is easily rearranged into eqn 16.52a by forming the exponential of both sides.

**(b) A dissociation equilibrium**

We shall illustrate the application of eqn 16.52 to an equilibrium in which a diatomic molecule  $X_2$  dissociates into its atoms:

According to eqn 16.52 (with  $a = 1$ ,  $b = 0$ ,  $c = 2$ , and  $d = 0$ ):

$$K = \frac{(q_{X,m}^\ominus/N_A)^2}{q_{X_2,m}^\ominus/N_A} e^{-\Delta_r E_0/RT} = \frac{(q_{X,m}^\ominus)^2}{q_{X_2,m}^\ominus N_A} e^{-\Delta_r E_0/RT} \quad (16.54a)$$

with

$$\Delta_r E_0 = 2U_m^\ominus(X,0) - U_m^\ominus(X_2,0) = D_0(X-X) \quad (16.54b)$$

where  $D_0(X-X)$  is the dissociation energy of the  $X-X$  bond. The standard molar partition functions of the atoms  $X$  are

$$q_{X,m}^\ominus = g_X \left( \frac{V_m^\ominus}{\Lambda_X^3} \right) = \frac{RT g_X}{p^\ominus \Lambda_X^3}$$

where  $g_X$  is the degeneracy of the electronic ground state of  $X$  and we have used  $V_m^\ominus = RT/p^\ominus$ . The diatomic molecule  $X_2$  also has rotational and vibrational degrees of freedom, so its standard molar partition function is

$$q_{X_2,m}^\ominus = g_{X_2} \left( \frac{V_m^\ominus}{\Lambda_{X_2}^3} \right) q_{X_2}^R q_{X_2}^V = \frac{RT g_{X_2} q_{X_2}^R q_{X_2}^V}{p^\ominus \Lambda_{X_2}^3}$$

where  $g_{X_2}$  is the degeneracy of the electronic ground state of  $X_2$ . It follows from eqn 16.52 that the equilibrium constant is

$$K = \frac{kT g_X^2 \Lambda_{X_2}^3}{p^\ominus g_{X_2} q_{X_2}^R q_{X_2}^V \Lambda_X^6} e^{-D_0/RT} \quad (16.55)$$

where we have used  $R/N_A = k$ . All the quantities in this expression can be calculated from spectroscopic data. The  $\Lambda$ s are defined in the *Checklist* and depend on the masses of the species and the temperature; the expressions for the rotational and vibrational partition functions are also available in the *Checklist* and depend on the rotational constant and vibrational wavenumber of the molecule.

• **A brief illustration**

To evaluate the equilibrium constant for the dissociation  $Na_2(g) \rightleftharpoons 2Na(g)$  at 1000 K we use the following data:  $\tilde{B} = 0.1547 \text{ cm}^{-1}$ ,  $\tilde{\nu} = 159.2 \text{ cm}^{-1}$ ,  $D_0 = 70.4 \text{ kJ mol}^{-1}$ . Then, noting that the Na atoms have doublet ground terms, the partition functions and other quantities required are as follows:

$$\begin{array}{ll} \Lambda(Na_2) = 8.14 \text{ pm} & \Lambda(Na) = 11.5 \text{ pm} \\ q^R(Na_2) = 2246 & q^V(Na_2) = 4.885 \\ g(Na) = 2 & g(Na_2) = 1 \end{array}$$

Then, from eqn 16.55,

$$K = \frac{(1.38 \times 10^{-23} \text{ J K}^{-1}) \times (1000 \text{ K}) \times 4 \times (8.14 \times 10^{-12} \text{ m})^3}{(10^5 \text{ Pa}) \times 2246 \times 4.885 \times (1.15 \times 10^{-11} \text{ m})^6} \times e^{-8.47} = 2.46$$

where we have used  $1 \text{ J} = 1 \text{ kg m}^2 \text{ s}^{-2}$  and  $1 \text{ Pa} = 1 \text{ kg m}^{-1} \text{ s}^{-2}$ . •

**(c) Contributions to the equilibrium constant**

We are now in a position to appreciate the physical basis of equilibrium constants. To see what is involved, consider a simple  $R \rightleftharpoons P$  gas-phase equilibrium (R for reactants, P for products).

Figure 16.19 shows two sets of energy levels: one set of states belongs to R, and the other belongs to P. The populations of the states are given by the Boltzmann distribution, and are independent of whether any given state happens to belong to R or to P. We can therefore imagine a single Boltzmann distribution spreading, without distinction, over the two sets of states. If the spacings of R and P are similar (as in Fig. 16.19), and P lies above R, the diagram indicates that R will dominate in the equilibrium mixture. However, if P has a high density of states (a large number of states in a given energy range, as in Fig. 16.20), then, even though its zero-point energy lies above that of R, the species P might still dominate at equilibrium.

It is quite easy to show (see the following *Justification*) that the ratio of numbers of R and P molecules at equilibrium is given by

$$\frac{N_P}{N_R} = \frac{q_P}{q_R} e^{-\Delta_r E_0/RT} \quad (16.56a)$$

and therefore that the equilibrium constant for the reaction is

$$K = \frac{q_P}{q_R} e^{-\Delta_r E_0/RT} \quad (16.56b)$$

just as would be obtained from eqn 16.52.

**A brief comment**

For an  $R \rightleftharpoons P$  equilibrium, the  $V$  factors in the partition functions cancel, so the appearance of  $q$  in place of  $q^\circ$  has no effect. In the case of a more general reaction, the conversion from  $q$  to  $q^\circ$  comes about at the stage of converting the pressures that occur in  $K$  to numbers of molecules.

**Fig. 16.19** The array of R(eactants) and P(roducts) energy levels. At equilibrium all are accessible (to differing extents, depending on the temperature), and the equilibrium composition of the system reflects the overall Boltzmann distribution of populations. As  $\Delta_r E_0$  increases, R becomes dominant.

**Fig. 16.20** It is important to take into account the densities of states of the molecules. Even though P might lie well above R in energy (that is,  $\Delta_r E_0$  is large and positive), P might have so many states that its total population dominates in the mixture. In classical thermodynamic terms, we have to take entropies into account as well as enthalpies when considering equilibria.

**Justification 16.4** *The equilibrium constant in terms of the partition function 2*

The population in a state  $i$  of the composite (R,P) system is

$$n_i = \frac{N e^{-\beta \epsilon_i}}{q}$$

where  $N$  is the total number of molecules. The total number of R molecules is the sum of these populations taken over the states belonging to R; these states we label  $r$  with energies  $\epsilon_r$ . The total number of P molecules is the sum over the states belonging to P; these states we label  $p$  with energies  $\epsilon'_p$  (the prime is explained in a moment):

$$N_R = \sum_r n_r = \frac{N}{q} \sum_r e^{-\beta \epsilon_r} \quad N_P = \sum_p n_p = \frac{N}{q} \sum_p e^{-\beta \epsilon'_p}$$

The sum over the states of R is its partition function,  $q_R$ , so

$$N_R = \frac{N q_R}{q}$$

The sum over the states of P is also a partition function, but the energies are measured from the ground state of the combined system, which is the ground state of R. However, because  $\epsilon'_p = \epsilon_p + \Delta \epsilon_0$  where  $\Delta \epsilon_0$  is the separation of zero-point energies,

$$N_P = \frac{N}{q} \sum_p e^{-\beta(\epsilon_p + \Delta \epsilon_0)} = \frac{N}{q} \left( \sum_p e^{-\beta \epsilon_p} \right) e^{-\beta \Delta \epsilon_0} = \frac{N q_P}{q} e^{-\Delta_r E_0 / RT}$$

The switch from  $\Delta \epsilon_0/k$  to  $\Delta_r E_0/R$  in the last step is the conversion of molecular energies to molar energies.

The equilibrium constant of the  $R \rightleftharpoons P$  reaction is proportional to the ratio of the numbers of the two types of molecule. Therefore,

$$K = \frac{N_P}{N_R} = \frac{q_P}{q_R} e^{-\Delta_r E_0 / RT}$$

as in eqn 16.56b.

**Fig. 16.21** The model used in the text for exploring the effects of energy separations and densities of states on equilibria. The products P can dominate provided  $\Delta E_0$  is not too large and P has an appreciable density of states.

The content of eqn 16.56 can be seen most clearly by exaggerating the molecular features that contribute to it. We shall suppose that R has only a single accessible level, which implies that  $q_R = 1$ . We also suppose that P has a large number of evenly, closely spaced levels (Fig. 16.21). The partition function of P is then  $q_P = kT/\epsilon$ . In this model system, the equilibrium constant is

$$K = \frac{kT}{\epsilon} e^{-\Delta_r E_0 / RT} \quad (16.57)$$

When  $\Delta_r E_0$  is very large, the exponential term dominates and  $K \ll 1$ , which implies that very little P is present at equilibrium. When  $\Delta_r E_0$  is small but still positive,  $K$  can exceed 1 because the factor  $kT/\epsilon$  may be large enough to overcome the small size of the exponential term. The size of  $K$  then reflects the predominance of P at equilibrium on account of its high density of states. At low temperatures  $K \ll 1$  and the system consists entirely of R. At high temperatures the exponential function approaches 1 and the pre-exponential factor is large. Hence P becomes dominant. We see that, in this endothermic reaction (endothermic because P lies above R), a rise in temperature favours P, because its states become accessible. This behaviour is what we saw, from the outside, in Chapter 6.

The model also shows why the Gibbs energy,  $G$ , and not just the enthalpy, determines the position of equilibrium. It shows that the density of states (and hence the entropy) of each species as well as their relative energies controls the distribution of populations and hence the value of the equilibrium constant.

#### IMPACT ON BIOCHEMISTRY

##### 116.1 The helix–coil transition in polypeptides

The hydrogen bonds between amino acids of a polypeptide give rise to stable helical or sheet structures, which may collapse into a random coil when certain conditions are changed. The unwinding of a helix into a random coil is a *cooperative transition*, in which the polymer becomes increasingly more susceptible to structural changes once the process has begun. We examine here a model based on the principles of statistical thermodynamics that accounts for the cooperativity of the helix–coil transition in polypeptides.

To calculate the fraction of polypeptide molecules present as helix or coil we need to set up the partition function for the various states of the molecule. To illustrate the approach, consider a short polypeptide with four amino acid residues, each labelled  $h$  if it contributes to a helical region and  $c$  if it contributes to a random coil region. We suppose that conformations  $hhhh$  and  $cccc$  contribute terms  $q_0$  and  $q_4$ , respectively, to the partition function  $q$ . Then we assume that each of the four conformations with one  $c$  amino acid (such as  $hchh$ ) contributes  $q_1$ . Similarly, each of the six states with two  $c$  amino acids contributes a term  $q_2$ , and each of the four states with three  $c$  amino acids contributes a term  $q_3$ . The partition function is then

$$q = q_0 + 4q_1 + 6q_2 + 4q_3 + q_4 = q_0 \left( 1 + \frac{4q_1}{q_0} + \frac{6q_2}{q_0} + \frac{4q_3}{q_0} + \frac{q_4}{q_0} \right)$$

We shall now suppose that each partition function differs from  $q_0$  only by the energy of each conformation relative to  $hhhh$ , and write

$$\frac{q_i}{q_0} = e^{-(\varepsilon_i - \varepsilon_0)/kT}$$

Next, we suppose that the conformational transformations are non-cooperative, in the sense that the energy associated with changing one  $h$  amino acid into one  $c$  amino acid has the same value regardless of how many  $h$  or  $c$  amino acid residues are in the reactant or product state and regardless of where in the chain the conversion occurs. That is, we suppose that the difference in energy between  $c^i h^{4-i}$  and  $c^{i+1} h^{3-i}$  has the same value  $\gamma$  for all  $i$ . This assumption implies that  $\varepsilon_i - \varepsilon_0 = i\gamma$  and therefore that

$$q/q_0 = 1 + 4s + 6s^2 + 4s^3 + s^4 = (1 + s)^4 \quad s = e^{-\gamma/kT} \quad (16.58)$$

where  $s$  is called the *stability parameter*. The extension of this treatment to take into account a longer chain of residues is now straightforward: we simply replace the 4 in the sum by  $N$ :

$$\frac{q}{q_0} = (1 + s)^N \quad (16.59)$$

A cooperative transformation is more difficult to accommodate, and depends on building a model of how neighbours facilitate each other's conformational change. In the simple *zipper model*, conversion from  $h$  to  $c$  is allowed only if a residue adjacent to the one undergoing the conversion is already a  $c$  residue. Thus, the zipper model allows a transition of the type  $\dots hhhch \dots \rightarrow \dots hhhcc \dots$ , but not a transition of the type  $\dots hhhch \dots \rightarrow \dots hchch \dots$ . The only exception to this rule is, of course,

**Fig. 16.22** Plots of the degree of conversion  $\theta$ , against  $s$  for several values of  $\sigma$ . The curves show the sigmoidal shape characteristics of cooperative behaviour.

the very first conversion from  $h$  to  $c$  in a fully helical chain. Cooperativity is included in the zipper model by assuming that the first conversion from  $h$  to  $c$ , called the *nucleation step*, is less favourable than the remaining conversions and replacing  $s$  for that step by  $ss$ , where  $s \ll 1$ . Each subsequent step is called a *propagation step* and has a stability parameter  $s$ .

A more sophisticated model for the helix–coil transition must allow for helical segments to form in different regions of a long polypeptide chain, with the nascent helices being separated by shrinking coil segments. Calculations based on this more complete *Zimm–Bragg model* give

$$\theta = \frac{1}{2} \left( 1 + \frac{(s-1) + 2\sigma}{[(s-1)^2 + 4s\sigma]^{1/2}} \right) \quad (16.60)$$

where  $\theta$  = (mean number of coil units)/(total units) is the *degree of conversion* of a polypeptide to a random coil. Figure 16.22 shows plots of  $\theta$  against  $s$  for several values of  $\sigma$ . The curves show the sigmoidal shape characteristic of cooperative behaviour. There is a sudden surge of transition to a random coil as  $s$  passes through 1 and, the smaller the parameter  $\sigma$ , the greater the sharpness and hence the greater the cooperativity of the transition. That is, the harder it is to get coil formation started, the sharper the transition from helix to coil.

## Checklist of key equations

| Property                                                    | Equation                                                                               | Comment                                                                                |

## Further information

**Further information 16.1** *The rotational partition function of a symmetric rotor*

The energies of a symmetric rotor are

$$E_{J,K,M_J} = hc\tilde{B}J(J+1) + hc(\tilde{A} - \tilde{B})K^2$$

with  $J = 0, 1, 2, \dots$ ,  $K = J, J-1, \dots, -J$ , and  $M_J = J, J-1, \dots, -J$ . Instead of considering these ranges, we can cover the same values by allowing  $K$  to range from  $-\infty$  to  $\infty$ , with  $J$  confined to  $|K|, |K|+1, \dots, \infty$  for each value of  $K$  (Fig. 16.23). Because the energy is independent of  $M_J$ , and there are  $2J+1$  values of  $M_J$  for each value of  $J$ , each value of  $J$  is  $(2J+1)$ -fold degenerate. It follows that the partition function

$$q = \sum_{J=0}^{\infty} \sum_{K=-J}^J \sum_{M_J=-J}^J e^{-E_{J,K,M_J}/kT} \quad (16.61)$$

can be written equivalently as

**Fig. 16.23** (a) The sum over  $J = 0, 1, 2, \dots$  and  $K = J, J-1, \dots, -J$  (depicted by the circles) can be covered (b) by allowing  $K$  to range from  $-\infty$  to  $\infty$ , with  $J$  confined to  $|K|, |K|+1, \dots, \infty$  for each value of  $K$ .

$$\begin{aligned} q &= \sum_{K=-\infty}^{\infty} \sum_{J=|K|}^{\infty} (2J+1) e^{-E_{J,K,M_J}/kT} \\ &= \sum_{K=-\infty}^{\infty} \sum_{J=|K|}^{\infty} (2J+1) e^{-\{hc(\tilde{B}J(J+1) + (\tilde{A}-\tilde{B})K^2)/kT\}} \\ &= \sum_{K=-\infty}^{\infty} e^{-\{hc(\tilde{A}-\tilde{B})/kT\}K^2} \sum_{J=|K|}^{\infty} (2J+1) e^{-hc\tilde{B}J(J+1)/kT} \end{aligned}$$

Now we assume that the temperature is so high that numerous states are occupied and that the sums may be approximated by integrals. Then

$$q = \int_{-\infty}^{\infty} e^{-\{hc(\tilde{A}-\tilde{B})/kT\}K^2} \int_{|K|}^{\infty} (2J+1) e^{-hc\tilde{B}J(J+1)/kT} dJ dK \quad (16.62)$$

As in *Justification 16.1*, the integral over  $J$  can be recognized as the integral of the derivative of a function, which is the function itself, so

$$\begin{aligned} \int_{|K|}^{\infty} (2J+1) e^{-hc\tilde{B}J(J+1)/kT} dJ &= \int_{|K|}^{\infty} \left( -\frac{kT}{hc\tilde{B}} \right) \frac{d}{dJ} e^{-hc\tilde{B}J(J+1)/kT} dJ \\ &= \left( -\frac{kT}{hc\tilde{B}} \right) e^{-hc\tilde{B}J(J+1)/kT} \Bigg|_{|K|}^{\infty} \\ &= \left( \frac{kT}{hc\tilde{B}} \right) e^{-hc\tilde{B}K(|K|+1)/kT} \quad (16.63) \\ &\approx \left( \frac{kT}{hc\tilde{B}} \right) e^{-hc\tilde{B}K^2/kT} \end{aligned}$$

In the last line we have supposed that  $|K| \gg 1$  for most contributions. Now we can write eqn 16.62 as

$$\begin{aligned} q &= \frac{kT}{hc\tilde{B}} \int_{-\infty}^{\infty} e^{-\{hc(\tilde{A}-\tilde{B})/kT\}K^2} e^{-hc\tilde{B}K^2/kT} dK \\ &= \frac{kT}{hc\tilde{B}} \int_{-\infty}^{\infty} e^{-\{hc\tilde{A}/kT\}K^2} dK = \left( \frac{kT}{hc\tilde{B}} \right) \left( \frac{kT}{hc\tilde{A}} \right)^{1/2} \int_{-\infty}^{\infty} e^{-x^2} dx \quad (16.64) \\ &= \left( \frac{kT}{hc} \right)^{3/2} \left( \frac{\pi}{\tilde{A}\tilde{B}^2} \right)^{1/2} \end{aligned}$$

For an asymmetric rotor, one of the  $\tilde{B}$ s is replaced by  $\tilde{C}$ , to give eqn 16.14b.

## Discussion questions

**16.1** Discuss the limitations of the expressions  $q^R = kT/hc\tilde{B}$ ,  $q^V = kT/hc\tilde{\nu}$ , and  $q^E = g^E$ .

**16.2** Explain the origin of the symmetry number.

**16.3** Explain the origin of residual entropy.

**16.4** Describe the molecular features that determine the magnitudes of the constant-volume molar heat capacity of a molecular substance.

**16.5** Describe the features that determine whether particles should be regarded as indistinguishable or not.

**16.6** Discuss and illustrate the proposition that  $1/T$  is a more natural measurement of temperature than  $T$  itself.

**16.7** Describe the molecular features that determine the magnitudes of equilibrium constants and their variation with temperature.

## Exercises

**16.1(a)** Evaluate the thermal wavelength of  $\text{CO}_2$  at  $25^\circ\text{C}$ .

**16.1(b)** Evaluate the thermal wavelength of  $\text{SO}_2$  at  $25^\circ\text{C}$ .

**16.2(a)** Evaluate the translational partition function of  $\text{CO}_2$  at  $25^\circ\text{C}$  in a container of volume  $1.0\text{ cm}^3$ .

**16.2(b)** Evaluate the translational partition function wavelength of  $\text{SO}_2$  at  $25^\circ\text{C}$  in a container of volume  $1.0\text{ cm}^3$ .

**16.3(a)** Use the equipartition theorem to estimate the constant-volume molar heat capacity of (a)  $\text{I}_2$ , (b)  $\text{CH}_4$ , (c)  $\text{C}_6\text{H}_6$  in the gas phase at  $25^\circ\text{C}$ .

**16.3(b)** Use the equipartition theorem to estimate the constant-volume molar heat capacity of (a)  $\text{O}_3$ , (b)  $\text{C}_2\text{H}_6$ , (c)  $\text{CO}_2$  in the gas phase at  $25^\circ\text{C}$ .

**16.4(a)** Evaluate the rotational temperature of  $\text{H}^{35}\text{Cl}$ .

**16.4(b)** Evaluate the rotational temperature of  $\text{H}_2$  and  $\text{D}_2$ .

**16.5(a)** Estimate the rotational partition function of  $\text{HCl}$  at (a)  $25^\circ\text{C}$  and (b)  $250^\circ\text{C}$ .

**16.5(b)** Estimate the rotational partition function of  $\text{O}_2$  at (a)  $25^\circ\text{C}$  and (b)  $250^\circ\text{C}$ .

**16.6(a)** Give the symmetry number for each of the following molecules: (a)  $\text{CO}$ , (b)  $\text{O}_2$ , (c)  $\text{H}_2\text{S}$ , (d)  $\text{SiH}_4$ , and (e)  $\text{CHCl}_3$ .

**16.6(b)** Give the symmetry number for each of the following molecules: (a)  $\text{CO}_2$ , (b)  $\text{O}_3$ , (c)  $\text{SO}_3$ , (d)  $\text{SF}_6$ , and (e)  $\text{Al}_2\text{Cl}_6$ .

**16.7(a)** Calculate the rotational partition function of  $\text{H}_2\text{O}$  at  $298\text{ K}$  from its rotational constants  $27.878\text{ cm}^{-1}$ ,  $14.509\text{ cm}^{-1}$ , and  $9.287\text{ cm}^{-1}$ . Above what temperature is the high-temperature approximation valid to within 10 per cent of the true value?

**16.7(b)** Calculate the rotational partition function of  $\text{SO}_2$  at  $298\text{ K}$  from its rotational constants  $2.027\text{ 36 cm}^{-1}$ ,  $0.344\text{ 17 cm}^{-1}$ , and  $0.293\text{ 535 cm}^{-1}$ . Above what temperature is the high-temperature approximation valid to within 10 per cent of the true value?

**16.8(a)** From the results of Exercise 16.7a, calculate the rotational contribution to the molar entropy of gaseous water at  $25^\circ\text{C}$ .

**16.8(b)** From the results of Exercise 16.7b, calculate the rotational contribution to the molar entropy of sulfur dioxide at  $25^\circ\text{C}$ .

**16.9(a)** Calculate the rotational partition function of  $\text{CH}_4$  (a) by direct summation of the energy levels at  $298\text{ K}$  and  $500\text{ K}$ , and (b) by the high-temperature approximation. Take  $\tilde{B} = 5.2412\text{ cm}^{-1}$ .

**16.9(b)** Calculate the rotational partition function of  $\text{CH}_3\text{CN}$  (a) by direct summation of the energy levels at  $298\text{ K}$  and  $500\text{ K}$ , and (b) by the high-temperature approximation. Take  $\tilde{A} = 5.28\text{ cm}^{-1}$  and  $\tilde{B} = 0.307\text{ cm}^{-1}$ .

**16.10(a)** The bond length of  $\text{O}_2$  is  $120.75\text{ pm}$ . Use the high-temperature approximation to calculate the rotational partition function of the molecule at  $300\text{ K}$ .

**16.10(b)** The  $\text{NOF}$  molecule is an asymmetric rotor with rotational constants  $3.1752\text{ cm}^{-1}$ ,  $0.3951\text{ cm}^{-1}$ , and  $0.3505\text{ cm}^{-1}$ . Calculate the rotational partition function of the molecule at (a)  $25^\circ\text{C}$ , (b)  $100^\circ\text{C}$ .

**16.11(a)** Estimate the values of  $\gamma = C_p/C_v$  for gaseous ammonia and methane. Do this calculation with and without the vibrational contribution to the energy. Which is closer to the expected experimental value at  $25^\circ\text{C}$ ?

**16.11(b)** Estimate the value of  $\gamma = C_p/C_v$  for carbon dioxide. Do this calculation with and without the vibrational contribution to the energy. Which is closer to the expected experimental value at  $25^\circ\text{C}$ ?

**16.12(a)** Plot the molar heat capacity of a collection of harmonic oscillators as a function of  $T/\theta_v$ , and predict the vibrational heat capacity of ethyne at (a)  $298\text{ K}$ , (b)  $500\text{ K}$ . The normal modes (and their degeneracies in parentheses) occur at wavenumbers  $612(2)$ ,  $729(2)$ ,  $1974$ ,  $3287$ , and  $3374\text{ cm}^{-1}$ .

**16.12(b)** Plot the molar entropy of a collection of harmonic oscillators as a function of  $T/\theta_v$ , and predict the standard molar entropy of ethyne at (a)  $298\text{ K}$ , (b)  $500\text{ K}$ . For data, see the preceding exercise.

**16.13(a)** A  $\text{CO}_2$  molecule is linear, and its vibrational wavenumbers are  $1388.2\text{ cm}^{-1}$ ,  $2349.2\text{ cm}^{-1}$ , and  $667.4\text{ cm}^{-1}$ , the last being doubly degenerate and the others nondegenerate. The rotational constant of the molecule is  $0.3902\text{ cm}^{-1}$ . Calculate the rotational and vibrational contributions to the molar Gibbs energy at  $298\text{ K}$ .

**16.13(b)** An  $\text{O}_3$  molecule is angular, and its vibrational wavenumbers are  $1110\text{ cm}^{-1}$ ,  $705\text{ cm}^{-1}$ , and  $1042\text{ cm}^{-1}$ . The rotational constants of the molecule are  $3.553\text{ cm}^{-1}$ ,  $0.4452\text{ cm}^{-1}$ , and  $0.3948\text{ cm}^{-1}$ . Calculate the rotational and vibrational contributions to the molar Gibbs energy at  $298\text{ K}$ .

**16.14(a)** The ground level of  $\text{Cl}$  is  $^2\text{P}_{3/2}$  and a  $^2\text{P}_{1/2}$  level lies  $881\text{ cm}^{-1}$  above it. Calculate the electronic partition function of  $\text{Cl}$  atoms at (a)  $500\text{ K}$  and (b)  $900\text{ K}$ .

**16.14(b)** The first electronically excited state of  $\text{O}_2$  is  $^1\Delta_g$  and lies  $7918.1\text{ cm}^{-1}$  above the ground state, which is  $^3\Sigma_g^-$ . Calculate the electronic partition function of  $\text{O}_2$  molecules at (a)  $500\text{ K}$  and (b)  $900\text{ K}$ .

**16.15(a)** Use the information in Exercise 16.14a to calculate the electronic contribution to the heat capacity of  $\text{Cl}$  atoms at (a)  $500\text{ K}$  and (b)  $900\text{ K}$ .

**16.15(b)** Use the information in Exercise 16.14b to calculate the electronic contribution to the heat capacity of  $\text{O}_2$  at 400 K.

**16.16(a)** Use the information in Exercise 16.14a to calculate the electronic contribution to the molar Gibbs energy of Cl atoms at (a) 500 K and (b) 900 K.

**16.16(b)** Use the information in Exercise 16.14a to calculate the electronic contribution to the molar Gibbs energy of  $\text{O}_2$  at 400 K.

**16.17(a)** The ground state of the  $\text{Co}^{2+}$  ion in  $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$  may be regarded as  $^4\text{T}_{9/2}$ . The entropy of the solid at temperatures below 1 K is derived almost entirely from the electron spin. Estimate the molar entropy of the solid at these temperatures.

**16.17(b)** Estimate the contribution of the spin to the molar entropy of a solid sample of a d-metal complex with  $S = \frac{5}{2}$ .

**16.18(a)** Sketch the form of the Mayer  $f$ -function for the hard-sphere potential specified in eqn 16.43.

**16.18(b)** Sketch the form of the Mayer  $f$ -function for an intermolecular potential energy of the form  $E_p = -\epsilon(\sigma^6/r^6 - \sigma^{12}/r^{12})$ .

**16.19(a)** Calculate the residual molar entropy of a solid in which the molecules can adopt (a) three, (b) five, (c) six orientations of equal energy at  $T = 0$ .

**16.19(b)** Suppose that the hexagonal molecule  $\text{C}_6\text{H}_n\text{F}_{6-n}$  has a residual entropy on account of the similarity of the H and F atoms. Calculate the residual for each value of  $n$ .

**16.20(a)** Calculate the equilibrium constant of the reaction  $\text{I}_2(\text{g}) \rightleftharpoons 2 \text{I}(\text{g})$  at 1000 K from the following data for  $\text{I}_2$ :  $\bar{\nu} = 214.36 \text{ cm}^{-1}$ ,  $\bar{B} = 0.0373 \text{ cm}^{-1}$ ,  $D_e = 1.5422 \text{ eV}$ . The ground state of the I atoms is  $^2\text{P}_{3/2}$ , implying fourfold degeneracy.

**16.20(b)** Calculate the equilibrium constant at 298 K for the gas-phase isotopic exchange reaction  $^{279}\text{Br}^{81}\text{Br} \rightleftharpoons ^{79}\text{Br}^{79}\text{Br} + ^{81}\text{Br}^{81}\text{Br}$ . The  $\text{Br}_2$  molecule has a nondegenerate ground state, with no other electronic states nearby. Base the calculation on the wavenumber of the vibration of  $^{79}\text{Br}^{81}\text{Br}$ , which is  $323.33 \text{ cm}^{-1}$ .

## Problems\*

### Numerical problems

**16.1** The NO molecule has a doubly degenerate electronic ground state and a doubly degenerate excited state at  $121.1 \text{ cm}^{-1}$ . Calculate and plot the electronic contribution to the molar heat capacity of the molecule up to 500 K.

**16.2** Explore whether a magnetic field can influence the heat capacity of a paramagnetic molecule by calculating the electronic contribution to the heat capacity of an  $\text{NO}_2$  molecule in a magnetic field. Estimate the total constant-volume heat capacity using equipartition, and calculate the percentage change in heat capacity brought about by a 5.0 T magnetic field at (a) 50 K, (b) 298 K.

**16.3** The energy levels of a  $\text{CH}_3$  group attached to a larger fragment are given by the expression for a particle on a ring, provided the group is rotating freely. What is the high-temperature contribution to the heat capacity and entropy of such a freely rotating group at  $25^\circ\text{C}$ ? The moment of inertia of  $\text{CH}_3$  about its threefold rotation axis (the axis that passes through the C atom and the centre of the equilateral triangle formed by the H atoms) is  $5.341 \times 10^{-47} \text{ kg m}^2$ .

**16.4** Calculate the temperature dependence of the heat capacity of  $p\text{-H}_2$  (in which only rotational states with even values of  $J$  are populated) at low temperatures on the basis that its rotational levels  $J = 0$  and  $J = 2$  constitute a system that resembles a two-level system except for the degeneracy of the upper level. Use  $\bar{B} = 60.864 \text{ cm}^{-1}$  and sketch the heat capacity curve. The experimental heat capacity of  $p\text{-H}_2$  does in fact show a peak at low temperatures.

**16.5** The pure rotational microwave spectrum of  $\text{H}^{35}\text{Cl}$  has absorption lines at the following wavenumbers (in  $\text{cm}^{-1}$ ): 21.19, 42.37, 63.56, 84.75, 105.93, 127.12, 148.31, 169.49, 190.68, 211.87, 233.06, 254.24, 275.43, 296.62, 317.80, 338.99, 360.18, 381.36, 402.55, 423.74, 444.92, 466.11, 487.30, 508.48. Calculate the rotational partition function at  $25^\circ\text{C}$  by direct summation.

**16.6** Calculate the standard molar entropy of  $\text{N}_2(\text{g})$  at 298 K from its rotational constant  $\bar{B} = 1.9987 \text{ cm}^{-1}$  and its vibrational wavenumber  $\bar{\nu} = 2358 \text{ cm}^{-1}$ . The thermochemical value is  $192.1 \text{ J K}^{-1} \text{ mol}^{-1}$ . What does this suggest about the solid at  $T = 0$ ?

**16.7‡** J.G. Dojahn *et al.* (*J. Phys. Chem.* **100**, 9649 (1996)) characterized the potential energy curves of the ground and electronic states of homonuclear

diatomic halogen anions. The ground state of  $\text{F}_2^-$  is  $^2\Sigma_u^+$  with a fundamental vibrational wavenumber of  $450.0 \text{ cm}^{-1}$  and equilibrium internuclear distance of 190.0 pm. The first two excited states are at 1.609 and 1.702 eV above the ground state. Compute the standard molar entropy of  $\text{F}_2^-$  at 298 K.

**16.8‡** In a spectroscopic study of buckminsterfullerene  $\text{C}_{60}$ , F. Negri *et al.* (*J. Phys. Chem.* **100**, 10849 (1996)) reviewed the wavenumbers of all the vibrational modes of the molecule:

| Mode            | Number | Degeneracy | Wavenumber/ $\text{cm}^{-1}$         |
|-----------------|--------|------------|--------------------------------------|
| $\text{A}_g$    | 1      | 1          | 976                                  |
| $\text{T}_{1u}$ | 4      | 3          | 525, 578, 1180, and 1430             |
| $\text{T}_{2u}$ | 5      | 3          | 354, 715, 1037, 1190, 1540           |
| $\text{G}_u$    | 6      | 4          | 345, 757, 776, 963, 1315, 1410       |
| $\text{H}_u$    | 7      | 5          | 403, 525, 667, 738, 1215, 1342, 1566 |

How many modes have a vibrational temperature  $\theta_v$  below 1000 K? Estimate the molar constant-volume heat capacity of  $\text{C}_{60}$  at 1000 K, counting as active all modes with  $\theta_v$  below this temperature.

**16.9‡** Treat carbon monoxide as a perfect gas and apply equilibrium statistical thermodynamics to the study of its properties, as specified below, in the temperature range 100–1000 K at 1 bar.  $\bar{\nu} = 2169.8 \text{ cm}^{-1}$ ,  $\bar{B} = 1.931 \text{ cm}^{-1}$ , and  $D_0 = 11.09 \text{ eV}$ ; neglect anharmonicity and centrifugal distortion. (a) Examine the probability distribution of molecules over available rotational and vibrational states. (b) Explore numerically the differences, if any, between the rotational molecular partition function as calculated with the discrete energy distribution and that calculated with the classical, continuous energy distribution. (c) Calculate the individual contributions to  $U_m(T) - U_m(100 \text{ K})$ ,  $C_{V,m}(T)$ , and  $S_m(T) - S_m(100 \text{ K})$  made by the translational, rotational, and vibrational degrees of freedom.

**16.10** Use mathematical software to evaluate the second virial coefficient in eqn 16.42 for an intermolecular potential energy of the form  $E_p = -\epsilon(\sigma^6/r^6 - \sigma^{12}/r^{12})$  and plot it as a function of temperature. Discuss how changing the range (as expressed by  $\sigma$ ) and the depth of the potential well (as expressed by  $\epsilon$ ) affect the value of  $B$ .

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp, Carmen Giunta, and Marshall Cady.

**16.11** Calculate and plot as a function of temperature, in the range 300 K to 1000 K, the equilibrium constant for the reaction  $\text{CD}_4(\text{g}) + \text{HCl}(\text{g}) \rightleftharpoons \text{CHD}_3(\text{g}) + \text{DCl}(\text{g})$  using the following data (numbers in parentheses are degeneracies):

| Molecule       | $\tilde{\nu}/\text{cm}^{-1}$                | $\tilde{B}/\text{cm}^{-1}$ | $\tilde{A}/\text{cm}^{-1}$ |
|----------------|---------------------------------------------|----------------------------|----------------------------|
| $\text{CHD}_3$ | 2993(1), 2142(1), 1003(3), 1291(2), 1036(2) | 3.28                       | 2.63                       |
| $\text{CD}_4$  | 2109(1), 1092(2), 2259(3), 996(3)           | 2.63                       |                            |
| HCl            | 2991(1)                                     | 10.59                      |                            |
| DCl            | 2145(1)                                     | 5.445                      |                            |

**16.12** The exchange of deuterium between acid and water is an important type of equilibrium, and we can examine it using spectroscopic data on the molecules. Calculate the equilibrium constant at (a) 298 K and (b) 800 K for the gas-phase exchange reaction  $\text{H}_2\text{O} + \text{DCl} \rightleftharpoons \text{HDO} + \text{HCl}$  from the following data:

| Molecule             | $\tilde{\nu}/\text{cm}^{-1}$ | $\tilde{A}/\text{cm}^{-1}$ | $\tilde{B}/\text{cm}^{-1}$ | $\tilde{C}/\text{cm}^{-1}$ |
|----------------------|------------------------------|----------------------------|----------------------------|----------------------------|
| $\text{H}_2\text{O}$ | 3656.7, 1594.8, 3755.8       | 27.88                      | 14.51                      | 9.29                       |
| HDO                  | 2726.7, 1402.2, 3707.5       | 23.38                      | 9.102                      | 6.417                      |
| HCl                  | 2991                         |                            | 10.59                      |                            |
| DCl                  | 2145                         |                            | 5.449                      |                            |

### Theoretical problems

**16.13** Derive the Sackur–Tetrode equation for a monatomic gas confined to a two-dimensional surface, and hence derive an expression for the standard molar entropy of condensation to form a mobile surface film.

**16.14†** For  $\text{H}_2$  at very low temperatures, only translational motion contributes to the heat capacity. At temperatures above  $\theta_R = hc\tilde{B}/k$ , the rotational contribution to the heat capacity becomes significant. At still higher temperatures, above  $\theta_V = hv/k$ , the vibrations contribute. But at this latter temperature, dissociation of the molecule into the atoms must be considered. (a) Explain the origin of the expressions for  $\theta_R$  and  $\theta_V$ , and calculate their values for hydrogen. (b) Obtain an expression for the molar constant-pressure heat capacity of hydrogen at all temperatures taking into account the dissociation of hydrogen. (c) Make a plot of the molar constant-pressure heat capacity as a function of temperature in the high-temperature region where dissociation of the molecule is significant.

**16.15** Derive expressions for the internal energy, heat capacity, entropy, Helmholtz energy, and Gibbs energy of a harmonic oscillator. Express the results in terms of the vibrational temperature,  $\theta_V$ , and plot graphs of each property against  $T/\theta_V$ .

**16.16** Use mathematical software to evaluate the heat capacity of the bound states of a Morse oscillator (Section 12.10) in which the energy levels are given by eqn 12.38:

$$E_v = (v + \frac{1}{2})hc\tilde{\nu} - (v + \frac{1}{2})^2hc\tilde{x}\tilde{\nu}$$

Plot the heat capacity as a function of temperature. Can you devise a way to include the unbound states that lie above the dissociation limit? Use the parameters for HCl (Exercise 12.12).

**16.17** Derive eqn 16.45, that  $\mu_T = B - TdB/dT$  in the limit  $p \rightarrow 0$ . *Hint:* Start by writing  $\mu = (V_m/C_{p,m})(\alpha T - 1)$  and  $\mu_T = -C_p\mu$  (see Sections 2.11 and 2.12 for definitions of these terms) and the virial equation in eqn 1.19.

**16.18** A formal way of arriving at the value of the symmetry number is to note that  $\sigma$  is the order (the number of elements) of the *rotational subgroup* of the molecule, the point group of the molecule with all but the identity and the rotations removed. The rotational subgroup of  $\text{H}_2\text{O}$  is  $\{E, C_2\}$ , so  $\sigma = 2$ . The rotational subgroup of  $\text{NH}_3$  is  $\{E, 2C_3\}$ , so  $\sigma = 3$ . This recipe makes it easy to find the symmetry numbers for more complicated molecules. The rotational

subgroup of  $\text{CH}_4$  is obtained from the  $T$  character table as  $\{E, 8C_3, 3C_2\}$ , so  $\sigma = 12$ . For benzene, the rotational subgroup of  $D_{6h}$  is  $\{E, 2C_6, 2C_3, C_2, 3C_2', 3C_2''\}$ , so  $\sigma = 12$ . (a) Estimate the rotational partition function of ethene at 25°C given that  $\tilde{A} = 4.828 \text{ cm}^{-1}$ ,  $\tilde{B} = 1.0012 \text{ cm}^{-1}$ , and  $\tilde{C} = 0.8282 \text{ cm}^{-1}$ . (b) Evaluate the rotational partition function of pyridine,  $\text{C}_5\text{H}_5\text{N}$ , at room temperature ( $\tilde{A} = 0.2014 \text{ cm}^{-1}$ ,  $\tilde{B} = 0.1936 \text{ cm}^{-1}$ ,  $\tilde{C} = 0.0987 \text{ cm}^{-1}$ ).

**16.19** Although expressions like  $\langle \epsilon \rangle = -d \ln q / d\beta$  are useful for formal manipulations in statistical thermodynamics, and for expressing thermodynamic functions in neat formulas, they are sometimes more trouble than they are worth in practical applications. When presented with a table of energy levels, it is often much more convenient to evaluate the following sums directly:

$$q = \sum_j e^{-\beta \epsilon_j} \quad \bar{q} = \sum_j \beta \epsilon_j e^{-\beta \epsilon_j} \quad \bar{q} = \sum_j (\beta \epsilon_j)^2 e^{-\beta \epsilon_j}$$

(a) Derive expressions for the internal energy, heat capacity, and entropy in terms of these three functions. (b) Apply the technique to the calculation of the electronic contribution to the constant-volume molar heat capacity of magnesium vapour at 5000 K using the following data:

| Term                         | $^1\text{S}$ | $^3\text{P}_0$ | $^3\text{P}_1$ | $^3\text{P}_2$ | $^1\text{P}_1$ | $^3\text{S}_1$ |
|------------------------------|--------------|----------------|----------------|----------------|----------------|----------------|
| Degeneracy                   | 1            | 1              | 3              | 5              | 3              | 3              |
| $\tilde{\nu}/\text{cm}^{-1}$ | 0            | 21 850         | 21 870         | 21 911         | 35 051         | 41 197         |

**16.20** Show how the heat capacity of a linear rotor is related to the following sum:

$$\zeta(\beta) = \frac{1}{q^2} \sum_{J,J'} \{ \epsilon(J) - \epsilon(J') \}^2 g(J') e^{-\beta[\epsilon(J) + \epsilon(J')]}$$

by

$$C = \frac{1}{2} N k \beta^2 \zeta(\beta)$$

where the  $\epsilon(J)$  are the rotational energy levels and  $g(J)$  their degeneracies. Then go on to show graphically that the total contribution to the heat capacity of a linear rotor can be regarded as a sum of contributions due to transitions  $0 \rightarrow 1, 0 \rightarrow 2, 1 \rightarrow 2, 1 \rightarrow 3$ , etc. In this way, construct Fig. 16.10 for the rotational heat capacities of a linear molecule.

**16.21** Set up a calculation like that in Problem 16.20 to analyse the vibrational contribution to the heat capacity in terms of excitations between levels and illustrate your results graphically in terms of a diagram like that in Fig. 16.10.

**16.22** Suppose that an intermolecular potential has a hard-sphere core of radius  $r_1$  and a shallow attractive well of uniform depth  $\epsilon$  out to a distance  $r_2$ . Show, by using eqn 16.41 and the condition  $\epsilon \ll kT$ , that such a model is approximately consistent with a van der Waals equation of state when  $b \ll V_m$ , and relate the van der Waals parameters and the Joule–Thomson coefficient to the parameters in this model.

**16.23** Explore the consequences of modelling the pair distribution function in eqn 16.49a as

$$g(r) = 1 + \cos\left(\frac{4r}{d} - 4\right) e^{-(r/d-1)}$$

for  $r \geq d$  and  $g(r) = 0$  for  $r < d$  and the intermolecular potential energy specified in Problem 16.10 ( $E_p = -\epsilon(\sigma^6/r^6 - \sigma^{12}/r^{12})$ ). Begin by plotting  $g(r)$  to verify that it resembles the form shown in Fig. 16.15. Then evaluate the virial for the potential energy (eqn 16.49a with  $V_2$  identified with  $E_p$ ). Finally, explore the internal pressure of the fluid and discuss how it varies with temperature and the parameters in the intermolecular potential energy.

**16.24** Determine whether a magnetic field can influence the value of an equilibrium constant. Consider the equilibrium  $\text{I}_2(\text{g}) \rightleftharpoons 2 \text{I}(\text{g})$  at 1000 K, and

calculate the ratio of equilibrium constants  $K(\mathcal{B})/K$ , where  $K(\mathcal{B})$  is the equilibrium constant when a magnetic field  $\mathcal{B}$  is present and removes the degeneracy of the four states of the  $^2P_{3/2}$  level. Data on the species are given in Exercise 16.20a. The electronic  $g$ -value of the atoms is  $\frac{4}{3}$ . Calculate the field required to change the equilibrium constant by 1 per cent.

**16.25** The heat capacity ratio of a gas determines the speed of sound in it through the formula  $c_s = (\gamma RT/M)^{1/2}$ , where  $\gamma = C_p/C_V$  and  $M$  is the molar mass of the gas. Deduce an expression for the speed of sound in a perfect gas of (a) diatomic, (b) linear triatomic, (c) nonlinear triatomic molecules at high temperatures (with translation and rotation active). Estimate the speed of sound in air at 25°C.

### Applications: to biology, materials science, environmental science, and astrophysics

**16.26** An average human DNA molecule has  $5 \times 10^8$  binucleotides (rungs on the DNA ladder) of four different kinds. If each rung were a random choice of one of these four possibilities, what would be the residual entropy associated with this typical DNA molecule?

**16.27** It is possible to write an approximate expression for the partition function of a protein molecule by including contributions from only two states: the native and denatured forms of the polymer. Proceeding with this crude model gives us insight into the contribution of denaturation to the heat capacity of a protein. According to this model, the total energy of a system of  $N$  protein molecules is

$$E = \frac{N\epsilon e^{-\epsilon/kT}}{1 + e^{-\epsilon/kT}}$$

where  $\epsilon$  is the energy separation between the denatured and native forms.

(a) Show that the constant-volume molar heat capacity is

$$C_{V,m} = \frac{R(\epsilon_m/RT)^2 e^{-\epsilon_m/RT}}{(1 + e^{-\epsilon_m/RT})^2}$$

(b) Plot the variation of  $C_{V,m}$  with temperature. (c) If the function  $C_{V,m}(T)$  has a maximum or minimum, derive an expression for the temperature at which it occurs.

**16.28†** R. Viswanathan *et al.* (*J. Phys. Chem.* **100**, 10784 (1996)) studied thermodynamic properties of several boron–silicon gas-phase species experimentally and theoretically. These species can occur in the high-temperature chemical vapour deposition (CVD) of silicon-based semiconductors. Among the computations they reported was computation of the Gibbs energy of BSi(g) at several temperatures based on a  $^4\Sigma^-$  ground state with equilibrium internuclear distance of 190.5 pm and fundamental vibrational wavenumber of  $772 \text{ cm}^{-1}$  and a  $^2P_0$  first excited level  $8000 \text{ cm}^{-1}$  above the ground level. Compute the standard molar Gibbs energy  $G_m^\circ(2000 \text{ K}) - G_m^\circ(0)$ .

**16.29†** The molecule  $\text{Cl}_2\text{O}_2$ , which is believed to participate in the seasonal depletion of ozone over Antarctica, has been studied by several means. M. Birk *et al.* (*J. Chem. Phys.* **91**, 6588 (1989)) report its rotational constants ( $B$ ) as 13 109.4, 2409.8, and 2139.7 MHz. They also report that its rotational spectrum indicates a molecule with a symmetry number of 2. J. Jacobs *et al.* (*J. Amer. Chem. Soc.* **116**, 1106 (1994)) report its vibrational wavenumbers as 753, 542, 310, 127, 646, and  $419 \text{ cm}^{-1}$ . Compute  $G_m^\circ(200 \text{ K}) - G_m^\circ(0)$  of  $\text{Cl}_2\text{O}_2$ .

**16.30†** J. Hutter *et al.* (*J. Amer. Chem. Soc.* **116**, 750 (1994)) examined the geometric and vibrational structure of several carbon molecules of formula  $C_n$ . Given that the ground state of  $C_3$ , a molecule found in interstellar space and in flames, is an angular singlet with moments of inertia 39.340, 39.032, and  $0.3082 m_u \text{ \AA}^2$  (where  $1 \text{ \AA} = 10^{-10} \text{ m}$ ) and with vibrational wavenumbers of 63.4, 1224.5, and  $2040 \text{ cm}^{-1}$ , compute  $G_m^\circ(10.00 \text{ K}) - G_m^\circ(0)$  and  $G_m^\circ(1000 \text{ K}) - G_m^\circ(0)$  for  $C_3$ .

Problems

In this chapter we examine molecular interactions in gases and liquids and interpret them in terms of electric properties of molecules, such as electric dipole moments and polarizabilities. All these properties reflect the degree to which the nuclei of atoms exert control over the electrons in a molecule, either by causing electrons to accumulate in particular regions, or by permitting them to respond more or less strongly to the effects of external electric fields. We shall see here and in Chapter 18 that molecular interactions govern the structures and functions of molecular assemblies.

Molecular interactions are responsible for the unique properties of substances as simple as water and as complex as biological and synthetic macromolecules. The shapes and chemical properties of molecular assemblies also result from specific patterns of interactions between two or more atoms, molecules, or macromolecules. **Supramolecular chemistry** is the field of chemistry that studies the relationships between structure and function in molecular assemblies, such as drug–receptor complexes (*Impact I17.1*) and nanoscale catalysts. Molecular assemblies are treated lightly in this chapter and more extensively in Chapter 18. The interaction between ions is treated in Chapter 5 (for solutions) and Chapter 19 (for solids).

We begin our examination of molecular interactions by describing the electric properties of molecules, which may be interpreted in terms of concepts of electronic structure introduced in Chapter 10. We shall see that small imbalances of charge distributions in molecules allow them to interact with one another. This interaction results in the cohesion of molecules to form supramolecular assemblies and the bulk phases of matter.

## Electric properties of molecules

Many of the electric properties of molecules can be traced to the competing influences of nuclei with different charges or to the competition between the control exercised by a nucleus and the influence of an externally applied field. The former competition may result in an electric dipole moment. The latter may result in properties such as refractive index and optical activity.

### 17.1 Electric dipole moments

**Key points** A polar molecule is a molecule with a permanent electric dipole moment. The magnitude of a dipole moment is the product of the partial charge and the separation.

An **electric dipole** consists of two electric charges  $+Q$  and  $-Q$  separated by a distance  $R$ . This arrangement of charges is represented by a vector  $\mu$  (1). The magnitude of  $\mu$  is

$\mu = QR$  and, although the SI unit of dipole moment is coulomb metre (C m), it is still commonly reported in the non-SI unit debye, D, named after Peter Debye, a pioneer in the study of dipole moments of molecules, where

$$1 \text{ D} = 3.335\,64 \times 10^{-30} \text{ C m} \quad (17.1)$$

The dipole moment of a pair of charges  $+e$  and  $-e$  separated by 100 pm is  $1.6 \times 10^{-29} \text{ C m}$ , corresponding to 4.8 D. Dipole moments of small molecules are typically about 1 D. The conversion factor in eqn 17.1 stems from the original definition of the debye in terms of c.g.s. units: 1 D is the dipole moment of two equal and opposite charges of magnitude 1 e.s.u. separated by 1 Å.

A **polar molecule** is a molecule with a permanent electric dipole moment. The permanent dipole moment stems from the partial charges on the atoms in the molecule that arise from differences in electronegativity or other features of bonding (Sections 10.6–10.8). Nonpolar molecules acquire an induced dipole moment in an electric field on account of the distortion the field causes in their electronic distributions and nuclear positions; however, this induced moment is only temporary, and disappears as soon as the perturbing field is removed. Polar molecules also have their existing dipole moments temporarily modified by an applied field.

Microwave spectroscopy (Section 12.5) is used to measure the electric dipole moments of molecules for which a rotational spectrum can be observed. Measurements on a liquid or solid bulk sample are made with a method explained later. Computational software is now widely available, and typically computes electric dipole moments by assessing the electron density at each point in the molecule and its coordinates relative to the centroid of the molecule. However, it is still important to be able to formulate simple models of the origin of these moments and to understand how they arise. The following paragraphs focus on this aspect.

All heteronuclear diatomic molecules are polar, and typical values of  $\mu$  include 1.08 D for HCl and 0.42 D for HI (Table 17.1). Molecular symmetry is of the greatest importance in deciding whether a polyatomic molecule is polar or not. Indeed, molecular symmetry is more important than the question of whether or not the atoms in the molecule belong to the same element. Homonuclear polyatomic molecules may be polar if they have low symmetry and the atoms are in inequivalent positions. For instance, the angular molecule ozone,  $\text{O}_3$  (2), is homonuclear; however, it is polar because the central O atom is different from the outer two (it is bonded to two atoms; they are bonded only to one); moreover, the dipole moments associated with each bond make an angle to each other and do not cancel. Heteronuclear polyatomic molecules may be nonpolar if they have high symmetry, because individual bond dipoles may then cancel. The heteronuclear linear triatomic molecule  $\text{CO}_2$ , for example, is nonpolar because, although there are partial charges on all three atoms, the dipole moment associated with the OC bond points in the opposite direction to the dipole moment associated with the CO bond, and the two cancel (3).

To a first approximation, it is possible to resolve the dipole moment of a polyatomic molecule into contributions from various groups of atoms in the molecule and the directions in which these individual contributions lie (Fig. 17.1). Thus, 1,4-dichlorobenzene is nonpolar by symmetry on account of the cancellation of two equal but opposing C–Cl moments (exactly as in carbon dioxide). 1,2-Dichlorobenzene, however, has a dipole moment that is approximately the resultant of two chlorobenzene dipole moments arranged at  $60^\circ$  to each other. This technique of ‘vector addition’ can be applied with fair success to other series of related molecules, and the resultant  $\mu_{\text{res}}$  of two dipole moments  $\mu_1$  and  $\mu_2$  that make an angle  $\theta$  to each other (4) is approximately (see *Mathematical background 4*)

$$\mu_{\text{res}} \approx (\mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 \cos \theta)^{1/2} \quad (17.2a)$$

#### A brief comment

In elementary chemistry, an electric dipole moment is often represented by the arrow  $\rightarrow$  added to the Lewis structure for the molecule, with the + marking the positive end. Note that the direction of the arrow is opposite to that of  $\mu$ .

**Table 17.1\*** Dipole moments ( $\mu$ ) and polarizability volumes ( $\alpha'$ )

|                      | $\mu/\text{D}$ | $\alpha'/(10^{-30} \text{ m}^3)$ |
|----------------------|----------------|----------------------------------|
| $\text{CCl}_4$       | 0              | 10.5                             |
| $\text{H}_2$         | 0              | 0.819                            |
| $\text{H}_2\text{O}$ | 1.85           | 1.48                             |
| HCl                  | 1.08           | 2.63                             |
| HI                   | 0.42           | 5.45                             |

\* More values are given in the Data section.

4 Addition of dipole moments

**Fig. 17.1** The resultant dipole moments (red in (c) and (d)) of the dichlorobenzene isomers (b) to (d) can be obtained approximately by vectorial addition of two chlorobenzene dipole moments (1.57 D).

When the two dipole moments have the same magnitude (as in the dichlorobenzenes), this equation simplifies to

$$\mu_{\text{res}} \approx 2\mu_1 \cos \frac{1}{2}\theta \quad (17.2b)$$

**Self-test 17.1** Estimate the ratio of the electric dipole moments of *ortho* (1,2-) and *meta* (1,3-) disubstituted benzenes.  $[\mu(\text{ortho})/\mu(\text{meta}) = 3^{1/2} \approx 1.7]$

A better approach to the calculation of dipole moments is to take into account the locations and magnitudes of the partial charges on all the atoms. These partial charges are included in the output of many molecular structure software packages. To calculate the  $x$ -component, for instance, we need to know the partial charge on each atom and the atom's  $x$ -coordinate relative to a point in the molecule and form the sum

$$\mu_x = \sum_j Q_j x_j \quad (17.3a)$$

Here  $Q_j$  is the partial charge of atom  $j$ ,  $x_j$  is the  $x$ -coordinate of atom  $j$ , and the sum is over all the atoms in the molecule. Analogous expressions are used for the  $y$ - and  $z$ -components. For an electrically neutral molecule, the origin of the coordinates is arbitrary, so it is best chosen to simplify the measurements. In common with all vectors, the magnitude of  $\mu$  is related to the three components  $\mu_x$ ,  $\mu_y$ , and  $\mu_z$  by

$$\mu = (\mu_x^2 + \mu_y^2 + \mu_z^2)^{1/2} \quad (17.3b)$$

**Example 17.1** Calculating a molecular dipole moment

Estimate the electric dipole moment of the amide group shown in (5) by using the partial charges (as multiples of  $e$ ) in Table 17.2 and the locations of the atoms shown.

**Method** We use eqn 17.3a to calculate each of the components of the dipole moment and then eqn 17.3b to assemble the three components into the magnitude of the dipole moment. Note that the partial charges are multiples of the fundamental charge,  $e = 1.609 \times 10^{-19} \text{ C}$ .

**Answer** The expression for  $\mu_x$  is

$$\begin{aligned} \mu_x &= (-0.36e) \times (132 \text{ pm}) + (0.45e) \times (0 \text{ pm}) + (0.18e) \times (182 \text{ pm}) \\ &\quad + (-0.38e) \times (-62.0 \text{ pm}) \\ &= 8.8e \text{ pm} \\ &= 8.8 \times (1.609 \times 10^{-19} \text{ C}) \times (10^{-12} \text{ m}) = 1.4 \times 10^{-30} \text{ C m} \end{aligned}$$

corresponding to  $\mu_x = +0.42 \text{ D}$ . The expression for  $\mu_y$  is:

$$\begin{aligned} \mu_y &= (-0.36e) \times (0 \text{ pm}) + (0.45e) \times (0 \text{ pm}) + (0.18e) \times (-87 \text{ pm}) \\ &\quad + (-0.38e) \times (107 \text{ pm}) \\ &= -56e \text{ pm} = -9.0 \times 10^{-30} \text{ C m} \end{aligned}$$

It follows that  $\mu_y = -2.7 \text{ D}$ . The amide group is planar, so  $\mu_z = 0$  and

$$\mu = \{(0.42 \text{ D})^2 + (-2.7 \text{ D})^2\}^{1/2} = 2.7 \text{ D}$$

We can find the orientation of the dipole moment by arranging an arrow of length 2.7 units of length to have  $x$ -,  $y$ -, and  $z$ -components of 0.42,  $-2.7$ , and 0 units; the orientation is superimposed on (6).

**Self-test 17.2** Calculate the electric dipole moment of formaldehyde by using the information in (7). [2.3 D]

## 17.2 Polarizabilities

**Key point** The polarizability is a measure of the ability of a molecule to undergo a redistribution of charge in response to the application of an electric field, resulting in the induction of a dipole moment.

An applied electric field can distort a molecule as well as align its permanent electric dipole moment. The **induced dipole moment**,  $\mu^*$ , is generally proportional to the field strength,  $\mathcal{E}$ , and we write

$$\mu^* = \alpha \mathcal{E} \quad \text{Definition of polarizability} \quad (17.4)$$

The constant of proportionality  $\alpha$  is the **polarizability** of the molecule. The greater the polarizability, the larger is the induced dipole moment for a given applied field. In a formal treatment, we should use vector quantities and allow for the possibility that the induced dipole moment might not lie parallel to the applied field, but for simplicity we discuss polarizabilities in terms of (scalar) magnitudes.

Polarizability has the units (coulomb metre)<sup>2</sup> per joule ( $\text{C}^2 \text{m}^2 \text{J}^{-1}$ ). That collection of units is awkward, so  $\alpha$  is often expressed as a **polarizability volume**,  $\alpha'$ , by using the relation

$$\alpha' = \frac{\alpha}{4\pi\epsilon_0} \quad \text{Definition of the polarizability volume} \quad [17.5]$$

where  $\epsilon_0$  is the vacuum permittivity. Because the units of  $4\pi\epsilon_0$  are coulomb-squared per joule per metre ( $\text{C}^2 \text{J}^{-1} \text{m}^{-1}$ ), it follows that  $\alpha'$  has the dimensions of volume (hence its name). Polarizability volumes are similar in magnitude to actual molecular volumes (of the order of  $10^{-30} \text{m}^3$ ,  $10^{-3} \text{nm}^3$ ,  $1 \text{\AA}^3$ ).

Some experimental polarizability volumes of molecules are given in Table 17.1. As shown in the following *Justification*, polarizability volumes correlate with the HOMO–LUMO separations in atoms and molecules. The electron distribution can be distorted readily if the LUMO lies close to the HOMO in energy, so the polarizability is then large. If the LUMO lies high above the HOMO, an applied field cannot perturb the electron distribution significantly, and the polarizability is low. Molecules with small HOMO–LUMO gaps are typically large, with numerous electrons.

### Justification 17.1 Polarizabilities and molecular structures

The quantum mechanical expression for the molecular polarizability in the  $z$ -direction is<sup>1</sup>

$$\alpha = 2 \sum_{n \neq 0} \frac{|\mu_{z,0n}|^2}{E_n - E_0} \quad (17.6)$$

where  $\mu_{z,0n}$  is the *transition* electric dipole moment in the  $z$ -direction, a measure of the extent to which electric charge is shifted when an electron migrates from

**Table 17.2** Partial charges in polypeptides

| Atom   | Partial charge/ $e$ |
|--------|---------------------|
| C(=O)  | +0.45               |
| C(–CO) | +0.06               |
| H(–C)  | +0.02               |
| H(–N)  | +0.18               |
| H(–O)  | +0.42               |
| N      | –0.36               |
| O      | –0.38               |

### A brief comment

When using older compilations of data, it is useful to note that polarizability volumes have the same numerical values as the ‘polarizabilities’ reported using c.g.s. electrical units, so the tabulated values previously called ‘polarizabilities’ can be used directly.

<sup>1</sup> For a derivation of eqn 17.6 see our *Quanta, matter and change—A molecular approach to physical chemistry* (2009).

the ground state to create an excited state. The sum is over the excited states, with energies  $E_n$ . The content of eqn 17.6 can be appreciated by approximating the excitation energies by a mean value  $\Delta E$  (an indication of the HOMO–LUMO separation) and supposing that the most important transition dipole moment is approximately equal to the charge of an electron multiplied by the molecular radius  $R$ . Then

$$\alpha \approx \frac{2e^2 R^2}{\Delta E}$$

This expression shows that  $\alpha$  increases with the size of the molecule and with the ease with which it can be excited (the smaller the value of  $\Delta E$ ).

If the excitation energy is approximated by the energy needed to remove an electron to infinity from a distance  $R$  from a single positive charge, we can write  $\Delta E \approx e^2/4\pi\epsilon_0 R$ . When this expression is substituted into the equation above, both sides are divided by  $4\pi\epsilon_0$ , and the factor of 2 ignored in this approximation, we obtain  $\alpha' \approx R^3$ , which is of the same order of magnitude as the molecular volume.

For most molecules, the polarizability is anisotropic, by which is meant that its value depends on the orientation of the molecule relative to the field. The polarizability volume of benzene when the field is applied perpendicular to the ring is  $0.0067 \text{ nm}^3$  and it is  $0.0123 \text{ nm}^3$  when the field is applied in the plane of the ring. The anisotropy of the polarizability determines whether a molecule is rotationally Raman active (Section 12.6).

### 17.3 Polarization

**Key points** The polarization is the electric dipole moment density. Orientation polarization is the polarization arising from the permanent dipole moments. Distortion polarization is the polarization arising from the distortion of the positions of the nuclei by the applied field. Electronic polarizability is the polarizability due to the distortion of the electron distribution.

The **polarization**,  $P$ , of a sample is the electric dipole moment density, the mean electric dipole moment of the molecules,  $\langle \mu \rangle$ , multiplied by the number density,  $\mathcal{N}$ :

$$P = \langle \mu \rangle \mathcal{N} \quad \text{Definition of polarization} \quad (17.7)$$

In the following pages we refer to the sample as a **dielectric**, by which is meant a polarizable, nonconducting medium.

The polarization of an isotropic fluid sample is zero in the absence of an applied field because the molecules adopt ceaselessly changing random orientations due to thermal motion, so  $\langle \mu \rangle = 0$ . In the presence of a weak electric field, the orientations of the molecular dipoles fluctuate but we show in the following *Justification* that the mean value of the dipole moment for the sample at a temperature  $T$  is

$$\langle \mu_z \rangle = \frac{\mu^2 \mathcal{E}}{3kT} \quad \text{Mean dipole moment in the presence of a weak electric field} \quad (17.8)$$

where  $z$  is the direction of the applied field  $\mathcal{E}$ . At very high electric fields the orientations of molecular dipoles fluctuate about the field direction to a lesser extent and the mean dipole moment approaches its maximum value of  $\langle \mu_z \rangle = \mu$ .

**Justification 17.2** *The thermally averaged dipole moment*

The probability  $dp$  that a dipole has an orientation in the range  $\theta$  to  $\theta + d\theta$  is given by the Boltzmann distribution (Section 15.1b), which in this case is

$$dp = \frac{e^{-E(\theta)/kT} \sin \theta d\theta}{\int_0^\pi e^{-E(\theta)/kT} \sin \theta d\theta}$$

where  $E(\theta)$  is the energy of the dipole in the field:  $E(\theta) = -\mu\mathcal{E} \cos \theta$ , with  $0 \leq \theta \leq \pi$ . The average value of the component of the dipole moment parallel to the applied electric field is therefore

$$\langle \mu_z \rangle = \int \mu \cos \theta dp = \mu \int \cos \theta dp = \frac{\mu \int_0^\pi e^{x \cos \theta} \cos \theta \sin \theta d\theta}{\int_0^\pi e^{x \cos \theta} \sin \theta d\theta}$$

with  $x = \mu\mathcal{E}/kT$ . The integral takes on a simpler appearance when we write  $y = \cos \theta$  and  $dy = -\sin \theta d\theta$ , and change the limits of integration to  $y = -1$  (at  $\theta = \pi$ ) and  $y = 1$  (at  $\theta = 0$ ):

$$\langle \mu_z \rangle = \frac{\mu \int_{-1}^1 y e^{xy} dy}{\int_{-1}^1 e^{xy} dy}$$

At this point we use

$$\int_{-1}^1 e^{xy} dy = \frac{e^x - e^{-x}}{x} \quad \int_{-1}^1 y e^{xy} dy = \frac{e^x + e^{-x}}{x} - \frac{e^x - e^{-x}}{x^2}$$

It is now straightforward algebra to combine these two results and to obtain

$$\langle \mu_z \rangle = \mu L(x) \quad L(x) = \frac{e^x + e^{-x}}{e^x - e^{-x}} - \frac{1}{x} \quad x = \frac{\mu\mathcal{E}}{kT} \quad (17.9)$$

$L(x)$  is called the **Langevin function**.

Under most circumstances,  $x$  is very small (for example, if  $\mu = 1$  D and  $T = 300$  K, then  $x$  exceeds 0.01 only if the field strength exceeds  $100 \text{ kV cm}^{-1}$ , and most measurements are done at much lower strengths). The exponentials in the Langevin function can be expanded as  $e^x = 1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \dots$  when the field is so weak that  $x \ll 1$ , and the largest term that survives is

$$L(x) = \frac{1}{3}x + \dots \quad (17.10)$$

Therefore, the average molecular dipole moment is given by eqn 17.8.

When the applied field changes direction slowly, the permanent dipole moment has time to reorient—the whole molecule rotates into a new direction—and follows the field. However, when the frequency of the field is high, a molecule cannot change direction fast enough to follow the change in direction of the applied field and the permanent dipole moment then makes no contribution to the polarization of the sample. Because a molecule takes about 1 ps to turn through about 1 radian in a fluid, the loss of this contribution to the polarization occurs when measurements are made at frequencies greater than about  $10^{11}$  Hz (in the microwave region). We say that

the **orientation polarization**, the polarization arising from the permanent dipole moments, is lost at such high frequencies.

The next contribution to the polarization to be lost as the frequency is raised is the **distortion polarization**, the polarization that arises from the distortion of the positions of the nuclei by the applied field. The molecule is bent and stretched by the applied field, and the molecular dipole moment changes accordingly. The time taken for a molecule to bend is approximately the inverse of the molecular vibrational frequency, so the distortion polarization disappears when the frequency of the radiation is increased through the infrared. The disappearance of polarization occurs in stages: as shown in the following *Justification*, each successive stage occurs as the incident frequency rises above the frequency of a particular mode of vibration. At even higher frequencies, in the visible region, only the electrons are mobile enough to respond to the rapidly changing direction of the applied field. The polarization that remains is now due entirely to the distortion of the electron distribution, and the surviving contribution to the molecular polarizability is called the **electronic polarizability**.

---

**Justification 17.3** *The frequency dependence of polarizabilities*

The quantum mechanical expression for the polarizability of a molecule in the presence of an electric field that is oscillating at a frequency  $\omega$  in the  $z$ -direction is<sup>2</sup>

$$\alpha(\omega) = \frac{2}{\hbar} \sum_n \frac{\omega_{n0} |\mu_{z,0n}|^2}{\omega_{n0}^2 - \omega^2} \quad \text{Frequency dependence of the polarizability} \quad (17.11)$$

The quantities in this expression (which is valid provided that  $\omega$  is not close to  $\omega_{n0}$ ) are the same as those in *Justification 17.1*, with  $\hbar\omega_{n0} = E_n - E_0$ . As  $\omega \rightarrow 0$ , the equation reduces to eqn 17.6 for the static polarizability. As  $\omega$  becomes very high (and much higher than any excitation frequency of the molecule so that the  $\omega_{n0}^2$  in the denominator can be ignored), the polarizability becomes

$$\alpha(\omega) = -\frac{2}{\hbar\omega^2} \sum_n \omega_{n0} |\mu_{z,0n}|^2 \rightarrow 0 \quad \text{as} \quad \omega \rightarrow \infty$$

That is, when the incident frequency is much higher than any excitation frequency, the polarizability becomes zero. The argument applies to each type of excitation, vibrational as well as electronic, and accounts for the successive decreases in polarizability as the frequency is increased.

---

## 17.4 Relative permittivities

**Key points** The permittivity is the quantity  $\epsilon$  in the Coulomb potential energy,  $V = Q_1 Q_2 / 4\pi\epsilon r$ . The relative permittivity is given by  $\epsilon_r = \epsilon / \epsilon_0$  and may be calculated from electric properties by using the Debye equation or the Clausius–Mossotti equation.

---

When two charges  $Q_1$  and  $Q_2$  are separated by a distance  $r$  in a vacuum, the Coulomb potential energy of their interaction is

$$V = \frac{Q_1 Q_2}{4\pi\epsilon_0 r} \quad (17.12a)$$

<sup>2</sup> For a derivation of eqn 17.11 see our *Quanta, matter and change—A molecular approach to physical chemistry* (2009).

When the same two charges are immersed in a medium (such as air or a liquid), their potential energy is reduced to

$$V = \frac{Q_1 Q_2}{4\pi\epsilon r} \quad (17.12b)$$

where  $\epsilon$  is the **permittivity** of the medium. The permittivity is normally expressed in terms of the dimensionless **relative permittivity**,  $\epsilon_r$ , (formerly and still widely called the dielectric constant) of the medium:

$$\epsilon_r = \frac{\epsilon}{\epsilon_0} \quad \text{Definition of relative permittivity} \quad [17.13]$$

The relative permittivity can have a very significant effect on the strength of the interactions between ions in solution. For instance, water has a relative permittivity of 78 at 25°C, so the interionic Coulombic interaction energy is reduced by nearly two orders of magnitude from its vacuum value. Some of the consequences of this reduction for electrolyte solutions were explored in Chapter 5.

The relative permittivity of a substance is large if its molecules are polar or highly polarizable. The quantitative relation between the relative permittivity and the electric properties of the molecules is obtained by considering the polarization of a medium, and is expressed by the **Debye equation**:

$$\frac{\epsilon_r - 1}{\epsilon_r + 2} = \frac{\rho P_m}{M} \quad \text{Debye equation} \quad (17.14)$$

where  $\rho$  is the mass density of the sample,  $M$  is the molar mass of the molecules, and  $P_m$  is the **molar polarization**, which is defined as

$$P_m = \frac{N_A}{3\epsilon_0} \left( \alpha + \frac{\mu^2}{3kT} \right) \quad \text{Definition of molar polarization} \quad [17.15]$$

(where  $\alpha$  is the polarizability, not the polarizability volume  $\alpha'$ ). The term  $\mu^2/3kT$  stems from the thermal averaging of the electric dipole moment in the presence of the applied field (eqn 17.8). The corresponding expression without the contribution from the permanent dipole moment is called the **Clausius–Mossotti equation**:

$$\frac{\epsilon_r - 1}{\epsilon_r + 2} = \frac{\rho N_A \alpha}{3M\epsilon_0} \quad \text{Clausius–Mossotti equation} \quad (17.16)$$

The Clausius–Mossotti equation is used when there is no contribution from permanent electric dipole moments to the polarization, either because the molecules are nonpolar or because the frequency of the applied field is so high that the molecules cannot orientate quickly enough to follow the change in direction of the field.

#### Example 17.2 Determining dipole moment and polarizability

The relative permittivity of a substance is measured by comparing the capacitance of a capacitor with and without the sample present ( $C$  and  $C_0$ , respectively) and using  $\epsilon_r = C/C_0$ . The relative permittivity of camphor (**8**) was measured at a series of temperatures with the results given below. Determine the dipole moment and the polarizability volume of the molecule.

**8** Camphor

| $\theta/^{\circ}\text{C}$ | $\rho/(\text{g cm}^{-3})$ | $\epsilon_r$ |
|---------------------------|---------------------------|--------------|
| 0                         | 0.99                      | 12.5         |
| 20                        | 0.99                      | 11.4         |
| 40                        | 0.99                      | 10.8         |
| 60                        | 0.99                      | 10.0         |
| 80                        | 0.99                      | 9.50         |
| 100                       | 0.99                      | 8.90         |
| 120                       | 0.97                      | 8.10         |
| 140                       | 0.96                      | 7.60         |
| 160                       | 0.95                      | 7.11         |
| 200                       | 0.91                      | 6.21         |

**Method** Equations 17.14 and 17.15 imply that the polarizability and permanent electric dipole moment of the molecules in a sample can be determined by measuring  $\epsilon_r$  at a series of temperatures, calculating  $P_m$ , and plotting it against  $1/T$ . The slope of the graph is  $N_A \mu^2/9\epsilon_0 k$  and its intercept at  $1/T=0$  is  $N_A \alpha/3\epsilon_0$ . We need to calculate  $(\epsilon_r - 1)/(\epsilon_r + 2)$  at each temperature, and then multiply by  $M/\rho$  to form  $P_m$ .

**Answer** For camphor,  $M = 152.23 \text{ g mol}^{-1}$ . We can therefore use the data to draw up the following table:

| $\theta/^{\circ}\text{C}$ | $(10^3 \text{ K})/T$ | $\epsilon_r$ | $(\epsilon_r - 1)/(\epsilon_r + 2)$ | $P_m/(\text{cm}^3 \text{ mol}^{-1})$ |
|---------------------------|----------------------|--------------|-------------------------------------|--------------------------------------|
| 0                         | 3.66                 | 12.5         | 0.793                               | 122                                  |
| 20                        | 3.41                 | 11.4         | 0.776                               | 119                                  |
| 40                        | 3.19                 | 10.8         | 0.766                               | 118                                  |
| 60                        | 3.00                 | 10.0         | 0.750                               | 115                                  |
| 80                        | 2.83                 | 9.50         | 0.739                               | 114                                  |
| 100                       | 2.68                 | 8.90         | 0.725                               | 111                                  |
| 120                       | 2.54                 | 8.10         | 0.703                               | 110                                  |
| 140                       | 2.42                 | 7.60         | 0.688                               | 109                                  |
| 160                       | 2.31                 | 7.11         | 0.670                               | 107                                  |
| 200                       | 2.11                 | 6.21         | 0.634                               | 106                                  |

**Fig. 17.2** The plot of  $P_m/(\text{cm}^3 \text{ mol}^{-1})$  against  $(10^3 \text{ K})/T$  used in Example 17.2 for the determination of the polarizability and dipole moment of camphor.

The points are plotted in Fig. 17.2. The intercept lies at 82.9, so  $\alpha' = 3.3 \times 10^{-23} \text{ cm}^3$ . The slope is 10.7, so  $\mu = 4.42 \times 10^{-30} \text{ C m}$ , corresponding to 1.33 D. Because the Debye equation describes molecules that are free to rotate, the data show that camphor, which does not melt until  $175^{\circ}\text{C}$ , is rotating even in the solid. It is an approximately spherical molecule.

**Self-test 17.3** The relative permittivity of chlorobenzene is 5.71 at  $20^{\circ}\text{C}$  and 5.62 at  $25^{\circ}\text{C}$ . Assuming a constant density ( $1.11 \text{ g cm}^{-3}$ ), estimate its polarizability volume and dipole moment.  $[1.4 \times 10^{-23} \text{ cm}^3, 1.1 \text{ D}]$

The Maxwell equations, which describe the properties of electromagnetic radiation, relate the refractive index at a (visible or ultraviolet) specified wavelength to the relative permittivity at that frequency:

$$n_r = \epsilon_r^{1/2} \quad \text{Relation between refractive index and relative permittivity} \quad (17.17)$$

where the refractive index,  $n_r$ , of the medium is the ratio of the speed of light in a vacuum,  $c$ , to its speed  $c'$  in the medium:  $n_r = c/c'$ . (A beam of light changes direction ('bends') when it passes from a region of one refractive index to a region with a different refractive index.) Therefore, the molar polarization,  $P_m$ , and the molecular polarizability,  $\alpha$ , can be measured at frequencies typical of visible light (about  $10^{15}$  to  $10^{16}$  Hz) by measuring the refractive index of the sample and using the Clausius–Mossotti equation.

## Interactions between molecules

A **van der Waals interaction** is the attractive interaction between closed-shell molecules; some strict definitions also require that it be an interaction with a potential energy that depends on the distance between the molecules as  $1/r^6$ . In addition, there are interactions between ions and the partial charges of polar molecules and repulsive interactions that prevent the complete collapse of matter to nuclear densities. The repulsive interactions arise from Coulombic repulsions and, indirectly, from the Pauli principle and the exclusion of electrons from regions of space where the orbitals of neighbouring species overlap.

### 17.5 Interactions between dipoles

**Key points** A van der Waals interaction between closed-shell molecules is an interaction that gives rise to a potential energy that is inversely proportional to the sixth power of their separation. The potential energy of each type of intermolecular interaction has a characteristic distance dependence: (a) point-dipole–point-charge ( $1/r^2$ ); (b) dipole–dipole ( $1/r^3$ , non-rotating molecules;  $1/r^6$ , rotating molecules); (c) dipole–induced-dipole interaction ( $1/r^6$ ); (d) dispersion (or London) interaction ( $1/r^6$ ). (e) A hydrogen bond is an interaction of the form  $A-H\cdots B$ , where A and B are N, O, or F. (f) A hydrophobic interaction favours the clustering of hydrophobic groups in aqueous environments. (g) The total attractive interaction energy between rotating molecules is then the sum of the three van der Waals contributions discussed above.

Most of the discussion in this section is based on the Coulombic potential energy of interaction between two charges (eqn 17.12a). We can easily adapt this expression to find the potential energy of a point charge and a dipole and extend it to the interaction between two dipoles.

#### (a) The potential energy of interaction

We show in the *Justification* below that the potential energy of interaction between a point dipole  $\mu_1 = Q_1 l$  and the point charge  $Q_2$  in the arrangement shown in (9) is

$$V = -\frac{\mu_1 Q_2}{4\pi\epsilon_0 r^2} \quad \text{Energy of interaction between a point dipole and a point charge} \quad (17.18)$$

With  $\mu$  in coulomb metres,  $Q_2$  in coulombs, and  $r$  in metres,  $V$  is obtained in joules. A **point dipole** is a dipole in which the separation between the charges is much smaller than the distance at which the dipole is being observed, ( $l \ll r$ ). The potential energy rises towards zero (the value at infinite separation of the charge and the dipole) more rapidly (as  $1/r^2$ ) than that between two point charges (which varies as  $1/r$ ) because, from the viewpoint of the point charge, the partial charges of the dipole seem to merge and cancel as the distance  $r$  increases (Fig. 17.3).

**Fig. 17.3** There are two contributions to the diminishing field of an electric dipole with distance (here seen from the side). The potentials of the charges decrease (shown here by a fading intensity) and the two charges appear to merge, so their combined effect approaches zero more rapidly than by the distance effect alone.

**Justification 17.4** *The interaction between a point charge and a point dipole*

The sum of the potential energies of repulsion between like charges and attraction between opposite charges in the orientation shown in (9) is

$$V = \frac{1}{4\pi\epsilon_0} \left( -\frac{Q_1 Q_2}{r - \frac{1}{2}l} + \frac{Q_1 Q_2}{r + \frac{1}{2}l} \right) = \frac{Q_1 Q_2}{4\pi\epsilon_0 r} \left( -\frac{1}{1-x} + \frac{1}{1+x} \right)$$

where  $x = l/2r$ . Because  $l \ll r$  for a point dipole, this expression can be simplified by expanding the terms in  $x$  by using

$$\frac{1}{1+x} = 1 - x + x^2 - \dots \quad \frac{1}{1-x} = 1 + x + x^2 + \dots$$

and retaining only the leading surviving term:

$$V = \frac{Q_1 Q_2}{4\pi\epsilon_0 r} \{ -(1+x+\dots) + (1-x+\dots) \} \approx -\frac{2xQ_1 Q_2}{4\pi\epsilon_0 r} = -\frac{Q_1 Q_2 l}{4\pi\epsilon_0 r^2}$$

With  $\mu_1 = Q_1 l$ , this expression becomes eqn 17.18. This expression should be multiplied by  $\cos \theta$  when the point charge lies at an angle  $\theta$  to the axis of the dipole.

**Example 17.3** *Calculating the interaction energy of two dipoles*

Calculate the potential energy of interaction of two dipoles in the arrangement shown in (10) when their separation is  $r$ .

**Method** We proceed in exactly the same way as in *Justification 17.4*, but now the total interaction energy is the sum of four pairwise terms, two attractions between opposite charges, which contribute negative terms to the potential energy, and two repulsions between like charges, which contribute positive terms.

**Answer** The sum of the four contributions is

$$V = \frac{1}{4\pi\epsilon_0} \left( -\frac{Q_1 Q_2}{r+l} + \frac{Q_1 Q_2}{r} + \frac{Q_1 Q_2}{r} - \frac{Q_1 Q_2}{r-l} \right) = -\frac{Q_1 Q_2}{4\pi\epsilon_0 r} \left( \frac{1}{1+x} - 2 + \frac{1}{1-x} \right)$$

with  $x = l/r$ . As before, provided  $l \ll r$  we can expand the two terms in  $x$  and retain only the first surviving term, which is equal to  $2x^2$ . This step results in the expression

$$V = -\frac{2x^2 Q_1 Q_2}{4\pi\epsilon_0 r}$$

Therefore, because  $\mu_1 = Q_1 l$  and  $\mu_2 = Q_2 l$ , the potential energy of interaction in the alignment shown in the illustration is

$$V = -\frac{\mu_1 \mu_2}{2\pi\epsilon_0 r^3}$$

This interaction energy approaches zero more rapidly (as  $1/r^3$ ) than for the previous case: now both interacting entities appear neutral to each other at large separations. See *Further information 17.1* for the general expression.

**Self-test 17.4** Derive an expression for the potential energy when the dipoles are in the arrangement shown in (11). [  $V = \mu_1 \mu_2 / 4\pi\epsilon_0 r^3$  ]

**Table 17.3** Multipole interaction potential energies

| Interaction type    | Distance dependence of potential energy | Typical energy/ (kJ mol <sup>-1</sup> ) | Comment                                                 |
|---------------------|-----------------------------------------|-----------------------------------------|---------------------------------------------------------|
| Ion–ion             | $1/r$                                   | 250                                     | Only between ions*                                      |
| Ion–dipole          | $1/r^2$                                 | 15                                      |                                                         |
| Dipole–dipole       | $1/r^3$                                 | 2                                       | Between stationary polar molecules                      |
|                     | $1/r^6$                                 | 0.6                                     | Between rotating polar molecules                        |
| London (dispersion) | $1/r^6$                                 | 2                                       | Between all types of molecules                          |
| Hydrogen bond       |                                         | 20                                      | Interaction of the type A–H···B, with A, B = O, N, or F |

\* Electrolyte solutions are treated in Chapter 5; ionic solids in Chapter 19.

Table 17.3 summarizes the various expressions for the interaction of charges and dipoles. It is quite easy to extend the formulas given there to obtain expressions for the energy of interaction of higher **multipoles**, or arrays of point charges (Fig. 17.4). Specifically, an  $n$ -pole is an array of point charges with an  $n$ -pole moment but no lower moment. Thus, a **monopole** ( $n = 1$ ) is a point charge, and the monopole moment is what we normally call the overall charge. A **dipole** ( $n = 2$ ), as we have seen, is an array of charges that has no monopole moment (no net charge). A **quadrupole** ( $n = 3$ ) consists of an array of point charges that has neither net charge nor dipole moment (as for CO<sub>2</sub> molecules, 3). An **octupole** ( $n = 4$ ) consists of an array of point charges that sum to zero and which has neither a dipole moment nor a quadrupole moment (as for CH<sub>4</sub> molecules, 12). The feature to remember is that the interaction energy falls off more rapidly the higher the order of the multipole. For the interaction of an  $n$ -pole with an  $m$ -pole, the potential energy varies with distance as

$$V \propto \frac{1}{r^{n+m-1}} \quad \text{Energy of interaction between multipoles} \quad (17.19)$$

The reason for the even steeper decrease with distance is the same as before: the array of charges appears to blend together into neutrality more rapidly with distance the higher the number of individual charges that contribute to the multipole. Note that a given molecule may have a charge distribution that corresponds to a superposition of several different multipoles.

The same kind of argument as that used to derive expressions for the potential energy can be used to establish the distance dependence of the strength of the electric field generated by a dipole. We shall need this expression when we calculate the dipole moment induced in one molecule by another.

The starting point for the calculation is the strength of the electric field generated by a point electric charge:

$$\mathcal{E} = \frac{Q}{4\pi\epsilon_0 r^2} \quad \text{Electric field generated by a point charge} \quad (17.20)$$

The field generated by a dipole is the sum of the fields generated by each partial charge. For the point-dipole arrangement shown in Fig. 17.5, the same procedure that was used to derive the potential energy gives

$$\mathcal{E} = \frac{\mu}{2\pi\epsilon_0 r^3} \quad \text{Electric field generated by a point dipole} \quad (17.21)$$

**Fig. 17.4** Typical charge arrays corresponding to electric multipoles. The field arising from an arbitrary finite charge distribution can be expressed as the superposition of the fields arising from a superposition of multipoles.

#### A brief comment

The electric field is actually a vector, and we cannot simply add and subtract magnitudes without taking into account the directions of the fields. In the cases we consider, this will not be a complication because the two charges of the dipoles will be collinear and give rise to fields in the same direction. Be careful, though, with more general arrangements of charges.

**Fig. 17.5** The electric field of a dipole is the sum of the opposing fields from the positive and negative charges, each of which is proportional to  $1/r^2$ . The difference, the net field, is proportional to  $1/r^3$ .

13

The electric field of a multipole (in this case a dipole) decreases more rapidly with distance (as  $1/r^3$  for a dipole) than a monopole (a point charge).

### (b) Dipole–dipole interactions

The potential energy of interaction between two polar molecules is a complicated function of their relative orientation. When the two dipoles are parallel (as in 13), the potential energy is simply (see *Further information 17.1*)

$$V = \frac{\mu_1 \mu_2 f(\theta)}{4\pi\epsilon_0 r^3} \quad f(\theta) = 1 - 3 \cos^2 \theta \quad \text{Energy of interaction between two fixed parallel dipoles} \quad (17.22)$$

This expression applies to polar molecules in a fixed, parallel, orientation in a solid. In a fluid of freely rotating molecules, the interaction between dipoles averages to zero because  $f(\theta)$  changes sign as the orientation changes, and its average value is zero. Physically, the like partial charges of two freely rotating molecules are close together as much as the two opposite charges, and the repulsion of the former is cancelled by the attraction of the latter. Mathematically, this result arises from the fact that the average (or mean value) of the function  $1 - 3 \cos^2 \theta$  is

$$(1/\pi) \int_0^\pi (1 - 3 \cos^2 \theta) \sin \theta \, d\theta = 0$$

The interaction energy of two *freely* rotating dipoles is zero. However, because their mutual potential energy depends on their relative orientation, the molecules do not in fact rotate completely freely, even in a gas. In fact, the lower energy orientations are marginally favoured, so there is a nonzero average interaction between polar molecules. We show in the following *Justification* that the average potential energy of two rotating molecules that are separated by a distance  $r$  is

$$\langle V \rangle = -\frac{C}{r^6} \quad C = \frac{2\mu_1^2 \mu_2^2}{3(4\pi\epsilon_0)^2 kT} \quad \text{Average energy of interaction between two rotating polar molecules} \quad (17.23)$$

This expression describes the **Keesom interaction**, and is the first of the contributions to the van der Waals interaction.

#### Justification 17.5 The Keesom interaction

The detailed calculation of the Keesom interaction energy is quite complicated, but the form of the final answer can be constructed quite simply. First, we note that the average interaction energy of two polar molecules rotating at a fixed separation  $r$  is given by

$$\langle V \rangle = \frac{\mu_1 \mu_2 \langle f \rangle}{4\pi\epsilon_0 r^3}$$

where  $\langle f \rangle$  now includes a weighting factor in the averaging that is equal to the probability that a particular orientation will be adopted. This probability is given by the Boltzmann distribution  $p \propto e^{-E/kT}$ , with  $E$  interpreted as the potential energy of interaction of the two dipoles in that orientation. That is,

$$p \propto e^{-V/kT} \quad V = \frac{\mu_1 \mu_2 f}{4\pi\epsilon_0 r^3}$$

When the potential energy of interaction of the two dipoles is very small compared with the energy of thermal motion, we can use  $V \ll kT$ , expand the exponential function in  $p$ , and retain only the first two terms:

$$p \propto 1 - V/kT + \dots$$

We now write the weighted average of  $f$  as

$$\langle f \rangle = \frac{\int_0^\pi f p \, d\theta}{\int_0^\pi d\theta} = \frac{1}{\pi} \int_0^\pi f e^{-V/kT} d\theta = \frac{1}{\pi} \int_0^\pi f (1 - V/kT) d\theta + \dots$$

It follows that

$$\begin{aligned} \langle f \rangle &= \frac{1}{\pi} \int_0^\pi f \, d\theta - \frac{1}{\pi} \int_0^\pi f (V/kT) d\theta + \dots = \frac{1}{\pi} \int_0^\pi f \, d\theta - \frac{1}{\pi} \int_0^\pi \frac{\mu_1 \mu_2}{4\pi \epsilon_0 k T r^3} f^2 d\theta + \dots \\ &= \overbrace{\frac{1}{\pi} \int_0^\pi f \, d\theta}^{\langle f \rangle_0} - \frac{\mu_1 \mu_2}{4\pi \epsilon_0 k T r^3} \left( \overbrace{\frac{1}{\pi} \int_0^\pi f^2 d\theta}^{\langle f^2 \rangle_0} \right) + \dots \\ &= \langle f \rangle_0 - \frac{\mu_1 \mu_2}{4\pi \epsilon_0 k T r^3} \langle f^2 \rangle_0 + \dots \end{aligned}$$

where  $\langle \dots \rangle_0$  denotes an unweighted spherical average. The spherical average of  $f$  is

$$\langle f \rangle_0 = \frac{1}{\pi} \int_0^\pi (1 - 3 \cos^2 \theta) \sin \theta \, d\theta = 0$$

so the first term in the expression for  $\langle f \rangle$  vanishes. However, the average value of  $f^2$  is nonzero because  $f^2$  is positive at all orientations, so we can write

$$\langle V \rangle = - \frac{\mu_1^2 \mu_2^2 \langle f^2 \rangle_0}{(4\pi \epsilon_0)^2 k T r^6}$$

The average value  $\langle f^2 \rangle_0$  turns out to be  $\frac{2}{3}$  when the calculation is carried through in detail. The final result is that quoted in eqn 17.23.

The important features of eqn 17.23 are:

- The negative sign shows that the average interaction is attractive.
- The dependence of the average interaction energy on the inverse sixth power of the separation identifies it as a van der Waals interaction.
- The inverse dependence on the temperature reflects the way in which the greater thermal motion overcomes the mutual orientating effects of the dipoles at higher temperatures.
- The inverse sixth power arises from the inverse third power of the interaction potential energy that is weighted by the energy in the Boltzmann term, which is also proportional to the inverse third power of the separation.

At 25°C the average interaction energy for pairs of molecules with  $\mu = 1$  D is about  $-0.06 \text{ kJ mol}^{-1}$  when the separation is 0.5 nm. This energy should be compared with the average molar kinetic energy of  $\frac{3}{2} RT = 3.7 \text{ kJ mol}^{-1}$  at the same temperature. The interaction energy is also much smaller than the energies involved in the making and breaking of chemical bonds.

**Fig. 17.6** (a) A polar molecule can induce a dipole in a nonpolar molecule, and (b) the latter's orientation follows the former's, so the interaction does not average to zero.

### (c) Dipole–induced-dipole interactions

A polar molecule with dipole moment  $\mu_1$  can induce a dipole  $\mu_2^*$  in a neighbouring polarizable molecule (Fig. 17.6). The induced dipole interacts with the permanent dipole of the first molecule, and the two are attracted together. The average interaction energy when the separation of the molecules is  $r$  is

$$V = -\frac{C}{r^6} \quad C = \frac{\mu_1^2 \alpha'_2}{4\pi\epsilon_0} \quad \text{Energy of interaction between a polar molecule and a polarizable molecule} \quad (17.24)$$

where  $\alpha'_2$  is the polarizability volume of molecule 2 and  $\mu_1$  is the permanent dipole moment of molecule 1. Note that the  $C$  in this expression is different from the  $C$  in eqn 17.23 and other expressions below: we are using the same symbol in  $C/r^6$  to emphasize the similarity of form of each expression.

The dipole–induced-dipole interaction energy is independent of the temperature because thermal motion has no effect on the averaging process. Moreover, like the dipole–dipole interaction, the potential energy depends on  $1/r^6$ : this distance dependence stems from the  $1/r^3$  dependence of the field (and hence the magnitude of the induced dipole) and the  $1/r^3$  dependence of the potential energy of interaction between the permanent and induced dipoles. For a molecule with  $\mu = 1$  D (such as HCl) near a molecule of polarizability volume  $\alpha' = 10 \times 10^{-30} \text{ m}^3$ , the average interaction energy is about  $-0.8 \text{ kJ mol}^{-1}$  when the separation is 0.3 nm.

### (d) Induced-dipole–induced-dipole interactions

Nonpolar molecules (including closed-shell atoms, such as Ar) attract one another even though neither has a permanent dipole moment. The abundant evidence for the existence of interactions between them is the formation of condensed phases of nonpolar substances, such as the condensation of hydrogen or argon to a liquid at low temperatures and the fact that benzene is a liquid at normal temperatures.

The interaction between nonpolar molecules arises from the transient dipoles that all molecules possess as a result of fluctuations in the instantaneous positions of electrons. To appreciate the origin of the interaction, suppose that the electrons in one molecule flicker into an arrangement that gives the molecule an instantaneous dipole moment  $\mu_1^*$ . This dipole generates an electric field that polarizes the other molecule, and induces in that molecule an instantaneous dipole moment  $\mu_2^*$ . The two dipoles attract each other and the potential energy of the pair is lowered. Although the first molecule will go on to change the size and direction of its instantaneous dipole, the electron distribution of the second molecule will follow, that is, the two dipoles are correlated in direction (Fig. 17.7). Because of this correlation, the attraction between the two instantaneous dipoles does not average to zero, and gives rise to an induced-dipole–induced-dipole interaction. This interaction is called either the **dispersion interaction** or the **London interaction** (for Fritz London, who first described it).

The strength of the dispersion interaction depends on the polarizability of the first molecule because the instantaneous dipole moment  $\mu_1^*$  depends on the looseness of the control that the nuclear charge exercises over the outer electrons. The strength of the interaction also depends on the polarizability of the second molecule, for that polarizability determines how readily a dipole can be induced by another molecule. The actual calculation of the dispersion interaction is quite involved, but a reasonable approximation to the interaction energy is given by the **London formula**:

$$V = -\frac{C}{r^6} \quad C = \frac{3}{2} \alpha'_1 \alpha'_2 \frac{I_1 I_2}{I_1 + I_2} \quad \text{London formula} \quad (17.25)$$

**Fig. 17.7** (a) In the dispersion interaction, an instantaneous dipole on one molecule induces a dipole on another molecule, and the two dipoles then interact to lower the energy. (b) The two instantaneous dipoles are correlated and, although they occur in different orientations at different instants, the interaction does not average to zero.

where  $I_1$  and  $I_2$  are the ionization energies of the two molecules (Table 9.3). This interaction energy is also proportional to the inverse sixth power of the separation of the molecules, which identifies it as a third contribution to the van der Waals interaction. The dispersion interaction generally dominates all the interactions between molecules other than hydrogen bonds.

#### • A brief illustration

For two  $\text{CH}_4$  molecules, we can substitute  $\alpha' = 2.6 \times 10^{-30} \text{ m}^3$  and  $I \approx 700 \text{ kJ mol}^{-1}$  to obtain  $V = -5 \text{ kJ mol}^{-1}$  for  $r = 0.3 \text{ nm}$ . A very rough check on this figure is the enthalpy of vaporization of methane, which is  $8.2 \text{ kJ mol}^{-1}$ . However, this comparison is insecure, partly because the enthalpy of vaporization is a many-body quantity and partly because the long-distance assumption breaks down. •

#### (e) Hydrogen bonding

The interactions described so far are universal in the sense that they are possessed by all molecules independent of their specific identity. However, there is a type of interaction possessed by molecules that have a particular constitution. A **hydrogen bond** is an attractive interaction between two species that arises from a link of the form  $\text{A-H}\cdots\text{B}$ , where A and B are highly electronegative elements and B possesses a lone pair of electrons. Hydrogen bonding is conventionally regarded as being limited to N, O, and F but, if B is an anionic species (such as  $\text{Cl}^-$ ), it may also participate in hydrogen bonding. There is no strict cut-off for an ability to participate in hydrogen bonding, but N, O, and F participate most effectively.

The formation of a hydrogen bond can be regarded either as the approach between a partial positive charge of H and a partial negative charge of B or as a particular example of delocalized molecular orbital formation in which A, H, and B each supply one atomic orbital from which three molecular orbitals are constructed (Fig. 17.8). Experimental evidence and theoretical arguments have been presented in favour of both views and the matter has not yet been resolved. The electrostatic interaction model can be understood readily in terms of the discussion in Section 17.5b. Here we develop the molecular orbital model.

Thus, if the A–H bond is regarded as formed from the overlap of an orbital on A,  $\psi_A$ , and a hydrogen 1s orbital,  $\psi_H$ , and the lone pair on B occupies an orbital on B,  $\psi_B$ , then, when the two molecules are close together, we can build three molecular orbitals from the three basis orbitals:

$$\psi = c_1 \psi_A + c_2 \psi_H + c_3 \psi_B$$

One of the molecular orbitals is bonding, one almost nonbonding, and the third antibonding. These three orbitals need to accommodate four electrons (two from the original A–H bond and two from the lone pair of B), so two enter the bonding orbital and two enter the nonbonding orbital. Because the anti-bonding orbital remains empty, the net effect—depending on the precise location of the almost nonbonding orbital—may be a lowering of energy.

In practice, the strength of the bond is found to be about  $20 \text{ kJ mol}^{-1}$ . Because the bonding depends on orbital overlap, it is virtually a contact-like interaction that is turned on when AH touches B and is zero as soon as the contact is broken. If hydrogen bonding is present, it dominates the other intermolecular interactions. The properties of liquid and solid water, for example, are dominated by the hydrogen bonding between  $\text{H}_2\text{O}$  molecules. The structure of DNA and hence the transmission of genetic information is crucially dependent on the strength of hydrogen bonds between base pairs. The structural evidence for hydrogen bonding comes from noting that the

**Fig. 17.8** The molecular orbital interpretation of the formation of an  $\text{A-H}\cdots\text{B}$  hydrogen bond. From the three A, H, and B orbitals, three molecular orbitals can be formed (their relative contributions are represented by the sizes of the spheres). Only the two lower energy orbitals are occupied, and there may therefore be a net lowering of energy compared with the separate AH and B species.

**Fig. 17.9** When a hydrocarbon molecule is surrounded by water, the  $\text{H}_2\text{O}$  molecules form a cage. As a result of this acquisition of structure, the entropy of the water decreases, so the dispersal of the hydrocarbon into the water is entropy-opposed; its coalescence is entropy-favoured.

internuclear distance between formally nonbonded atoms is less than their van der Waals contact distance, which suggests that a dominating attractive interaction is present. For example, the O–O distance in  $\text{O–H}\cdots\text{O}$  is expected to be 280 pm on the basis of van der Waals radii, but is found to be 270 pm in typical compounds. Moreover, the  $\text{H}\cdots\text{O}$  distance is expected to be 260 pm but is found to be only 170 pm.

Hydrogen bonds may be either symmetric or unsymmetric. In a symmetric hydrogen bond, the H atom lies midway between the two other atoms. This arrangement is rare, but occurs in  $\text{F–H}\cdots\text{F}^-$ , where both bond lengths are 120 pm. More common is the unsymmetrical arrangement, where the A–H bond is shorter than the  $\text{H}\cdots\text{B}$  bond. Simple electrostatic arguments, treating  $\text{A–H}\cdots\text{B}$  as an array of point charges (partial negative charges on A and B, partial positive on H) suggest that the lowest energy is achieved when the bond is linear, because then the two partial negative charges are furthest apart. The experimental evidence from structural studies supports a linear or near-linear arrangement.

#### (f) The hydrophobic interaction

Nonpolar molecules do dissolve slightly in polar solvents, but strong interactions between solute and solvent are not possible and as a result it is found that each individual solute molecule is surrounded by a solvent cage (Fig. 17.9). To understand the consequences of this effect, consider the thermodynamics of transfer of a nonpolar hydrocarbon solute from a nonpolar solvent to water, a polar solvent. Experiments indicate that the process is endergonic ( $\Delta_{\text{transfer}}G > 0$ ), as expected on the basis of the increase in polarity of the solvent, but exothermic ( $\Delta_{\text{transfer}}H < 0$ ). Therefore, it is a large decrease in the entropy of the system ( $\Delta_{\text{transfer}}S < 0$ ) that accounts for the positive Gibbs energy of transfer. For example, the process

has  $\Delta_{\text{transfer}}G = +12 \text{ kJ mol}^{-1}$ ,  $\Delta_{\text{transfer}}H = -10 \text{ kJ mol}^{-1}$ , and  $\Delta_{\text{transfer}}S = -75 \text{ J K}^{-1} \text{ mol}^{-1}$  at 298 K. Substances characterized by a positive Gibbs energy of transfer from a nonpolar to a polar solvent are called **hydrophobic**.

It is possible to quantify the hydrophobicity of a small molecular group R by defining the **hydrophobicity constant**,  $\pi$ , as

$$\pi = \log \frac{S}{S_0}$$

Definition of  
hydrophobicity constant

[17.26]

where  $S$  is the ratio of the molar solubility of the compound R–A in octanol, a nonpolar solvent, to that in water, and  $S_0$  is the ratio of the molar solubility of the compound H–A in octanol to that in water. Therefore, positive values of  $\pi$  indicate hydrophobicity and negative values of  $\pi$  indicate hydrophilicity, the thermodynamic preference for water as a solvent. It is observed experimentally that the  $\pi$  values of most groups do not depend on the nature of A. However, measurements do suggest group additivity of  $\pi$  values, as the following data show:

|       |               |                          |                              |                              |                              |
|-------|---------------|--------------------------|------------------------------|------------------------------|------------------------------|
| R     | $\text{CH}_3$ | $\text{CH}_3\text{CH}_2$ | $\text{CH}_3(\text{CH}_2)_2$ | $\text{CH}_3(\text{CH}_2)_3$ | $\text{CH}_3(\text{CH}_2)_4$ |
| $\pi$ | 0.5           | 1.0                      | 1.5                          | 2.0                          | 2.5                          |

Thus, acyclic saturated hydrocarbons become more hydrophobic as the carbon chain length increases. This trend can be rationalized by  $\Delta_{\text{transfer}}H$  becoming more positive and  $\Delta_{\text{transfer}}S$  more negative as the number of carbon atoms in the chain increases.

At the molecular level, formation of a solvent cage around a hydrophobic molecule involves the formation of new hydrogen bonds among solvent molecules. This process is exothermic and accounts for the negative values of  $\Delta_{\text{transfer}}H$ . On the other

hand, the increase in order associated with formation of a very large number of small solvent cages decreases the entropy of the system and accounts for the negative values of  $\Delta_{\text{transfer}} S$ . However, when many solute molecules cluster together, fewer (albeit larger) cages are required and more solvent molecules are free to move. The net effect of formation of large clusters of hydrophobic molecules is then a decrease in the organization of the solvent and therefore a net *increase* in entropy of the system. This increase in entropy of the solvent is large enough to render spontaneous the association of hydrophobic molecules in a polar solvent.

The increase in entropy that results from fewer structural demands on the solvent placed by the clustering of nonpolar molecules is the origin of the **hydrophobic interaction**, which tends to stabilize aggregation of hydrophobic groups in micelles and biopolymers (Chapter 18). The hydrophobic interaction is an example of an ordering process that is driven by a tendency toward greater disorder of the solvent.

### (g) The total attractive interaction

We shall consider molecules that are unable to participate in hydrogen bond formation. The total attractive interaction energy between rotating molecules is then the sum of the dipole–dipole, dipole–induced-dipole, and dispersion interactions. Only the dispersion interaction contributes if both molecules are nonpolar. In a fluid phase, all three contributions to the potential energy vary as the inverse sixth power of the separation of the molecules, so we may write

$$V = -\frac{C_6}{r^6} \quad (17.27)$$

where  $C_6$  is a coefficient that depends on the identity of the molecules.

Although attractive interactions between molecules are often expressed as in eqn 17.27, we must remember that this equation has only limited validity. First, we have taken into account only dipolar interactions of various kinds, for they have the longest range and are dominant if the average separation of the molecules is large. However, in a complete treatment we should also consider quadrupolar and higher-order multipole interactions, particularly if the molecules do not have permanent dipole moments. Secondly, the expressions have been derived by assuming that the molecules can rotate reasonably freely. That is not the case in most solids, and in rigid media the dipole–dipole interaction is proportional to  $1/r^3$  because the Boltzmann averaging procedure is irrelevant when the molecules are trapped into a fixed orientation.

A different kind of limitation is that eqn 17.27 relates to the interactions of pairs of molecules. There is no reason to suppose that the energy of interaction of three (or more) molecules is the sum of the pairwise interaction energies alone. The total dispersion energy of three closed-shell atoms, for instance, is given approximately by the **Axilrod–Teller formula**:

$$V = -\frac{C_6}{r_{AB}^6} - \frac{C_6}{r_{BC}^6} - \frac{C_6}{r_{CA}^6} + \frac{C'}{(r_{AB}r_{BC}r_{CA})^3} \quad (17.28a)$$

Axilrod–Teller  
formula

where

$$C' = a(3 \cos \theta_A \cos \theta_B \cos \theta_C + 1) \quad (17.28b)$$

The parameter  $a$  is approximately equal to  $\frac{3}{4}\alpha'C_6$ ; the angles  $\theta$  are the internal angles of the triangle formed by the three atoms (14). The term in  $C'$  (which represents the non-additivity of the pairwise interactions) is negative for a linear arrangement of atoms (so that arrangement is stabilized) and positive for an equilateral triangular cluster (so that arrangement is destabilized). It is found that the three-body term contributes about 10 per cent of the total interaction energy in liquid argon.

## IMPACT ON MEDICINE

## 17.1 Molecular recognition and drug design

Here we encounter the first of a series of examples of work being done in the area of supramolecular chemistry that illustrate some of the roles of intermolecular interactions in chemistry. Our focus here is on the binding of a drug, a small molecule or protein, to a specific receptor site of a target molecule, such as a larger protein or nucleic acid. The chemical result of the formation of this supramolecular assembly is the inhibition of the progress of disease.

The binding of a ligand, or *guest*, to a biopolymer, or *host*, is governed by molecular interactions. To devise efficient therapies, we need to know how to characterize and optimize molecular interactions between the host and the guest. Examples of biological *host–guest complexes* include enzyme–substrate complexes, antigen–antibody complexes, and drug–receptor complexes. In all these cases, a site on the guest contains functional groups that can interact with complementary functional groups of the host. For example, a hydrogen bond donor group of the guest must be positioned near a hydrogen bond acceptor group of the host for tight binding to occur. It is generally true that many specific intermolecular contacts must be made in a biological host–guest complex and, as a result, a guest binds only hosts that are chemically similar. The strict rules governing molecular recognition of a guest by a host control every biological process, from metabolism to immunological response, and provide important clues for the design of effective drugs for the treatment of disease.

Interactions between nonpolar groups can be important in the binding of a guest to a host. For example, many enzyme active sites have hydrophobic pockets that bind nonpolar groups of a substrate. In addition to dispersion, repulsive, and hydrophobic interactions,  $\pi$ -stacking interactions are also possible, in which the planar  $\pi$  systems of aromatic macrocycles lie one on top of the other, in a nearly parallel orientation. Such interactions are responsible for the stacking of hydrogen-bonded base pairs in DNA (Fig. 17.10). Some drugs with planar  $\pi$  systems (for example, the molecule shown in Fig. 17.10 as a space-filling model) are effective because they intercalate between base pairs through  $\pi$  stacking interactions, causing the helix to unwind slightly and altering the function of DNA.

Coulombic interactions can be important in the interior of a biopolymer host, where the relative permittivity can be much lower than that of the aqueous exterior. For example, at physiological pH, amino acid side chains containing carboxylic acid or amine groups are negatively and positively charged, respectively, and can attract each other. Dipole–dipole interactions are also possible because many of the building blocks of biopolymers are polar, including the peptide link,  $-\text{CONH}-$  (see *Example 17.1*). However, hydrogen bonding interactions are by far the most prevalent in a biological host–guest complexes. Many effective drugs bind tightly and inhibit the action of enzymes that are associated with the progress of a disease. In many cases, a successful inhibitor will be able to form the same hydrogen bonds with the binding site that the normal substrate of the enzyme can form, except that the drug is chemically inert towards the enzyme.

There are two main strategies for the discovery of a drug. In *structure-based design*, new drugs are developed on the basis of the known structure of the receptor site of a known target. However, in many cases a number of so-called *lead compounds* are known to have some biological activity but little information is available about the target. To design a molecule with improved pharmacological efficacy, **quantitative structure–activity relationships** (QSAR) are often established by correlating data on activity of lead compounds with molecular properties, also called *molecular descriptors*, which can be determined either experimentally or computationally.

**Fig. 17.10** Some drugs with planar  $\pi$  systems intercalate between base pairs of DNA.

In broad terms, the first stage of the QSAR method consists of compiling molecular descriptors for a very large number of lead compounds. Descriptors such as molar mass, molecular dimensions and volume, and relative solubility in water and nonpolar solvents are available from routine experimental procedures. Quantum mechanical descriptors determined by semi-empirical and *ab initio* calculations include bond orders and HOMO and LUMO energies.

In the second stage of the process, biological activity is expressed as a function of the molecular descriptors. An example of a QSAR equation is:

$$\text{Activity} = c_0 + c_1 d_1 + c_2 d_1^2 + c_3 d_2 + c_4 d_2^2 + \dots \quad \text{A QSAR equation} \quad (17.29)$$

where  $d_i$  is the value of the descriptor and  $c_i$  is a coefficient calculated by fitting the data by regression analysis. The quadratic terms account for the fact that biological activity can have a maximum or minimum value at a specific descriptor value. For example, a molecule might not cross a biological membrane and become available for binding to targets in the interior of the cell if it is too hydrophilic, in which case it will not partition into the hydrophobic layer of the cell membrane (see Section 18.7 for details of membrane structure), or too hydrophobic, for then it may bind too tightly to the membrane. It follows that the activity will peak at some intermediate value of a parameter that measures the relative solubility of the drug in water and organic solvents.

In the final stage of the QSAR process, the activity of a drug candidate can be estimated from its molecular descriptors and the QSAR equation either by interpolation or extrapolation of the data. The predictions are more reliable when a large number of lead compounds and molecular descriptors are used to generate the QSAR equation.

The traditional QSAR technique has been refined into 3D QSAR, in which sophisticated computational methods are used to gain further insight into the three-dimensional features of drug candidates that lead to tight binding to the receptor site of a target. The process begins by using a computer to superimpose three-dimensional structural models of lead compounds and looking for common features, such as similarities in shape, location of functional groups, and electrostatic potential plots, which can be obtained from molecular orbital calculations. The key assumption of the method is that common structural features are indicative of molecular properties that enhance binding of the drug to the receptor. The collection of superimposed molecules is then placed inside a three-dimensional grid of points. An atomic probe, typically an  $sp^3$ -hybridized carbon atom, visits each grid point and two energies of interaction are calculated:  $E_{\text{steric}}$ , the steric energy reflecting interactions between the probe and electrons in uncharged regions of the drug, and  $E_{\text{elec}}$ , the electrostatic energy arising from interactions between the probe and a region of the molecule carrying a partial charge. The measured equilibrium constant for binding of the drug to the target,  $K_{\text{bind}}$ , is then assumed to be related to the interaction energies at each point  $r$  by the 3D QSAR equation

$$\log K_{\text{bind}} = c_0 + \sum_r \{c_s(r)E_{\text{steric}}(r) + c_e(r)E_{\text{elec}}(r)\} \quad \text{A 3D QSAR equation} \quad (17.30)$$

where the  $c(r)$  are coefficients calculated by regression analysis, with the coefficients  $c_s$  and  $c_e$  reflecting the relative importance of steric and electrostatic interactions, respectively, at the grid point  $r$ . Visualization of the regression analysis is facilitated by colouring each grid point according to the magnitude of the coefficients. Figure 17.11 shows results of a 3D QSAR analysis of the binding of steroids, molecules with the carbon skeleton shown, to human corticosteroid-binding globulin (CBG). Indeed, we

**Fig. 17.11** A 3D QSAR analysis of the binding of steroids, molecules with the carbon skeleton shown, to human corticosteroid-binding globulin (CBG). The ellipses indicate areas in the protein's binding site with positive or negative electrostatic potentials and with little or much steric crowding. It follows from the calculations that addition of large substituents near the left-hand side of the molecule (as it is drawn on the page) leads to poor affinity of the drug to the binding site. Also, substituents that lead to the accumulation of negative electrostatic potential at either end of the drug are likely to show enhanced affinity for the binding site. (Adapted from P. Krogsgaard-Larsen, T. Liljefors, U. Madsen (ed.), *Textbook of drug design and discovery*, Taylor & Francis, London (2002).)

**Fig. 17.12** The general form of an intermolecular potential energy curve. At long range the interaction is attractive, but at close range the repulsions dominate.

**Fig. 17.13** The Lennard-Jones potential, and the relation of the parameters to the features of the curve. The green and purple lines are the two contributions.

**Table 17.4\*** Lennard-Jones (12,6) parameters

|                | $(\epsilon/k)/\text{K}$ | $r_0/\text{pm}$ |
|----------------|-------------------------|-----------------|
| Ar             | 111.84                  | 362.3           |
| $\text{CCl}_4$ | 378.86                  | 624.1           |

\* More values are given in the *Data section*.

see that the technique lives up to the promise of opening a window into the chemical nature of the binding site even when its structure is not known.

The QSAR and 3D QSAR methods, though powerful, have limited power: the predictions are only as good as the data used in the correlations are both reliable and abundant. However, the techniques have been used successfully to identify compounds that deserve further synthetic elaboration, such as addition or removal of functional groups, and testing.

## 17.6 Repulsive and total interactions

**Key point** The Lennard-Jones (12,6) potential is a model of the total intermolecular potential energy, with a term proportional to  $r^{-6}$  that represents attractive interactions and a term proportional to  $r^{-12}$  that represents repulsive interactions.

When molecules are squeezed together, the nuclear and electronic repulsions and the rising electronic kinetic energy begin to dominate the attractive forces. The repulsions increase steeply with decreasing separation in a way that can be deduced only by very extensive, complicated molecular structure calculations of the kind described in Chapter 10 (Fig. 17.12).

In many cases, however, progress can be made by using a greatly simplified representation of the potential energy, where the details are ignored and the general features expressed by a few adjustable parameters. One such approximation is the **hard-sphere potential**, in which it is assumed that the potential energy rises abruptly to infinity as soon as the particles come within a separation  $d$ :

$$V = \infty \quad \text{for } r \leq d \quad V = 0 \quad \text{for } r > d \quad \text{Hard-sphere potential} \quad (17.31)$$

This very simple potential is surprisingly useful for assessing a number of properties. Another widely used approximation is the **Mie potential**:

$$V = \frac{C_n}{r^n} - \frac{C_m}{r^m} \quad \text{Mie potential} \quad (17.32)$$

with  $n > m$ . The first term represents repulsions and the second term attractions. The **Lennard-Jones potential** is a special case of the Mie potential with  $n = 12$  and  $m = 6$  (Fig. 17.13); it is often written in the form

$$V = 4\epsilon \left\{ \left( \frac{r_0}{r} \right)^{12} - \left( \frac{r_0}{r} \right)^6 \right\} \quad \text{Lennard-Jones potential} \quad (17.33)$$

The two parameters are  $\epsilon$ , the depth of the well (not to be confused with the symbol of the permittivity of a medium used in Section 17.4), and  $r_0$ , the separation at which  $V = 0$  (Table 17.4). The well minimum occurs at  $r_e = 2^{1/6}r_0$ . Although the Lennard-Jones potential has been used in many calculations, there is plenty of evidence to show that  $1/r^{12}$  is a very poor representation of the repulsive potential, and that an exponential form,  $e^{-r/r_0}$ , is greatly superior. An exponential function is more faithful to the exponential decay of atomic wavefunctions at large distances, and hence to the overlap that is responsible for repulsion. The potential with an exponential repulsive term and a  $1/r^6$  attractive term is known as an **exp-6 potential**. These potentials can be used to calculate the virial coefficients of gases, as explained in Section 16.5, and through them various properties of real gases, such as the Joule–Thompson coefficient. The potentials are also used to model the structures of condensed fluids.

With the advent of **atomic force microscopy** (AFM), in which the force between a molecular sized probe and a surface is monitored (see *Impact 18.2*), it has become possible to measure directly the forces acting between molecules. The force,  $F$ , is the negative slope of potential, so for a Lennard-Jones potential between individual molecules we write

$$F = -\frac{dV}{dr} = \frac{24\epsilon}{r_0} \left\{ 2 \left( \frac{r_0}{r} \right)^{13} - \left( \frac{r_0}{r} \right)^7 \right\} \quad (17.34)$$

The net attractive force is greatest (from  $dF/dr = 0$ ) at  $r = (26/7)^{1/6}r_0$ , or  $1.244r_0$ , and at that distance is equal to  $-144(7/26)^{7/6}\epsilon/13r_0$ , or  $-2.396\epsilon/r_0$ . For typical parameters, the magnitude of this force is about 10 pN.

#### IMPACT ON MATERIALS SCIENCE

##### 17.2 Hydrogen storage in molecular clathrates

Another example of supramolecular chemistry is the work leading to technologies that will make hydrogen gas a widely used alternative fuel. Hydrogen gas is efficient and environmentally clean in the sense that it is possible to use it in fuel cells without generating carbon dioxide, a greenhouse gas. Effective storage and delivery of hydrogen gas is key to the commercial development of devices that use it as a fuel. However, because  $H_2$  molecules interact only weakly with one another, the liquefaction of hydrogen for storage and transport requires very high pressures, very low temperatures, or both. For example, at 1 atm hydrogen gas condenses only at 20 K. Whereas adsorption of hydrogen on solid surfaces, a process discussed in more detail in Chapter 23, is one way to solve the storage problem, more recent solutions involve insertion of  $H_2$  molecules as guests in cage-like structures called **clathrates**.

Water is a common host, leading to solid materials known as *solid hydrogen gas hydrates*. One such clathrate forms at 2.5–6.0 MPa (25–60 atm) and 249 K. Hydrogen molecules are encapsulated by weak van der Waals interactions with host molecules and can be released either by increasing the temperature or by decreasing the pressure on the material.

The tetrahedral coordination geometry of the O atom in a water molecule and hydrogen bonding between water molecules lead to a variety of structures for water clathrates. Figure 17.14 shows that these structures, typically represented by adjoining polyhedra with vertices denoting the positions of O atoms, possess cages of different sizes. The so-called T cavity is a tetrakaidecahedron cage consisting of 12 pentagonal faces and two hexagonal faces. The smaller D cavity (shown in Fig. 17.14) is a pentagonal dodecahedron cage consisting of 12 pentagonal faces. The H cavity (also shown in Fig. 17.14) is a hexakaidecahedron structure consisting of 12 pentagonal and four hexagonal faces.

Spectroscopic and diffraction studies of hydrogen gas hydrates indicate that this type of material can encapsulate 5.2 per cent  $H_2$  by mass. This percentage is a promising level for hydrogen storage, but more research is needed to result in a material with reasonable commercial utility.

## Gases and liquids

The form of matter with the least order is a gas. In a perfect gas there are no intermolecular interactions and the distribution of molecules is completely random. In a real gas there are weak attractions and repulsions that have minimal effect on the

**Fig. 17.14** A gas hydrate showing representative D and H cavities in a partial representation of the structure. The D cavity is a pentagonal dodecahedron cage consisting of 12 pentagonal faces. The H cavity is a hexakaidecahedron structure consisting of 12 pentagonal and four hexagonal faces.

**Fig. 17.15** The definition of the solid angle,  $d\Omega$ , for scattering.

**Fig. 17.16** The definition of the impact parameter,  $b$ , as the perpendicular separation of the initial paths of the particles.

**Fig. 17.17** Three typical cases for the collisions of two hard spheres: (a)  $b = 0$ , giving backward scattering; (b)  $b > R_A + R_B$ , giving forward scattering; (c)  $0 < b < R_A + R_B$ , leading to scattering into one direction on a ring of possibilities. (The target molecule is taken to be so heavy that it remains virtually stationary.)

relative locations of the molecules but that cause deviations from the perfect gas law for the dependence of pressure on the volume, temperature, and amount (Section 1.3).

The attractions between molecules are responsible for the condensation of gases into liquids at low temperatures. First, at low enough temperatures the molecules of a gas have insufficient kinetic energy to escape from each other's attraction and they stick together. Second, although molecules attract each other when they are a few diameters apart, as soon as they come into contact they repel each other. This repulsion is responsible for the fact that liquids and solids have a definite bulk and do not collapse to an infinitesimal point. The molecules are held together by molecular interactions, but their kinetic energies are comparable to their potential energies. As a result, we saw in Section 16.6 that, although the molecules of a liquid are not free to escape completely from the bulk, the whole structure is very mobile and we can speak only of the *average* relative locations of molecules. In the following sections we build on those concepts and add thermodynamic arguments to describe the surface of a liquid and the condensation of a gas into a liquid.

## 17.7 Molecular interactions in gases

**Key points** A molecular beam is a collimated, narrow stream of molecules travelling through an evacuated vessel. Molecular beam techniques are used to investigate molecular interactions in gases. van der Waals molecules are complexes of the form AB in which A and B are held together by van der Waals forces.

Molecular interactions in the gas phase can be studied in **molecular beams**, which consist of a collimated, narrow stream of molecules travelling through an evacuated vessel. The beam is directed towards other molecules, and the scattering that occurs on impact is related to the intermolecular interactions.

The primary experimental information from a molecular beam experiment is the fraction of the molecules in the incident beam that are scattered into a particular direction. The fraction is normally expressed in terms of  $dI$ , the rate at which molecules are scattered into a cone (described by a solid angle  $d\Omega$ ) that represents the area covered by the 'eye' of the detector (Fig. 17.15). This rate is reported as the **differential scattering cross-section**,  $\sigma$ , the constant of proportionality between the value of  $dI$  and the intensity,  $I$ , of the incident beam, the number density of target molecules,  $\mathcal{N}$ , and the infinitesimal path length  $dx$  through the sample:

$$dI = \sigma I \mathcal{N} dx \quad (17.35)$$

The value of  $\sigma$  (which has the dimensions of area) depends on the **impact parameter**,  $b$ , the initial perpendicular separation of the paths of the colliding molecules (Fig. 17.16), and the details of the intermolecular potential. The role of the impact parameter is most easily seen by considering the impact of two hard spheres (Fig. 17.17). If  $b = 0$ , the lighter projectile is on a trajectory that leads to a head-on collision, so the only scattering intensity is detected when the detector is at  $\theta = \pi$ . When the impact parameter is so great that the spheres do not make contact ( $b > R_A + R_B$ ), there is no scattering and the scattering cross-section is zero at all angles except  $\theta = 0$ . Glancing blows, with  $0 < b \leq R_A + R_B$ , lead to scattering intensity in cones around the forward direction.

The scattering pattern of real molecules, which are not hard spheres, depends on the details of the intermolecular potential, including the anisotropy that is present when the molecules are non-spherical. The scattering also depends on the relative speed of approach of the two particles: a very fast particle might pass through the interaction region without much deflection, whereas a slower one on the same path might be temporarily captured and undergo considerable deflection (Fig. 17.18). The variation

of the scattering cross-section with the relative speed of approach should therefore give information about the strength and range of the intermolecular potential.

A further point is that the outcome of collisions is determined by quantum, not classical, mechanics. The wave nature of the particles can be taken into account, at least to some extent, by drawing all classical trajectories that take the projectile particle from source to detector, and then considering the effects of interference between them.

Two quantum mechanical effects are of great importance. A particle with a certain impact parameter might approach the attractive region of the potential in such a way that the particle is deflected towards the repulsive core (Fig. 17.19), which then repels it out through the attractive region to continue its flight in the forward direction. Some molecules, however, also travel in the forward direction because they have impact parameters so large that they are undeflected. The wavefunctions of the particles that take the two types of path interfere, and the intensity in the forward direction is modified. The effect is called **quantum oscillation**. The same phenomenon accounts for the optical ‘glory effect’, in which a bright halo can sometimes be seen surrounding an illuminated object. (The coloured rings around the shadow of an aircraft cast on clouds by the Sun, and often seen in flight, is an example of an optical glory.)

The second quantum effect we need consider is the observation of a strongly enhanced scattering in a non-forward direction. This effect is called **rainbow scattering** because the same mechanism accounts for the appearance of an optical rainbow. The origin of the phenomenon is illustrated in Fig. 17.20. As the impact parameter decreases, there comes a stage at which the scattering angle passes through a maximum and the interference between the paths results in a strongly scattered beam. The **rainbow angle**,  $\theta_r$ , is the angle for which  $d\theta/db = 0$  and the scattering is strong.

Another phenomenon that can occur in certain beams is the capturing of one species by another. The vibrational temperature in supersonic beams is so low that **van der Waals molecules** may be formed, which are complexes of the form AB in which A and B are held together by van der Waals forces or hydrogen bonds. Large numbers of such molecules have been studied spectroscopically, including ArHCl, (HCl)<sub>2</sub>, ArCO<sub>2</sub>, and (H<sub>2</sub>O)<sub>2</sub>. More recently, van der Waals clusters of water molecules have been pursued as far as (H<sub>2</sub>O)<sub>6</sub>. The study of their spectroscopic properties gives detailed information about the intermolecular potentials involved.

## 17.8 The liquid–vapour interface

**Key points** (a) Liquids tend to adopt shapes that minimize their surface area. (b) The minimization of surface area results in the formation of bubbles, cavities, and droplets. (c) Capillary action is the tendency of liquids to rise up narrow tubes.

So far, we have concentrated on the properties of gases. In Section 16.6, we described the structure of liquids. Now we turn our attention to the physical boundary between phases, such as the surface where solid is in contact with liquid or liquid is in contact with its vapour. In this section we concentrate on the liquid–vapour interface, which is interesting because it is so mobile. Chapter 19 deals with solid surfaces and their important role in catalysis.

### (a) Surface tension

Liquids tend to adopt shapes that minimize their surface area, for then the maximum number of molecules are in the bulk and hence surrounded by and interacting with neighbours. Droplets of liquids therefore tend to be spherical, because a sphere is the shape with the smallest surface-to-volume ratio. However, there may be other forces

**Fig. 17.18** The extent of scattering may depend on the relative speed of approach as well as the impact parameter. The dark central zone represents the repulsive core; the fuzzy outer zone represents the long-range attractive potential.

**Fig. 17.19** Two paths leading to the same destination will interfere quantum mechanically; in this case they give rise to quantum oscillations in the forward direction.

**Fig. 17.20** The interference of paths leading to rainbow scattering. The rainbow angle,  $\theta_r$ , is the maximum scattering angle reached as  $b$  is decreased. Interference between the numerous paths at that angle modifies the scattering intensity markedly.

present that compete against the tendency to form this ideal shape and, in particular, gravity may flatten spheres into puddles or oceans.

Surface effects may be expressed in the language of Helmholtz and Gibbs energies (Chapter 3). The link between these quantities and the surface area is the work needed to change the area by a given amount, and the fact that  $dA$  and  $dG$  are equal (under different conditions) to the work done in changing the energy of a system. The work needed to change the surface area,  $\sigma$ , of a sample by an infinitesimal amount  $d\sigma$  is proportional to  $d\sigma$ , and we write

$$dw = \gamma d\sigma$$

Definition of  
surface tension

[17.36]

**Table 17.5\*** Surface tensions of liquids at 293 K

|          | $\gamma/(\text{mN m}^{-1})$ |
|----------|-----------------------------|
| Benzene  | 28.88                       |
| Mercury  | 472                         |
| Methanol | 22.6                        |
| Water    | 72.75                       |

\* More values are given in the *Data section*. Note that  $1 \text{ N m}^{-1} = 1 \text{ J m}^{-2}$ .

**Fig. 17.21** The model used for calculating the work of forming a liquid film when a wire of length  $l$  is raised and pulls the surface with it through a height  $h$ .

The constant of proportionality,  $\gamma$ , is called the **surface tension**; its dimensions are energy/area and its units are typically joules per metre squared ( $\text{J m}^{-2}$ ). However, as in Table 17.5, values of  $\gamma$  are usually reported in newtons per metre ( $\text{N m}^{-1}$  because  $1 \text{ J} = 1 \text{ N m}$ ). The work of surface formation at constant volume and temperature can be identified with the change in the Helmholtz energy, and we can write

$$dA = \gamma d\sigma \quad (17.37)$$

Because the Helmholtz energy decreases ( $dA < 0$ ) if the surface area decreases ( $d\sigma < 0$ ), surfaces have a natural tendency to contract. This is a more formal way of expressing what we have already described.

#### Example 17.4 Using the surface tension

Calculate the work needed to raise a wire of length  $l$  and to stretch the surface of a liquid through a height  $h$  in the arrangement shown in Fig. 17.21. Disregard gravitational potential energy.

**Method** According to eqn 17.36, the work required to create a surface of area  $\sigma$  given that the surface tension does not vary as the surface is formed is  $w = \gamma\sigma$ . Therefore, all we need do is to calculate the surface area of the two-sided rectangle formed as the frame is withdrawn from the liquid.

**Answer** When the wire of length  $l$  is raised through a height  $h$  it increases the area of the liquid by twice the area of the rectangle (because there is a surface on each side). The total increase is therefore  $2lh$  and the work done is  $2\gamma lh$ .

The expression  $2\gamma lh$  can be expressed as force  $\times$  distance by writing it as  $2\gamma l \times h$ , and identifying  $\gamma l$  as the opposing force on the wire of length  $l$ . This interpretation is why  $\gamma$  is called a tension and why its units are often chosen to be newtons per metre ( $\text{N m}^{-1}$ , so  $\gamma l$  is a force in newtons).

**Self-test 17.5** Calculate the work of creating a spherical cavity of radius  $r$  in a liquid of surface tension  $\gamma$ . [ $4\pi r^2\gamma$ ]

#### (b) Curved surfaces

The minimization of the surface area of a liquid may result in the formation of a curved surface. A **bubble** is a region in which vapour (and possibly air too) is trapped by a thin film; a **cavity** is a vapour-filled hole in a liquid. What are widely called 'bubbles' in liquids are therefore strictly cavities. True bubbles have two surfaces (one on each side of the film); cavities have only one. The treatments of both are similar, but a factor of 2 is required for bubbles to take into account the doubled surface area.

A **droplet** is a small volume of liquid at equilibrium surrounded by its vapour (and possibly also air).

The pressure on the concave side of an interface,  $p_{\text{in}}$ , is always greater than the pressure on the convex side,  $p_{\text{out}}$ . This relation is expressed by the **Laplace equation**, which is derived in the following *Justification*:

$$p_{\text{in}} = p_{\text{out}} + \frac{2\gamma}{r} \quad \text{Laplace equation} \quad (17.38)$$

**Justification 17.6** *The Laplace equation*

The cavities in a liquid are at equilibrium when the tendency for their surface area to decrease is balanced by the rise of internal pressure which would then result. When the pressure inside a cavity is  $p_{\text{in}}$  and its radius is  $r$ , the outward force is

$$\text{pressure} \times \text{area} = 4\pi r^2 p_{\text{in}}$$

The force inwards arises from the external pressure and the surface tension. The former has magnitude  $4\pi r^2 p_{\text{out}}$ . The latter is calculated as follows. The change in surface area when the radius of a sphere changes from  $r$  to  $r + dr$  is

$$d\sigma = 4\pi(r + dr)^2 - 4\pi r^2 = 8\pi r dr$$

(The second-order infinitesimal,  $(dr)^2$ , is ignored.) The work done when the surface is stretched by this amount is therefore

$$dw = 8\pi \gamma r dr$$

As force  $\times$  distance is work, the force opposing stretching through a distance  $dr$  when the radius is  $r$  is

$$F = 8\pi \gamma r$$

The total inward force is therefore  $4\pi r^2 p_{\text{out}} + 8\pi \gamma r$ . At equilibrium, the outward and inward forces are balanced, so we can write

$$4\pi r^2 p_{\text{in}} = 4\pi r^2 p_{\text{out}} + 8\pi \gamma r$$

which rearranges into eqn 17.38.

The Laplace equation shows that the difference in pressure decreases to zero as the radius of curvature becomes infinite (when the surface is flat, Fig. 17.22). Small cavities have small radii of curvature, so the pressure difference across their surface is quite large. For instance, a ‘bubble’ (actually, a cavity) of radius 0.10 mm in champagne implies a pressure difference of 1.5 kPa, which is enough to sustain a column of water of height 15 cm.

**(c) Capillary action**

The tendency of liquids to rise up capillary tubes (tubes of narrow bore; the name comes from the Latin word for ‘hair’), which is called **capillary action**, is a consequence of surface tension. Consider what happens when a glass capillary tube is first immersed in water or any liquid that has a tendency to adhere to the walls. The energy is lowest when a thin film covers as much of the glass as possible. As this film creeps up the inside wall it has the effect of curving the surface of the liquid inside the tube. This curvature implies that the pressure just beneath the curving meniscus is less than the atmospheric pressure by approximately  $2\gamma/r$ , where  $r$  is the radius of the tube and we assume a hemispherical surface. The pressure immediately under the flat surface outside the tube is  $P$ , the atmospheric pressure; but inside the tube under the curved

**Fig. 17.22** The dependence of the pressure inside a curved surface on the radius of the surface, for two different values of the surface tension.

**Fig. 17.23** When a capillary tube is first stood in a liquid, the latter climbs up the walls, so curving the surface. The pressure just under the meniscus is less than that arising from the atmosphere by  $2\gamma/r$ . The pressure is equal at equal heights throughout the liquid provided the hydrostatic pressure (which is equal to  $\rho gh$ ) cancels the pressure difference arising from the curvature.

**Fig. 17.24** The variation of the surface tension of water with temperature.

surface it is only  $P - 2\gamma/r$ . The excess external pressure presses the liquid up the tube until hydrostatic equilibrium (equal pressures at equal depths) has been reached (Fig. 17.23).

To calculate the height to which the liquid rises, we note that the pressure exerted by a column of liquid of mass density  $\rho$  and height  $h$  is

$$p = \rho gh \quad (17.39)$$

This hydrostatic pressure matches the pressure difference  $2\gamma/r$  at equilibrium. Therefore, the height of the column at equilibrium is obtained by equating  $2\gamma/r$  and  $\rho gh$ , which gives

$$h = \frac{2\gamma}{\rho gr} \quad (17.40)$$

This simple expression provides a reasonably accurate way of measuring the surface tension of liquids. Surface tension decreases with increasing temperature (Fig. 17.24).

#### • A brief illustration

If water at  $25^\circ\text{C}$  (and density  $997.1 \text{ kg m}^{-3}$ ) rises through  $7.36 \text{ cm}$  in a capillary of radius  $0.20 \text{ mm}$ , its surface tension at that temperature is

$$\begin{aligned} \gamma &= \frac{1}{2} \rho g h r \\ &= \frac{1}{2} \times (997.1 \text{ kg m}^{-3}) \times (9.81 \text{ m s}^{-2}) \times (7.36 \times 10^{-2} \text{ m}) \times (2.0 \times 10^{-4} \text{ m}) \\ &= 72 \text{ mN m}^{-1} \end{aligned}$$

where we have used  $1 \text{ kg m s}^{-2} = 1 \text{ N}$ . •

When the adhesive forces between the liquid and the material of the capillary wall are weaker than the cohesive forces within the liquid (as for mercury in glass), the liquid in the tube retracts from the walls. This retraction curves the surface with the concave, high pressure side downwards. To equalize the pressure at the same depth throughout the liquid the surface must fall to compensate for the heightened pressure arising from its curvature. This compensation results in a capillary depression.

In many cases there is a nonzero angle between the edge of the meniscus and the wall. If this contact angle is  $\theta_c$ , then eqn 17.40 should be modified by multiplying the right-hand side by  $\cos \theta_c$ . The origin of the contact angle can be traced to the balance of forces at the line of contact between the liquid and the solid (Fig. 17.25). If the solid–gas, solid–liquid, and liquid–gas surface tensions (essentially the energy needed to create unit area of each of the interfaces) are denoted  $\gamma_{\text{sg}}$ ,  $\gamma_{\text{sl}}$ , and  $\gamma_{\text{lg}}$ , respectively, then the vertical forces are in balance if

$$\gamma_{\text{sg}} = \gamma_{\text{sl}} + \gamma_{\text{lg}} \cos \theta_c \quad (17.41)$$

This expression solves to

$$\cos \theta_c = \frac{\gamma_{\text{sg}} - \gamma_{\text{sl}}}{\gamma_{\text{lg}}} \quad (17.42)$$

If we note that the superficial work of adhesion of the liquid to the solid (the work of adhesion divided by the area of contact) is

$$w_{\text{ad}} = \gamma_{\text{sg}} + \gamma_{\text{lg}} - \gamma_{\text{sl}} \quad (17.43)$$

eqn 17.42 can be written

$$\cos \theta_c = \frac{w_{\text{ad}}}{\gamma_{\text{lg}}} - 1 \quad (17.44)$$

**Fig. 17.25** The balance of forces that results in a contact angle,  $\theta_c$ .

**Fig. 17.26** The variation of contact angle (shown by the semaphore-like object) as the ratio  $w_{ad}/\gamma_{lg}$  changes.

We now see that the liquid ‘wets’ (spreads over) the surface, corresponding to  $0 < \theta_c < 90^\circ$ , when  $1 < w_{ad}/\gamma_{lg} < 2$  (Fig. 17.26). The liquid does not wet the surface, corresponding to  $90^\circ < \theta_c < 180^\circ$ , when  $0 < w_{ad}/\gamma_{lg} < 1$ . For mercury in contact with glass,  $\theta_c = 140^\circ$ , which corresponds to  $w_{ad}/\gamma_{lg} = 0.23$ , indicating a relatively low work of adhesion of the mercury to glass on account of the strong cohesive forces within mercury.

## 17.9 Surface films

**Key points** (a) The surface pressure is the difference between the surface tension of the pure solvent and the solution. The collapse pressure is the highest surface pressure that a surface film can sustain. (b) A surfactant modifies the surface tension and surface pressure.

The compositions of surface layers have been investigated by the simple but technically elegant procedure of slicing thin layers off the surfaces of solutions and analysing their compositions. The physical properties of surface films have also been investigated. Surface films one molecule thick are called **monolayers**. When a monolayer has been transferred to a solid support, it is called a **Langmuir–Blodgett film**, after Irving Langmuir and Katherine Blodgett, who developed experimental techniques for studying them.

### (a) Surface pressure

The principal apparatus used for the study of surface monolayers is a **surface film balance** (Fig. 17.27). This device consists of a shallow trough and a barrier that can be moved along the surface of the liquid in the trough, and hence compress any monolayer on the surface. The **surface pressure**,  $\pi$ , the difference between the surface tension of the pure solvent and the solution ( $\pi = \gamma^* - \gamma$ ) is measured by using a torsion wire attached to a strip of mica that rests on the surface and pressing against one edge of the monolayer. The parts of the apparatus that are in touch with liquids are coated in polytetrafluoroethene to eliminate effects arising from the liquid–solid interface. In an actual experiment, a small amount (about 0.01 mg) of the surfactant under investigation is dissolved in a volatile solvent and then poured on to the surface of the water; the compression barrier is then moved across the surface and the surface pressure exerted on the mica bar is monitored.

**Fig. 17.27** A schematic diagram of the apparatus used to measure the surface pressure and other characteristics of a surface film. The surfactant is spread on the surface of the liquid in the trough, and then compressed horizontally by moving the compression barrier towards the mica float. The latter is connected to a torsion wire, so the difference in force on either side of the float can be monitored.

**Fig. 17.28** The variation of surface pressure with the area occupied by each surfactant molecule. The collapse pressures are indicated by the horizontal arrow.

Some typical results are shown in Fig. 17.28. One parameter obtained from the isotherms is the area occupied by the molecules when the monolayer is closely packed. This quantity is obtained from the extrapolation of the steepest part of the isotherm to the horizontal axis. As can be seen from the illustration, even though stearic acid (15) and isostearic acid (16) are chemically very similar (they differ only in the location of a methyl group at the end of a long hydrocarbon chain), they occupy significantly different areas in the monolayer. Neither, though, occupies as much area as the tri-*p*-cresyl phosphate molecule (17), which is like a wide bush rather than a lanky tree.

The second feature to note from Fig. 17.28 is that the tri-*p*-cresyl phosphate isotherm is much less steep than the stearic acid isotherms. This difference indicates that the tri-*p*-cresyl phosphate film is more compressible than the stearic acid films, which is consistent with their different molecular structures.

A third feature of the isotherms is the **collapse pressure**, the highest surface pressure. When the monolayer is compressed beyond the point represented by the collapse pressure, the monolayer buckles and collapses into a film several molecules thick. As can be seen from the isotherms in Fig. 17.28, stearic acid has a high collapse pressure, but that of tri-*p*-cresyl phosphate is significantly smaller, indicating a much weaker film.

### (b) The thermodynamics of surface layers

A **surfactant** is a species that is active at the interface between two phases, such as at the interface between hydrophilic and hydrophobic phases. A surfactant accumulates at the interface, and modifies its surface tension and hence the surface pressure. To establish the relation between the concentration of surfactant at a surface and the change in surface tension it brings about, we consider two phases  $\alpha$  and  $\beta$  in contact and suppose that the system consists of several components  $J$ , each one present in an overall amount  $n_J$ . If the components were distributed uniformly through the two phases right up to the interface, which is taken to be a plane of surface area  $\sigma$ , the total Gibbs energy,  $G$ , would be the sum of the Gibbs energies of both phases,  $G = G(\alpha) + G(\beta)$ . However, the components are not uniformly distributed because one may accumulate at the interface. As a result, the sum of the two Gibbs energies differs from  $G$  by an amount called the **surface Gibbs energy**,  $G(\sigma)$ :

$$G(\sigma) = G - \{G(\alpha) + G(\beta)\}$$

Definition of surface  
Gibbs energy

[17.45]

Similarly, if it is supposed that the concentration of a species  $J$  is uniform right up to the interface, then from its volume we would conclude that it contains an amount  $n_J(\alpha)$  of  $J$  in phase  $\alpha$  and an amount  $n_J(\beta)$  in phase  $\beta$ . However, because a species may accumulate at the interface, the total amount of  $J$  differs from the sum of these two

**15** Stearic acid,  
 $C_{17}H_{35}COOH$

**16** Isostearic acid,  
 $C_{17}H_{35}COOH$

**17** Tri-*p*-cresylphosphate

amounts by  $n_j(\sigma) = n_j - \{n_j(\alpha) + n_j(\beta)\}$ . This difference is expressed in terms of the **surface excess**,  $\Gamma_j$ :

$$\Gamma_j = \frac{n_j(\sigma)}{\sigma} \quad \begin{array}{|l|} \hline \text{Definition of} \\ \text{surface excess} \\ \hline \end{array} \quad [17.46]$$

The surface excess may be either positive (an accumulation of J at the interface) or negative (a deficiency there).

The relation between the change in surface tension and the composition of a surface (as expressed by the surface excess) was derived by Gibbs. In the following *Justification* we derive the **Gibbs isotherm**, between the changes in the chemical potentials of the substances present in the interface and the change in surface tension:

$$d\gamma = - \sum_j \Gamma_j d\mu_j \quad \begin{array}{|l|} \hline \text{Gibbs isotherm} \\ \hline \end{array} \quad (17.47)$$

**Justification 17.7** *The Gibbs isotherm*

A general change in  $G$  is brought about by changes in  $T$ ,  $p$ , and the  $n_j$ :

$$dG = -SdT + Vdp + \gamma d\sigma + \sum_j \mu_j dn_j$$

When this relation is applied to  $G$ ,  $G(\alpha)$ , and  $G(\beta)$  we find

$$dG(\sigma) = -S(\sigma)dT + \gamma d\sigma + \sum_j \mu_j dn_j(\sigma)$$

because at equilibrium the chemical potential of each component is the same in every phase,  $\mu_j(\alpha) = \mu_j(\beta) = \mu_j(\sigma)$ . Just as in the discussion of partial molar quantities (Section 5.1), the last equation integrates at constant temperature to

$$G(\sigma) = \gamma\sigma + \sum_j \mu_j n_j(\sigma)$$

We are seeking a connection between the change of surface tension  $d\gamma$  and the change of composition at the interface. Therefore, we use the argument that in Section 5.1 led to the Gibbs–Duhem equation (eqn 5.12b), but this time we compare the expression

$$dG(\sigma) = \gamma d\sigma + \sum_j \mu_j dn_j(\sigma)$$

(which is valid at constant temperature) with the expression for the same quantity but derived from the preceding equation:

$$dG(\sigma) = \gamma d\sigma + \sigma d\gamma + \sum_j \mu_j dn_j(\sigma) + \sum_j n_j(\sigma) d\mu_j$$

The comparison implies that, at constant temperature,

$$\sigma d\gamma + \sum_j n_j(\sigma) d\mu_j = 0$$

Division by  $\sigma$  then gives eqn 17.47.

Now consider a simplified model of the interface in which the ‘oil’ and ‘water’ phases are separated by a geometrically flat surface. This approximation implies that only the surfactant, S, accumulates at the surface, and hence that  $\Gamma_{\text{oil}}$  and  $\Gamma_{\text{water}}$  are both zero. Then the Gibbs isotherm equation becomes

$$d\gamma = -\Gamma_S d\mu_S \quad (17.48)$$

For dilute solutions,

$$d\mu_s = RT \ln c \quad (17.49)$$

where  $c$  is the molar concentration of the surfactant. It follows that

$$d\gamma = -RT\Gamma_s \frac{dc}{c}$$

at constant temperature, or

$$\left( \frac{\partial \gamma}{\partial c} \right)_T = -\frac{RT\Gamma_s}{c} \quad (17.50)$$

If the surfactant accumulates at the interface, its surface excess is positive and eqn 17.50 implies that  $(\partial\gamma/\partial c)_T < 0$ . That is, the surface tension decreases when a solute accumulates at a surface. Conversely, if the concentration dependence of  $\gamma$  is known, then the surface excess may be predicted and used to infer the area occupied by each surfactant molecule on the surface.

### 17.10 Condensation

**Key point** Nucleation provides surfaces to which molecules can attach and thereby induce condensation.

We now bring together concepts from this chapter and Chapter 4 to explain the condensation of a gas to a liquid. We saw in Section 4.4 that the vapour pressure of a liquid depends on the pressure applied to the liquid. Because curving a surface gives rise to a pressure differential of  $2\gamma/r$ , we can expect the vapour pressure above a curved surface to be different from that above a flat surface. By substituting this value of the pressure difference into eqn 4.4 ( $p = p^* e^{V_m \Delta P / RT}$ , where  $p^*$  is the vapour pressure when the pressure difference is zero) we obtain the **Kelvin equation** for the vapour pressure of a liquid when it is dispersed as droplets of radius  $r$ :

$$p = p^* e^{2\gamma V_m / rRT} \quad \text{Kelvin equation} \quad (17.51)$$

The analogous expression for the vapour pressure inside a cavity can be written at once. The pressure of the liquid outside the cavity is less than the pressure inside, so the only change is in the sign of the exponent in the last expression.

For droplets of water of radius 1  $\mu\text{m}$  and 1 nm the ratios  $p/p^*$  at 25°C are about 1.001 and 3, respectively. The second figure, although quite large, is unreliable because at that radius the droplet is less than about 10 molecules in diameter and the basis of the calculation is suspect. The first figure shows that the effect is usually small; nevertheless it may have important consequences.

Consider, for example, the formation of a cloud. Warm, moist air rises into the cooler regions higher in the atmosphere. At some altitude the temperature is so low that the vapour becomes thermodynamically unstable with respect to the liquid and we expect it to condense into a cloud of liquid droplets. The initial step can be imagined as a swarm of water molecules congregating into a microscopic droplet. Because the initial droplet is so small it has an enhanced vapour pressure. Therefore, instead of growing it evaporates. This effect stabilizes the vapour because an initial tendency to condense is overcome by a heightened tendency to evaporate. The vapour phase is then said to be **super-saturated**. It is thermodynamically unstable with respect to the liquid but not unstable with respect to the small droplets that need to form before the bulk liquid phase can appear, so the formation of the latter by a simple, direct mechanism is hindered.

Clouds do form, so there must be a mechanism. Two processes are responsible. The first is that a sufficiently large number of molecules might congregate into a droplet so big that the enhanced evaporative effect is unimportant. The chance of one of these **spontaneous nucleation centres** forming is low, and in rain formation it is not a dominant mechanism. The more important process depends on the presence of minute dust particles or other kinds of foreign matter. These **nucleate** the condensation (that is, provide centres at which it can occur) by providing surfaces to which the water molecules can attach.

Liquids may be **superheated** above their boiling temperatures and **supercooled** below their freezing temperatures. In each case the thermodynamically stable phase is not achieved on account of the kinetic stabilization that occurs in the absence of nucleation centres. For example, superheating occurs because the vapour pressure inside a cavity is artificially low, so any cavity that does form tends to collapse. This instability is encountered when an unstirred beaker of water is heated, for its temperature may be raised above its boiling point. Violent bumping often ensues as spontaneous nucleation leads to bubbles big enough to survive. To ensure smooth boiling at the true boiling temperature, nucleation centres, such as small pieces of sharp-edged glass or bubbles (cavities) of air, should be introduced.

## Checklist of key equations

| Property                                                                  | Equation                                                                                | Comment                                                                         |

## Further information

### Further information 17.1 The dipole–dipole interaction

An important problem in physical chemistry is the calculation of the potential energy of interaction between two point dipoles with moments  $\mu_1$  and  $\mu_2$ , separated by a vector  $r$ . From classical electromagnetic theory, the potential energy of  $\mu_2$  in the electric field  $\mathcal{E}_1$  generated by  $\mu_1$  is given by the dot (scalar) product

$$V = -\mathcal{E}_1 \cdot \mu_2 \quad (17.52)$$

To calculate  $\mathcal{E}_1$ , we consider a distribution of point charges  $Q_i$  located at  $x_i, y_i$ , and  $z_i$  from the origin. The Coulomb potential  $\phi$  due to this distribution at a point with coordinates  $x, y$ , and  $z$  is:

$$\phi = \sum_i \frac{Q_i}{4\pi\epsilon_0} \frac{1}{\{(x-x_i)^2 + (y-y_i)^2 + (z-z_i)^2\}^{1/2}} \quad (17.53)$$

where  $r$  is the location of the point of interest and the  $r_i$  are the locations of the charges  $Q_i$ .

### A brief comment

The potential energy of a charge  $Q_1$  in the presence of another charge  $Q_2$  may be written as  $V = Q_1\phi$  where  $\phi = Q_2/4\pi\epsilon_0 r$  is the Coulomb potential (Fundamentals F.6). If there are several charges  $Q_2, Q_3, \dots$  present in the system, then the total potential experienced by the charge  $Q_1$  is the sum of the potential generated by each charge:  $\phi = \phi_2 + \phi_3 + \dots$ . The electric field strength is the negative gradient of the electric potential:  $\mathcal{E} = -\nabla\phi$ .

If we suppose that all the charges are close to the origin (in the sense that  $r_i \ll r$ ), we can use a Taylor expansion to write

$$\begin{aligned} \phi(r) &= \sum_i \frac{Q_i}{4\pi\epsilon_0} \left\{ \frac{1}{r} + \left( \frac{\partial\{(x-x_i)^2 + (y-y_i)^2 + (z-z_i)^2\}^{1/2}}{\partial x_i} \right)_{x_i=0} x_i + \dots \right\} \\ &= \sum_i \frac{Q_i}{4\pi\epsilon_0} \left\{ \frac{1}{r} + \frac{xx_i}{r^3} + \dots \right\} \end{aligned} \quad (17.54)$$

where the ellipses include the terms arising from derivatives with respect to  $y_i$  and  $z_i$  and higher derivatives. If the charge distribution is electrically neutral, the first term disappears because  $\sum_i Q_i = 0$ . Next we note that,  $\sum_i Q_i x_i = \mu_x$  and likewise for the  $y$ - and  $z$ -components. That is,

$$\phi = \frac{1}{4\pi\epsilon_0 r^3} (\mu_x x + \mu_y y + \mu_z z) = \frac{1}{4\pi\epsilon_0 r^3} \mu_1 \cdot r \quad (17.55)$$

The electric field strength is

$$\mathcal{E}_1 = \frac{1}{4\pi\epsilon_0} \nabla \frac{\mu_1 \cdot r}{r^3} = -\frac{\mu_1}{4\pi\epsilon_0 r^3} - \frac{\mu_1 \cdot r}{4\pi\epsilon_0} \nabla \frac{1}{r^3} \quad (17.56)$$

It follows from eqns 17.52 and 17.56 that

$$V = \frac{\mu_1 \cdot \mu_2}{4\pi\epsilon_0 r^3} - 3 \frac{(\mu_1 \cdot r)(\mu_2 \cdot r)}{4\pi\epsilon_0 r^5} \quad (17.57)$$

For the arrangement shown in (13), in which  $\mu_1 \cdot r = \mu_1 r \cos \theta$  and  $\mu_2 \cdot r = \mu_2 r \cos \theta$ , eqn 17.57 becomes:

$$V = \frac{\mu_1 \mu_2 f(\theta)}{4\pi\epsilon_0 r^3} \quad f(\theta) = 1 - 3 \cos^2 \theta \quad (17.58)$$

which is eqn 17.22.

### Further information 17.2 The basic principles of molecular beams

The basic arrangement for a molecular beam experiment is shown in Fig. 17.29. If the pressure of vapour in the source is increased so that the mean free path of the molecules in the emerging beam is much shorter than the diameter of the pinhole, many collisions take place even outside the source. The net effect of these collisions, which give rise to **hydrodynamic flow**, is to transfer momentum into the direction of the beam. The molecules in the beam then travel with very similar speeds, so further downstream few collisions take place between them. This condition is called **molecular flow**. Because the spread in speeds is so small, the molecules are effectively in a state of very low translational temperature (Fig. 17.30). The translational

**Fig. 17.29** The basic arrangement of a molecular beam apparatus. The atoms or molecules emerge from a heated source, and pass through the velocity selector, a rotating slotted cylinder. The scattering occurs from the target gas (which might take the form of another beam), and the flux of particles entering the detector set at some angle is recorded.

**Fig. 17.30** The shift in the mean speed and the width of the distribution brought about by use of a supersonic nozzle.

**Fig. 17.31** A supersonic nozzle skims off some of the molecules of the beam and leads to a beam with well defined velocity.

temperature may reach as low as 1 K. Such jets are called **supersonic** because the average speed of the molecules in the jet is much greater than the speed of sound in the jet.

A supersonic jet can be converted into a more parallel **supersonic beam** if it is 'skimmed' in the region of hydrodynamic flow and the excess gas pumped away. A skimmer consists of a conical nozzle shaped to avoid any supersonic shock waves spreading back into the gas and so increasing the translational temperature (Fig. 17.31). A jet or beam may also be formed by using helium or neon as the principal

gas, and injecting molecules of interest into it in the hydrodynamic region of flow.

The low translational temperature of the molecules is reflected in the low rotational and vibrational temperatures of the molecules. In this context, a rotational or vibrational temperature means the temperature that should be used in the Boltzmann distribution to reproduce the observed populations of the states. However, as rotational modes equilibrate more slowly, and vibrational modes equilibrate even more slowly, the rotational and vibrational populations of the species correspond to somewhat higher temperatures, of the order of 10 K for rotation and 100 K for vibrations.

The target gas may be either a bulk sample or another molecular beam. The latter **crossed beam technique** gives a lot of information because the states of both the target and projectile molecules may be controlled. The intensity of the incident beam is measured by the **incident beam flux**,  $I$ , which is the number of particles passing through a given area in a given interval divided by the area and the duration of the interval.

The detectors may consist of a chamber fitted with a sensitive pressure gauge, a bolometer (a detector that responds to the incident energy by making use of the temperature dependence of resistance), or an ionization detector, in which the incoming molecule is first ionized and then detected electronically. The state of the scattered molecules may also be determined spectroscopically, and is of interest when the collisions change their vibrational or rotational states.

## Discussion questions

- 17.1** Explain how the permanent dipole moment and the polarizability of a molecule arise.
- 17.2** Explain why the polarizability of a molecule decreases at high frequencies.
- 17.3** Describe the experimental procedures available for determining the electric dipole moment of a molecule.
- 17.4** Identify the terms in and limit the generality of the following expressions: (a)  $V = -Q_2\mu_1/4\pi\epsilon_0 r^2$ , (b)  $V = -Q_2\mu_1 \cos \theta / 4\pi\epsilon_0 r^2$ , and (c)  $V = \mu_2\mu_1(1 - 3 \cos^2 \theta) / 4\pi\epsilon_0 r^3$ .
- 17.5** Draw examples of the arrangement of electrical charges that correspond to a monopole, dipole, quadrupole, and octupole and suggest a reason for the different distance dependencies of their electric fields.
- 17.6** Account for the theoretical conclusion that many attractive interactions between molecules vary with their separation as  $1/r^6$ .
- 17.7** Describe the formation of a hydrogen bond in terms of molecular orbitals. How does this description relate to one in terms of electrostatic interactions between partial charges?
- 17.8** Account for the hydrophobic interaction and discuss its manifestations.
- 17.9** Describe the process of condensation.
- 17.10** Describe how molecular beams are used to investigate intermolecular potentials.

## Exercises

- 17.1(a)** Which of the following molecules may be polar:  $\text{ClF}_3$ ,  $\text{O}_3$ ,  $\text{H}_2\text{O}_2$ ?
- 17.1(b)** Which of the following molecules may be polar:  $\text{SO}_3$ ,  $\text{XeF}_4$ ,  $\text{SF}_4$ ?
- 17.2(a)** Calculate the resultant of two dipole moments of magnitude 1.5 D and 0.80 D that make an angle of  $109.5^\circ$  to each other.
- 17.2(b)** Calculate the resultant of two dipole moments of magnitude 2.5 D and 0.50 D that make an angle of  $120^\circ$  to each other.
- 17.3(a)** Calculate the magnitude and direction of the dipole moment of the following arrangement of charges in the  $xy$ -plane:  $3e$  at  $(0,0)$ ,  $-e$  at  $(0.32 \text{ nm}, 0)$ , and  $-2e$  at an angle of  $20^\circ$  from the  $x$ -axis and a distance of  $0.23 \text{ nm}$  from the origin.
- 17.3(b)** Calculate the magnitude and direction of the dipole moment of the following arrangement of charges in the  $xy$ -plane:  $4e$  at  $(0,0)$ ,  $-2e$  at  $(162 \text{ pm}, 0)$ , and  $-2e$  at an angle of  $30^\circ$  from the  $x$ -axis and a distance of  $143 \text{ pm}$  from the origin.

**17.4(a)** Calculate the molar energy required to reverse the direction of an  $\text{H}_2\text{O}$  molecule located 100 pm from a  $\text{Li}^+$  ion. Take the dipole moment of water as 1.85 D.

**17.4(b)** Calculate the molar energy required to reverse the direction of an  $\text{HCl}$  molecule located 300 pm from a  $\text{Mg}^{2+}$  ion. Take the dipole moment of  $\text{HCl}$  as 1.08 D.

**17.5(a)** The polarizability volume of  $\text{H}_2\text{O}$  is  $1.48 \times 10^{-24} \text{ cm}^3$ ; calculate the dipole moment of the molecule (in addition to the permanent dipole moment) induced by an applied electric field of strength  $1.0 \text{ kV cm}^{-1}$ .

**17.5(b)** The polarizability volume of  $\text{NH}_3$  is  $2.22 \times 10^{-30} \text{ m}^3$ ; calculate the dipole moment of the molecule (in addition to the permanent dipole moment) induced by an applied electric field of strength  $15.0 \text{ kV m}^{-1}$ .

**17.6(a)** The molar polarization of fluorobenzene vapour varies linearly with  $T^{-1}$ , and is  $70.62 \text{ cm}^3 \text{ mol}^{-1}$  at 351.0 K and  $62.47 \text{ cm}^3 \text{ mol}^{-1}$  at 423.2 K. Calculate the polarizability and dipole moment of the molecule.

**17.6(b)** The molar polarization of the vapour of a compound was found to vary linearly with  $T^{-1}$ , and is  $75.74 \text{ cm}^3 \text{ mol}^{-1}$  at 320.0 K and  $71.43 \text{ cm}^3 \text{ mol}^{-1}$  at 421.7 K. Calculate the polarizability and dipole moment of the molecule.

**17.7(a)** At  $0^\circ\text{C}$ , the molar polarization of liquid chlorine trifluoride is  $27.18 \text{ cm}^3 \text{ mol}^{-1}$  and its density is  $1.89 \text{ g cm}^{-3}$ . Calculate the relative permittivity of the liquid.

**17.7(b)** At  $0^\circ\text{C}$ , the molar polarization of a liquid is  $32.16 \text{ cm}^3 \text{ mol}^{-1}$  and its density is  $1.92 \text{ g cm}^{-3}$ . Calculate the relative permittivity of the liquid. Take  $M = 55.0 \text{ g mol}^{-1}$ .

**17.8(a)** The refractive index of  $\text{CH}_2\text{I}_2$  is 1.732 for 656 nm light. Its density at  $20^\circ\text{C}$  is  $3.32 \text{ g cm}^{-3}$ . Calculate the polarizability of the molecule at this wavelength.

**17.8(b)** The refractive index of a compound is 1.622 for 643 nm light. Its density at  $20^\circ\text{C}$  is  $2.99 \text{ g cm}^{-3}$ . Calculate the polarizability of the molecule at this wavelength. Take  $M = 65.5 \text{ g mol}^{-1}$ .

**17.9(a)** The polarizability volume of  $\text{H}_2\text{O}$  at optical frequencies is  $1.5 \times 10^{-24} \text{ cm}^3$ ; estimate the refractive index of water. The experimental value is 1.33; what may be the origin of the discrepancy?

**17.9(b)** The polarizability volume of a liquid of molar mass  $72.3 \text{ g mol}^{-1}$  and density  $865 \text{ kg mol}^{-1}$  at optical frequencies is  $2.2 \times 10^{-30} \text{ m}^3$ ; estimate the refractive index of the liquid.

**17.10(a)** The dipole moment of chlorobenzene is 1.57 D and its polarizability volume is  $1.23 \times 10^{-23} \text{ cm}^3$ . Estimate its relative permittivity at  $25^\circ\text{C}$ , when its density is  $1.173 \text{ g cm}^{-3}$ .

**17.10(b)** The dipole moment of bromobenzene is  $5.17 \times 10^{-30} \text{ C m}$  and its polarizability volume is approximately  $1.5 \times 10^{-19} \text{ m}^3$ . Estimate its relative permittivity at  $25^\circ\text{C}$ , when its density is  $1491 \text{ kg m}^{-3}$ .

**17.11(a)** Estimate the energy of the dispersion interaction (use the London formula) for two He atoms separated by 1.0 nm. Relevant data can be found in the *Data section*.

**17.11(b)** Estimate the energy of the dispersion interaction (use the London formula) for two Ar atoms separated by 1.0 nm. Relevant data can be found in the *Data section*.

**17.12(a)** How much energy (in  $\text{kJ mol}^{-1}$ ) is required to break the hydrogen bond in a vacuum ( $\epsilon_r = 1$ )? (Use the electrostatic model of the hydrogen bond.)

**17.12(b)** How much energy (in  $\text{kJ mol}^{-1}$ ) is required to break the hydrogen bond in water ( $\epsilon_r \approx 80.0$ )? Use the electrostatic model of the hydrogen bond.

**17.13(a)** Calculate the vapour pressure of a spherical droplet of water of radius 10 nm at  $20^\circ\text{C}$ . The vapour pressure of bulk water at that temperature is 2.3 kPa and its density is  $0.9982 \text{ g cm}^{-3}$ .

**17.13(b)** Calculate the vapour pressure of a spherical droplet of water of radius 20.0 nm at  $35.0^\circ\text{C}$ . The vapour pressure of bulk water at that temperature is 5.623 kPa and its density is  $994.0 \text{ kg m}^{-3}$ .

**17.14(a)** The contact angle for water on clean glass is close to zero. Calculate the surface tension of water at  $20^\circ\text{C}$  given that at that temperature water climbs to a height of 4.96 cm in a clean glass capillary tube of internal radius 0.300 mm. The density of water at  $20^\circ\text{C}$  is  $998.2 \text{ kg m}^{-3}$ .

**17.14(b)** The contact angle for water on clean glass is close to zero. Calculate the surface tension of water at  $30^\circ\text{C}$  given that at that temperature water climbs to a height of 9.11 cm in a clean glass capillary tube of internal radius 0.320 mm. The density of water at  $30^\circ\text{C}$  is  $0.9956 \text{ g cm}^{-3}$ .

**17.15(a)** Calculate the pressure differential of water across the surface of a spherical droplet of radius 200 nm at  $20^\circ\text{C}$ .

**17.15(b)** Calculate the pressure differential of ethanol across the surface of a spherical droplet of radius 220 nm at  $20^\circ\text{C}$ . The surface tension of ethanol at that temperature is  $22.39 \text{ mN m}^{-1}$ .

## Problems\*

### Numerical problems

**17.1** Suppose an  $\text{H}_2\text{O}$  molecule ( $\mu = 1.85 \text{ D}$ ) approaches an anion. What is the favourable orientation of the molecule? Calculate the electric field (in volts per metre) experienced by the anion when the water dipole is (a) 1.0 nm, (b) 0.3 nm, (c) 30 nm from the ion.

**17.2** The electric dipole moment of toluene (methylbenzene) is 0.4 D. Estimate the dipole moments of the three xylenes (dimethylbenzene). Which answer can you be sure about?

**17.3** Plot the magnitude of the electric dipole moment of hydrogen peroxide as the  $\text{H}-\text{O}-\text{O}-\text{H}$  (azimuthal) angle  $\phi$  changes from 0 to  $2\pi$ . Use the dimensions shown in (18).

18

**17.4** An  $\text{H}_2\text{O}$  molecule is aligned by an external electric field of strength  $1.0 \text{ kV m}^{-1}$  and an Ar atom ( $\alpha' = 1.66 \times 10^{-24} \text{ cm}^3$ ) is brought up slowly from one side. At what separation is it energetically favourable for the  $\text{H}_2\text{O}$  molecule to flip over and point towards the approaching Ar atom?

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp and Carmen Giunta.

**17.5** The relative permittivity of chloroform was measured over a range of temperatures with the following results:

| $\theta/^\circ\text{C}$   | -80  | -70  | -60  | -40  | -20  | 0    | 20   |
|---------------------------|------|------|------|------|------|------|------|
| $\epsilon$                | 3.1  | 3.1  | 7.0  | 6.5  | 6.0  | 5.5  | 5.0  |
| $\rho/(\text{g cm}^{-3})$ | 1.65 | 1.64 | 1.64 | 1.61 | 1.57 | 1.53 | 1.50 |

The freezing point of chloroform is  $-64^\circ\text{C}$ . Account for these results and calculate the dipole moment and polarizability volume of the molecule.

**17.6** The relative permittivities of methanol (m.p.  $-95^\circ\text{C}$ ) corrected for density variation are given below. What molecular information can be deduced from these values? Take  $\rho = 0.791 \text{ g cm}^{-3}$  at  $20^\circ\text{C}$ .

| $\theta/^\circ\text{C}$ | -185 | -170 | -150 | -140 | -110 | -80 | -50 | -20 | 0  | 20 |
|-------------------------|------|------|------|------|------|-----|-----|-----|----|----|
| $\epsilon_r$            | 3.2  | 3.6  | 4.0  | 5.1  | 67   | 57  | 49  | 43  | 38 | 34 |

**17.7** In his classic book *Polar molecules*, Debye reports some early measurements of the polarizability of ammonia. From the selection below, determine the dipole moment and the polarizability volume of the molecule.

| $T/\text{K}$                         | 292.2 | 309.0 | 333.0 | 387.0 | 413.0 | 446.0 |
|--------------------------------------|-------|-------|-------|-------|-------|-------|
| $P_m/(\text{cm}^3 \text{ mol}^{-1})$ | 57.57 | 55.01 | 51.22 | 44.99 | 42.51 | 39.59 |

The refractive index of ammonia at 273 K and 100 kPa is 1.000 379 (for yellow sodium light). Calculate the molar polarizability of the gas at this temperature and at 292.2 K. Combine the value calculated with the static molar polarizability at 292.2 K and deduce from this information alone the molecular dipole moment.

**17.8** Values of the molar polarization of gaseous water at 100 kPa as determined from capacitance measurements are given below as a function of temperature.

| $T/\text{K}$                         | 384.3 | 420.1 | 444.7 | 484.1 | 522.0 |
|--------------------------------------|-------|-------|-------|-------|-------|
| $P_m/(\text{cm}^3 \text{ mol}^{-1})$ | 57.4  | 53.5  | 50.1  | 46.8  | 43.1  |

Calculate the dipole moment of  $\text{H}_2\text{O}$  and its polarizability volume.

**17.9†** F. Luo *et al.* (*J. Chem. Phys.* **98**, 3564 (1993)) reported experimental observation of the  $\text{He}_2$  complex, a species that had escaped detection for a long time. The fact that the observation required temperatures in the neighbourhood of 1 mK is consistent with computational studies that suggest that  $hc\bar{D}_e$  for  $\text{He}_2$  is about  $1.51 \times 10^{-23} \text{ J}$ ,  $hc\bar{D}_0$  about  $2 \times 10^{-26} \text{ J}$ , and  $R$  about 297 pm. (a) Determine the Lennard-Jones parameters,  $r_0$  and  $\epsilon$ , and plot the Lennard-Jones potential for He–He interactions. (b) Plot the Morse potential given that  $a = 5.79 \times 10^{10} \text{ m}^{-1}$ .

**17.10†** D.D. Nelson *et al.* (*Science* **238**, 1670 (1987)) examined several weakly bound gas-phase complexes of ammonia in search of examples in which the H atoms in  $\text{NH}_3$  formed hydrogen bonds, but found none. For example, they found that the complex of  $\text{NH}_3$  and  $\text{CO}_2$  has the carbon atom nearest the nitrogen (299 pm away): the  $\text{CO}_2$  molecule is at right angles to the C–N ‘bond’, and the H atoms of  $\text{NH}_3$  are pointing away from the  $\text{CO}_2$ . The permanent dipole moment of this complex is reported as 1.77 D. If the N and C atoms are the centres of the negative and positive charge distributions, respectively, what is the magnitude of those partial charges (as multiples of  $e$ )?

**17.11†** From data in Table 17.1 calculate the molar polarization, relative permittivity, and refractive index of methanol at  $20^\circ\text{C}$ . Its density at that temperature is  $0.7914 \text{ g cm}^{-3}$ .

**17.12** The surface tensions of a series of aqueous solutions of a surfactant A were measured at  $20^\circ\text{C}$ , with the following results:

| $[A]/(\text{mol dm}^{-3})$  | 0    | 0.10 | 0.20 | 0.30 | 0.40 | 0.50 |
|-----------------------------|------|------|------|------|------|------|
| $\gamma/(\text{mN m}^{-1})$ | 72.8 | 70.2 | 67.7 | 65.1 | 62.8 | 59.8 |

Calculate the surface excess concentration.

## Theoretical problems

**17.13** Calculate the potential energy of the interaction between two linear quadrupoles when they are (a) collinear, (b) parallel and separated by a distance  $r$ .

**17.14** Show that, in a gas (for which the refractive index is close to 1), the refractive index depends on the pressure as  $n_r = 1 + \text{const} \times p$ , and find the constant of proportionality. Go on to show how to deduce the polarizability volume of a molecule from measurements of the refractive index of a gaseous sample.

**17.15** Acetic acid vapour contains a proportion of planar, hydrogen-bonded dimers. The relative permittivity of pure liquid acetic acid is 7.14 at 290 K and increases with increasing temperature. Suggest an interpretation of the latter observation. What effect should isothermal dilution have on the relative permittivity of solutions of acetic acid in benzene?

**17.16** Show that the mean interaction energy of  $N$  atoms of diameter  $d$  interacting with a potential energy of the form  $C_6/R^6$  is given by  $U = -2N^2C_6/3Vd^3$ , where  $V$  is the volume in which the molecules are confined and all effects of clustering are ignored. Hence, find a connection between the van der Waals parameter  $a$  and  $C_6$ , from  $n^2dV^2 = (\partial U/\partial V)_T$ .

**17.17** Suppose the repulsive term in a Lennard-Jones (12,6)-potential is replaced by an exponential function of the form  $e^{-r/d}$ . Sketch the form of the potential energy and locate the distance at which it is a minimum.

**17.18** The *cohesive energy density*,  $\mathcal{U}$ , is defined as  $U/V$ , where  $U$  is the mean potential energy of attraction within the sample and  $V$  its volume. Show that  $\mathcal{U} = \frac{1}{2}\mathcal{N}\int V(R)d\tau$ , where  $\mathcal{N}$  is the number density of the molecules and  $V(R)$  is their attractive potential energy and where the integration ranges from  $d$  to infinity and over all angles. Go on to show that the cohesive energy density of a uniform distribution of molecules that interact by a van der Waals attraction of the form  $-C_6/R^6$  is equal to  $(2\pi/3)(N_A^2/d^3M^2)\rho^2C_6$ , where  $\rho$  is the mass density of the solid sample and  $M$  is the molar mass of the molecules.

**17.19** Consider the collision between a hard-sphere molecule of radius  $R_1$  and mass  $m$ , and an infinitely massive impenetrable sphere of radius  $R_2$ . Plot the scattering angle  $\theta$  as a function of the impact parameter  $b$ . Carry out the calculation using simple geometrical considerations.

**17.20** The dependence of the scattering characteristics of atoms on the energy of the collision can be modelled as follows. We suppose that the two colliding atoms behave as impenetrable spheres, as in Problem 17.19, but that the effective radius of the heavy atoms depends on the speed  $v$  of the light atom. Suppose its effective radius depends on  $v$  as  $R_2e^{-v/v^*}$ , where  $v^*$  is a constant. Take  $R_1 = \frac{1}{2}R_2$  for simplicity and an impact parameter  $b = \frac{1}{2}R_2$ , and plot the scattering angle as a function of (a) speed, (b) kinetic energy of approach.

## Applications: to biochemistry

**17.21** Phenylalanine (Phe, 19) is a naturally occurring amino acid. What is the energy of interaction between its phenyl group and the electric dipole moment of a neighbouring peptide group? Take the distance between the groups as 4.0 nm and treat the phenyl group as a benzene molecule. The dipole moment of the peptide group is  $\mu = 2.7 \text{ D}$  and the polarizability volume of benzene is  $\alpha' = 1.04 \times 10^{-29} \text{ m}^3$ .

**17.22** Now consider the London interaction between the phenyl groups of two Phe residues (see Problem 17.21). (a) Estimate the potential energy of interaction between two such rings (treated as benzene molecules) separated by 4.0 nm. For the ionization energy, use  $I = 5.0$  eV. (b) Given that force is the negative slope of the potential, calculate the distance dependence of the force acting between two nonbonded groups of atoms, such as the phenyl groups of Phe, in a polypeptide chain that can have a London dispersion interaction with each other. What is the separation at which the force between the phenyl groups (treated as benzene molecules) of two Phe residues is zero? (*Hint*. Calculate the slope by considering the potential energy at  $r$  and  $r + \delta r$ , with  $\delta r \ll r$ , and evaluating  $\{V(r + \delta r) - V(r)\}/\delta r$ . At the end of the calculation, let  $\delta r$  become vanishingly small).

**17.23** Molecular orbital calculations may be used to predict structures of intermolecular complexes. Hydrogen bonds between purine and pyrimidine bases are responsible for the double helix structure of DNA (see Chapter 18). Consider methyl-adenine (20, with  $R = \text{CH}_3$ ) and methyl-thymine (21, with  $R = \text{CH}_3$ ) as models of two bases that can form hydrogen bonds in DNA. (a) Using molecular modelling software and the computational method of your choice, calculate the atomic charges of all atoms in methyl-adenine and methyl-thymine. (b) Based on your tabulation of atomic charges, identify the atoms in methyl-adenine and methyl-thymine that are likely to participate in hydrogen bonds. (c) Draw all possible adenine–thymine pairs that can be linked by hydrogen bonds, keeping in mind that linear arrangements of the  $\text{A} \cdots \text{H} \cdots \text{B}$  fragments are preferred in DNA. For this step, you may want to use your molecular modelling software to align the molecules properly. (d) Consult Chapter 18 and determine which of the pairs that you drew in part (c) occur naturally in DNA molecules. (e) Repeat parts (a)–(d) for cytosine and guanine, which also form base pairs in DNA (see Chapter 18 for the structures of these bases).

**17.24** Molecular orbital calculations may be used to predict the dipole moments of molecules. (a) Using molecular modelling software and the computational method of your choice, calculate the dipole moment of the peptide link, modelled as a *trans*-*N*-methylacetamide (22). Plot the energy of interaction between these dipoles against the angle  $\theta$  for  $r = 3.0$  nm (see eqn 17.22). (b) Compare the maximum value of the dipole–dipole interaction energy from part (a) to  $20 \text{ kJ mol}^{-1}$ , a typical value for the energy of a hydrogen bonding interaction in biological systems.

**17.25** This problem gives a simple example of a quantitative structure–activity relation (QSAR). The binding of nonpolar groups of amino acid to hydrophobic sites in the interior of proteins is governed largely by hydrophobic interactions. (a) Consider a family of hydrocarbons  $\text{R}-\text{H}$ . The hydrophobicity constants,  $\pi$ , for  $\text{R} = \text{CH}_3$ ,  $\text{CH}_2\text{CH}_3$ ,  $(\text{CH}_2)_2\text{CH}_3$ ,  $(\text{CH}_2)_3\text{CH}_3$ , and  $(\text{CH}_2)_4\text{CH}_3$  are, respectively, 0.5, 1.0, 1.5, 2.0, and 2.5. Use these data to predict the  $\pi$  value for  $(\text{CH}_2)_6\text{CH}_3$ . (b) The equilibrium constants  $K_1$  for the dissociation of inhibitors (23) from the enzyme chymotrypsin were measured for different substituents  $\text{R}$ :

| R          | $\text{CH}_3\text{CO}$ | CN     | $\text{NO}_2$ | $\text{CH}_3$ | Cl    |
|------------|------------------------|--------|---------------|---------------|-------|
| $\pi$      | −0.20                  | −0.025 | 0.33          | 0.5           | 0.9   |
| $\log K_1$ | −1.73                  | −1.90  | −2.43         | −2.55         | −3.40 |

Plot  $\log K_1$  against  $\pi$ . Does the plot suggest a linear relationship? If so, what are the slope and intercept to the  $\log K_1$  axis of the line that best fits the data?

(c) Predict the value of  $K_1$  for the case  $\text{R} = \text{H}$ .

**17.26** Derivatives of the compound TIBO (24) inhibit the enzyme reverse transcriptase, which catalyses the conversion of retroviral RNA to DNA. A QSAR analysis of the activity  $A$  of a number of TIBO derivatives suggests the following equation:

$$\log A = b_0 + b_1 S + b_2 W$$

where  $S$  is a parameter related to the drug's solubility in water and  $W$  is a parameter related to the width of the first atom in a substituent  $\text{X}$  shown in 24. (a) Use the following data to determine the values of  $b_0$ ,  $b_1$ , and  $b_2$ . *Hint*. The QSAR equation relates one dependent variable,  $\log A$ , to two independent variables,  $S$  and  $W$ . To fit the data, you must use the mathematical procedure of *multiple regression*, which can be performed with mathematical software or an electronic spreadsheet.

| X        | H    | Cl   | $\text{SCH}_3$ | $\text{OCH}_3$ | CN   | CHO  | Br   | $\text{CH}_3$ | CCH  |
|----------|------|------|----------------|----------------|------|------|------|---------------|------|
| $\log A$ | 7.36 | 8.37 | 8.3            | 7.47           | 7.25 | 6.73 | 8.52 | 7.87          | 7.53 |
| $S$      | 3.53 | 4.24 | 4.09           | 3.45           | 2.96 | 2.89 | 4.39 | 4.03          | 3.80 |
| $W$      | 1.00 | 1.80 | 1.70           | 1.35           | 1.60 | 1.60 | 1.95 | 1.60          | 1.60 |

(b) What should be the value of  $W$  for a drug with  $S = 4.84$  and  $\log A = 7.60$ ?

# Materials 1: macromolecules and self-assembly

Atoms, small molecules, and macromolecules can form large assemblies, sometimes by processes involving self-assembly, that are held together by one or more of the molecular interactions described in Chapter 17. Macromolecules, although built from covalently linked components, adopt shapes that are governed by these interactions. We consider a range of structures in this chapter, beginning with a structureless random coil, partially structured coils, and then the structurally precise forces that operate in polypeptides and nucleic acids. We go on to explore colloids, micelles, and biological membranes, which are assemblies with some of the typical properties of molecules but also with their own characteristic features. Macromolecules, whether natural or synthetic, need to be characterized in terms of their molar mass, their size, and their shape and we conclude the chapter by considering how these features are determined experimentally.

There are macromolecules everywhere, inside us and outside us. Some are natural: they include polysaccharides such as cellulose, polypeptides such as protein enzymes, and polynucleotides such as deoxyribonucleic acid (DNA). Others are synthetic: they include **polymers** such as nylon and polystyrene that are manufactured by stringing together and (in some cases) cross-linking smaller units known as **monomers**. Molecules both large and small may also gather together in a process that is called ‘self-assembly’ and give rise to aggregates that to some extent behave like macromolecules. One example is the assembly of the protein actin into filaments in muscle tissue. Solutions of macromolecules are examples of a large class of systems known as ‘colloids’ that consist of a stable dispersion of one finely divided material in another.

Macromolecules and aggregates give rise to special problems that include the investigation and description of their shapes, the determination of their sizes, and the large deviations from ideality of their solutions. Natural macromolecules differ in certain respects from synthetic macromolecules, particularly in their composition and the resulting structure, but the two share a number of common properties. We concentrate on these common properties here.

## Structure and dynamics

The concept of the ‘structure’ of a macromolecule takes on different meanings at the different levels at which we think about the arrangement of the chain or network of monomers. The term **configuration** refers to the structural features that can be changed only by breaking chemical bonds and forming new ones. Thus, the chains  $-A-B-C-$  and  $-A-C-B-$  have different configurations. The term **conformation** refers to the spatial arrangement of the different parts of a chain, and one conformation can be changed into another by rotating one part of a chain around a bond.

## 18.1 The different levels of structure

**Key points** The primary structure of a macromolecule is the sequence of small molecular residues making up the polymer. The secondary structure is the spatial arrangement of a chain of residues. The tertiary structure is the overall three-dimensional structure of a macromolecule. The quaternary structure is the manner in which large molecules are formed by the aggregation of others.

The **primary structure** of a macromolecule is the sequence of small molecular residues making up the polymer. The residues may form either a chain, as in polyethene, or a more complex network in which cross-links connect different chains, as in cross-linked polyacrylamide. In a synthetic polymer, virtually all the residues are identical and it is sufficient to name the monomer used in the synthesis. Thus, the repeating unit of polyethene and its derivatives is  $-\text{CHXCH}_2-$ , and the primary structure of the chain is specified by denoting it as  $-(\text{CHXCH}_2)_n-$ .

The concept of primary structure ceases to be trivial in the case of synthetic copolymers and biological macromolecules, for in general these substances are chains formed from different molecules. For example, proteins are **polypeptides** formed from different amino acids (about twenty occur naturally) strung together by the **peptide link**,  $-\text{CONH}-$ . The determination of the primary structure is then a highly complex problem of chemical analysis called **sequencing**. The **degradation** of a polymer is a disruption of its primary structure, when the chain breaks into shorter components.

The **secondary structure** of a macromolecule is the (often local) spatial arrangement of a chain. The secondary structure of a molecule of polyethene in a good solvent is typically a random coil; in the absence of a solvent polyethene forms lamellar crystals with a hairpin-like bend about every 100 monomer units, presumably because for that number of monomers the intermolecular (in this case *intramolecular*) potential energy is sufficient to overcome thermal disordering. The secondary structure of a protein is a highly organized arrangement determined largely by hydrogen bonds, and taking the form of random coils, helices (Fig. 18.1a), or sheets in various segments of the molecule. The loss of secondary structure is called **denaturation**. When the hydrogen bonds in a protein are destroyed (for instance, by heating, as when cooking an egg) the structure denatures into a random coil.

The **tertiary structure** is the overall three-dimensional structure of a macromolecule. For instance, the hypothetical protein shown in Fig. 18.1b has helical regions connected by short random-coil sections. The helices interact to form a compact tertiary structure. Denaturation may also occur at this level.

The **quaternary structure** of a macromolecule is the manner in which large molecules are formed by the aggregation of others. Figure 18.2 shows how four molecular subunits, each with a specific tertiary structure, aggregate together. Quaternary structure can be very important in biology. For example, the oxygen-transport protein haemoglobin consists of four subunits that work together to take up and release  $\text{O}_2$ .

**Fig. 18.1** (a) A polymer adopts a highly organized helical conformation, an example of a secondary structure. The helix is represented as a cylinder. (b) Several helical segments connected by short random coils pack together, providing an example of tertiary structure.

**Fig. 18.2** Several subunits with specific tertiary structures pack together, providing an example of quaternary structure.

## 18.2 Random coils

**Key points** The least structured conformation of a macromolecule is a random coil, which can be modelled as a freely jointed chain. (a) The root mean square separation between the ends of a chain and the radius of gyration are useful measures of the size of a random coil. (b) The conformational entropy is the statistical entropy arising from the arrangement of bonds in a random coil. (c) The freely jointed chain model is improved by removing the freedom of bond angles to take any value. (d) The persistence length is a measure of the rigidity of a region of a polymer chain.

The most likely conformation of a chain of identical units not capable of forming hydrogen bonds or any other type of specific bond is a **random coil**. Polyethene is a simple example. The random coil model is a helpful starting point for estimating the orders of magnitude of the hydrodynamic properties of polymers and denatured proteins in solution.

The simplest model of a random coil is a **freely jointed chain**, in which any bond is free to make any angle with respect to the preceding one (Fig. 18.3). We assume that the residues occupy zero volume, so different parts of the chain can occupy the same region of space. The model is obviously an oversimplification because a bond is actually constrained to a cone of angles around a direction defined by its neighbour (Fig. 18.4) and real chains are self-avoiding in the sense that distant parts of the same chain cannot occupy the same space.

In a hypothetical one-dimensional freely jointed chain all the residues lie in a straight line, and the angle between neighbours is either  $0^\circ$  or  $180^\circ$ . The residues in a three-dimensional freely jointed chain are not restricted to lie in a line or a plane.

### (a) Measures of size

As shown in *Further information 18.1*, the probability,  $P$ , that the ends of a long one-dimensional freely jointed chain composed of  $N$  units of length  $l$  (and therefore of total length  $Nl$ ) are a distance  $nl$  apart is

$$P = \left( \frac{2}{\pi N} \right)^{1/2} e^{-n^2/2N} \quad \text{Probability distribution for a one-dimensional random coil} \quad (18.1)$$

This function is plotted in Fig. 18.5. We also show in *Further information 18.1* that eqn 18.1 can be used to calculate the probability that the ends of a long three-dimensional freely jointed chain lie in the range  $r$  to  $r + dr$ . We write this probability as  $f(r)dr$ , where

$$f(r) = 4\pi \left( \frac{a}{\pi^{1/2}} \right)^3 r^2 e^{-a^2 r^2} \quad a = \left( \frac{3}{2Nl^2} \right)^{1/2} \quad \text{Probability distribution for a three-dimensional random coil} \quad (18.2)$$

In some coils, the ends may be far apart whereas in others their separation is small. Here and elsewhere we are ignoring the fact that the chain cannot be longer than  $Nl$ . Although eqn 18.2 gives a nonzero probability for  $r > Nl$ , the values are so small that the errors in pretending that  $r$  can range up to infinity are negligible. An alternative interpretation of eqn 18.2 is to regard each coil in a sample as ceaselessly writhing from one conformation to another; then  $f(r)dr$  is the probability that at any instant the chain will be found with the separation of its ends between  $r$  and  $r + dr$ .

#### • A brief illustration

Suppose that  $N = 1000$  and  $l = 150$  pm; then the probability that the ends of a one-dimensional random coil are 3 nm apart is given by eqn 18.1 by setting  $n = (3000 \text{ pm}) / (150 \text{ pm}) = 20$  and is 0.0207 (1 in 48 chance of being found there). If the coil is three-dimensional, we set  $a = 2.58 \times 10^{-4} \text{ pm}^{-1}$ . Then the probability density at  $r = 3$  nm is given by eqn 18.2 as  $f = 1.92 \times 10^{-4} \text{ pm}^{-1}$ . The probability that the ends will be found in a shell of radius 3 nm and thickness 10 pm (regardless of direction) is therefore  $1.92 \times 10^{-3}$  (1 in 520). •

**Fig. 18.3** A freely jointed chain is like a three-dimensional random walk, each step being in an arbitrary direction but of the same length.

**Fig. 18.4** A better description is obtained by fixing the bond angle (for example, at the tetrahedral angle) and allowing free rotation about a bond direction.

**Fig. 18.5** The probability distribution for the separation of the ends of a one-dimensional random coil. The separation of the ends is  $nl$ , where  $l$  is the bond length.

**Fig. 18.6** A schematic illustration of the calculation of the root mean square separation of the ends of a random coil.

**Fig. 18.7** The variation of the root mean square separation of the ends of a three-dimensional random coil,  $R_{\text{rms}}$ , with the number of monomers.

There are several measures of the geometrical size of a random coil. The **contour length**,  $R_c$ , is the length of the macromolecule measured along its backbone from atom to atom. For a polymer of  $N$  monomer units each of length  $l$ , the contour length is

$$R_c = Nl$$

Contour length [18.3]

The **root mean square separation**,  $R_{\text{rms}}$ , is a measure of the average separation of the ends of a random coil: it is the square root of the mean value of  $R^2$ . To determine its value we note that the vector joining the two ends of the chain is the vector sum of the vectors joining neighbouring monomers:  $R = \sum_{i=1}^N r_i$  (Fig. 18.6). The mean square separation of the ends of the chain is therefore

$$\langle R^2 \rangle = \langle R \cdot R \rangle = \sum_{i,j} \langle r_i \cdot r_j \rangle = \sum_i \langle r_i^2 \rangle + \sum_{i \neq j} \langle r_i \cdot r_j \rangle$$

When  $N$  is large (which we assume throughout) the second sum vanishes because the individual vectors all lie in random directions. The first sum is  $Nl^2$  as all bond lengths are the same (and equal to  $l$ ); so, after taking square roots, we conclude that

$$R_{\text{rms}} = N^{1/2}l$$

Root mean square separation (18.4)

We see that, as the number of monomer units increases, the root mean square separation of its end increases as  $N^{1/2}$  (Fig. 18.7), and consequently its volume increases as  $N^{3/2}$ . The result must be multiplied by a factor when the chain is not freely jointed (see below).

#### • A brief illustration

For  $N = 1000$  and  $l = 150$  pm, the contour length is  $R_c = 1000 \times 150$  pm = 150 nm. The root mean square separation of the ends of the coil is  $R_{\text{rms}} = (1000)^{1/2} \times 150$  pm = 4.74 nm. •

Another convenient measure of size is the **radius of gyration**,  $R_g$ , which is the radius of a hollow sphere of mass  $m$  that has the same moment of inertia (and therefore rotational characteristics) as the actual molecule of the same mass. We show in the following *Justification* that

$$R_g = N^{1/2}l$$

Radius of gyration of a one-dimensional random coil (18.5)

A similar calculation for a three-dimensional random coil (Problem 18.17) gives

$$R_g = \left( \frac{N}{6} \right)^{1/2} l$$

Radius of gyration of a three-dimensional random coil (18.6)

The radius of gyration is smaller in this case because the extra dimensions enable the coil to be more compact. The radius of gyration may also be calculated for other geometries. For example, a solid uniform sphere of radius  $R$  has  $R_g = (\frac{3}{5})^{1/2}R$ , and a long thin uniform rod of length  $l$  has  $R_g = l/(12)^{1/2}$  for rotation about an axis perpendicular to the long axis. A solid sphere with the same radius and mass as a random coil will have a greater radius of gyration as it is entirely dense throughout.

**Justification 18.1** *The radius of gyration*

For a one-dimensional random coil with  $N + 1$  identical monomers (and therefore  $N$  bonds) each of mass  $m$ , the moment of inertia around the centre of the chain (which is also at the first monomer, because steps occur in equal numbers to left and right) is

$$I = \sum_{i=0}^N m_i r_i^2 = m \sum_{i=0}^N r_i^2$$

This moment of inertia is set equal to  $m_{\text{tot}} R_g^2$ , where  $m_{\text{tot}}$  is the total mass of the polymer,  $m_{\text{tot}} = (N + 1)m$ . Therefore, after averaging over all conformations,

$$R_g^2 = \frac{1}{N + 1} \sum_{i=0}^N \langle r_i^2 \rangle$$

For a linear random chain,  $\langle r_i^2 \rangle = Nl^2$  (see Problem 18.16) and, as there are  $N + 1$  such terms in the sum, we find

$$R_g^2 = Nl^2$$

Equation 18.5 then follows after taking the square root of each side.

The random coil model ignores the role of the solvent: a poor solvent will tend to cause the coil to tighten so that solute–solvent contacts are minimized; a good solvent does the opposite. Therefore, calculations based on this model are better regarded as lower bounds to the dimensions for a polymer in a good solvent and as an upper bound for a polymer in a poor solvent. The model is most reliable for a polymer in a bulk solid sample, where the coil is likely to have its natural dimensions.

**(b) Conformational entropy**

The random coil is the least structured conformation of a polymer chain and corresponds to the state of greatest entropy. Any stretching of the coil introduces order and reduces the entropy. Conversely, the formation of a random coil from a more extended form is a spontaneous process (provided enthalpy contributions do not interfere). As shown in the following *Justification*, we can use the same model to deduce that the change in **conformational entropy**, the statistical entropy arising from the arrangement of bonds, when a one-dimensional chain containing  $N$  bonds of length  $l$  is stretched or compressed by  $nl$  is

$$\Delta S = -\frac{1}{2} kN \ln \{ (1 + \nu)^{1+\nu} (1 - \nu)^{1-\nu} \} \quad \nu = n/N \quad (18.7)$$

 Conformational  
entropy of a  
random coil

This function is plotted in Fig. 18.8, and we see that minimum extension corresponds to maximum entropy.

• **A brief illustration**

As before, suppose  $N = 1000$  and  $l = 150$  pm. The change in entropy when the (one-dimensional) random coil is stretched through 1.5 nm (corresponding to  $n = 10$  and  $\nu = 1/100$ ) is  $\Delta S = -0.050k$ . The change in molar entropy is therefore  $\Delta S_m = -0.050R$ , or  $-0.42 \text{ J K}^{-1} \text{ mol}^{-1}$  (we have used  $R = N_A k$ ). •

**Fig. 18.8** The change in molar entropy of a perfect elastomer as its extension changes;  $\nu = 1$  corresponds to complete extension;  $\nu = 0$ , the conformation of highest entropy, corresponds to the random coil.

**Justification 18.2** *The conformational entropy of a freely jointed chain*

The conformational entropy of the chain is  $S = k \ln W$ , where  $W$  is given by eqn 18.38 in *Further information 18.1*. Therefore,

$$S/k = \ln N! - \ln\left\{\frac{1}{2}(N+n)\right\}! - \ln\left\{\frac{1}{2}(N-n)\right\}!$$

Because the factorials are large (except for large extensions), we can use Stirling's approximation to obtain

$$S/k = -\ln(2\pi)^{1/2} + (N+1)\ln 2 + (N+\frac{1}{2})\ln N - \frac{1}{2}\ln\{(N+n)^{N+n+1}(N-n)^{N-n+1}\}$$

We have seen that the most probable conformation of a one-dimensional chain is the one with the ends close together ( $n = 0$ ). This conformation also corresponds to maximum entropy, as may be confirmed by differentiation. Therefore, the maximum entropy is

$$S/k = -\ln(2\pi)^{1/2} + (N+1)\ln 2 + \frac{1}{2}\ln N$$

The change in entropy when the chain is stretched or compressed by  $nl$  is therefore the difference of these two quantities, and the resulting expression is eqn 18.7.

**(c) Constrained chains**

The freely jointed chain model is improved by removing the freedom of bond angles to take any value. For long chains, we can simply take groups of neighbouring bonds and consider the direction of their resultant. Although each successive individual bond is constrained to a single cone of angle  $\theta$  relative to its neighbour, the resultant of several bonds lies in a random direction. By concentrating on such groups rather than individuals, it turns out that for long chains the expressions for the root mean square separation and the radius of gyration given above should be multiplied by

$$F = \left( \frac{1 - \cos \theta}{1 + \cos \theta} \right)^{1/2} \quad (18.8)$$

For tetrahedral bonds, for which  $\cos \theta = \frac{1}{3}$  (that is,  $\theta = 109.5^\circ$ ),  $F = 2^{1/2}$ . Therefore:

$$R_{\text{rms}} = (2N)^{1/2}l \quad R_g = \left( \frac{N}{3} \right)^{1/2} l \quad (18.9)$$

Dimensions of  
a tetrahedrally  
constrained chain

The model of a randomly coiled molecule is still an approximation, even after the bond angles have been restricted, because it does not take into account the impossibility of two or more atoms occupying the same place. Such self-avoidance tends to swell the coil, so (in the absence of solvent effects) it is better to regard  $R_{\text{rms}}$  and  $R_g$  as lower bounds to the actual values.

**(d) Partly rigid coils**

An important measure of the flexibility of a chain is the **persistence length**,  $l_p$ , a measure of the length over which the direction of the first monomer–monomer direction is sustained. If the chain is a rigid rod, then the persistence length is the same as the contour length. For a freely jointed random coil, the persistence length is just the length of the monomer–monomer bond. Therefore, the persistence length can be regarded as a measure of the stiffness of the chain. In general, the persistence length of a chain of identical monomers of length  $l$  is defined as the average value of the projection of the end-to-end vector on the first bond of the chain (Fig. 18.9):

**Fig. 18.9** The persistence length is defined as the average value of the projection of the end-to-end vector on the first bond of the chain.

$$l_p = \left\langle \frac{r_1}{l} \cdot R \right\rangle = \frac{1}{l} \sum_{i=0}^{N-1} \langle r_1 \cdot r_i \rangle \quad \text{Definition of persistence length} \quad [18.10]$$

(The sum ends at  $N-1$  because the last atom is atom  $N$  and the last bond is from atom  $N-1$  to atom  $N$ .) Experimental values of persistence lengths are as follows:

|               |                 |                 |
|---------------|-----------------|-----------------|
| poly(glycine) | poly(L-alanine) | poly(L-proline) |
| 0.6 nm        | 2 nm            | 22 nm           |

These values suggest that the stiffness of the chain increases from left to right along the series.

The mean square distance between the ends of a chain that has a nonzero persistence length can be expected to be greater than for a random coil because the partial rigidity of the coil does not let it roll up so tightly. We show in *Further information 18.1* that

$$R_{\text{rms}} = N^{1/2} l F \quad \text{where} \quad F = \left( \frac{2l_p}{l} - 1 \right)^{1/2} \quad (18.11)$$

For a random coil,  $l_p = l$ , so  $R_{\text{rms}} = N^{1/2} l$ , as we have already found. For  $l_p > l$ ,  $F > 1$ , so the coil has swollen, as we anticipated.

### 18.3 The mechanical properties of polymers

**Key points** The elastic properties of a material are summarized by a stress–strain curve. A perfect elastomer is a polymer for which the internal energy is independent of the extension. The disruption of long-range order in a polymer occurs at a melting temperature. Synthetic polymers undergo a transition from a state of high to low chain mobility at the glass transition temperature.

The stress–strain curve shown in Fig. 18.10 shows how a material responds to stress. The region of **elastic deformation** is where the strain is proportional to the stress and is reversible: when the stress is removed, the sample returns to its initial shape. As we shall see in more detail in Section 19.8, the slope of the stress–strain curve in this region is ‘Young’s modulus’,  $E$ , for the material. At the **yield point**, the reversible, linear deformation gives way to **plastic deformation**, where the strain is no longer linearly proportional to the stress and the initial shape of the sample is not recovered when the stress is removed. Thermosetting plastics have only a very short elastic range; thermoplastics typically (but not universally) have a long plastic range. An **elastomer** is specifically a polymer with a long elastic range. They typically have numerous cross-links (such as the sulfur links in vulcanized rubber) that pull them back into their original shape when the stress is removed.

Although practical elastomers are typically extensively cross-linked, even a freely jointed chain behaves as an elastomer for small extensions. It is a model of a **perfect elastomer**, a polymer in which the internal energy is independent of the extension. We saw in Section 18.2b that the contraction of an extended chain to a random coil is spontaneous in the sense that it corresponds to an increase in entropy; the entropy change of the surroundings is zero because no energy is released when the coil forms. In the following *Justification* we also see that the restoring force,  $\mathcal{F}$ , of a one-dimensional random coil when the chain is stretched or compressed by  $nl$  is

$$\mathcal{F} = \frac{kT}{2l} \ln \left( \frac{1+\nu}{1-\nu} \right) \quad \nu = n/N \quad (18.12a)$$

Fig. 18.10 A typical stress–strain curve.

**Fig. 18.11** The restoring force,  $\mathcal{F}$ , of a one-dimensional perfect elastomer. For small strains,  $\mathcal{F}$  is linearly proportional to the extension, corresponding to Hooke's law.

where  $N$  is the total number of bonds of length  $l$ . This function is plotted in Fig. 18.11. At low extensions, when  $v \ll 1$  we can use  $\ln(1+x) = x - \frac{1}{2}x^2 + \dots$  and find (retaining only linear terms) that

$$\mathcal{F} \approx \frac{vkT}{l} = \frac{nkT}{Nl} \quad (18.12b)$$

That is, for small displacements the sample obeys Hooke's law: the restoring force is proportional to the displacement (which is proportional to  $n$ ). For small displacements, therefore, the whole coil shakes with simple harmonic motion. When this equation is rearranged to

$$nl = \left( \frac{Nl^2}{kT} \right) \mathcal{F} \quad (18.12c)$$

we see that for small displacements, the strain, as measured by the extension  $nl$ , is proportional to the applied force, as is characteristic of the elastic deformation region of an elastomer.

### Justification 18.3 Hooke's law

The work done on an elastomer when it is extended through a distance  $dx$  is  $\mathcal{F}dx$ , where  $\mathcal{F}$  is the restoring force. The change in internal energy is therefore

$$dU = T dS + \mathcal{F} dx$$

It follows that

$$\left( \frac{\partial U}{\partial x} \right)_T = T \left( \frac{\partial S}{\partial x} \right)_T + \mathcal{F}$$

In a perfect elastomer, as in a perfect gas, the internal energy is independent of the dimensions (at constant temperature), so  $(\partial U/\partial x)_T = 0$ . The restoring force is therefore

$$\mathcal{F} = -T \left( \frac{\partial S}{\partial x} \right)_T$$

If now we substitute eqn 18.7 into this expression, we obtain

$$\mathcal{F} = -\frac{T}{l} \left( \frac{\partial S}{\partial n} \right)_T = \frac{T}{Nl} \left( \frac{\partial S}{\partial v} \right)_T = \frac{kT}{2l} \ln \left( \frac{1+v}{1-v} \right)$$

as in eqn 18.12a.

The crystallinity of synthetic polymers can be destroyed by thermal motion at sufficiently high temperatures. This change in crystallinity may be thought of as a kind of intramolecular melting from a crystalline solid to a more fluid random coil. Polymer melting also occurs at a specific **melting temperature**,  $T_m$ , which increases with the strength and number of intermolecular interactions in the material. Thus, polyethylene, which has chains that interact only weakly in the solid, has  $T_m = 414$  K and nylon-66 fibres, in which there are strong hydrogen bonds between chains, has  $T_m = 530$  K. High melting temperatures are desirable in most practical applications involving fibres and plastics.

All synthetic polymers undergo a transition from a state of high to low chain mobility at the **glass transition temperature**,  $T_g$ . To visualize the glass transition, we consider what happens to an elastomer as we lower its temperature. There is sufficient

energy available at normal temperatures for limited bond rotation to occur and the flexible chains writhe. At lower temperatures, the amplitudes of the writhing motion decrease until a specific temperature,  $T_g$ , is reached at which motion is frozen completely and the sample forms a glass. Glass transition temperatures well below 300 K are desirable in elastomers that are to be used at normal temperatures. Both the glass transition temperature and the melting temperature of a polymer may be measured by differential scanning calorimetry (*Impact I2.1*). Because the motion of the segments of a polymer chain increases at the glass transition temperature,  $T_g$  may also be determined from a plot of the specific volume of a polymer (the reciprocal of its mass density) against temperature (Fig. 18.12).

### 18.4 The electrical properties of polymers

**Key points** In conducting polymers conjugated double bonds facilitate electron conduction along the chain. These polymers are slightly better electrical conductors than silicon semiconductors but are worse than metallic conductors.

Most of the macromolecules and self-assembled structures considered in this chapter are insulators, or very poor electrical conductors. However, a variety of newly developed macromolecular materials have electrical conductivities that rival those of silicon-based semiconductors and even metallic conductors. We examine one example in detail: **conducting polymers**, in which extensively conjugated double bonds facilitate electron conduction along the polymer chain.

One example of a conducting polymer is polyacetylene (polyethyne, Fig. 18.13). Whereas the delocalized  $\pi$  bonds do suggest that electrons can move up and down the chain, the electrical conductivity of polyacetylene increases significantly when it is partially oxidized by  $I_2$  and other strong oxidants. The product is a **polaron**, a partially localized cation radical that travels through the chain, as shown in Fig. 18.13. Oxidation of the polymer by one more equivalent forms either **bipolarons**, a di-cation that moves as a unit through the chain, or **solitons**, two separate cation radicals that move independently. Polarons and solitons contribute to the mechanism of charge conduction in polyacetylene.

Conducting polymers are slightly better electrical conductors than silicon semiconductors but are far worse than metallic conductors. They are currently used in a number of devices, such as electrodes in batteries, electrolytic capacitors, and sensors. Recent studies of photon emission by conducting polymers may lead to new technologies for light-emitting diodes and flat-panel displays. Conducting polymers also show promise as molecular wires that can be incorporated into nanometre-sized electronic devices.

### 18.5 The structures of biological macromolecules

**Key points** (a) The secondary structure of a protein is the spatial arrangement of the polypeptide chain and includes the  $\alpha$ -helix and  $\beta$ -sheet. Helical and sheet-like polypeptide chains are folded into a tertiary structure by bonding influences between the residues of the chain. Some proteins have a quaternary structure as aggregates of two or more polypeptide chains. (b) In DNA, two polynucleotide chains held together by hydrogen-bonded base pairs wind around each other to form a double helix. In RNA, single chains fold into complex structures by formation of specific base pairs.

A protein is a polypeptide composed of linked  $\alpha$ -amino acids,  $NH_2CH(R)COOH$ , where R is one of about 20 groups. For a protein to function correctly, it needs to have

**Fig. 18.12** The variation of specific volume with temperature of a synthetic polymer. The glass transition temperature,  $T_g$ , is at the point of intersection of extrapolations of the two linear parts of the curve.

#### A brief comment

The 2000 Nobel Prize in chemistry was awarded to A.J. Heeger, A.G. MacDiarmid, and H. Shirakawa for their pioneering work in the synthesis and characterization of conducting polymers.

**Fig. 18.13** The mechanism of migration of a partially localized cation radical, or polaron, in polyacetylene.

**Fig. 18.14** The dimensions that characterize the peptide link. The C–NH–CO–C atoms define a plane (the C–N bond has partial double-bond character), but there is rotational freedom around the C–CO and N–C bonds.

**Fig. 18.15** The definition of the torsional angles  $\psi$  and  $\phi$  between two peptide units. In this case (an  $\alpha$ -L-polypeptide) the chain has been drawn in its all-*trans* form, with  $\psi = \phi = 180^\circ$ .

a well defined conformation. For example, an enzyme has its greatest catalytic efficiency only when it is in a specific conformation. The amino acid sequence of a protein contains the necessary information to create the active conformation of the protein as it is formed. However, the prediction of the observed conformation from the primary structure, the so-called *protein folding problem*, is extraordinarily difficult and is still the focus of much research. Nucleic acids are key components of the mechanism of storage and transfer of genetic information in biological cells. Deoxyribonucleic acid (DNA) contains the instructions for protein synthesis, which is carried out by different forms of ribonucleic acid (RNA).

### (a) Proteins

The origin of the secondary structures of proteins is found in the rules formulated by Linus Pauling and Robert Corey in 1951 that seek to identify the principal contributions to the lowering of energy of the molecule by focusing on the role of hydrogen bonds and the peptide link,  $-\text{CONH}-$ . The latter can act both as a donor of the H atom (the NH part of the link) and as an acceptor (the CO part). The **Corey–Pauling rules** are as follows (Fig. 18.14):

1. The four atoms of the peptide link lie in a relatively rigid plane.

The planarity of the link is due to delocalization of  $\pi$  electrons over the O, C, and N atoms and the maintenance of maximum overlap of their p orbitals.

2. The N, H, and O atoms of a hydrogen bond lie in a straight line (with displacements of H tolerated up to not more than  $30^\circ$  from the N–O vector).
3. All NH and CO groups are engaged in hydrogen bonding.

The rules are satisfied by two structures. One, in which hydrogen bonding between peptide links leads to a helical structure, is a *helix*, which can be arranged as either a right- or a left-handed screw. The other, in which hydrogen bonding between peptide links leads to a planar structure, is a *sheet*; this form is the secondary structure of the protein fibroin, the constituent of silk.

Because the planar peptide link is relatively rigid, the geometry of a polypeptide chain can be specified by the two angles that two neighbouring planar peptide links make to each other. Figure 18.15 shows the two angles  $\phi$  and  $\psi$  commonly used to specify this relative orientation. The sign convention is that a positive angle means that the front atom must be rotated clockwise to bring it into an eclipsed position relative to the rear atom. For an all-*trans* form of the chain, all  $\phi$  and  $\psi$  are  $180^\circ$ . A helix is obtained when all the  $\phi$  are equal and when all the  $\psi$  are equal. For a right-handed helix (Fig. 18.16), all  $\phi = 57^\circ$  and all  $\psi = -47^\circ$ . For a left-handed helix, both angles are positive. The torsional contribution to the total potential energy is

$$V_{\text{torsion}} = A(1 + \cos 3\phi) + B(1 + \cos 3\psi) \quad (18.13)$$

in which  $A$  and  $B$  are constants of the order of  $1 \text{ kJ mol}^{-1}$ . Because only two angles are needed to specify the conformation of a helix, and they range from  $-180^\circ$  to  $+180^\circ$ , the torsional potential energy of the entire molecule can be represented on a **Ramachandran plot**, a contour diagram in which one axis represents  $\phi$  and the other represents  $\psi$ .

Figure 18.17 shows the Ramachandran plots for the helical form of polypeptide chains formed from the nonchiral amino acid glycine ( $R = \text{H}$ ) and the chiral amino acid L-alanine ( $R = \text{CH}_3$ ). The glycine map is almost symmetrical, with minima of equal depth at  $\phi = -80^\circ, \psi = -60^\circ$  and at  $\phi = +80^\circ, \psi = -0^\circ$ . In contrast, the map for L-alanine is unsymmetrical, and there are three distinct low-energy conformations (marked I, II, III). The minima of regions I and II lie close to the angles typical of

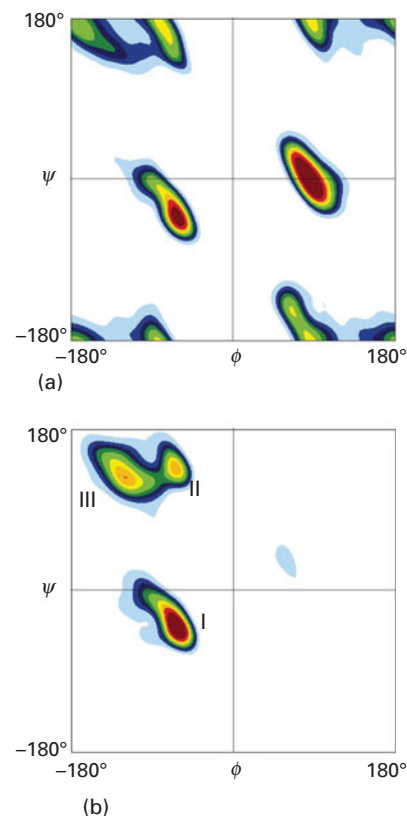

**Fig. 18.16** The polypeptide  $\alpha$  helix, with poly-L-glycine as an example. There are 3.6 residues per turn, and a translation along the helix of 150 pm per residue, giving a pitch of 540 pm. The diameter (ignoring side chains) is about 600 pm.

right- and left-handed helices, but the former has a lower minimum. This result is consistent with the observation that polypeptides of the naturally occurring L-amino acids tend to form right-handed helices.

A  $\beta$ -sheet (also called the  $\beta$ -pleated sheet) is formed by hydrogen bonding between two extended polypeptide chains (large absolute values of the torsion angles  $\phi$  and  $\psi$ ). In an **antiparallel  $\beta$ -sheet** (Fig. 18.18a),  $\phi = -139^\circ$ ,  $\psi = 113^\circ$ , and the N–H $\cdots$ O atoms of the hydrogen bonds form a straight line. This arrangement is a consequence of the antiparallel arrangement of the chains: every N–H bond on one chain is aligned with a C–O bond from another chain. Antiparallel  $\beta$ -sheets are very common in proteins. In a **parallel  $\beta$ -sheet** (Fig. 18.18b),  $\phi = -119^\circ$ ,  $\psi = 113^\circ$ , and the N–H $\cdots$ O atoms of the hydrogen bonds are not perfectly aligned. This arrangement is a result of the parallel arrangement of the chains: each N–H bond on one chain is aligned with a N–H bond of another chain and, as a result, each C–O bond of one chain is aligned with a C–O bond of another chain. These structures are not common in proteins.

Covalent and non-covalent interactions may cause polypeptide chains with well defined secondary structures to fold into tertiary structures. Although the rules that govern protein folding are still being elucidated, a few general conclusions may be drawn from X-ray diffraction studies of water-soluble natural proteins and synthetic polypeptides. In an aqueous environment, the chains fold in such a way as to place nonpolar R groups in the interior (which is often not very accessible to solvent) and charged R groups on the surface (in direct contact with the polar solvent). Other factors that promote the folding of proteins include covalent disulfide (–S–S–) links, Coulombic interactions between ions (which depend on the degree of protonation of groups and therefore on the pH), van der Waals interactions, and hydrophobic interactions (Section 17.5f). The clustering of nonpolar, hydrophobic, amino acids into the interior of a protein is driven primarily by hydrophobic interactions.

Proteins are relatively unstable towards chemical and thermal **denaturation**, the loss of structure. Thermal denaturation is similar to the melting of synthetic polymers. Denaturation is a **cooperative process** in the sense that the biopolymer becomes

**Fig. 18.17** Contour plots of potential energy against the angles  $\psi$  and  $\phi$ , also known as a Ramachandran diagram, for (a) a glycyl residue of a polypeptide chain and (b) an alanyl residue. The glycyl diagram is symmetrical, but that for alanyl is unsymmetrical and the global minimum corresponds to an  $\alpha$ -helix. (Reproduced with permission, T. Hovmöller *et al.*, *Acta Cryst. D58*, 768 (2002).)

**Fig. 18.18** The two types of  $\beta$ -sheets: (a) antiparallel ( $\phi = -139^\circ$ ,  $\psi = 113^\circ$ ), in which the N–H $\cdots$ O atoms of the hydrogen bonds form a straight line; (b) parallel ( $\phi = -119^\circ$ ,  $\psi = 113^\circ$ ) in which the N–H $\cdots$ O atoms of the hydrogen bonds are not perfectly aligned.

**Fig. 18.19** A protein unfolds as the temperature of the sample increases. The sharp step in the plot of fraction of unfolded protein against temperature indicates that the transition is cooperative. The melting temperature,  $T_m$ , is the temperature at which the fraction of unfolded polymer is 0.5.

increasingly more susceptible to denaturation once the process begins. This cooperativity is observed as a sharp step in a plot of fraction of unfolded polymer versus temperature. The **melting temperature**,  $T_m$ , is the temperature at which the fraction of unfolded polymer is 0.5 (Fig. 18.19). For example,  $T_m = 320$  K for ribonuclease  $T_1$  (an enzyme that cleaves RNA in the cell), which is not far above the temperature at which the enzyme must operate (close to body temperature, 310 K). More surprisingly, the Gibbs energy for the unfolding of ribonuclease  $T_1$  at pH 7.0 and 298 K is only  $19.5 \text{ kJ mol}^{-1}$ , which is comparable to the energy required to break a single hydrogen bond (about  $20 \text{ kJ mol}^{-1}$ ). The stability of a protein does not increase in a simple way with the number of hydrogen bonding interactions. While the reasons for the low stability of proteins are not known, the answer probably lies in a delicate balance of the intra- and intermolecular interactions that allow a protein to fold into its active conformation.

### (b) Nucleic acids

Both DNA and RNA are *polynucleotides* (1), in which base-sugar-phosphate units are linked by phosphodiester bonds. In RNA the sugar is  $\beta$ -D-ribose and in DNA it is  $\beta$ -D-2-deoxyribose (as shown in 1). The most common bases are adenine (A, 2), cytosine (C, 3), guanine (G, 4), thymine (T, found in DNA only, 5), and uracil (U, found in RNA only, 6). At physiological pH, each phosphate group of the chain carries a negative charge and the bases are deprotonated and neutral. This charge distribution leads to two important properties. One is that the polynucleotide chain is a **polyelectrolyte**, a macromolecule with many different charged sites, with a large and negative overall surface charge. The second is that the bases can interact by hydrogen bonding, as shown for A-T (7) and C-G base pairs (8). The secondary and tertiary structures of DNA and RNA arise primarily from the pattern of this hydrogen bonding between bases of one or more chains.

In DNA, two polynucleotide chains wind around each other to form a double helix (Fig. 18.20). The chains are held together by links involving A-T and C-G base pairs that lie parallel to each other and perpendicular to the major axis of the helix. The structure is stabilized further by interactions between the planar  $\pi$  systems of the bases. In B-DNA, the most common form of DNA found in biological cells, the helix is right-handed with a diameter of 2.0 nm and a pitch of 3.4 nm.

## Aggregation and self-assembly

Much of the material discussed in this chapter also applies to aggregates of particles that form by **self-assembly**, the spontaneous formation of complex structures of molecules or macromolecules held together by molecular interactions, such as Coulombic, dispersion, hydrogen bonding, or hydrophobic interactions. We have already encountered a few examples of self-assembly, such as the formation of liquid crystals (*Impact I5.2*), of protein quaternary structures from two or more polypeptide chains, and (by implication) of a DNA double helix from two polynucleotide chains. Now we concentrate on the specific properties of additional self-assembled systems, including small aggregates that are at the heart of detergent action and extended sheets like those forming biological cell membranes. We also consider examples in which the controlled design of new materials with enhanced properties is informed by an understanding of the principles underlying self-assembly.

### 18.6 Colloids

**Key points** A disperse system is a dispersion of small particles of one material in another. (a) Colloids are classified as lyophilic and lyophobic. A surfactant is a species that accumulates at the interface of two phases or substances. (b) Many colloid particles are thermodynamically unstable but kinetically nonlabile. (c) The radius of shear is the radius of the sphere that captures the rigid layer of charge attached to a colloid particle. The zeta potential is the electric potential at the radius of shear relative to its value in the distant, bulk medium. The inner shell of charge and the outer atmosphere jointly constitute the electric double layer. Flocculation is the reversible aggregation of colloidal particles; coagulation is the irreversible aggregation of colloidal particles. The Schultze–Hardy rule states that hydrophobic colloids are flocculated most efficiently by ions of opposite charge type and high charge number.

A **colloid**, or **disperse phase**, is a dispersion of small particles of one material in another that does not settle out under gravity. In this context, ‘small’ means that one dimension at least is smaller than about 500 nm in diameter (about the wavelength of visible light). Many colloids are suspensions of nanoparticles (particles of diameter up to about 100 nm). In general, colloidal particles are aggregates of numerous atoms or molecules, but are commonly but not universally too small to be seen with an ordinary optical microscope. They pass through most filter papers, but can be detected by light-scattering and sedimentation.

#### (a) Classification and preparation

The name given to the colloid depends on the two phases involved. A **sol** is a dispersion of a solid in a liquid (such as clusters of gold atoms in water) or of a solid in a solid (such as ruby glass, which is a gold-in-glass sol, and achieves its colour by light scattering). An **aerosol** is a dispersion of a liquid in a gas (like fog and many sprays) or a solid in a gas (such as smoke): the particles are often large enough to be seen with a microscope. An **emulsion** is a dispersion of a liquid in a liquid (such as milk). A **foam** is a dispersion of a gas in a liquid.

A further classification of colloids is as **lyophilic**, or solvent attracting, and **lyophobic**, solvent repelling. If the solvent is water, the terms **hydrophilic** and **hydrophobic**, respectively, are used instead. Lyophobic colloids include the metal sols. Lyophilic colloids generally have some chemical similarity to the solvent, such as –OH groups able to form hydrogen bonds. A **gel** is a semirigid mass of a lyophilic sol.

**Fig. 18.20** DNA double helix, in which two polynucleotide chains are linked together by hydrogen bonds between adenine (A) and thymine (T) and between cytosine (C) and guanine (G).

The preparation of aerosols can be as simple as sneezing (which produces an imperfect aerosol). Laboratory and commercial methods make use of several techniques. Material (for example, quartz) may be ground in the presence of the dispersion medium. Passing a heavy electric current through a cell may lead to the sputtering (crumbling) of an electrode into colloidal particles. Arcing between electrodes immersed in the support medium also produces a colloid. Chemical precipitation sometimes results in a colloid. A precipitate (for example, silver iodide) already formed may be dispersed by the addition of a peptizing agent (for example, potassium iodide). Clays may be peptized by alkalis, the OH ion being the active agent.

Emulsions are normally prepared by shaking the two components together vigorously, although some kind of emulsifying agent usually has to be added to stabilize the product. This emulsifying agent may be a soap (the salt of a long-chain carboxylic acid) or other **surfactant** (surface active) species, or a lyophilic sol that forms a protective film around the dispersed phase. In milk, which is an emulsion of fats in water, the emulsifying agent is casein, a protein containing phosphate groups. It is clear from the formation of cream on the surface of milk that casein is not completely successful in stabilizing milk: the dispersed fats coalesce into oily droplets which float to the surface. This coagulation may be prevented by ensuring that the emulsion is dispersed very finely initially: intense agitation with ultrasonics brings this dispersion about, the product being 'homogenized' milk.

One way to form an aerosol is to tear apart a spray of liquid with a jet of gas. The dispersal is aided if a charge is applied to the liquid, for then electrostatic repulsions help to blast it apart into droplets. This procedure may also be used to produce emulsions, for the charged liquid phase may be directed into another liquid.

Colloids are often purified by dialysis (*Impact I5.1*). The aim is to remove much (but not all, for reasons explained later) of the ionic material that may have accompanied their formation. A membrane (for example, cellulose) is selected that is permeable to solvent and ions, but not to the colloid particles. Dialysis is very slow, and is normally accelerated by applying an electric field and making use of the charges carried by many colloidal particles; the technique is then called **electrodialysis**.

**Fig. 18.21** Although the attraction between individual molecules is proportional to  $1/R^6$ , more molecules are within range at large separations (pale region) than at small separation (dark region), so the total interaction energy declines more slowly and is proportional to a lower power of  $R$ .

### (b) Structure and stability

Colloids are thermodynamically unstable with respect to the bulk. This instability can be expressed thermodynamically by noting that because the change in Helmholtz energy,  $dA$ , when the surface area of the sample changes by  $d\sigma$  at constant temperature and pressure is  $dA = \gamma d\sigma$ , where  $\gamma$  is the interfacial surface tension (Section 17.8a), it follows that  $dA < 0$  if  $d\sigma < 0$ . The survival of colloids must therefore be a consequence of the kinetics of collapse: colloids are thermodynamically unstable but kinetically nonlabile.

At first sight, even the kinetic argument seems to fail: colloidal particles attract each other over large distances, so there is a long-range force that tends to condense them into a single blob. The reasoning behind this remark is as follows. The energy of attraction between two individual atoms  $i$  and  $j$  separated by a distance  $R_{ij}$ , one in each colloidal particle, varies with their separation as  $1/R_{ij}^6$  (Section 17.5). The sum of all these pairwise interactions, however, decreases only as approximately  $1/R^2$  (the precise variation depending on the shape of the particles and their closeness), where  $R$  is the separation of the centres of the particles. The change in the power from 6 to 2 stems from the fact that at short distances only a few molecules interact but at large distances many individual molecules are at about the same distance from one another, and contribute equally to the sum (Fig. 18.21), so the total interaction does not fall off as fast as the single molecule–molecule interaction.

Several factors oppose the long-range dispersion attraction. For example, there may be a protective film at the surface of the colloid particles that stabilizes the interface and cannot be penetrated when two particles touch. Thus the surface atoms of a platinum sol in water react chemically and are turned into  $\text{Pt}(\text{OH})_3\text{H}_3$ , and this layer encases the particle like a shell. A fat can be emulsified by a soap because the long hydrocarbon tails penetrate the oil droplet but the carboxylate head groups (or other hydrophilic groups in synthetic detergents) surround the surface, form hydrogen bonds with water, and give rise to a shell of negative charge that repels a possible approach from another similarly charged particle.

### (c) The electrical double layer

A major source of kinetic nonlability of colloids is the existence of an electric charge on the surfaces of the particles. On account of this charge, ions of opposite charge tend to cluster nearby, and an ionic atmosphere is formed, just as for ions (Section 5.13).

We need to distinguish two regions of charge. First, there is a fairly immobile layer of ions that adhere tightly to the surface of the colloidal particle, and which may include water molecules (if that is the support medium). The radius of the sphere that captures this rigid layer is called the **radius of shear** and is the major factor determining the mobility of the particles. The electric potential at the radius of shear relative to its value in the distant, bulk medium is called the **zeta potential**,  $\zeta$ , or the **electrokinetic potential**. Second, the charged unit attracts an oppositely charged atmosphere of mobile ions. The inner shell of charge and the outer ionic atmosphere is called the **electrical double layer**.

The theory of the stability of lyophobic dispersions was developed by B. Derjaguin and L. Landau and independently by E. Verwey and J.T.G. Overbeek, and is known as the **DLVO theory**.<sup>1</sup> It assumes that there is a balance between the repulsive interaction between the charges of the electrical double layers on neighbouring particles and the attractive interactions arising from van der Waals interactions between the molecules in the particles. The potential energy arising from the repulsion of double layers on particles of radius  $a$  has the form

$$V_{\text{repulsion}} = + \frac{Aa^2\zeta^2}{R} e^{-s/r_D} \quad (18.14)$$

where  $A$  is a constant,  $\zeta$  is the zeta potential,  $R$  is the separation of centres,  $s$  is the separation of the surfaces of the two particles ( $s = R - 2a$  for spherical particles of radius  $a$ ), and  $r_D$  is the thickness of the double layer. This expression is valid for small particles with a thick double layer ( $a \ll r_D$ ). When the double layer is thin ( $r_D \ll a$ ), the expression is replaced by

$$V_{\text{repulsion}} = \frac{1}{2} Aa\zeta^2 \ln(1 + e^{-s/r_D}) \quad (18.15)$$

In each case, the thickness of the double layer can be estimated from an expression like that derived for the thickness of the ionic atmosphere in the Debye–Hückel theory (eqn 5.91) in which there is a competition between the assembling influences of the attraction between opposite charges and the disruptive effect of thermal motion:

$$r_D = \left( \frac{\epsilon RT}{2\rho F^2 I b^\ominus} \right)^{1/2} \quad \boxed{\text{Thickness of the electrical double layer}} \quad (18.16)$$

<sup>1</sup> The derivation of the expressions quoted here is too complicated to include here. For a full description, see Volume 1 of R.J. Hunter, *Foundations of colloid science*, Oxford University Press (1987).

**Fig. 18.22** The potential energy of interaction as a function of the separation of the centres of the two particles and its variation with the ratio of the particle size (radius  $a$  for spherical particles) to the thickness of the electrical double layer,  $r_D$ . The regions labelled coagulation and flocculation show the dips in the potential energy curves where these processes occur.

where  $I$  is the ionic strength of the solution,  $\rho$  its mass density, and  $b^\circ = 1 \text{ mol kg}^{-1}$  ( $F$  is Faraday's constant and  $\epsilon$  is the permittivity,  $\epsilon = \epsilon_r \epsilon_0$ ). The potential energy arising from the attractive interaction has the form

$$V_{\text{attraction}} = -\frac{B}{s} \quad (18.17)$$

where  $B$  is another constant. The variation of the total potential energy with separation is shown in Fig. 18.22.

At high ionic strengths, the ionic atmosphere is dense and the potential shows a secondary minimum at large separations. Aggregation of the particles arising from the stabilizing effect of this secondary minimum is called **flocculation**. The flocculated material can often be redispersed by agitation because the well is so shallow. **Coagulation**, the irreversible aggregation of distinct particles into large particles, occurs when the separation of the particles is so small that they enter the primary minimum of the potential energy curve and van der Waals forces are dominant.

The ionic strength is increased by the addition of ions, particularly those of high charge type, so such ions act as flocculating agents. This increase is the basis of the empirical **Schulze–Hardy rule**, that hydrophobic colloids are flocculated most efficiently by ions of opposite charge type and high charge number. The  $\text{Al}^{3+}$  ions in alum are very effective, and are used to induce the congealing of blood. When river water containing colloidal clay flows into the sea, the salt water induces flocculation and coagulation, and is a major cause of silting in estuaries. Metal oxide sols tend to be positively charged, whereas sulfur and the noble metals tend to be negatively charged.

The primary role of the electric double layer is to confer kinetic non-lability. Colliding colloidal particles break through the double layer and coalesce only if the collision is sufficiently energetic to disrupt the layers of ions and solvating molecules, or if thermal motion has stirred away the surface accumulation of charge. This disruption may occur at high temperatures, which is one reason why sols precipitate when they are heated.

## 18.7 Micelles and biological membranes

**Key points** (a) A micelle is a colloid-sized cluster of molecules that forms at the critical micelle concentration and at the Krafft temperature. Micelles can assume a number of shapes, depending on temperature, shape, and concentration of constituent molecules. (b) Some micelles exist as parallel sheets two molecules thick that are either extended (planar bilayers) or fold back on to themselves (unilamellar vesicles). (c) Self-assembled monolayers are ordered molecular aggregates that form a single layer of material on a surface.

**Fig. 18.23** A schematic version of a spherical micelle. The hydrophilic groups are represented by spheres and the hydrophobic hydrocarbon chains are represented by the stalks; these stalks are mobile.

In aqueous solutions surfactant molecules or ions can cluster together as **micelles**, which are colloid-sized clusters of molecules, for their hydrophobic tails tend to congregate (through hydrophobic interactions—see Section 17.5f), and their hydrophilic head groups provide protection (Fig. 18.23).

### (a) Micelle formation

Micelles form only above the **critical micelle concentration** (CMC) and above the **Krafft temperature**. The CMC is detected by noting a pronounced change in physical properties of the solution, particularly the molar conductivity (Fig. 18.24). There is no abrupt change in properties at the CMC; rather, there is a transition region corresponding to a range of concentrations around the CMC where physical properties vary smoothly but nonlinearly with the concentration. The hydrocarbon interior of a micelle is like a droplet of oil. Nuclear magnetic resonance shows that the hydrocarbon

tails are mobile, but slightly more restricted than in the bulk. Micelles are important in industry and biology on account of their solubilizing function: matter can be transported by water after it has been dissolved in their hydrocarbon interiors. For this reason, micellar systems are used as detergents, for organic synthesis, froth flotation, and petroleum recovery.

Non-ionic surfactant molecules may cluster together in clumps of 1000 or more, but ionic species tend to be disrupted by the electrostatic repulsions between head groups and are normally limited to groups of less than about 100. However, the disruptive effect depends more on the effective size of the head group than the charge. For example, ionic surfactants such as sodium dodecyl sulfate (SDS) and cetyl trimethylammonium bromide (CTAB) form rods at moderate concentrations, whereas sugar surfactants form small, approximately spherical micelles. The micelle population is often polydisperse, and the shapes of the individual micelles vary with shape of the constituent surfactant molecules, surfactant concentration, and temperature. A useful predictor of the shape of the micelle is the **surfactant parameter**,  $N_s$ , defined as

$$N_s = \frac{V}{Al} \quad \text{Definition of the surfactant parameter} \quad [18.18]$$

where  $V$  is the volume of the hydrophobic surfactant tail,  $A$  is the area of the hydrophilic surfactant head group, and  $l$  is the maximum length of the surfactant tail. Table 18.1 summarizes the dependence of aggregate structure on the surfactant parameter.

In aqueous solutions spherical micelles form, as shown in Fig. 18.23, with the polar head groups of the surfactant molecules on the micellar surface and interacting favorably with solvent and ions in solution. Hydrophobic interactions stabilize the aggregation of the hydrophobic surfactant tails in the micellar core. Under certain experimental conditions, a **liposome** may form, with an inward pointing inner surface of molecules surrounded by an outward pointing outer layer (Fig. 18.25). Liposomes may be used to carry nonpolar drug molecules in blood.

Increasing the ionic strength of the aqueous solution reduces repulsions between surface head groups, and cylindrical micelles can form. These cylinders may stack together in reasonably close-packed (hexagonal) arrays, forming **lyotropic mesomorphs** and, more colloquially, ‘liquid crystalline phases’.

**Reverse micelles** form in nonpolar solvents, with small polar surfactant head groups in a micellar core and more voluminous hydrophobic surfactant tails extending into the organic bulk phase. These spherical aggregates can solubilize water in organic solvents by creating a pool of trapped water molecules in the micellar core. As aggregates arrange at high surfactant concentrations to yield long-range positional order, many other types of structures are possible including cubic and hexagonal shapes.

The enthalpy of micelle formation reflects the contributions of interactions between micelle chains within the micelles and between the polar head groups and the

**Fig. 18.24** The typical variation of some physical properties of an aqueous solution of sodium dodecylsulfate close to the critical micelle concentration (CMC).

**Fig. 18.25** The cross-sectional structure of a spherical liposome.

**Table 18.1** Variation of micelle shape with the surfactant parameter

| Value or range of the surfactant parameter, $N_s$ | Micelle shape                     |
|---------------------------------------------------|-----------------------------------|
| < 0.33                                            | Spherical                         |
| 0.33 to 0.50                                      | Cylindrical rods                  |
| 0.50 to 1.00                                      | Vesicles                          |
| 1.00                                              | Planar bilayers                   |
| > 1.00                                            | Reverse micelles and other shapes |

9 Phosphatidyl choline

**Fig. 18.26** A depiction of the variation with temperature of the flexibility of hydrocarbon chains in a lipid bilayer. (a) At physiological temperature, the bilayer exists as a liquid crystal, in which some order exists but the chains writhe. (b) At a specific temperature, the chains are largely frozen and the bilayer is said to exist as a gel.

surrounding medium. Consequently, enthalpies of micelle formation display no readily discernible pattern and may be positive (endothermic) or negative (exothermic). Many non-ionic micelles form endothermically, with  $\Delta H$  of the order of 10 kJ per mole of surfactant molecules. That such micelles do form above the CMC indicates that the entropy change accompanying their formation must then be positive, and measurements suggest a value of about  $+140 \text{ J K}^{-1} \text{ mol}^{-1}$  at room temperature. The fact that the entropy change is positive even though the molecules are clustering together shows that hydrophobic interactions are important in the formation of micelles.

### (b) Bilayers, vesicles, and membranes

Some micelles at concentrations well above the CMC form extended parallel sheets two molecules thick, called **planar bilayers**. The individual molecules lie perpendicular to the sheets, with hydrophilic groups on the outside in aqueous solution and on the inside in nonpolar media. When segments of planar bilayers fold back on themselves, **unilamellar vesicles** may form where the spherical hydrophobic bilayer shell separates an inner aqueous compartment from the external aqueous environment.

Bilayers show a close resemblance to biological membranes, and are often a useful model on which to base investigations of biological structures. However, actual membranes are highly sophisticated structures. The basic structural element of a membrane is a phospholipid, such as phosphatidyl choline (9), which contains long hydrocarbon chains (typically in the range  $C_{14}$ – $C_{24}$ ) and a variety of polar groups, such as  $-\text{CH}_2\text{CH}_2\text{N}(\text{CH}_3)_3^+$ . The hydrophobic chains stack together to form an extensive layer about 5 nm across. The lipid molecules form layers instead of micelles because the hydrocarbon chains are too bulky to allow packing into nearly spherical clusters.

The bilayer is a highly mobile structure, as shown by EPR studies with spin-labelled phospholipids (*Impact I14.2*). Not only are the hydrocarbon chains ceaselessly twisting and turning in the region between the polar groups, but the phospholipid and cholesterol molecules migrate over the surface. It is better to think of the membrane as a viscous fluid rather than a permanent structure, with a viscosity about 100 times that of water. In common with diffusional behaviour in general (Section 20.8), the average distance a phospholipid molecule diffuses is proportional to the square-root of the time; more precisely, for a molecule confined to a two-dimensional plane, the average distance travelled in a time  $t$  is equal to  $(4Dt)^{1/2}$ . Typically, a phospholipid molecule migrates through about  $1 \mu\text{m}$  in about 1 min.

All lipid bilayers undergo a transition from a state of high to low chain mobility at a temperature that depends on the structure of the lipid. To visualize the transition, we consider what happens to a membrane as we lower its temperature (Fig. 18.26). There is sufficient energy available at normal temperatures for limited bond rotation to occur and the flexible chains writhe. However, the membrane is still highly organized in the sense that the bilayer structure does not come apart and the system is best described as a liquid crystal. At lower temperatures, the amplitudes of the writhing motion decrease until a specific temperature is reached at which motion is largely frozen. The membrane is said to exist as a gel. Biological membranes exist as liquid crystals at physiological temperatures.

Phase transitions in membranes are often observed as ‘melting’ from gel to liquid crystal by differential scanning calorimetry (*Impact I2.1*). The data show relations between the structure of the lipid and the melting temperature. For example, the melting temperature increases with the length of the hydrophobic chain of the lipid. This correlation is reasonable, as we expect longer chains to be held together more strongly by hydrophobic interactions than shorter chains. It follows that stabilization

of the gel phase in membranes of lipids with long chains results in relatively high melting temperatures. On the other hand, any structural elements that prevent alignment of the hydrophobic chains in the gel phase lead to low melting temperatures. Indeed, lipids containing unsaturated chains, those containing some C=C bonds, form membranes with lower melting temperatures than those formed from lipids with fully saturated chains, those consisting of C–C bonds only.

Interspersed among the phospholipids of biological membranes are sterols, such as cholesterol (10), which is largely hydrophobic but does contain a hydrophilic –OH group. Sterols, which are present in different proportions in different types of cells, prevent the hydrophobic chains of lipids from ‘freezing’ into a gel and, by disrupting the packing of the chains, spread the melting point of the membrane over a range of temperatures.

10 Cholesterol

**Fig. 18.27** Self-assembled monolayers of alkylthiols formed on to a gold surface by reaction of the thiol groups with the surface and aggregation of the alkyl chains.

### (c) Self-assembled monolayers

Molecular self-assembly can be used as the basis for manipulation of surfaces on the nanometre scale. Of current interest are **self-assembled monolayers** (SAMs), ordered molecular aggregates that form a single layer of material on a surface. To understand the formation of SAMs, consider exposing molecules such as alkyl thiols RSH, where R represents an alkyl chain, to an Au(0) surface. The thiols react with the surface, forming RS<sup>−</sup>Au(I) adducts:

If R is a sufficiently long chain, van der Waals interactions between the adsorbed RS units lead to the formation of a highly ordered monolayer on the surface, as shown in Fig. 18.27. It is observed that the Gibbs energy of formation of SAMs increases with the length of the alkyl chain, with each methylene group contributing 400–4000 J mol<sup>−1</sup> to the overall Gibbs energy of formation.

A self-assembled monolayer alters the properties of the surface. For example, a hydrophilic surface may be rendered hydrophobic once covered with a SAM. Furthermore, attaching functional groups to the exposed ends of the alkyl groups may impart specific chemical reactivity or ligand-binding properties to the surface, leading to applications in chemical (or biochemical) sensors and reactors.

## Determination of size and shape

We have seen the importance of knowing the sizes of macromolecules. X-ray diffraction (which is described in detail in Chapter 19) can reveal the position of almost every atom other than hydrogen even in very large molecules. However, there are several reasons why other techniques must also be used. In the first place, the sample might be a mixture of molecules with different chain lengths and extents of cross-linking, in which case sharp X-ray images are not obtained. Even if all the molecules in the sample are identical, it might prove impossible to obtain a single crystal, which is essential for diffraction studies because only then does the electron density (which is responsible for the scattering) have a large-scale periodic variation. Furthermore, although work on proteins and DNA has shown how immensely interesting and motivating the data can be, the information is incomplete. For instance, what can be said about the shape of the molecule in its natural environment, a biological cell? What can be said about the response of its shape to changes in its environment?

## 18.8 Mean molar masses

**Key points** Macromolecules can be monodisperse, with a single molar mass, or polydisperse, with various molar masses. Depending on the measurement technique, the mean values of molar masses of polydisperse systems are obtained as the number-average, viscosity-average, weight-average, and Z-average molar masses.

A pure protein is **monodisperse**, meaning that it has a single, definite molar mass. There may be small variations, such as one amino acid replacing another, depending on the source of the sample. A synthetic polymer, however, is **polydisperse**, in the sense that a sample is a mixture of molecules with various chain lengths and molar masses. The various techniques that are used to measure molar mass result in different types of mean values of polydisperse systems.

The mean obtained from the determination of molar mass by osmometry (Section 5.5e) is the **number-average molar mass**,  $\bar{M}_n$ , which is the value obtained by weighting each molar mass by the number of molecules of that mass present in the sample:

$$\bar{M}_n = \frac{1}{N} \sum_i N_i M_i = \langle M \rangle \quad \text{Definition of the number-average molar mass} \quad [18.19]$$

where  $N_i$  is the number of molecules with molar mass  $M_i$  and there are  $N$  molecules in all. The notation  $\langle X \rangle$  denotes the usual (number) average of a property  $X$ , and we shall use it again below. For reasons related to the ways in which macromolecules contribute to physical properties, viscosity measurements give the **viscosity-average molar mass**,  $\bar{M}_v$ , light-scattering experiments give the **weight-average molar mass**,  $\bar{M}_w$ , and sedimentation experiments give the **Z-average molar mass**,  $\bar{M}_Z$ . (The name is derived from the z-coordinate used to depict data in a procedure for determining the average.) Although such averages are often best left as empirical quantities, some may be interpreted in terms of the composition of the sample. Thus, the weight-average molar mass is the average calculated by weighting the molar masses of the molecules by the mass of each one present in the sample:

$$\bar{M}_w = \frac{1}{m} \sum_i m_i M_i \quad \text{Definition of the weight-average molar mass} \quad [18.20a]$$

In this expression,  $m_i$  is the total mass of molecules of molar mass  $M_i$  and  $m$  is the total mass of the sample. Because  $m_i = N_i M_i / N_A$ , we can also express this average as

$$\bar{M}_w = \frac{\sum_i N_i M_i^2}{\sum_i N_i M_i} = \frac{\langle M^2 \rangle}{\langle M \rangle} \quad \text{Interpretation of the weight-average molar mass} \quad (18.20b)$$

This expression shows that the weight-average molar mass is proportional to the mean square molar mass. Similarly, the Z-average molar mass turns out to be proportional to the mean cubic molar mass:

$$\bar{M}_Z = \frac{\sum_i N_i M_i^3}{\sum_i N_i M_i^2} = \frac{\langle M^3 \rangle}{\langle M^2 \rangle} \quad \text{Interpretation of the Z-average molar mass} \quad (18.20c)$$

**Example 18.1** Calculating number and mass averages

Determine the number-average and the weight-average molar masses of a sample of poly(vinyl chloride) from the following data:

| Molar mass interval/<br>(kg mol <sup>-1</sup> ) | Average molar mass within<br>interval/(kg mol <sup>-1</sup> ) | Mass of sample<br>within interval/g |
|-------------------------------------------------|---------------------------------------------------------------|-------------------------------------|
| 5–10                                            | 7.5                                                           | 9.6                                 |
| 10–15                                           | 12.5                                                          | 8.7                                 |
| 15–20                                           | 17.5                                                          | 8.9                                 |
| 20–25                                           | 22.5                                                          | 5.6                                 |
| 25–30                                           | 27.5                                                          | 3.1                                 |
| 30–35                                           | 32.5                                                          | 1.7                                 |

**Method** The relevant equations are eqns 18.19 and 18.20a. Calculate the two averages by weighting the molar mass within each interval by the number and mass, respectively, of the molecules in each interval. Obtain the numbers in each interval by dividing the mass of the sample in each interval by the average molar mass for that interval. Because the number of molecules is proportional to the amount of substance (the number of moles), the number-weighted average can be obtained directly from the amounts in each interval.

**Answer** The amounts in each interval are as follows:

| Interval                           | 5–10 | 10–15 | 15–20 | 20–25 | 25–30  | 30–35 |
|------------------------------------|------|-------|-------|-------|--------|-------|
| Molar mass/(kg mol <sup>-1</sup> ) | 7.5  | 12.5  | 17.5  | 22.5  | 27.5   | 32.5  |
| Amount/mmol                        | 1.3  | 0.70  | 0.51  | 0.25  | 0.11   | 0.052 |
|                                    |      |       |       |       | Total: | 2.92  |

The number-average molar mass is therefore

$$\begin{aligned}\bar{M}_n/(\text{kg mol}^{-1}) &= \frac{1}{2.92} (1.3 \times 7.5 + 0.70 \times 12.5 + 0.51 \times 17.5 + 0.25 \times 22.5 \\ &\quad + 0.11 \times 27.5 + 0.052 \times 32.5) \\ &= 13\end{aligned}$$

The weight-average molar mass is calculated directly from the data after noting that the total mass of the sample is 37.6 g:

$$\begin{aligned}\bar{M}_w/(\text{kg mol}^{-1}) &= \frac{1}{37.6} (9.6 \times 7.5 + 8.7 \times 12.5 + 8.9 \times 17.5 + 5.6 \times 22.5 \\ &\quad + 3.1 \times 27.5 + 1.7 \times 32.5) \\ &= 16\end{aligned}$$

Note the different values of the two averages. In this instance,  $\bar{M}_w/\bar{M}_n = 1.2$ .

**Self-test 18.1** Evaluate the *Z*-average molar mass of the sample. [19 kg mol<sup>-1</sup>]

The ratio  $\bar{M}_w/\bar{M}_n$  is called the **heterogeneity index** (or ‘polydispersity index’). It follows from eqns 18.19 and 18.20b that

$$\frac{\bar{M}_w}{\bar{M}_n} = \frac{\langle M^2 \rangle}{\langle M \rangle^2} \quad \text{Definition of the heterogeneity index} \quad [18.21]$$

**A note on good practice** The masses of macromolecules are often reported in daltons (Da), where  $1 \text{ Da} = m_{\text{u}}$  (with  $m_{\text{u}} = 1.661 \times 10^{-27} \text{ kg}$ ). Note that 1 Da is a measure of *molecular* mass not of *molar* mass. We might say that the mass (not the molar mass) of a certain macromolecule is 100 kDa (that is, its mass is  $100 \times 10^3 \times m_{\text{u}}$ ); we could also say that its molar mass is  $100 \text{ kg mol}^{-1}$ ; we should not say (even though it is common practice) that its molar mass is 100 kDa.

**Fig. 18.28** A matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometer. A laser beam ejects macromolecules and ions from the solid matrix. The ionized macromolecules are accelerated by an electrical potential difference over a distance  $d$  and then travel through a drift region of length  $l$ . Ions with the smallest mass to charge ratio ( $m/z$ ) reach the detector first.

That is, the index is proportional to the ratio of the mean square molar mass to the square of the mean molar mass. In the determination of protein molar masses we expect the various averages to be the same because the sample is monodisperse (unless there has been degradation). A synthetic polymer normally spans a range of molar masses and the different averages yield different values. Typical synthetic materials have  $\bar{M}_w/\bar{M}_n \approx 4$  but much recent research has been devoted to developing methods that give much lower polydispersities. The term ‘monodisperse’ is conventionally applied to synthetic polymers in which this index is less than 1.1; commercial polyethylene samples might be much more heterogeneous, with a ratio close to 30. One consequence of a narrow molar mass distribution for synthetic polymers is often a higher degree of three-dimensional long-range order in the solid and therefore higher density and melting point. The spread of values is controlled by the choice of catalyst and reaction conditions. In practice, it is found that long-range order is determined more by structural factors (branching, for instance) than by molar mass.

## 18.9 The techniques

Average molar masses may be determined by osmotic pressure of polymer solutions. The upper limit for the reliability of membrane osmometry is about  $1000 \text{ kg mol}^{-1}$ . A major problem for macromolecules of relatively low molar mass (less than about  $10 \text{ kg mol}^{-1}$ ) is their ability to percolate through the membrane. One consequence of this partial permeability is that membrane osmometry tends to overestimate the average molar mass of a polydisperse mixture. Several techniques for the determination of molar mass and polydispersity that are not so limited include mass spectrometry, laser light scattering, ultracentrifugation, electrophoresis, and viscosity measurements.

### (a) Mass spectrometry

**Key point** In the MALDI-TOF technique, matrix-assisted laser desorption/ionization is coupled with a time-of-flight mass spectrometer to measure the molar masses of macromolecules.

Mass spectrometry is among the most accurate techniques for the determination of molar masses. The procedure consists of ionizing the sample in the gas phase and then measuring the mass-to-charge number ratio ( $m/z$ ; more precisely, the dimensionless ratio  $m/zm_{\text{u}}$ ) of all ions. Macromolecules present a challenge because it is difficult to produce gaseous ions of large species without fragmentation. However, two new techniques have emerged that circumvent this problem: **matrix-assisted laser desorption/ionization (MALDI)** and **electrospray ionization**. We shall discuss **MALDI-TOF mass spectrometry**, so called because the MALDI technique is coupled to a time-of-flight (TOF) ion detector.

Figure 18.28 shows a schematic view of a MALDI-TOF mass spectrometer. The macromolecule is first embedded in a solid matrix that often consists of an organic material such as *trans*-3-indoleacrylic acid and inorganic salts such as sodium chloride or silver trifluoroacetate. This sample is then irradiated with a pulsed laser. The laser beam ejects electronically excited matrix ions, cations, and neutral macromolecules, thus creating a dense gas plume above the sample surface. The macromolecule is ionized by collisions and complexation with small cations, such as  $\text{H}^+$ ,  $\text{Na}^+$ , and  $\text{Ag}^+$ .

Figure 18.29 shows the MALDI-TOF mass spectrum of a polydisperse sample of poly(butylene adipate) (PBA, 11). The MALDI technique produces mostly singly charged molecular ions that are not fragmented. Therefore, the multiple peaks in the spectrum arise from polymers of different lengths, with the intensity of each peak being proportional to the abundance of each polymer in the sample. Values of  $\bar{M}_n$ ,  $\bar{M}_w$ , and the heterogeneity index can be calculated from the data. It is also possible

to use the mass spectrum to verify the structure of a polymer, as shown in the following example.

**Example 18.2** *Interpreting the mass spectrum of a polymer*

The mass spectrum in Fig. 18.29 consists of peaks spaced by  $200 \text{ g mol}^{-1}$ . The peak at  $4113 \text{ g mol}^{-1}$  corresponds to the polymer for which  $n = 20$ . From these data, verify that the sample consists of polymers with the general structure given by (11).

**Method** Because each peak corresponds to a different value of  $n$ , the molar mass difference,  $\Delta M$ , between peaks corresponds to the molar mass,  $M$ , of the repeating unit (the group inside the brackets in 11). Furthermore, the molar mass of the terminal groups (the groups outside the brackets in 11) may be obtained from the molar mass of any peak by using

$$M(\text{terminal groups}) = M(\text{polymer with } n \text{ repeating units}) - n\Delta M - M(\text{cation})$$

where the last term corresponds to the molar mass of the cation that attaches to the macromolecule during ionization.

**Answer** The value of  $\Delta M$  is consistent with the molar mass of the repeating unit shown in (11), which is  $200 \text{ g mol}^{-1}$ . The molar mass of the terminal group is calculated by recalling that  $\text{Na}^+$  is the cation in the matrix:

$$M(\text{terminal group}) = 4113 \text{ g mol}^{-1} - 20(200 \text{ g mol}^{-1}) - 23 \text{ g mol}^{-1} = 90 \text{ g mol}^{-1}$$

The result is consistent with the molar mass of the  $-\text{O}(\text{CH}_2)_4\text{OH}$  terminal group ( $89 \text{ g mol}^{-1}$ ) plus the molar mass of the  $-\text{H}$  terminal group ( $1 \text{ g mol}^{-1}$ ).

**Self-test 18.2** What would be the molar mass of the  $n = 20$  polymer if silver trifluoroacetate were used instead of  $\text{NaCl}$  in the preparation of the matrix?

$$[4198 \text{ g mol}^{-1}]$$

**Fig. 18.29** MALDI-TOF spectrum of a sample of poly(butylene adipate) with  $\bar{M}_n = 4525 \text{ g mol}^{-1}$  (Adapted from Mudiman *et al.*, *J. Chem. Educ.*, **74**, 1288 (1997).)

## (b) Laser light scattering

**Key points** (a) The intensity of Rayleigh light scattering by a sample increases with decreasing wavelength of the incident radiation and increasing size of the particles in the sample. Analysis of Rayleigh scattering leads to the determination of the molar mass of a macromolecule or aggregate. (b) The analysis of Rayleigh scattering needs to take into account the non-ideality of solutions of macromolecules. (c) Dynamic light scattering is a technique for the determination of the diffusion properties and molar masses of macromolecules and aggregates.

The intensity of light scattered from a dilute solution excited by plane-polarized light measured at a distance  $r$  from the solution is proportional to the intensity of incident light,  $I_0$ , and to  $(1/r^2)\sin^2\phi$  where  $r$  is the distance of the detector from the sample (the factor  $1/r^2$  occurs because the wave is spreading out over a sphere of radius  $r$  and surface area  $4\pi r^2$ , so any sample of the radiation is diluted by a factor proportional to  $r^2$ ), and we write

**Fig. 18.30** Rayleigh scattering from a sample of point-like particles. The intensity of scattered light depends on the angle  $\theta$  between the incident and scattered beams. The inset shows the angle  $\phi$  between the plane of polarization of the incident beam and the plane defined by the incident and scattered beams. In a typical experimental arrangement,  $\phi = 90^\circ$ .

$$I(\theta, \phi, r) = R(\theta) I_0 \times \frac{\sin^2 \phi}{r^2}$$

Definition of the Rayleigh ratio [18.22a]

where the coefficient of proportionality  $R(\theta)$ , which depends on the angle  $\theta$ , is called the **Rayleigh ratio** (Fig. 18.30). The value of  $R(\theta)$  is found by inverting this expression and inserting the measured value of the intensity at the location  $\theta$ ,  $\phi$ , and  $r$ :

$$R(\theta) = \frac{I(\theta, \phi, r)}{I_0} \times \frac{r^2}{\sin^2 \phi} \quad (18.22b)$$

The intensity of scattered radiation is proportional to the concentration of scattering molecules and for a solution of a polymer of mass concentration  $c_p$ , the Rayleigh ratio may be written<sup>2</sup>

$$R(\theta) = K c_p \bar{M}_w$$

Relation between the Rayleigh ratio and the polymer molar mass (18.23)

The proportionality constant  $K$  recognizes that the scattering by the macromolecules depends on the difference of refractive index ( $n_r$ ) between them and the solvent (if the refractive indexes were the same, the solute would be invisible) and in a calculation that we do not reproduce here, it is found that

$$K = \frac{2\pi^2 n_r^2}{N_A \lambda^4} \frac{dn_r}{dc_p} \quad (18.24)$$

All the quantities in this expression can be measured in separate experiments, so  $K$  is, in principle, known.

When the size of the molecule is not negligible compared with the wavelength of the incident radiation, interference between different parts of the same molecule must be taken into account. This effect is taken into account by multiplying the right-hand side of eqn 8.22b by a structure factor,  $P(\theta)$ :<sup>2</sup>

$$P(\theta) \approx 1 - p(\theta) \quad \text{with} \quad p(\theta) = \frac{16\pi^2 R_g^2 \sin^2 \frac{1}{2}\theta}{3\lambda^2}$$

Structure factor of a small macromolecule (18.25)

where  $R_g$  is the radius of gyration of the macromolecule. (The radius of gyration plays a role not through its normal appearance in expressions relating to hydrodynamic behaviour but because it turns out to be the appropriate measure of the size of the molecule.) As we show in the following *Justification*, we should expect a straight line when  $1/R(\theta)$  is plotted against  $(\sin^2 \frac{1}{2}\theta)/R(\theta)$ , from which the weight-average molar mass and the radius of gyration can be determined from the intercept and slope, respectively. Table 18.2 lists some experimental values of  $R_g$  obtained in this way.

**Table 18.2\*** Radius of gyration

|               | $M/(\text{kg mol}^{-1})$ | $R_g/\text{nm}$ |
|---------------|--------------------------|-----------------|
| Serum albumin | 66.2                     | 2.98            |
| Polystyrene   | $3.2 \times 10^3$        | $50^\ddagger$   |
| DNA           | $4 \times 10^3$          | 117             |

\* More values are given in the *Data section*.

<sup>‡</sup> In a poor solvent.

#### Justification 18.4 The analysis of scattering intensity

Equations 18.22b and 18.25 can be combined as follows:

$$\frac{1}{R(\theta)} = \frac{1}{K P(\theta) c_p \bar{M}_w} \approx \frac{1}{K c_p \bar{M}_w (1 - p(\theta))}$$

Then we use  $(1 - x)^{-1} \approx 1 + x$  (which is valid when  $x \ll 1$ ) to write

$$\frac{1}{R(\theta)} \approx \frac{1}{K c_p \bar{M}_w} (1 + p(\theta)) = \frac{1}{K c_p \bar{M}_w} + \frac{p(\theta)}{K c_p \bar{M}_w}$$

<sup>2</sup> For a derivation of this and the following equation, see C.A. Johnson and D.A. Gabriel, *Laser light scattering*, Dover, New York (1995) and references cited therein. See also R.J. Hunter, cited in footnote 1.

As we are ignoring terms of order  $x^2$ , we can replace the factor  $Kc_p\bar{M}_w$  in the second term by  $R(\theta)$ , and so obtain

$$\frac{1}{R(\theta)} \approx \frac{1}{Kc_p\bar{M}_w} + \frac{p(\theta)}{R(\theta)} \quad (18.26a)$$

Because  $p(\theta) \propto \sin^2 \frac{1}{2}\theta$ , this expression has the form

$$\frac{1}{R(\theta)} \approx \frac{1}{Kc_p\bar{M}_w} + a \times \frac{\sin^2 \frac{1}{2}\theta}{R(\theta)} \quad a = \frac{16\pi^2 R_g^2}{3\lambda^2} \quad (18.26b)$$

where the weight-average molar mass can be determined from the intercept and the radius of gyration can be determined from the slope  $a$ .

### Example 18.3 Determining the size of a polymer by light scattering

The following data for a sample of polystyrene in butanone were obtained at 20°C with plane-polarized light at  $\lambda = 546$  nm.

|                        |      |      |      |      |       |
|------------------------|------|------|------|------|-------|
| $\theta/^\circ$        | 26.0 | 36.9 | 66.4 | 90.0 | 113.6 |
| $R(\theta)/\text{m}^2$ | 19.7 | 18.8 | 17.1 | 16.0 | 14.4  |

In separate experiments, it was determined that  $K = 6.42 \times 10^{-5} \text{ mol m}^5 \text{ kg}^{-2}$ . From this information, calculate  $R_g$  and  $\bar{M}_w$  for the sample. Assume that the polymer is small enough that eqn 18.25 holds. Take  $c_p = 311 \text{ kg m}^{-3}$ .

**Method** As shown in the text, a plot of  $1/R(\theta)$  against  $(\sin^2 \frac{1}{2}\theta)/R(\theta)$  should be a straight line with slope  $16\pi^2 R_g^2/3\lambda^2$  and  $y$ -intercept  $1/Kc_p\bar{M}_w$ .

**Answer** We construct a table of values of  $1/R(\theta)$  and  $(\sin^2 \frac{1}{2}\theta)/R(\theta)$  and plot the data (Fig. 18.31).

|                                                                      |      |      |      |      |       |
|----------------------------------------------------------------------|------|------|------|------|-------|
| $\theta/^\circ$                                                      | 26.0 | 36.9 | 66.4 | 90.0 | 113.6 |
| $\{10^2/R(\theta)\}/\text{m}^{-2}$                                   | 5.08 | 5.32 | 5.85 | 6.25 | 6.94  |
| $\{10^3 \times (\sin^2 \frac{1}{2}\theta)/R(\theta)\}/\text{m}^{-2}$ | 2.57 | 5.33 | 17.5 | 31.3 | 48.6  |

The best straight line through the data has a slope of 0.388 and a  $y$ -intercept of  $5.07 \times 10^{-2}$ . From these values and the value of  $K$ , we calculate  $R_g = 4.69 \times 10^{-8} \text{ m} = 46.9 \text{ nm}$  and  $\bar{M}_w = 987 \text{ kg mol}^{-1}$ .

**Self-test 18.3** The following data for an aqueous solution of a protein with  $c_p = 2.0 \text{ kg m}^{-3}$  were obtained at 20°C with laser light at  $\lambda = 532$  nm:

|                        |      |      |      |      |      |
|------------------------|------|------|------|------|------|
| $\theta/^\circ$        | 15.0 | 45.0 | 70.0 | 85.0 | 90.0 |
| $R(\theta)/\text{m}^2$ | 23.8 | 22.9 | 21.6 | 20.7 | 20.4 |

In a separate experiment, it was determined that  $K = 2.40 \times 10^{-2} \text{ mol m}^5 \text{ kg}^{-2}$ . From this information, calculate the radius of gyration and the molar mass of the protein. Assume the protein is small enough that eqn 18.25 holds.

$$[R_g = 39.8 \text{ nm}; M = 498 \text{ kg mol}^{-1}]$$

Fig. 18.31 Plot of the data for Example 18.3.

### (c) Sedimentation

**Key points** (a) The rate of sedimentation in an ultracentrifuge depends on molar masses and shapes of the macromolecules in the sample. (b) The weight-average and Z-average molar mass of a sample of macromolecules can be determined from equilibrium measurements of sedimentation in an ultracentrifuge.

In a gravitational field, heavy particles settle towards the foot of a column of solution by the process called **sedimentation**. The rate of sedimentation depends on the strength of the field and on the masses and shapes of the particles. Spherical molecules (and compact molecules in general) sediment faster than rod-like and extended molecules. When the sample is at equilibrium, the particles are dispersed over a range of heights in accord with the Boltzmann distribution (because the gravitational field competes with the stirring effect of thermal motion). The spread of heights depends on the masses of the molecules, so the equilibrium distribution is another way to determine molar mass.

Sedimentation is normally very slow, but it can be accelerated by **ultracentrifugation**, a technique that replaces the gravitational field with a centrifugal field. The effect can be achieved in an ultracentrifuge, which is essentially a cylinder that can be rotated at high speed about its axis with a sample in a cell near its outer edge. Modern ultracentrifuges can produce accelerations equivalent to about  $10^5$  that of gravity ( $10^5 g$ ). Initially the sample is uniform, but the ‘top’ (innermost) boundary of the solute moves outwards as sedimentation proceeds.

A solute particle of mass  $m$  has an effective mass  $m_{\text{eff}} = bm$  on account of the buoyancy of the medium, with

$$b = 1 - \rho v_s \quad (18.27)$$

where  $\rho$  is the solution density,  $v_s$  is the partial specific volume of the solute ( $v_s = (\partial V / \partial m_B)_T$ , with  $m_B$  the total mass of solute), and  $\rho v_s$  is the mass of solvent displaced per gram of solute. The solute particles at a distance  $r$  from the axis of a rotor spinning at an angular velocity  $\omega$  experience a centrifugal force of magnitude  $m_{\text{eff}} r \omega^2$ . The acceleration outwards is countered by a frictional force proportional to the speed,  $s = dr/dt$ , of the particles through the medium. This force is written  $fs$ , where  $f$  is the **frictional coefficient**. The particles therefore adopt a **drift speed**, a constant speed through the medium, which is found by equating the two forces  $m_{\text{eff}} r \omega^2$  and  $fs$ . The forces are equal when

$$s = \frac{m_{\text{eff}} r \omega^2}{f} = \frac{bmr \omega^2}{f} \quad (18.28)$$

The drift speed depends on the angular velocity and the radius, and it is convenient to define the **sedimentation constant**,  $S$ , as

$$S = \frac{s}{r \omega^2} \quad \text{Definition of the sedimentation constant} \quad [18.29]$$

Then, because the average molecular mass is related to the average molar mass  $\bar{M}_n$  through  $m = \bar{M}_n / N_A$

$$S = \frac{b \bar{M}_n}{f N_A} \quad (18.30)$$

For a spherical particle of radius  $a$  in a solvent of viscosity  $\eta$ , the frictional coefficient  $f$  is given by **Stokes' relation**:

$$f = 6\pi a \eta \quad (18.31)$$

On substituting this expression into eqn 18.30, we obtain

$$S = \frac{b \bar{M}_n}{6\pi a \eta N_A} \quad \text{Relation between } S \text{ and the molar mass of a spherical polymer} \quad (18.32)$$

and  $S$  may be used to determine either  $\bar{M}_n$  or  $a$ . Again, if the molecules are not spherical, we use the appropriate value of  $f$  given in Table 18.3. As always when dealing with macromolecules, the measurements must be carried out at a series of concentrations and then extrapolated to zero concentration to avoid the complications that arise from the interference between bulky molecules.

**Example 18.4** *Determining a sedimentation constant*

The sedimentation of the protein bovine serum albumin (BSA) was monitored at 25°C. The initial location of the solute surface was at 5.50 cm from the axis of rotation, and during centrifugation at 56 850 r.p.m. it receded as follows:

|        |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|
| $t/s$  | 0    | 500  | 1000 | 2000 | 3000 | 4000 | 5000 |
| $r/cm$ | 5.50 | 5.55 | 5.60 | 5.70 | 5.80 | 5.91 | 6.01 |

Calculate the sedimentation coefficient.

**Method** Equation 18.29 can be interpreted as a differential equation for  $s = dr/dt$  in terms of  $r$ ; so integrate it to obtain a formula for  $r$  in terms of  $t$ . The integrated expression, an expression for  $r$  as a function of  $t$ , will suggest how to plot the data and obtain from it the sedimentation constant.

**Answer** Equation 18.29 may be written

$$\frac{dr}{dt} = r\omega^2 S$$

This equation integrates to

$$\ln \frac{r}{r_0} = \omega^2 S t$$

It follows that a plot of  $\ln(r/r_0)$  against  $t$  should be a straight line of slope  $\omega^2 S$ . Use  $\omega = 2\pi\nu$ , where  $\nu$  is in cycles per second, and draw up the following table:

|                   |   |       |      |      |      |      |      |
|-------------------|---|-------|------|------|------|------|------|
| $t/s$             | 0 | 500   | 1000 | 2000 | 3000 | 4000 | 5000 |
| $10^2 \ln(r/r_0)$ | 0 | 0.905 | 1.80 | 3.57 | 5.31 | 7.19 | 8.87 |

The straight-line graph (Fig. 18.32) has a slope of  $1.78 \times 10^{-5}$ ; so  $\omega^2 S = 1.78 \times 10^{-5} \text{ s}^{-1}$ . Because  $\omega = 2\pi \times (56\,850/60) \text{ s}^{-1} = 5.95 \times 10^3 \text{ s}^{-1}$ , it follows that  $S = 5.02 \times 10^{-13} \text{ s}$ . The unit  $10^{-13} \text{ s}$  is sometimes called a 'svedberg' and denoted Sv; in this case  $S = 5.02 \text{ Sv}$ .

**Self-test 18.4** Calculate the sedimentation constant given the following data (the other conditions being the same as above):

|        |      |      |      |      |      |      |           |
|--------|------|------|------|------|------|------|-----------|
| $t/s$  | 0    | 500  | 1000 | 2000 | 3000 | 4000 | 5000      |
| $r/cm$ | 5.65 | 5.68 | 5.71 | 5.77 | 5.84 | 5.9  | 5.97      |
|        |      |      |      |      |      |      | [3.11 Sv] |

The difficulty with using sedimentation rates to measure molar masses lies in the inaccuracies inherent in the determination of diffusion coefficients of polydisperse systems. This problem can be avoided by allowing the system to reach equilibrium, for the transport property  $D$  is then no longer relevant. As we show in the following *Justification*, the weight-average molar mass can be obtained from the ratio of concentrations of the macromolecules at two different radii in a centrifuge operating at angular frequency  $\omega$ :

**Table 18.3\*** Frictional coefficients and molecular geometry†

| $a/b$ | Prolate | Oblate |
|-------|---------|--------|
| 2     | 1.04    | 1.04   |
| 3     | 1.18    | 1.17   |
| 6     | 1.31    | 1.28   |
| 8     | 1.43    | 1.37   |
| 10    | 1.54    | 1.46   |

\* More values and analytical expressions are given in the *Data section*.

† Entries are the ratio  $f/f_0$ , where  $f_0 = 6\pi\eta c$ , where  $c = (ab^2)^{1/3}$  for prolate ellipsoids and  $c = (a^2b)^{1/3}$  for oblate ellipsoids;  $2a$  is the major axis and  $2b$  is the minor axis.

**Fig. 18.32** A plot of the data for Example 18.4.

$$\bar{M}_w = \frac{2RT}{(r_2^2 - r_1^2)b\omega^2} \ln \frac{c_2}{c_1} \quad (18.33)$$

An alternative treatment of the data leads to the *Z*-average molar mass. The centrifuge is run more slowly in this technique than in the sedimentation rate method to avoid having all the solute pressed in a thin film against the bottom of the cell. At these slower speeds, several days may be needed for equilibrium to be reached.

**Justification 18.5** *The weight-average molar mass from sedimentation experiments*

The centrifugal force acting on a molecule at a radius  $r$  when it is rotating around the axis of the centrifuge at a frequency  $\omega$  is  $m\omega^2 r$ . This force corresponds to a difference in potential energy (using  $F = -dV/dr$ ) of  $-\frac{1}{2}m\omega^2 r^2$ . The difference in potential energy between  $r_1$  and  $r_2$  (with  $r_2 > r_1$ ) is therefore  $\frac{1}{2}m\omega^2(r_1^2 - r_2^2)$ . According to the Boltzmann distribution, the ratio of concentrations of molecules at these two radii should therefore be

$$\frac{c_2}{c_1} = e^{-\frac{1}{2}m_{\text{eff}}\omega^2(r_1^2 - r_2^2)/kT}$$

The effective mass,  $m_{\text{eff}}$ , which allows for buoyancy effects, is  $m(1 - v\rho)$ , and  $m/k$  can be replaced by  $M/R$ , where  $R = N_A k$  is the gas constant. Then, by taking logarithms of both sides, the last equation becomes

$$\ln \frac{c_2}{c_1} = \frac{M(1 - v\rho)\omega^2(r_2^2 - r_1^2)}{2RT}$$

which rearranges into eqn 18.33.

#### (d) Viscosity

**Key point** The viscosity-average molar mass can be determined from measurements of the viscosity of solutions of macromolecules.

The formal definition of viscosity is given in Section 20.4; for now, we need to know that highly viscous liquids flow slowly and retard the motion of objects through them. The presence of a macromolecular solute increases the viscosity of a solution. The effect is large even at low concentration, because big molecules affect the fluid flow over an extensive region surrounding them. At low concentrations the viscosity,  $\eta$ , of the solution is related to the viscosity of the pure solvent,  $\eta_0$ , by

$$\eta = \eta_0(1 + [\eta]c + [\eta]'c^2 + \dots) \quad (18.34)$$

The **intrinsic viscosity**,  $[\eta]$ , is the analogue of a virial coefficient (and has dimensions of 1/concentration). It follows from eqn 18.34 that

$$[\eta] = \lim_{c \rightarrow 0} \left( \frac{\eta - \eta_0}{c\eta_0} \right) = \lim_{c \rightarrow 0} \left( \frac{\eta/\eta_0 - 1}{c} \right) \quad \text{Definition of the intrinsic viscosity} \quad [18.35]$$

Viscosities are measured in several ways. In the **Ostwald viscometer** shown in Fig. 18.33, the time taken for a solution to flow through the capillary is noted, and compared with a standard sample. The method is well suited to the determination of  $[\eta]$  because the ratio of the viscosities of the solution and the pure solvent is proportional to the drainage time  $t$  and  $t_0$  after correcting for different densities  $\rho$  and  $\rho_0$ :

$$\frac{\eta}{\eta_0} = \frac{t}{t_0} \times \frac{\rho}{\rho_0} \quad (18.36)$$

**Fig. 18.33** An Ostwald viscometer. The viscosity is measured by noting the time required for the liquid to drain between the two marks.

**Table 18.4\*** Intrinsic viscosity

|                     | Solvent                                                       | $\theta/^{\circ}\text{C}$ | $K/(\text{cm}^3 \text{g}^{-1})$ | $a$  |
|---------------------|---------------------------------------------------------------|---------------------------|---------------------------------|------|
| Polystyrene         | Benzene                                                       | 25                        | $9.5 \times 10^{-3}$            | 0.74 |
| Poly(methylpropene) | Benzene                                                       | 23                        | $8.3 \times 10^{-2}$            | 0.50 |
| Various proteins    | Guanidine hydrochloride + $\text{HSCH}_2\text{CH}_2\text{OH}$ |                           | $7.2 \times 10^{-3}$            | 0.66 |

\* More values are given in the Data section.

This ratio can be used directly in eqn 18.35. Viscometers in the form of rotating concentric cylinders are also used (Fig. 18.34), and the torque on the inner cylinder is monitored while the outer one is rotated. Such **rotating rheometers** (some instruments for the measurement of viscosity are also called rheometers, from the Greek word for ‘flow’) have the advantage over the Ostwald viscometer that the shear gradient between the cylinders is simpler than in the capillary and effects of the kind discussed shortly can be studied more easily.

There are many complications in the interpretation of viscosity measurements. Much of the work is based on empirical observations, and the determination of molar mass is usually based on comparisons with a standard, nearly monodisperse sample. Some regularities are observed that help in the determination. For example, it is found that some solutions of macromolecules often fit the **Mark–Kuhn–Houwink–Sakurada equation**:

$$[\eta] = K\bar{M}_v^a \quad \text{Mark–Kuhn–Houwink–Sakurada equation} \quad (18.37)$$

where  $K$  and  $a$  are constants that depend on the solvent and type of macromolecule (Table 18.4); the viscosity-average molar mass,  $\bar{M}_v$ , appears in this expression.

#### Example 18.5 Using intrinsic viscosity to measure molar mass

The viscosities of a series of solutions of polystyrene in toluene were measured at 25°C with the following results:

|                                                   |      |      |      |      |      |      |
|---------------------------------------------------|------|------|------|------|------|------|
| $c/(\text{g dm}^{-3})$                            | 0    | 2    | 4    | 6    | 8    | 10   |
| $\eta/(10^{-4} \text{ kg m}^{-1} \text{ s}^{-1})$ | 5.58 | 6.15 | 6.74 | 7.35 | 7.98 | 8.64 |

Calculate the intrinsic viscosity and estimate the molar mass of the polymer by using eqn 18.37 with  $K = 3.80 \times 10^{-5} \text{ dm}^3 \text{g}^{-1}$  and  $a = 0.63$ .

**Method** The intrinsic viscosity is defined in eqn 18.35; therefore, form this ratio at the series of data points and extrapolate to  $c = 0$ . Interpret  $\bar{M}_v$  as  $\bar{M}_v/(\text{g mol}^{-1})$  in eqn 18.37.

**Answer** We draw up the following table:

|                                               |   |       |       |       |      |       |
|-----------------------------------------------|---|-------|-------|-------|------|-------|
| $c/(\text{g dm}^{-3})$                        | 0 | 2     | 4     | 6     | 8    | 10    |
| $\eta/\eta_0$                                 | 1 | 1.102 | 1.208 | 1.317 | 1.43 | 1.549 |
| $100[(\eta/\eta_0) - 1]/(c/\text{g dm}^{-3})$ |   | 5.11  | 5.20  | 5.28  | 5.38 | 5.49  |

The points are plotted in Fig. 18.35. The extrapolated intercept at  $c = 0$  is 0.0504, so  $[\eta] = 0.0504 \text{ dm}^3 \text{g}^{-1}$ . Therefore

$$\bar{M}_v = \left( \frac{[\eta]}{K} \right)^{1/a} = 9.0 \times 10^4 \text{ g mol}^{-1}$$

**Fig. 18.34** A rotating rheometer. The torque on the inner drum is observed when the outer container is rotated.

**Fig. 18.35** The plot used for the determination of intrinsic viscosity, which is taken from the intercept at  $c = 0$ ; see Example 18.5.

**Self-test 18.5** Show that the intrinsic viscosity may also be obtained as  $[\eta] = \lim_{c \rightarrow 0} (\eta/\eta_0)$  and evaluate the viscosity-average molar mass by using this relation. [90 kg mol<sup>-1</sup>]

In some cases, the flow is non-Newtonian in the sense that the viscosity of the solution changes as the rate of flow increases. A decrease in viscosity with increasing rate of flow indicates the presence of long rod-like molecules that are orientated by the flow and hence slide past each other more freely. In some somewhat rare cases the stresses set up by the flow are so great that long molecules are broken up, with further consequences for the viscosity.

### Checklist of key equations

| Property                                                                    | Equation                                                                        | Comment                       |
|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------|-------------------------------|
| Contour length of a random coil                                             | $R_c = Nl$                                                                      |                               |
| Root-mean-square separation of a random coil                                | $R_{rms} = N^{1/2}l$                                                            | Unconstrained chain           |
|                                                                             | $R_{rms} = (2N)^{1/2}l$                                                         | Constrained tetrahedral chain |
| Radius of gyration of a 3D random coil                                      | $R_g = (N/6)^{1/2}l$                                                            | Unconstrained chain           |
|                                                                             | $R_g = (N/3)^{1/2}l$                                                            | Constrained tetrahedral chain |
| Conformational entropy of a random coil                                     | $\Delta S = -\frac{1}{2}kN \ln\{(1+v)^{1+v}(1-v)^{1-v}\}$                       |                               |
|                                                                             | $v = n/N$                                                                       |                               |
| Thickness of the electrical double layer                                    | $r_D \propto (T/I)^{1/2}$                                                       | Debye–Hückel theory           |
| Number-average molar mass                                                   | $\bar{M}_n = (1/N) \sum_i N_i M_i$                                              | Definition                    |

## Further information

### Further information 18.1 Random and nearly random coils

In this section, we consider various statistical aspects of the structures of random and nearly random coils in one and three dimensions and derive the expressions quoted in the text.

#### (a) A one-dimensional freely jointed random coil

Consider a one-dimensional freely jointed polymer. We can specify the conformation of a molecule by stating the number of bonds pointing to the right ( $N_R$ ) and the number pointing to the left ( $N_L$ ). The distance between the ends of the chain is  $(N_R - N_L)l$ , where  $l$  is the length of an individual bond. We write  $n = N_R - N_L$  and the total number of bonds as  $N = N_R + N_L$ .

The number of ways  $W$  of forming a chain with a given end-to-end distance  $nl$  is the number of ways of having  $N_R$  right-pointing and  $N_L$  left-pointing bonds. There are  $N(N-1)(N-2) \cdots 1 = N!$  ways of selecting whether a step should be to the right or the left. If  $N_L$  steps are to the left,  $N_R = N - N_L$  will be to the right. However, we end up at the same point for all  $N_L!$  and  $N_R!$  choices of which step is to the left and which to the right. Therefore

$$W = \frac{N!}{N_L!N_R!} = \frac{N!}{\{\frac{1}{2}(N+n)\}!\{\frac{1}{2}(N-n)\}!} \quad (18.38)$$

The probability that the separation is  $nl$  is

$$P = \frac{\text{number of polymers with } N_R \text{ bonds to the right}}{\text{total number of arrangements of bonds}} \\ = \frac{N!/N_R!(N-N_R)!}{2^N} = \frac{N!}{\{\frac{1}{2}(N+n)\}!\{\frac{1}{2}(N-n)\}!2^N}$$

When the chain is compact in the sense that  $n \ll N$ , it is more convenient to evaluate  $\ln P$ : the factorials are then large and we can use Stirling's approximation (Section 15.1a) in the form

$$\ln x! \approx \ln(2\pi)^{1/2} + (x + \frac{1}{2})\ln x - x$$

The result, after quite a lot of algebra (see Problem 18.20), is

$$\ln P = \ln \left( \frac{2}{\pi N} \right)^{1/2} - \frac{1}{2}(N+n+1)\ln(1+v) - \frac{1}{2}(N-n+1)\ln(1-v) \quad (18.39)$$

where  $v = n/N$ . For a compact coil ( $v \ll 1$ ) we use the approximation  $\ln(1 \pm v) \approx \pm v - \frac{1}{2}v^2$  and so obtain

$$\ln P \approx \ln \left( \frac{2}{\pi N} \right)^{1/2} - \frac{1}{2}Nv^2$$

which rearranges into eqn 18.1:

$$P = \left( \frac{2}{\pi N} \right)^{1/2} e^{-n^2/2N} \quad (18.40)$$

To show that the total probability of the chain ends being at any separation, we integrate  $P$  over all values of  $n$ . However, because  $n$  can change only in steps of 2, the integration step size is  $\frac{1}{2}dn$ , not  $dn$  itself. Then (with  $N$  allowed to become infinite),

$$\sum_{n=-N}^N P \rightarrow \int_{-\infty}^{\infty} P(n) \left( \frac{1}{2}dn \right) = \frac{1}{2} \left( \frac{2}{\pi N} \right)^{1/2} \int_{-\infty}^{\infty} e^{-n^2/2N} dn = 1$$

#### (b) A three-dimensional freely jointed random coil

The length of a step in three dimensions,  $l$ , can be expressed in terms of its projections on each of three orthogonal axes as  $l^2 = l_x^2 + l_y^2 + l_z^2$ . The average values of  $l_x^2$ ,  $l_y^2$ , and  $l_z^2$  are all the same in a spherically symmetric environment, so the average length of a step in the  $x$ -direction (or any of the other two directions) can be obtained by writing  $l^2 = 3\langle l_x^2 \rangle$ , and is  $x = \langle l_x^2 \rangle^{1/2} = l/3^{1/2}$ . The probability that the random walk will end up at a distance  $x$  from the origin is given by eqn 18.1 with  $n = x/(l/3^{1/2}) = 3^{1/2}x/l$ :

$$P(x) = \left( \frac{2}{\pi N} \right)^{1/2} e^{-3x^2/2Nl^2} \quad (18.41)$$

If  $x$  is regarded as continuously variable, we need to replace this probability by a probability density  $f(x)$  such that  $f(x)dx$  is the probability that the ends of the chain will be found between  $x$  and  $x + dx$ . Because  $dx = 2(l/3^{1/2})dn$  (for the factor 2, see the remark at the end of the preceding section),  $dn = (3^{1/2}/2l)dx$ , so

$$f(x) = \frac{1}{2l} \left( \frac{6}{\pi N} \right)^{1/2} e^{-3x^2/2Nl^2} \quad (18.42)$$

Because the probabilities of making steps along all three coordinates are independent, the probability of finding the ends of the chain in a region of volume  $dV = dx dy dz$  at a distance  $r$  is the product of these densities:

$$f(x,y,z)dV = f(x)f(y)f(z)dx dy dz = \frac{1}{8l^3} \left( \frac{6}{\pi N} \right)^{3/2} e^{-3r^2/2Nl^2} dV \quad (18.43)$$

The volume of a spherical shell at a distance  $r$  is  $4\pi r^2$ , so the total probability of finding the ends at a separation between  $r$  and  $r + dr$ , regardless of orientation, is

$$f(r)dr = \frac{4\pi}{8l^3} \left( \frac{6}{\pi N} \right)^{3/2} r^2 e^{-3r^2/2Nl^2} dr \quad (18.44)$$

from which  $f(r)$  can be identified, as in eqn 18.2.

#### (c) A partially rigid coil

In each of the following steps we use  $N \rightarrow \infty$  when necessary. We start from

$$\langle R^2 \rangle = \sum_i \langle r_i^2 \rangle + \sum_{i \neq j}^N \langle \mathbf{r}_i \cdot \mathbf{r}_j \rangle \quad (18.45)$$

The first term is  $Nl^2$  regardless of the rigidity of the coil. The second term can be written as follows:

$$\sum_{i \neq j}^N \langle \mathbf{r}_i \cdot \mathbf{r}_j \rangle = 2 \sum_{i=2}^N \langle \mathbf{r}_1 \cdot \mathbf{r}_i \rangle + 2 \sum_{i=3}^N \langle \mathbf{r}_2 \cdot \mathbf{r}_i \rangle + \dots$$

There are  $N - 1$  such terms, and provided we allow  $N$  to become infinite, all the sums on the right have the same value, so

$$\sum_{i \neq j}^N \langle \mathbf{r}_i \cdot \mathbf{r}_j \rangle = 2(N - 1) \sum_{i=2}^N \langle \mathbf{r}_1 \cdot \mathbf{r}_i \rangle \approx 2N \sum_{i=2}^N \langle \mathbf{r}_1 \cdot \mathbf{r}_i \rangle$$

The sum on the right is essentially the persistence length. Specifically

$$\sum_{j=2}^N \langle \mathbf{r}_1 \cdot \mathbf{r}_j \rangle = \sum_{j=1}^N \langle \mathbf{r}_1 \cdot \mathbf{r}_j \rangle - \langle r_1^2 \rangle = l_p - l^2 \quad (18.46)$$

Now we bring the three pieces of the calculation together:

$$\langle R^2 \rangle = Nl^2 + 2N(l_p - l^2) = 2Nl_p - Nl^2 \quad (18.47)$$

which, on taking the square root of both sides, is eqn 18.11.

## Discussion questions

**18.1** Describe the various measures of the size of a random coil and identify how they depend on the number of units.

**18.2** What are the consequences of there being partial rigidity in an otherwise random coil?

**18.3** It is observed that the critical micelle concentration of sodium dodecyl sulfate in aqueous solution decreases as the concentration of added sodium chloride increases. Explain this effect.

**18.4** Distinguish between number-average, weight-average, and Z-average molar masses. Identify experimental techniques that can measure each of these properties.

**18.5** Suggest reasons why different techniques produce different mass averages.

**18.6** Why is the protein-folding problem so difficult to resolve?

## Exercises

**18.1(a)** A polymer chain consists of 700 segments, each 0.90 nm long. If the chain were ideally flexible, what would be the r.m.s. separation of the ends of the chain?

**18.1(b)** A polymer chain consists of 1200 segments, each 1.125 nm long. If the chain were ideally flexible, what would be the r.m.s. separation of the ends of the chain?

**18.2(a)** Calculate the contour length (the length of the extended chain) and the root mean square separation (the end-to-end distance) for polyethylene with a molar mass of 280 kg mol<sup>-1</sup>.

**18.2(b)** Calculate the contour length (the length of the extended chain) and the root mean square separation (the end-to-end distance) for polypropylene of molar mass 174 kg mol<sup>-1</sup>.

**18.3(a)** The radius of gyration of a long chain molecule is found to be 7.3 nm. The chain consists of C–C links. Assume the chain is randomly coiled and estimate the number of links in the chain.

**18.3(b)** The radius of gyration of a long chain molecule is found to be 18.9 nm. The chain consists of links of length 450 pm. Assume the chain is randomly coiled and estimate the number of links in the chain.

**18.4(a)** What is the probability that the ends of a polyethene chain of molar mass 65 kg mol<sup>-1</sup> are 10 nm apart when the polymer is treated as a one-dimensional freely jointed chain?

**18.4(b)** What is the probability that the ends of a polyethene chain of molar mass 85 kg mol<sup>-1</sup> are 15 nm apart when the polymer is treated as a one-dimensional freely jointed chain?

**18.5(a)** What is the probability that the ends of a polyethene chain of molar mass 65 kg mol<sup>-1</sup> are between 10 nm and 10.1 nm apart when the polymer is treated as a three-dimensional freely jointed chain?

**18.5(b)** What is the probability that the ends of a polyethene chain of molar mass 85 kg mol<sup>-1</sup> are between 15 nm and 15.1 nm apart when the polymer is treated as a three-dimensional freely jointed chain?

**18.6(a)** Calculate the change in molar entropy when the ends of a one-dimensional polyethene chain of molar mass 65 kg mol<sup>-1</sup> are moved apart by 1.0 nm.

**18.6(b)** Calculate the change in molar entropy when the ends of a one-dimensional polyethene chain of molar mass 85 kg mol<sup>-1</sup> are moved apart by 2.0 nm.

**18.7(a)** By what percentage does the radius of gyration of a polymer chain increase (+) or decrease (–) when the bond angle between units is limited to 109°? What is the percentage change in volume of the coil?

**18.7(b)** By what percentage does the root mean square separation of the ends of a polymer chain increase (+) or decrease (–) when the bond angle between units is limited to 120°? What is the percentage change in volume of the coil?

**18.8(a)** By what percentage does the radius of gyration of a polymer chain increase (+) or decrease (–) when the persistence length changes from  $l$  (the bond length) to 5.0 per cent of the contour length? What is the percentage change in volume of the coil?

**18.8(b)** By what percentage does the root mean square separation of the ends of a polymer chain increase (+) or decrease (–) when the persistence length changes from  $l$  (the bond length) to 2.5 per cent of the contour length? What is the percentage change in volume of the coil?

**18.9(a)** The radius of gyration of a three-dimensional partially rigid polymer of 1000 units each of length 150 pm was measured as 2.1 nm. What is the persistence length of the polymer?

**18.9(b)** The radius of gyration of a three-dimensional partially rigid polymer of 1500 units each of length 164 pm was measured as 3.0 nm. What is the persistence length of the polymer?

**18.10(a)** Calculate the restoring force when the ends of a one-dimensional polyethylene chain of molar mass  $65 \text{ kg mol}^{-1}$  are moved apart by 1.0 nm at  $20^\circ\text{C}$ .

**18.10(b)** Calculate the restoring force when the ends of a one-dimensional polyethylene chain of molar mass  $85 \text{ kg mol}^{-1}$  are moved apart by 2.0 nm at  $25^\circ\text{C}$ .

**18.11(a)** Calculate the number-average molar mass and the mass-average molar mass of a mixture of equal amounts of two polymers, one having  $M = 62 \text{ kg mol}^{-1}$  and the other  $M = 78 \text{ kg mol}^{-1}$ .

**18.11(b)** Calculate the number-average molar mass and the mass-average molar mass of a mixture of two polymers, one having  $M = 62 \text{ kg mol}^{-1}$  and the other  $M = 78 \text{ kg mol}^{-1}$ , with their amounts (numbers of moles) in the ratio 3:2.

**18.12(a)** A solution consists of solvent, 30 per cent by mass, of a dimer with  $M = 30 \text{ kg mol}^{-1}$  and its monomer. What average molar mass would be obtained from measurement of (a) osmotic pressure, (b) light scattering?

**18.12(b)** A solution consists of 25 per cent by mass of a trimer with  $M = 22 \text{ kg mol}^{-1}$  and its monomer. What average molar mass would be obtained from measurement of: (a) osmotic pressure, (b) light scattering?

**18.13(a)** What is the relative rate of sedimentation for two spherical particles of the same density, but which differ in radius by a factor of 10?

**18.13(b)** What is the relative rate of sedimentation for two spherical particles with densities  $1.10 \text{ g cm}^{-3}$  and  $1.18 \text{ g cm}^{-3}$  and which differ in radius by a factor of 8.4, the former being the larger? Use  $\rho = 0.794 \text{ g cm}^{-3}$  for the density of the solution.

**18.14(a)** Human haemoglobin has a specific volume of  $0.749 \times 10^3 \text{ m}^3 \text{ kg}^{-1}$ , a sedimentation constant of 4.48 Sv, and a diffusion coefficient of  $6.9 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$ . Determine its molar mass from this information.

**18.14(b)** A synthetic polymer has a specific volume of  $8.01 \times 10^{-4} \text{ m}^3 \text{ kg}^{-1}$ , a sedimentation constant of 7.46 Sv, and a diffusion coefficient of  $7.72 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$ . Determine its molar mass from this information.

**18.15(a)** Find the drift speed of a particle of radius  $20 \mu\text{m}$  and density  $1750 \text{ kg m}^{-3}$  which is settling from suspension in water (density  $1000 \text{ kg m}^{-3}$ ) under the influence of gravity alone. The viscosity of water is  $8.9 \times 10^{-4} \text{ kg m}^{-1} \text{ s}^{-1}$ .

**18.15(b)** Find the drift speed of a particle of radius  $15.5 \mu\text{m}$  and density  $1250 \text{ kg m}^{-3}$  which is settling from suspension in water (density  $1000 \text{ kg m}^{-3}$ ) under the influence of gravity alone. The viscosity of water is  $8.9 \times 10^{-4} \text{ kg m}^{-1} \text{ s}^{-1}$ .

**18.16(a)** At  $20^\circ\text{C}$  the diffusion coefficient of a macromolecule is found to be  $8.3 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$ . Its sedimentation constant is 3.2 Sv in a solution of density  $1.06 \text{ g cm}^{-3}$ . The specific volume of the macromolecule is  $0.656 \text{ cm}^3 \text{ g}^{-1}$ . Determine the molar mass of the macromolecule.

**18.16(b)** At  $20^\circ\text{C}$  the diffusion coefficient of a macromolecule is found to be  $7.9 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$ . Its sedimentation constant is 5.1 Sv in a solution of density  $997 \text{ kg m}^{-3}$ . The specific volume of the macromolecule is  $0.721 \text{ cm}^3 \text{ g}^{-1}$ . Determine the molar mass of the macromolecule.

**18.17(a)** The data from a sedimentation equilibrium experiment performed at 300 K on a macromolecular solute in aqueous solution show that a graph of  $\ln c$  against  $r^2$  is a straight line with a slope of  $729 \text{ cm}^{-2}$ . The rotational rate of the centrifuge was 50 000 r.p.m. The specific volume of the solute is  $0.61 \text{ cm}^3 \text{ g}^{-1}$ . Calculate the molar mass of the solute.

**18.17(b)** The data from a sedimentation equilibrium experiment performed at 293 K on a macromolecular solute in aqueous solution show that a graph of  $\ln c$  against  $(r/\text{cm})^2$  is a straight line with a slope of 821. The rotation rate of the centrifuge was 1080 Hz. The specific volume of the solute is  $7.2 \times 10^{-4} \text{ m}^3 \text{ kg}^{-1}$ . Calculate the molar mass of the solute.

## Problems\*

### Numerical problems

**18.1** The following table lists the glass transition temperatures,  $T_g$ , of several polymers. Discuss the reasons why the structure of the monomer unit has an effect on the value of  $T_g$ .

| Polymer        | Poly(oxyethylene)    | Polyethylene                   | Poly(vinyl chloride)            | Polystyrene                                         |
|----------------|----------------------|--------------------------------|---------------------------------|-----------------------------------------------------|
| Structure      | $-(\text{OCH}_2)_n-$ | $-(\text{CH}_2\text{CH}_2)_n-$ | $-(\text{CH}_2-\text{CHCl})_n-$ | $-(\text{CH}_2-\text{CH}(\text{C}_6\text{H}_5))_n-$ |
| $T_g/\text{K}$ | 198                  | 253                            | 354                             | 381                                                 |

**18.2** In a sedimentation experiment the position of the boundary as a function of time was found to be as follows:

|                |      |      |      |      |
|----------------|------|------|------|------|
| $t/\text{min}$ | 15.5 | 29.1 | 36.4 | 58.2 |
| $r/\text{cm}$  | 5.05 | 5.09 | 5.12 | 5.19 |

The rotation rate of the centrifuge was 45 000 r.p.m. Calculate the sedimentation constant of the solute.

**18.3** Evaluate the radius of gyration,  $R_g$ , of (a) a solid sphere of radius  $a$ , (b) a long straight rod of radius  $a$  and length  $l$ . Show that, in the case of a solid sphere of specific volume  $v_s$ ,  $R_g/\text{nm} \approx 0.056902 \times \{(v_s/\text{cm}^3 \text{ g}^{-1})(M/\text{g mol}^{-1})\}^{1/3}$ . Evaluate  $R_g$  for a species with  $M = 100 \text{ kg mol}^{-1}$ ,  $v_s = 0.750 \text{ cm}^3 \text{ g}^{-1}$ , and, in the case of the rod, of radius 0.50 nm.

**18.4** Calculate the speed of operation (in r.p.m.) of an ultracentrifuge needed to obtain a readily measurable concentration gradient in a sedimentation equilibrium experiment. Take that gradient to be a concentration at the bottom of the cell about five times greater than at the top. Use  $r_{\text{top}} = 5.0 \text{ cm}$ ,  $r_{\text{bott}} = 7.0 \text{ cm}$ ,  $M \approx 10^5 \text{ g mol}^{-1}$ ,  $\rho v_s \approx 0.75$ ,  $T = 298 \text{ K}$ .

**18.5** The concentration dependence of the viscosity of a polymer solution is found to be as follows:

|                                         |      |      |      |      |
|-----------------------------------------|------|------|------|------|
| $c/(\text{g dm}^{-3})$                  | 1.32 | 2.89 | 5.73 | 9.17 |
| $\eta/(\text{g m}^{-1} \text{ s}^{-1})$ | 1.08 | 1.20 | 1.42 | 1.73 |

The viscosity of the solvent is  $0.985 \text{ g m}^{-1} \text{ s}^{-1}$ . What is the intrinsic viscosity of the polymer?

**18.6** The times of flow of dilute solutions of polystyrene in benzene through a viscometer at  $25^\circ\text{C}$  are given in the table below. From these data, calculate the molar mass of the polystyrene samples. Since the solutions are dilute, assume that the densities of the solutions are the same as those of pure benzene.  $\eta(\text{benzene}) = 0.601 \times 10^{-3} \text{ kg m}^{-1} \text{ s}^{-1}$  (0.601 cP) at  $25^\circ\text{C}$ .

|                        |       |       |       |       |       |
|------------------------|-------|-------|-------|-------|-------|
| $c/(\text{g dm}^{-3})$ | 0     | 2.22  | 5.00  | 8.00  | 10.00 |
| $t/\text{s}$           | 208.2 | 248.1 | 303.4 | 371.8 | 421.3 |

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp and Carmen Giunta.

**18.7** The viscosities of solutions of polyisobutene in benzene were measured at 24°C (the  $\theta$  temperature for the system) with the following results:

|                                                          |       |       |       |       |       |       |
|----------------------------------------------------------|-------|-------|-------|-------|-------|-------|
| $c/(\text{g}/10^2 \text{ cm}^3)$                         | 0     | 0.2   | 0.4   | 0.6   | 0.8   | 1.0   |
| $\eta/(\text{10}^{-3} \text{ kg m}^{-1} \text{ s}^{-1})$ | 0.647 | 0.690 | 0.733 | 0.777 | 0.821 | 0.865 |

Use the information in Table 18.4 to deduce the molar mass of the polymer.

**18.8†** Polystyrene in cyclohexane at 34.5°C forms a  $\theta$  solution, with an intrinsic viscosity related to the molar mass by  $[\eta] = KM^a$ . The following data on polystyrene in cyclohexane are taken from L.J. Fetters *et al.*, (*J. Phys. Chem. Ref. Data* 23, 619 (1994)):

|                                       |      |      |      |      |      |      |       |      |      |        |
|---------------------------------------|------|------|------|------|------|------|-------|------|------|--------|
| $M/(\text{kg mol}^{-1})$              | 10.0 | 19.8 | 106  | 249  | 359  | 860  | 1800  | 5470 | 9720 | 56 800 |
| $[\eta]/(\text{cm}^3 \text{ g}^{-1})$ | 8.90 | 11.9 | 28.1 | 44.0 | 51.2 | 77.6 | 113.9 | 195  | 275  | 667    |

Determine the parameters  $K$  and  $a$ . What is the molar mass of a polystyrene that forms a  $\theta$  solution in cyclohexane with  $[\eta] = 100 \text{ cm}^3 \text{ g}^{-1}$ ?

**18.9†** Standard polystyrene solutions of known average molar masses continue to be used as for the calibration of many methods of characterizing polymer solutions. M. Kolinsky and J. Janca (*J. Polym. Sci., Polym. Chem.* 12, 1181 (1974)) studied polystyrene in tetrahydrofuran (THF) for use in calibrating a gel permeation chromatograph. Their results for the intrinsic viscosity,  $[\eta]$ , as a function of average molar mass at 25°C are given in the table below. (a) Obtain the Mark–Houwink constants that fit these data. (b) Compare your values to those in Table 18.4 and Example 18.5. How might you explain the differences?

|                                       |     |      |       |      |      |      |       |       |
|---------------------------------------|-----|------|-------|------|------|------|-------|-------|
| $\bar{M}_v/(\text{kg mol}^{-1})$      | 5.0 | 10.3 | 19.85 | 51   | 98.2 | 173  | 411   | 867   |
| $[\eta]/(\text{cm}^3 \text{ g}^{-1})$ | 5.2 | 8.8  | 14.0  | 27.6 | 43.6 | 67.0 | 125.0 | 206.7 |

**18.10** The concentration dependence of the osmotic pressure of solutions of a macromolecule at 20°C was found to be as follows:

|                        |      |      |      |      |
|------------------------|------|------|------|------|
| $c/(\text{g dm}^{-3})$ | 1.21 | 2.72 | 5.08 | 6.60 |
| $\Pi/\text{Pa}$        | 134  | 321  | 655  | 898  |

Determine the molar mass of the macromolecule and the osmotic virial coefficient.

**18.11** The osmotic pressure of a fraction of poly(vinyl chloride) in a ketone solvent was measured at 25°C. The density of the solvent (which is virtually equal to the density of the solution) was  $0.798 \text{ g cm}^{-3}$ . Calculate the molar mass and the osmotic virial coefficient,  $B$ , of the fraction from the following data:

|                                  |       |       |       |       |       |
|----------------------------------|-------|-------|-------|-------|-------|
| $c/(\text{g}/10^2 \text{ cm}^3)$ | 0.200 | 0.400 | 0.600 | 0.088 | 1.000 |
| $h/\text{cm}$                    | 0.48  | 1.2   | 1.86  | 2.76  | 3.88  |

### Theoretical problems

**18.12** Derive an expression for the fundamental vibrational frequency of a one-dimensional random coil that has been slightly stretched and then released. Evaluate this frequency for a sample of polyethene of molar mass  $65 \text{ kg mol}^{-1}$  at 20°C. Account physically for the dependence of frequency on temperature and molar mass.

**18.13** In formamide as solvent, poly( $\gamma$ -benzyl-L-glutamate) is found by light scattering experiments to have a radius of gyration proportional to  $M$ ; in contrast, polystyrene in butanone has  $R_g$  proportional to  $M^{1/2}$ . Present arguments to show that the first polymer is a rigid rod whereas the second is a random coil.

**18.14** A polymerization process produced a Gaussian distribution of polymers in the sense that the proportion of molecules having a molar mass in the range  $M$  to  $M + dM$  was proportional to  $e^{-(M-M)^2/2\gamma}$ . What is the number average molar mass when the distribution is narrow?

**18.15** Use eqn 18.2 to deduce expressions for (a) the root mean square separation of the ends of the chain, (b) the mean separation of the ends, and (c) their most probable separation. Evaluate these three quantities for a fully flexible chain with  $N = 4000$  and  $l = 154 \text{ pm}$ .

**18.16** Deduce the relation  $\langle r_i^2 \rangle = Nl^2$  for the mean square distance of a monomer from the origin in a freely jointed chain of  $N$  units each of length  $l$ . *Hint.* Use the distribution in eqn 18.2.

**18.17** Deduce an expression for the radius of gyration of a three-dimensional freely jointed chain (eqn 18.6).

**18.18** Derive expressions for the moments of inertia and hence the radii of gyration of (a) a uniform thin disc, (b) a long uniform rod, (c) a uniform sphere.

**18.19** Construct a two-dimensional random walk by using a random number generating routine with mathematical software or electronic spreadsheet. Construct a walk of 50 and 100 steps. If there are many people working on the problem, investigate the mean and most probable separations in the plots by direct measurement. Do they vary as  $N^{1/2}$ ?

**18.20** Confirm the expression for  $\ln P$  in eqn 18.39.

**18.21** The effective radius,  $a$ , of a random coil is related to its radius of gyration,  $R_g$ , by  $a = \gamma R_g$ , with  $\gamma = 0.85$ . Deduce an expression for the osmotic virial coefficient,  $B$ , in terms of the number of chain units for (a) a freely jointed chain, (b) a chain with tetrahedral bond angles. Evaluate  $B$  for  $l = 154 \text{ pm}$  and  $N = 4000$ . Estimate  $B$  for a randomly coiled polyethylene chain of arbitrary molar mass,  $M$ , and evaluate it for  $M = 56 \text{ kg mol}^{-1}$ . Use  $B = \frac{1}{2} N_A v_p$ , where  $v_p$  is the excluded volume due to a single molecule.

**18.22** Radius of gyration is defined in *Justification* 18.1. Show that an equivalent definition is that  $R_g$  is the average root mean square distance of the atoms or groups (all assumed to be of the same mass), that is, that  $R_g^2 = (1/N) \sum_j R_j^2$ , where  $R_j$  is the distance of atom  $j$  from the centre of mass.

**18.23** Consider the thermodynamic description of stretching rubber. The observables are the tension,  $t$ , and length,  $l$  (the analogues of  $p$  and  $V$  for gases). Because  $dw = tdl$ , the basic equation is  $dU = TdS + tdl$ . If  $G = U - TS - tl$ , find expressions for  $dG$  and  $dA$ , and deduce the Maxwell relations

$$\left( \frac{\partial S}{\partial l} \right)_T = - \left( \frac{\partial t}{\partial T} \right)_l \quad \left( \frac{\partial S}{\partial t} \right)_T = - \left( \frac{\partial l}{\partial T} \right)_t$$

Go on to deduce the equation of state for rubber

$$\left( \frac{\partial U}{\partial l} \right)_T = t - \left( \frac{\partial t}{\partial T} \right)_l$$

**18.24** On the assumption that the tension required to keep a sample at a constant length is proportional to the temperature ( $t = aT$ , the analogue of  $p \propto T$ ), show that the tension can be ascribed to the dependence of the entropy on the length of the sample. Account for this result in terms of the molecular nature of the sample.

### Applications: to biochemistry and technology

**18.25** Commercial software (more specifically ‘molecular mechanics’ or ‘conformational search’ software) automate the calculations that lead to Ramachandran plots, such as those in Fig. 18.17. In this problem our model for the protein is the dipeptide (12) in which the terminal methyl groups replace the rest of the polypeptide chain. (a) Draw three initial conformers of the dipeptide with  $R = H$ : one with  $\phi = +75^\circ$ ,  $\psi = -65^\circ$ , a second with  $\phi = \psi = +180^\circ$ , and a third with  $\phi = +65^\circ$ ,  $\psi = +35^\circ$ . Use software of your instructor’s choice to optimize the geometry of each conformer and find the final  $\phi$  and  $\psi$  angles in each case. Did all of the initial conformers converge to the same final conformation? If not, what do these final conformers represent?

12

(b) Use the approach in part (a) to investigate the case  $R = \text{CH}_3$ , with the same three initial conformers as starting points for the calculations. Rationalize any similarities and differences between the final conformers of the dipeptides with  $R = \text{H}$  and  $R = \text{CH}_3$ .

**18.26** Calculate the excluded volume in terms of the molecular volume on the basis that the molecules are spheres of radius  $a$ . Evaluate the osmotic virial coefficient in the case of bushy stunt virus,  $a = 14.0$  nm, and haemoglobin,  $a = 3.2$  nm (see Problem 18.21). Evaluate the percentage deviation of the Rayleigh ratios of  $1.00 \text{ g}/(100 \text{ cm}^3)$  solutions of bushy stunt virus ( $M = 1.07 \times 10^4 \text{ kg mol}^{-1}$ ) and haemoglobin ( $M = 66.5 \text{ kg mol}^{-1}$ ) from the ideal solution values. In eqn 18.8, let  $P_\theta = 1$  and assume that both solutions have the same  $K$  value.

**18.27** Use the information below and the expression for  $R_g$  of a solid sphere quoted in the text (following eqn 18.6), to classify the species below as globular or rod-like.

|                   | $M/(\text{g mol}^{-1})$ | $v_s/(\text{cm}^3 \text{ g}^{-1})$ | $R_g/\text{nm}$ |
|-------------------|-------------------------|------------------------------------|-----------------|
| Serum albumin     | $66 \times 10^3$        | 0.752                              | 2.98            |
| Bushy stunt virus | $10.6 \times 10^6$      | 0.741                              | 12.0            |
| DNA               | $4 \times 10^6$         | 0.556                              | 117.0           |

**18.28** Suppose that a rod-like DNA molecule of length 250 nm undergoes a conformational change to a closed-circular (cc) form. (a) Use the information in Problem 18.27 and an incident wavelength  $\lambda = 488$  nm to calculate the ratio of scattering intensities by each of these conformations,  $I_{\text{rod}}/I_{\text{cc}}$ , when  $\theta = 20^\circ$ ,  $45^\circ$ , and  $90^\circ$ . (b) Suppose that you wish to use light scattering as a technique for the study of conformational changes in DNA molecules. Based on your answer to part (a), at which angle would you conduct the experiments? Justify your choice.

**18.29** In an ultracentrifugation experiment at  $20^\circ\text{C}$  on bovine serum albumin the following data were obtained:  $\rho = 1.001 \text{ g cm}^{-3}$ ,  $v_s = 1.112 \text{ cm}^3 \text{ g}^{-1}$ ,  $\omega/2\pi = 322 \text{ Hz}$ ,

| $r/\text{cm}$           | 5.0   | 5.1   | 5.2   | 5.3   | 5.4   |
|-------------------------|-------|-------|-------|-------|-------|
| $c/(\text{mg cm}^{-3})$ | 0.536 | 0.284 | 0.148 | 0.077 | 0.039 |

Evaluate the molar mass of the sample.

**18.30** Sedimentation studies on haemoglobin in water gave a sedimentation constant  $S = 4.5 \text{ Sv}$  at  $20^\circ\text{C}$ . The diffusion coefficient is  $6.3 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$  at the same temperature. Calculate the molar mass of haemoglobin using  $v_s = 0.75 \text{ cm}^3 \text{ g}^{-1}$  for its partial specific volume and  $\rho = 0.998 \text{ g cm}^{-3}$  for the density of the solution. Estimate the effective radius of the haemoglobin molecule given that the viscosity of the solution is  $1.00 \times 10^3 \text{ kg m}^{-1} \text{ s}^{-1}$ .

**18.31** The rate of sedimentation of a recently isolated protein was monitored at  $20^\circ\text{C}$  and with a rotor speed of 50 000 r.p.m. The boundary receded as follows:

| $t/\text{s}$  | 0     | 300   | 600   | 900   | 1200  | 1500  | 1800  |
|---------------|-------|-------|-------|-------|-------|-------|-------|
| $r/\text{cm}$ | 6.127 | 6.153 | 6.179 | 6.206 | 6.232 | 6.258 | 6.284 |

Calculate the sedimentation constant and the molar mass of the protein on the basis that its partial specific volume is  $0.728 \text{ cm}^3 \text{ g}^{-1}$  and its diffusion coefficient is  $7.62 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$  at  $20^\circ\text{C}$ , the density of the solution then being  $0.9981 \text{ g cm}^{-3}$ . Suggest a shape for the protein given that the viscosity of the solution is  $1.00 \times 10^3 \text{ kg m}^{-1} \text{ s}^{-1}$  at  $20^\circ\text{C}$ .

**18.32** For some proteins, the isoelectric point must be obtained by extrapolation because the macromolecule might not be stable over a very wide pH range. Estimate the pH of the isoelectric point from the following data for a protein:

| pH                                  | 4.5   | 5.0   | 5.5   | 6.0   |
|-------------------------------------|-------|-------|-------|-------|
| Drift speed/ $(\mu\text{m s}^{-1})$ | -0.10 | -0.20 | -0.30 | -0.35 |

**18.33** Here we use concepts developed in Chapter 15 and this chapter to enhance our understanding of closed-circular and supercoiled DNA. (a) The average end-to-end distance of a flexible polymer (such as a fully denatured polypeptide or a strand of DNA) is  $N^{1/2}l$ , where  $N$  is the number of groups (residues or bases) and  $l$  is the length of each group. Initially, therefore, one end of the polymer can be found anywhere within a sphere of radius  $N^{1/2}l$  centred on the other end. When the ends join to form a circle, they are confined to a volume of radius  $l$ . What is the change in molar entropy? Plot the function you derive as a function of  $N$ . (b) The energy necessary to twist ccDNA by  $i$  turns is  $\epsilon_i = ki^2$ , with  $k$  an empirical constant and  $i$  being negative or positive depending on the sense of the twist. For example, one twist ( $i = \pm 1$ ) makes ccDNA resemble the number 8. (i) Show that the distribution of the populations  $p_i = n_i/N$  of ccDNA molecules with  $i$  turns at a specified temperature has the form of a Gaussian function. (ii) Plot the expression you derived in part (a) for several values of the temperature. Does the curve have a maximum? If so, at what value of  $i$ ? Comment on variations of the shape of the curve with temperature. (iii) Calculate  $p_0, p_1, p_2$ , and  $p_{10}$  at  $298 \text{ K}$ .

**18.34** The melting temperature of a DNA molecule can be determined by differential scanning calorimetry (Impact I2.1). The following data were obtained in aqueous solutions containing the specified concentration  $c_{\text{salt}}$  of an soluble ionic solid for a series of DNA molecules with varying base pair composition, with  $f$  the fraction of GC base pairs:

| $c_{\text{salt}} = 1.0 \times 10^{-2} \text{ mol dm}^{-3}$ |       |       |       |       |       |
|------------------------------------------------------------|-------|-------|-------|-------|-------|
| $f$                                                        | 0.375 | 0.509 | 0.589 | 0.688 | 0.750 |
| $T_m/\text{K}$                                             | 339   | 344   | 348   | 351   | 354   |
| $c_{\text{salt}} = 0.15 \text{ mol dm}^{-3}$               |       |       |       |       |       |
| $f$                                                        | 0.375 | 0.509 | 0.589 | 0.688 | 0.750 |
| $T_m/\text{K}$                                             | 359   | 364   | 368   | 371   | 374   |

(a) Estimate the melting temperature of a DNA molecule containing 40.0 per cent GC base pairs in both samples. *Hint.* Begin by plotting  $T_m$  against fraction of GC base pairs and examining the shape of the curve. (b) Do the data show an effect of concentration of ions in solution on the melting temperature of DNA? If so, provide a molecular interpretation for the effect you observe.

**18.35** The fluidity of a lipid bilayer dispersed in aqueous solution depends on temperature and there are two important melting transitions. One transition is from a 'solid crystalline' state in which the hydrophobic chains are packed together tightly (hence move very little) to a 'liquid crystalline state', in which there is increased but still limited movement of the of the chains. The second transition, which occurs at a higher temperature than the first, is from the liquid crystalline state to a liquid state, in which the hydrophobic interactions holding the aggregate together are largely disrupted. (a) It is observed that the transition temperatures increase with the hydrophobic chain length and decrease with the number of C=C bonds in the chain. Explain these observations. (b) What effect is the inclusion of cholesterol likely to have on the transition temperatures of a lipid bilayer? Justify your answer.

**18.36** Polystyrene is a synthetic polymer with the structure  $-(\text{CH}_2-\text{CH}(\text{C}_6\text{H}_5))_n-$ . A batch of polydisperse polystyrene was prepared by initiating the polymerization with  $t$ -butyl radicals. As a result, the  $t$ -butyl group is expected to be covalently attached to the end of the final products. A sample from this batch was embedded in an organic matrix containing

silver trifluoroacetate and the resulting MALDI-TOF spectrum consisted of a large number of peaks separated by 104 g mol<sup>-1</sup>, with the most intense peak at 25 578 g mol<sup>-1</sup>. Comment on the purity of this sample and determine the number of (CH<sub>2</sub>-CH(C<sub>6</sub>H<sub>5</sub>)) units in the species that gives rise to the most intense peak in the spectrum.

**18.37** A manufacturer of polystyrene beads claims that they have an average molar mass of 250 kg mol<sup>-1</sup>. Solutions of these beads are studied by a physical chemistry student by dilute solution viscometry with an Ostwald viscometer in both the ‘good’ solvent toluene and the theta solvent cyclohexane. The drainage times, *t*<sub>D</sub>, as a function of concentration for the two solvents are given in the table below. (a) Fit the data to the virial equation for viscosity,

$$\eta = \eta^*(1 + [\eta]c + k'[\eta]^2c^2 + \dots)$$

where *k'* is called the *Huggins constant* and is typically in the range 0.35–0.40. From the fit, determine the intrinsic viscosity and the Huggins constant. (b) Use the empirical Mark–Kuhn–Houwink–Sakurada equation (eqn 18.37) to determine the molar mass of polystyrene in the two solvents. For theta solvents, *a* = 0.5 and *K* = 8.2 × 10<sup>-5</sup> dm<sup>-3</sup> g<sup>-1</sup> for cyclohexane; for the good solvent toluene *a* = 0.72 and *K* = 1.15 × 10<sup>-5</sup> dm<sup>-3</sup> g<sup>-1</sup>. (c) According to a general theory proposed by Kirkwood and Riseman, the root mean square end-to-end distance of a polymer chain in solution is related to  $[\eta]$  by  $\phi\langle r^2 \rangle^{3/2}/M$ , where  $\phi$  is a universal constant with the value 2.84 × 10<sup>26</sup> when  $[\eta]$  is expressed in cubic decimetres per gram and the distance is in metres. Calculate this quantity for each solvent. (d) From the molar masses calculate the average number of styrene (C<sub>6</sub>H<sub>5</sub>CH=CH<sub>2</sub>) monomer units,  $\langle n \rangle$ .

(e) Calculate the length of a fully stretched, planar zigzag configuration, taking the C–C distance as 154 pm and the CCC bond angle to be 109°. (f) Use eqn 18.6 to calculate the radius of gyration, *R*<sub>g</sub>. Also calculate  $\langle r^2 \rangle^{1/2} = n^{1/2}l$ . Compare this result with that predicted by the Kirkwood–Riseman theory: which gives the better fit? (g) Compare your values for *M* to the results of Problem 18.36. Is there any reason why they should or should not agree? Is the manufacturer’s claim valid?

|                                            |      |      |       |       |
|--------------------------------------------|------|------|-------|-------|
| <i>c</i> /(g dm <sup>-3</sup> toluene)     | 0    | 1.0  | 3.0   | 5.0   |
| <i>t</i> <sub>D</sub> /s                   | 8.37 | 9.11 | 10.72 | 12.52 |
| <i>c</i> /(g dm <sup>-3</sup> cyclohexane) | 0    | 1.0  | 1.5   | 2.0   |
| <i>t</i> <sub>D</sub> /s                   | 8.32 | 8.67 | 8.85  | 9.03  |

**18.38†** The determination of the average molar masses of conducting polymers is an important part of their characterization. S. Holdcroft (*J. Polym. Sci., Polym. Phys.* **29**, 1585 (1991)) has determined the molar masses and Mark–Houwink constants for the electronically conducting polymer, poly(3-hexylthiophene) (P3HT) in tetrahydrofuran (THF) at 25°C by methods similar to those used for nonconducting polymers. The values for molar mass and intrinsic viscosity in the table below are adapted from their data. Determine the constants in the Mark–Kuhn–Houwink–Sakurada equation from these results and compare to the values obtained in your solution to Problem 18.9.

|                                              |      |       |       |       |
|----------------------------------------------|------|-------|-------|-------|
| $\bar{M}_v$ /(kg mol <sup>-1</sup> )         | 3.8  | 11.1  | 15.3  | 58.8  |
| $[\eta]$ /(cm <sup>3</sup> g <sup>-1</sup> ) | 6.23 | 17.44 | 23.73 | 85.28 |

# Materials 2: solids

# 19

First, we see how to describe the regular arrangement of atoms in crystals and the symmetry of their arrangement. Then we consider the basic principles of X-ray diffraction and see how the diffraction pattern can be interpreted in terms of the distribution of electron density in a unit cell. X-ray diffraction leads to information about the structures of metallic, ionic, and molecular solids, and we review some typical results and their rationalization in terms of atomic and ionic radii. With structures established, we move on to the properties of solids, and see how their mechanical, electrical, optical, and magnetic properties stem from the properties of their constituent atoms and molecules.

The solid state includes most of the materials that make modern technology possible. It includes the wide varieties of steel that are used in architecture and engineering, the semiconductors and metallic conductors that are used in information technology and power distribution, the ceramics that increasingly are replacing metals, and the synthetic and natural polymers discussed in Chapter 18 that are used in the textile industry and in the fabrication of many of the common objects of the modern world. The properties of solids stem, of course, from the arrangement and properties of the constituent atoms, and one of the challenges of this chapter is to see how a wide range of bulk properties, including rigidity, electrical conductivity, and optical and magnetic properties, stem from the properties of atoms. One crucial aspect of this link is the pattern in which the atoms (and molecules) are stacked together, and we start this chapter with an examination of how the structures of solids are described and determined.

## Crystallography

Early in the history of modern science it was suggested that the regular external form of crystals implied an internal regularity of their constituents. In this section we see how to describe and determine the arrangement of atoms inside crystals.

### 19.1 Lattices and unit cells

**Key points** A space lattice is the pattern formed by points representing the locations of structural motifs. A unit cell is an imaginary parallelepiped that contains one unit of a translationally repeating pattern. Unit cells are classified into seven crystal systems according to their rotational symmetries. The Bravais lattices are the 14 distinct space lattices in three dimensions.

A crystal is built up from regularly repeating ‘structural motifs’, which may be atoms, molecules, or groups of atoms, molecules, or ions. A space lattice is the pattern

Problems

**Fig. 19.1** Each lattice point specifies the location of a structural motif (for example, a molecule or a group of molecules). The crystal lattice is the array of lattice points; the crystal structure is the collection of structural motifs arranged according to the lattice.

**Fig. 19.2** A unit cell is a parallel-sided (but not necessarily rectangular) figure from which the entire crystal structure can be constructed by using only translations (not reflections, rotations, or inversions).

**Fig. 19.3** A unit cell can be chosen in a variety of ways, as shown here. It is conventional to choose the cell that represents the full symmetry of the lattice. In this rectangular lattice, the rectangular unit cell would normally be adopted.

**Fig. 19.4** The notation for the sides and angles of a unit cell. Note that the angle  $\alpha$  lies in the plane  $(b, c)$  and perpendicular to the axis  $a$ .

#### A brief comment

A *symmetry operation* is an action (such as a rotation, reflection, or inversion) that leaves an object looking the same after it has been carried out. There is a corresponding *symmetry element* for each symmetry operation, which is the point, line, or plane with respect to which the symmetry operation is performed. For instance, an *n-fold rotation* (the symmetry operation) about an *n-fold axis of symmetry* (the corresponding symmetry element) is a rotation through  $360^\circ/n$ . See Chapter 11 for a more detailed discussion of symmetry.

formed by points representing the locations of these motifs (Fig. 19.1). The space lattice is, in effect, an abstract scaffolding for the crystal structure. More formally, a space lattice is a three-dimensional, infinite array of points, each of which is surrounded in an identical way by its neighbours, and which defines the basic structure of the crystal. In some cases there may be a structural motif centred on each lattice point, but that is not necessary. The crystal structure itself is obtained by associating with each lattice point an identical structural motif.

The **unit cell** is an imaginary parallelepiped (parallel-sided figure) that contains one unit of the translationally repeating pattern (Fig. 19.2). A unit cell can be thought of as the fundamental region from which the entire crystal may be constructed by purely translational displacements (like bricks in a wall). A unit cell is commonly formed by joining neighbouring lattice points by straight lines (Fig. 19.3). Such unit cells are called **primitive**. It is sometimes more convenient to draw larger **non-primitive unit cells** that also have lattice points at their centres or on pairs of opposite faces. An infinite number of different unit cells can describe the same lattice, but the one with sides that have the shortest lengths and that are most nearly perpendicular to one another is normally chosen. The lengths of the sides of a unit cell are denoted  $a$ ,  $b$ , and  $c$ , and the angles between them are denoted  $\alpha$ ,  $\beta$ , and  $\gamma$  (Fig. 19.4).

Unit cells are classified into seven **crystal systems** by noting the rotational symmetry elements they possess. A *cubic unit cell*, for example, has four threefold axes in a tetrahedral array (Fig. 19.5). A *monoclinic unit cell* has one twofold axis; the unique axis is by convention the  $b$  axis (Fig. 19.6). A *triclinic unit cell* has no rotational symmetry, and typically all three sides and angles are different (Fig. 19.7). Table 19.1 lists the **essential symmetries**, the elements that must be present for the unit cell to belong to a particular crystal system.

There are only 14 distinct space lattices in three dimensions. These **Bravais lattices** are illustrated in Fig. 19.8. It is conventional to portray these lattices by primitive unit cells in some cases and by non-primitive unit cells in others. A **primitive unit cell** (with lattice points only at the corners) is denoted P. A **body-centred unit cell** (I) also has a lattice point at its centre. A **face-centred unit cell** (F) has lattice points at its corners and also at the centres of its six faces. A **side-centred unit cell** (A, B, or C) has

**Fig. 19.5** A unit cell belonging to the cubic system has four threefold axes, denoted  $C_3$ , arranged tetrahedrally. The insert shows the threefold symmetry.

**Fig. 19.6** A unit belonging to the monoclinic system has a twofold axis (denoted  $C_2$  and shown in more detail in the insert).

**Fig. 19.7** A triclinic unit cell has no axes of rotational symmetry.

lattice points at its corners and at the centres of two opposite faces. For simple structures, it is often convenient to choose an atom belonging to the structural motif, or the centre of a molecule, as the location of a lattice point or the vertex of a unit cell, but that is not a necessary requirement.

## 19.2 The identification of lattice planes

**Key point** Crystal planes are specified by a set of Miller indices.

The spacing of the planes of lattice points in a crystal is an important quantitative aspect of its structure. However, there are many different sets of planes (Fig. 19.9), and we need to be able to label them. Two-dimensional lattices are easier to visualize

**Table 19.1** The seven crystal systems

| System       | Essential symmetries                         |
|--------------|----------------------------------------------|
| Triclinic    | None                                         |
| Monoclinic   | One $C_2$ axis                               |
| Orthorhombic | Three perpendicular $C_2$ axes               |
| Rhombohedral | One $C_3$ axis                               |
| Tetragonal   | One $C_4$ axis                               |
| Hexagonal    | One $C_6$ axis                               |
| Cubic        | Four $C_3$ axes in a tetrahedral arrangement |

**Fig. 19.8** The fourteen Bravais lattices. The points are lattice points and are not necessarily occupied by atoms. P denotes a primitive unit cell (R is used for a trigonal lattice), I a body-centred unit cell, F a face-centred unit cell, and C (or A or B) a cell with lattice points on two opposite faces.

**Fig. 19.9** Some of the planes that can be drawn through the points of a rectangular space lattice and their corresponding Miller indices ( $hkl$ ): (a) (110), (b) (230), (c) ( $\bar{1}10$ ), and (d) (010).

**Fig. 19.10** Some representative planes in three dimensions and their Miller indices. Note that a 0 indicates that a plane is parallel to the corresponding axis, and that the indexing may also be used for unit cells with non-orthogonal axes.

than three-dimensional lattices, so we shall introduce the concepts involved by referring to two dimensions initially and then extend the conclusions by analogy to three dimensions.

Consider a two-dimensional rectangular lattice formed from a unit cell of sides  $a$ ,  $b$  (as in Fig. 19.9). Each plane in the illustration (except the plane passing through the origin) can be distinguished by the distances at which it intersects the  $a$  and  $b$  axes. One way to label each set of parallel planes would therefore be to quote the smallest intersection distances. For example, we could denote the four sets in the illustration as  $(1a, 1b)$ ,  $(\frac{1}{2}a, \frac{1}{3}b)$ ,  $(-1a, 1b)$ , and  $(\infty a, 1b)$ . However, if we agree to quote distances along the axes as multiples of the lengths of the unit cell, then we can label the planes more simply as  $(1, 1)$ ,  $(\frac{1}{2}, \frac{1}{3})$ ,  $(-1, 1)$ , and  $(\infty, 1)$ . If the lattice in Fig. 19.9 is the top view of a three-dimensional orthorhombic lattice in which the unit cell has a length  $c$  in the  $z$ -direction, all four sets of planes intersect the  $z$ -axis at infinity. Therefore, the full labels are  $(1, 1, \infty)$ ,  $(\frac{1}{2}, \frac{1}{3}, \infty)$ ,  $(-1, 1, \infty)$ , and  $(\infty, 1, \infty)$ .

The presence of fractions and infinity in the labels is inconvenient. They can be eliminated by taking the reciprocals of the labels. As we shall see, taking reciprocals turns out to have further advantages. The **Miller indices**, ( $hkl$ ), are the reciprocals of intersection distances (with fractions cleared by multiplying through by an appropriate factor, if taking the reciprocal results in a fraction). For example, the  $(1, 1, \infty)$  planes in Fig. 19.9a are the (110) planes in the Miller notation. Similarly, the  $(\frac{1}{2}, \frac{1}{3}, \infty)$  planes are denoted (230). Negative indices are written with a bar over the number, and Fig. 19.9c shows the ( $\bar{1}10$ ) planes. The Miller indices for the four sets of planes in Fig. 19.9 are therefore (110), (230), ( $\bar{1}10$ ), and (010). Figure 19.10 shows a three-dimensional representation of a selection of planes, including one in a lattice with non-orthogonal axes.

The notation ( $hkl$ ) refers to an *individual* plane. To specify a *set* of parallel planes we use the notation  $\{hkl\}$ . Thus, we speak of the (110) plane in a lattice, and the set of all  $\{110\}$  planes that lie parallel to the (110) plane. A helpful feature to remember is that, the smaller the absolute value of  $h$  in  $\{hkl\}$ , the more nearly parallel the set of planes is to the  $a$  axis (the  $\{h00\}$  planes are an exception). The same is true of  $k$  and the  $b$  axis and  $l$  and the  $c$  axis. When  $h = 0$ , the planes intersect the  $a$  axis at infinity, so the  $\{0kl\}$  planes are parallel to the  $a$  axis. Similarly, the  $\{h0l\}$  planes are parallel to  $b$  and the  $\{hk0\}$  planes are parallel to  $c$ .

The Miller indices are very useful for expressing the separation of planes. The separation of the  $\{hk0\}$  planes in the square lattice shown in Fig. 19.11 is given by

$$\frac{1}{d_{hk0}^2} = \frac{h^2 + k^2}{a^2} \quad \text{or} \quad d_{hk0} = \frac{a}{(h^2 + k^2)^{1/2}} \quad (19.1)$$

By extension to three dimensions, the separation of the  $\{hkl\}$  planes of a cubic lattice is given by

$$\frac{1}{d_{hkl}^2} = \frac{h^2 + k^2 + l^2}{a^2} \quad \text{or} \quad d_{hkl} = \frac{a}{(h^2 + k^2 + l^2)^{1/2}} \quad (19.2)$$

The corresponding expression for a general orthorhombic lattice is the generalization of this expression:

$$\frac{1}{d_{hkl}^2} = \frac{h^2}{a^2} + \frac{k^2}{b^2} + \frac{l^2}{c^2} \quad (19.3)$$

**Example 19.1** Using the Miller indices

Calculate the separation of (a) the {123} planes and (b) the {246} planes of an orthorhombic unit cell with  $a = 0.82$  nm,  $b = 0.94$  nm, and  $c = 0.75$  nm.

**Method** For the first part, simply substitute the information into eqn 19.3. For the second part, instead of repeating the calculation, note that, if all three Miller indices are multiplied by  $n$ , then their separation is reduced by that factor (Fig. 19.12):

$$\frac{1}{d_{nh,nk,nl}^2} = \frac{(nh)^2}{a^2} + \frac{(nk)^2}{b^2} + \frac{(nl)^2}{c^2} = n^2 \left( \frac{h^2}{a^2} + \frac{k^2}{b^2} + \frac{l^2}{c^2} \right) = \frac{n^2}{d_{hkl}^2}$$

which implies that

$$d_{nh,nk,nl} = \frac{d_{hkl}}{n}$$

**Answer** Substituting the indices into eqn 19.3 gives

$$\frac{1}{d_{123}^2} = \frac{1^2}{(0.82 \text{ nm})^2} + \frac{2^2}{(0.94 \text{ nm})^2} + \frac{3^2}{(0.75 \text{ nm})^2} = 0.22 \text{ nm}^{-2}$$

Hence,  $d_{123} = 0.21$  nm. It then follows immediately that  $d_{246}$  is one-half this value, or 0.11 nm.

**Self-test 19.1** Calculate the separation of (a) the {133} planes and (b) the {399} planes in the same lattice. [0.19 nm, 0.063 nm]

**Fig. 19.11** The dimensions of a unit cell and their relation to the plane passing through the lattice points.

**Fig. 19.12** The separation of the {220} planes is half that of the {110} planes. In general, the separation of the planes  $\{nh,nk,nl\}$  is  $n$  times smaller than the separation of the  $\{hkl\}$  planes.

**A note on good practice** It is always sensible to look for analytical relations between quantities rather than to evaluate expressions numerically each time for that emphasizes the relations between quantities (and avoids unnecessary work).

### 19.3 The investigation of structure

**Key points** (a) The positions of atoms in a solid may be revealed by analysing the pattern of diffraction of X-rays by a single crystal or powder (a collection of crystallites). (b) Bragg's law relates the glancing angle of incidence of X-rays and the separation of lattice planes. (c) The scattering factor is a measure of the ability of an atom to diffract radiation. (d) The structure factor is the overall amplitude of a wave diffracted by the  $\{hkl\}$  planes. Fourier synthesis is the construction of the electron density distribution from structure factors. (e) A Patterson synthesis is a map of interatomic vectors obtained by Fourier analysis of diffraction intensities. (f) Structure refinement is the adjustment of structural parameters to give the best fit between the observed intensities and those calculated from the model of the structure deduced from the diffraction pattern.

A characteristic property of waves is that they interfere with one another, giving a greater displacement where peaks coincide with peaks or troughs coincide with troughs, and a smaller displacement where peaks coincide with troughs (Fig. 19.13). According to classical electromagnetic theory, the intensity of electromagnetic radiation is

**Fig. 19.13** When two waves are in the same region of space they interfere. Depending on their relative phase, they may interfere (a) constructively, to give an enhanced amplitude, or (b) destructively, to give a smaller amplitude. The component waves are shown in blue and purple and the resultant in black.

**Fig. 19.14** X-rays are generated by directing an electron beam on to a cooled metal target. Beryllium is transparent to X-rays (on account of the small number of electrons in each atom) and is used for the windows.

proportional to the square of the amplitude of the waves. Therefore, the regions of constructive or destructive interference show up as regions of enhanced or diminished intensities. The phenomenon of **diffraction** is the interference caused by an object in the path of waves, and the pattern of varying intensity that results is called the **diffraction pattern**. Diffraction occurs when the dimensions of the diffracting object are comparable to the wavelength of the radiation.

### (a) X-ray diffraction

Wilhelm Röntgen discovered X-rays in 1895. Seventeen years later, Max von Laue suggested that they might be diffracted when passed through a crystal, for by then he had realized that their wavelengths are comparable to the separation of lattice planes. This suggestion was confirmed almost immediately by Walter Friedrich and Paul Knipping and has grown since then into a technique of extraordinary power. The bulk of this section will deal with the determination of structures using X-ray diffraction. The mathematical procedures necessary for the determination of structure from X-ray diffraction data are enormously complex, but such is the degree of integration of computers into the experimental apparatus that the technique is almost fully automated, even for large molecules and complex solids. The analysis is aided by molecular modelling techniques, which can guide the investigation towards a plausible structure.

X-rays are electromagnetic radiation with wavelengths of the order of  $10^{-10}$  m. They are typically generated by bombarding a metal with high-energy electrons (Fig. 19.14). The electrons decelerate as they plunge into the metal and generate radiation with a continuous range of wavelengths called **Bremsstrahlung** (*Bremse* is German for deceleration, *Strahlung* for ray.) Superimposed on the continuum are a few high-intensity, sharp peaks (Fig. 19.15). These peaks arise from collisions of the incoming electrons with the electrons in the inner shells of the atoms. A collision expels an electron from an inner shell, and an electron of higher energy drops into the vacancy, emitting the excess energy as an X-ray photon (Fig. 19.16). If the electron

**Fig. 19.15** The X-ray emission from a metal consists of a broad, featureless Bremsstrahlung background, with sharp transitions superimposed on it. The label K indicates that the radiation comes from a transition in which an electron falls into a vacancy in the K shell of the atom.

**Fig. 19.16** The processes that contribute to the generation of X-rays. An incoming electron collides with an electron (in the K shell), and ejects it. Another electron (from the L shell in this illustration) falls into the vacancy and emits its excess energy as an X-ray photon.

falls into a K shell (a shell with  $n = 1$ ), the X-rays are classified as **K-radiation**, and similarly for transitions into the L ( $n = 2$ ) and M ( $n = 3$ ) shells. Strong, distinct lines are labelled  $K_\alpha$ ,  $K_\beta$ , and so on. Increasingly, X-ray diffraction makes use of the radiation available from synchrotron sources (*Further information 12.1*), for its high intensity greatly enhances the sensitivity of the technique.

von Laue's original method consisted of passing a broad-band beam of X-rays into a single crystal, and recording the diffraction pattern photographically. The idea behind the approach was that a crystal might not be suitably orientated to act as a diffraction grating for a single wavelength but, whatever its orientation, diffraction would be achieved for at least one of the wavelengths if a range of wavelengths was used. There is currently a resurgence of interest in this approach because synchrotron radiation spans a range of X-ray wavelengths.

An alternative technique was developed by Peter Debye and Paul Scherrer and independently by Albert Hull. They used monochromatic radiation and a powdered sample. When the sample is a powder, at least some of the crystallites will be orientated so as to give rise to diffraction. In modern powder diffractometers the intensities of the reflections are monitored electronically as the detector is rotated around the sample in a plane containing the incident ray (Fig. 19.17). Powder diffraction techniques are used to identify a sample of a solid substance by comparison of the positions of the diffraction lines and their intensities with diffraction patterns stored in a large data bank. Powder diffraction data are also used to help determine phase diagrams, for different crystalline phases result in different diffraction patterns, and to determine the relative amounts of each phase present in a mixture. The technique is also used for the initial determination of the dimensions and symmetries of unit cells.

The method developed by the Braggs (William and his son Lawrence, who later jointly won the Nobel Prize) is the foundation of almost all modern work in X-ray crystallography. They used a single crystal and a monochromatic beam of X-rays, and rotated the crystal until a reflection was detected. There are many different sets of planes in a crystal, so there are many angles at which a reflection occurs. The complete set of data consists of the list of angles at which reflections are observed and their intensities.

Single-crystal diffraction patterns are measured by using a **four-circle diffractometer** (Fig. 19.18). The computer linked to the diffractometer determines the unit cell dimensions and the angular settings of the diffractometer's four circles that are needed to observe any particular intensity peak in the diffraction pattern. The computer controls the settings, and moves the crystal and the detector for each one in turn. At each setting, the diffraction intensity is measured, and background intensities are assessed by making measurements at slightly different settings. Computing techniques are now available that lead not only to automatic indexing but also to the automated determination of the shape, symmetry, and size of the unit cell. Moreover, several techniques are now available for sampling large amounts of data, including area detectors and image plates, which sample whole regions of diffraction patterns simultaneously.

### (b) Bragg's law

An early approach to the analysis of diffraction patterns produced by crystals was to regard a lattice plane as a semi-transparent mirror, and to model a crystal as stacks of reflecting lattice planes of separation  $d$  (Fig. 19.19). The model makes it easy to calculate the angle the crystal must make to the incoming beam of X-rays for constructive interference to occur. It has also given rise to the name **reflection** to denote an intense beam arising from constructive interference.

Consider the reflection of two parallel rays of the same wavelength by two adjacent planes of a lattice, as shown in Fig. 19.19. One ray strikes a point on the upper plane

**Fig. 19.17** X-ray powder diffraction patterns of (a) NaCl, (b) KCl. The smaller number of lines in (b) is a consequence of the similarity of the  $K^+$  and  $Cl^-$  scattering factors, as discussed later in the chapter.

**Fig. 19.18** A four-circle diffractometer. The settings of the orientations ( $\phi$ ,  $\chi$ ,  $\theta$ , and  $\Omega$ ) of the components are controlled by computer; each  $(hkl)$  reflection is monitored in turn, and their intensities are recorded.

**Fig. 19.19** The conventional derivation of Bragg's law treats each lattice plane as a reflecting the incident radiation. The path lengths differ by  $AB + BC$ , which depends on the glancing angle,  $\theta$ . Constructive interference (a 'reflection') occurs when  $AB + BC$  is equal to an integer number of wavelengths.

but the other ray must travel an additional distance  $AB$  before striking the plane immediately below. Similarly, the reflected rays will differ in path length by a distance  $BC$ . The net path length difference of the two rays is then

$$AB + BC = 2d \sin \theta$$

where  $\theta$  is the **glancing angle**. For many glancing angles the path-length difference is not an integer number of wavelengths, and the waves interfere largely destructively. However, when the path-length difference is an integer number of wavelengths ( $AB + BC = n\lambda$ ), the reflected waves are in phase and interfere constructively. It follows that a reflection should be observed when the glancing angle satisfies **Bragg's law**:

$$n\lambda = 2d \sin \theta \quad \text{Bragg's law} \quad (19.4)$$

Reflections with  $n = 2, 3, \dots$  are called second-order, third-order, and so on; they correspond to path-length differences of 2, 3,  $\dots$  wavelengths. In modern work it is normal to absorb the  $n$  into  $d$ , to write Bragg's law as

$$\lambda = 2d \sin \theta \quad \text{Alternative form of Bragg's law} \quad (19.5)$$

and to regard the  $n$ th-order reflection as arising from the  $\{nh, nk, nl\}$  planes (see Example 19.1).

The primary use of Bragg's law is in the determination of the spacing between the layers in the lattice for, once the angle  $\theta$  corresponding to a reflection has been determined,  $d$  may readily be calculated.

#### • A brief illustration

A first-order reflection from the  $\{111\}$  planes of a cubic crystal was observed at a glancing angle of  $11.2^\circ$  when  $\text{Cu}(K_\alpha)$  X-rays of wavelength 154 pm were used. According to eqn 19.5, the  $\{111\}$  planes responsible for the diffraction have separation  $d_{111} = \lambda/2 \sin \theta$ . The separation of the  $\{111\}$  planes of a cubic lattice of side  $a$  is given by eqn 19.2 as  $d_{111} = a/3^{1/2}$ . Therefore,

$$a = \frac{3^{1/2} \lambda}{2 \sin \theta} = \frac{3^{1/2} \times (154 \text{ pm})}{2 \sin 11.2^\circ} = 687 \text{ pm} \quad \bullet$$

**Self-test 19.2** Calculate the angle at which the same crystal will give a reflection from the  $\{123\}$  planes. [24.8°]

Some types of unit cell give characteristic and easily recognizable patterns of lines. For example, in a cubic lattice of unit cell dimension  $a$  the spacing is given by eqn 19.2, so the angles at which the  $\{hkl\}$  planes give first-order reflections are given by

$$\sin \theta = (h^2 + k^2 + l^2)^{1/2} \frac{\lambda}{2a}$$

The reflections are then predicted by substituting the values of  $h$ ,  $k$ , and  $l$ :

| $\{hkl\}$         | $\{100\}$ | $\{110\}$ | $\{111\}$ | $\{200\}$ | $\{210\}$ | $\{211\}$ | $\{220\}$ | $\{300\}$ | $\{221\}$ | $\{310\}$ | $\dots$ |
|-------------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|---------|
| $h^2 + k^2 + l^2$ | 1         | 2         | 3         | 4         | 5         | 6         | 8         | 9         | 9         | 10        | $\dots$ |

Notice that 7 (and 15,  $\dots$ ) is missing because the sum of the squares of three integers cannot equal 7 (or 15,  $\dots$ ). Therefore the pattern has absences that are characteristic of the cubic P lattice.

**Self-test 19.3** Normally, experimental procedures measure  $2\theta$  rather than  $\theta$  itself. A diffraction examination of the element polonium gave lines at the following values of  $2\theta$  (in degrees) when 71.0 pm Mo X-rays were used: 12.1, 17.1, 21.0, 24.3, 27.2, 29.9, 34.7, 36.9, 38.9, 40.9, 42.8. Identify the unit cell and determine its dimensions. [cubic P;  $a = 337$  pm]

### (c) Scattering factors

To prepare the way to discussing modern methods of structural analysis we need to note that the scattering of X-rays is caused by the oscillations an incoming electromagnetic wave generates in the electrons of atoms, and heavy atoms give rise to stronger scattering than light atoms. This dependence on the number of electrons is expressed in terms of the **scattering factor**,  $f$ , of the element. If the scattering factor is large, then the atoms scatter X-rays strongly. The scattering factor of an atom is related to the electron density distribution in the atom,  $\rho(r)$ , by

$$f = 4\pi \int_0^\infty \rho(r) \frac{\sin kr}{kr} r^2 dr \quad k = \frac{4\pi}{\lambda} \sin \theta \quad \text{Scattering factor} \quad (19.6)$$

The value of  $f$  is greatest in the forward direction and smaller for directions away from the forward direction (Fig. 19.20). The detailed analysis of the intensities of reflections must take this dependence on direction into account (in single crystal studies as well as for powders). We show in the following *Justification* that, in the forward direction (for  $\theta = 0$ ),  $f$  is equal to the total number of electrons in the atom.

#### Justification 19.1 The forward scattering factor

As  $\theta \rightarrow 0$ , so  $k \rightarrow 0$ . Because  $\sin x = x - \frac{1}{6}x^3 + \dots$ ,

$$\lim_{x \rightarrow 0} \frac{\sin x}{x} = \lim_{x \rightarrow 0} \frac{x - \frac{1}{6}x^3 + \dots}{x} = \lim_{x \rightarrow 0} \left(1 - \frac{1}{6}x^2 + \dots\right) = 1$$

The factor  $(\sin kr)/kr$  is therefore equal to 1 for forward scattering. It follows that in the forward direction

$$f = 4\pi \int_0^\infty \rho(r) r^2 dr$$

The integral over the electron density  $\rho$  (the number of electrons in an infinitesimal region divided by the volume of the region) multiplied by the volume element  $4\pi r^2 dr$  is the total number of electrons,  $N_e$ , in the atom. Hence, in the forward direction,  $f = N_e$ . For example, the scattering factors of  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Cl}^-$  are 10, 18, and 18, respectively. The scattering factor is smaller in non-forward directions because  $(\sin kr)/kr < 1$  for  $\theta > 0$ , so the integral is smaller than the value calculated here.

**Fig. 19.20** The variation of the scattering factor of atoms and ions with atomic number and angle. The scattering factor in the forward direction (at  $\theta = 0$ , and hence at  $(\sin \theta)/\lambda = 0$ ) is equal to the number of electrons present in the species.

### (d) The electron density

The problem we now address is how to interpret the data from a diffractometer in terms of the detailed structure of a crystal. To do so, we must go beyond Bragg's law.

If a unit cell contains several atoms with scattering factors  $f_j$  and coordinates  $(x_j, y_j, z_j)$ , then we show in the following *Justification* that the overall amplitude of a wave diffracted by the  $\{hkl\}$  planes is given by

**Fig. 19.21** Diffraction from a crystal containing two kinds of atoms. (a) For a (100) reflection from the A planes, there is a phase difference of  $2\pi$  between waves reflected by neighbouring planes. (b) For a (200) reflection, the phase difference is  $4\pi$ . The reflection from a B plane at a fractional distance  $xa$  from an A plane has a phase that is  $x$  times these phase differences.

**Fig. 19.22** The location of the atoms for the structure factor calculation in Example 19.2. The purple circles are  $\text{Na}^+$ , the green circles are  $\text{Cl}^-$ .

$$F_{hkl} = \sum_j f_j e^{i\phi_{hkl}(j)} \quad \text{where} \quad \phi_{hkl}(j) = 2\pi(hx_j + ky_j + lz_j) \quad \text{Definition of structure factor} \quad [19.7]$$

where  $i = (-1)^{1/2}$ . The sum is over all the atoms in the unit cell. The quantity  $F_{hkl}$  is called the **structure factor**.

#### Justification 19.2 The structure factor

We begin by showing that, if in the unit cell there is an A atom at the origin and a B atom at the coordinates  $(xa, yb, zc)$ , where  $x$ ,  $y$ , and  $z$  lie in the range 0 to 1, then the phase difference between the  $hkl$  reflections of the A and B atoms is  $\phi_{hkl} = 2\pi(hx + ky + lz)$ .

Consider the crystal shown schematically in Fig. 19.21. The reflection corresponds to two waves from adjacent A planes, the phase difference of the waves being  $2\pi$ . If there is a B atom at a fraction  $x$  of the distance between the two A planes, then it gives rise to a wave with a phase difference  $2\pi x$  relative to an A reflection. To see this conclusion, note that, if  $x = 0$ , there is no phase difference; if  $x = \frac{1}{2}$  the phase difference is  $\pi$ ; if  $x = 1$ , the B atom lies where the upper A atom is and the phase difference is  $2\pi$ . Now consider a (200) reflection. There is now a  $2 \times 2\pi$  difference between the waves from the two A layers, and if B were to lie at  $x = 0.5$  it would give rise to a wave that differed in phase by  $2\pi$  from the wave from the lower A layer. Thus, for a general fractional position  $x$ , the phase difference for a (200) reflection is  $2 \times 2\pi x$ . For a general  $(h00)$  reflection, the phase difference is therefore  $h \times 2\pi x$ . For three dimensions, this result generalizes to  $\phi_{hkl} = 2\pi(hx + ky + lz)$ .

If the amplitude of the waves scattered from A is  $f_A$  at the detector, that of the waves scattered from B is  $f_B e^{i\phi_{hkl}}$ , with  $\phi_{hkl}$  as the phase difference given in eqn 19.7. The total amplitude at the detector is therefore

$$F_{hkl} = f_A + f_B e^{i\phi_{hkl}}$$

This expression generalizes to eqn 19.7 when there are several atoms present each with scattering factor  $f_j$ .

#### Example 19.2 Calculating a structure factor

Calculate the structure factors for the unit cell in Fig. 19.22.

**Method** The structure factor is defined by eqn 19.7. To use this equation, consider the ions at the locations specified in Fig. 19.22. Write  $f^+$  for the  $\text{Na}^+$  scattering factor and  $f^-$  for the  $\text{Cl}^-$  scattering factor. Note that ions in the body of the cell contribute to the scattering with a strength  $f$ . However, ions on faces are shared between two cells (use  $\frac{1}{2}f$ ), those on edges by four cells (use  $\frac{1}{4}f$ ) and those at corners by eight cells (use  $\frac{1}{8}f$ ). Two useful relations are

$$e^{i\pi} = -1 \quad \cos \phi = \frac{1}{2}(e^{i\phi} + e^{-i\phi})$$

**Answer** From eqn 19.7, and summing over the coordinates of all 27 atoms in the illustration:

$$F_{hkl} = f^+ \left( \frac{1}{8} + \frac{1}{8} e^{2\pi i l} + \dots + \frac{1}{2} e^{2\pi i (\frac{1}{2}h + \frac{1}{2}k + l)} \right) + f^- \left( e^{2\pi i (\frac{1}{2}h + \frac{1}{2}k + \frac{1}{2}l)} + \frac{1}{4} e^{2\pi i (\frac{1}{2}h)} + \dots + \frac{1}{4} e^{2\pi i (\frac{1}{2}h + l)} \right)$$

To simplify this 27-term expression, we use

$$e^{2\pi i h} = e^{2\pi i k} = e^{2\pi i l} = 1$$

because  $h$ ,  $k$ , and  $l$  are all integers:

$$F_{hkl} = f^+ \{1 + \cos(h+k)\pi + \cos(h+l)\pi + \cos(k+l)\pi\} \\ + f^- \{(-1)^{h+k+l} + \cos k\pi + \cos l\pi + \cos h\pi\}$$

Then, because  $\cos h\pi = (-1)^h$

$$F_{hkl} = f^+ \{1 + (-1)^{h+k} + (-1)^{h+l} + (-1)^{l+k}\} + f^- \{(-1)^{h+k+l} + (-1)^h + (-1)^k + (-1)^l\}$$

Now note that:

- if  $h$ ,  $k$ , and  $l$  are all even,  $F_{hkl} = f^+ \{1 + 1 + 1 + 1\} + f^- \{1 + 1 + 1 + 1\} = 4(f^+ + f^-)$
- if  $h$ ,  $k$ , and  $l$  are all odd,  $F_{hkl} = 4(f^+ - f^-)$
- if one index is odd and two are even, or vice versa,  $F_{hkl} = 0$

The  $hkl$  all-odd reflections are less intense than the  $hkl$  all-even. For  $f^+ = f^-$ , which is the case for identical atoms in a cubic P arrangement, the  $hkl$  all-odd have zero intensity.

**Self-test 19.4** Which reflections cannot be observed for a cubic I lattice?

[for  $h + k + l$  odd,  $F_{hkl} = 0$ ]

Because the intensity is proportional to the square modulus of the amplitude of the wave, the intensity,  $I_{hkl}$ , at the detector is

$$I_{hkl} \propto F_{hkl}^* F_{hkl} = (f_A + f_B e^{-i\phi_{hkl}})(f_A + f_B e^{i\phi_{hkl}})$$

This expression expands to

$$I_{hkl} \propto f_A^2 + f_B^2 + f_A f_B (e^{i\phi_{hkl}} + e^{-i\phi_{hkl}}) = f_A^2 + f_B^2 + 2f_A f_B \cos \phi_{hkl}$$

The cosine term either adds to or subtracts from  $f_A^2 + f_B^2$  depending on the value of  $\phi_{hkl}$ , which in turn depends on  $h$ ,  $k$ , and  $l$  and  $x$ ,  $y$ , and  $z$ . Hence, there is a variation in the intensities of the lines with different  $hkl$ . The A and B reflections interfere destructively when the phase difference is  $\pi$ , and the total intensity is zero if the atoms have the same scattering power. For example, if the unit cells are cubic I with a B atom at  $x = y = z = \frac{1}{2}$ , then the A,B phase difference is  $(h + k + l)\pi$ . Therefore, all reflections for odd values of  $h + k + l$  vanish (as we saw in Self-test 19.4) because the waves are displaced in phase by  $\pi$ . Hence the diffraction pattern for a cubic I lattice can be constructed from that for the cubic P lattice (a cubic lattice without points at the centre of its unit cells) by striking out all reflections with odd values of  $h + k + l$ . Recognition of these **systematic absences** in a powder spectrum immediately indicates a cubic I lattice (Fig. 19.23).

Because the intensity of the  $(hkl)$  reflection is proportional to  $|F_{hkl}|^2$ , in principle we can determine the structure factors experimentally by taking the square root of the corresponding intensities (but see below). Then, once we know all the structure factors  $F_{hkl}$ , we can calculate the electron density distribution,  $\rho(r)$ , in the unit cell by using the expression

$$\rho(r) = \frac{1}{V} \sum_{hkl} F_{hkl} e^{-2\pi i(hx + ky + lz)} \quad \text{Fourier synthesis of the electron density} \quad (19.8)$$

where  $V$  is the volume of the unit cell. Equation 19.8 is called a **Fourier synthesis** of the electron density. (See *Mathematical background* 7 which follows this chapter for more information on Fourier series and transforms.)

**Fig. 19.23** The powder diffraction patterns and the systematic absences of three versions of a cubic cell: cubic F (fcc;  $h$ ,  $k$ ,  $l$  all even or all odd are present), cubic I (bcc;  $h + k + l = \text{odd}$  are absent), cubic P. Comparison of the observed pattern with patterns like these enables the unit cell to be identified. The locations of the lines give the cell dimensions.

**Fig. 19.24** The plot of the electron density calculated in Example 19.3 (green) and Self-test 19.5 (purple).

**InterActivity** If you do not have access to mathematical software, perform the calculations suggested in Self-test 19.5 by using the interactive applets found in the text's web site.

### Example 19.3 Calculating an electron density by Fourier synthesis

Consider the  $\{h00\}$  planes of a crystal extending indefinitely in the  $x$ -direction. In an X-ray analysis the structure factors were found as follows:

|       |    |     |    |    |    |     |   |    |   |    |
|-------|----|-----|----|----|----|-----|---|----|---|----|
| $h$ : | 0  | 1   | 2  | 3  | 4  | 5   | 6 | 7  | 8 | 9  |
| $F_h$ | 16 | -10 | 2  | -1 | 7  | -10 | 8 | -3 | 2 | -3 |
| $h$ : | 10 | 11  | 12 | 13 | 14 | 15  |   |    |   |    |
| $F_h$ | 6  | -5  | 3  | -2 | 2  | -3  |   |    |   |    |

(and  $F_{-h} = F_h$ ). Construct a plot of the electron density projected on to the  $x$ -axis of the unit cell.

**Method** Because  $F_{-h} = F_h$ , it follows from eqn 19.8 that

$$\begin{aligned} V\rho(x) &= \sum_{h=-\infty}^{\infty} F_h e^{-2\pi i h x} = F_0 + \sum_{h=1}^{\infty} (F_h e^{-2\pi i h x} + F_{-h} e^{2\pi i h x}) \\ &= F_0 + \sum_{h=1}^{\infty} F_h (e^{-2\pi i h x} + e^{2\pi i h x}) = F_0 + 2 \sum_{h=1}^{\infty} F_h \cos 2\pi h x \end{aligned}$$

and we evaluate the sum (truncated at  $h = 15$ ) for points  $0 < x < 1$  using mathematical software.

**Answer** The results are plotted in Fig. 19.24 (green line). The positions of three atoms can be discerned very readily. The more terms there are included, the more accurate the density plot. Terms corresponding to high values of  $h$  (short wavelength cosine terms in the sum) account for the finer details of the electron density; low values of  $h$  account for the broad features.

**Self-test 19.5** Use mathematical software to experiment with different structure factors (including changing signs as well as amplitudes). For example, use the same values of  $F_h$  as above, but with positive signs for all values of  $h$ .

[Fig. 19.24 (purple line)]

### (e) The phase problem

A problem with the procedure outlined so far is that, as we have seen, the observed intensity  $I_{hkl}$  is proportional to the square modulus  $|F_{hkl}|^2$ , so we cannot say whether we should use  $|F_{hkl}|$  or  $-|F_{hkl}|$  in the sum in eqn 19.8. In fact, the difficulty is more severe for non-centrosymmetric unit cells because, if we write  $F_{hkl}$  as the complex number  $|F_{hkl}|e^{i\alpha}$  where  $\alpha$  is the phase of  $F_{hkl}$  and  $|F_{hkl}|$  is its magnitude, then the intensity lets us determine  $|F_{hkl}|$  but tells us nothing of its phase, which may lie anywhere from 0 to  $2\pi$ . This ambiguity is called the **phase problem**; its consequences are illustrated by comparing the two plots in Fig. 19.24. Some way must be found to assign phases to the structure factors, for otherwise the sum for  $\rho$  cannot be evaluated and the method would be useless.

The phase problem can be overcome to some extent by a variety of methods. One procedure that is widely used for inorganic materials with a reasonably small number of atoms in a unit cell and for organic molecules with a small number of heavy atoms is the **Patterson synthesis**. Instead of the structure factors  $F_{hkl}$ , the values of  $|F_{hkl}|^2$ , which can be obtained without ambiguity from the intensities, are used in an expression that resembles eqn 19.8:

$$P(\mathbf{r}) = \frac{1}{V} \sum_{hkl} |F_{hkl}|^2 e^{-2\pi i(hx + ky + lz)} \quad \text{Patterson synthesis} \quad (19.9)$$

The outcome of a Patterson synthesis is a map of the vector separations of the atoms (the distances and directions between atoms) in the unit cell. Thus, if atom A is at the coordinates  $(x_A, y_A, z_A)$  and atom B is at  $(x_B, y_B, z_B)$ , then there will be a peak at  $(x_A - x_B, y_A - y_B, z_A - z_B)$  in the Patterson map. There will also be a peak at the negative of these coordinates, because there is a vector from B to A as well as a vector from A to B. The height of the peak in the map is proportional to the product of the atomic numbers of the two atoms,  $Z_A Z_B$ . For example, if the unit cell has the structure shown in Fig. 19.25a, the Patterson synthesis would be the map shown in Fig. 19.25b, where the location of each spot relative to the origin gives the separation and relative orientation of each pair of atoms in the original structure.

Heavy atoms dominate the scattering because their scattering factors are large, of the order of their atomic numbers, and their locations may be deduced quite readily. The sign of  $F_{hkl}$  can then be calculated from the locations of the heavy atoms in the unit cell, and to a high probability the phase calculated for them will be the same as the phase for the entire unit cell. To see why this is so, we have to note that a structure factor of a centrosymmetric cell has the form

$$F = (\pm)f_{\text{heavy}} + (\pm)f_{\text{light}} + (\pm)f_{\text{light}} + \dots \quad (19.10)$$

where  $f_{\text{heavy}}$  is the scattering factor of the heavy atom and  $f_{\text{light}}$  the scattering factors of the light atoms. The  $f_{\text{light}}$  are all much smaller than  $f_{\text{heavy}}$ , and their phases are more or less random if the atoms are distributed throughout the unit cell. Therefore, the net effect of the  $f_{\text{light}}$  is to change  $F$  only slightly from  $f_{\text{heavy}}$ , and we can be reasonably confident that  $F$  will have the same sign as that calculated from the location of the heavy atom. This phase can then be combined with the observed  $|F|$  (from the reflection intensity) to perform a Fourier synthesis of the full electron density in the unit cell, and hence to locate the light atoms as well as the heavy atoms.

Modern structural analyses make extensive use of **direct methods**. Direct methods are based on the possibility of treating the atoms in a unit cell as being virtually randomly distributed (from the radiation's point of view), and then using statistical techniques to compute the probabilities that the phases have a particular value. It is possible to deduce relations between some structure factors and sums (and sums of squares) of others, which have the effect of constraining the phases to particular values (with high probability, so long as the structure factors are large). For example, the **Sayre probability relation** has the form

$$\begin{aligned} \text{sign of } F_{h+h', k+k', l+l'} &\text{ is probably} \\ \text{equal to } (\text{sign of } F_{hkl}) \times (\text{sign of } F_{h'k'l'}) \end{aligned} \quad \text{Sayre probability relation} \quad (19.11)$$

For example, if  $F_{122}$  and  $F_{232}$  are both large and negative, then it is highly likely that  $F_{354}$ , provided it is large, will be positive.

#### (f) Structure refinement

In the final stages of the determination of a crystal structure, the parameters describing the structure (atom positions, for instance) are adjusted systematically to give the best fit between the observed intensities and those calculated from the model of the structure deduced from the diffraction pattern. This process is called **structure refinement**. Not only does the procedure give accurate positions for all the atoms in the unit cell, but it also gives an estimate of the errors in those positions and in the bond

**Fig. 19.25** The Patterson synthesis corresponding to the pattern in (a) is the pattern in (b). The distance and orientation of each spot from the origin gives the orientation and separation of one atom–atom separation in (a). Some of the typical distances and their contribution to (b) are shown as  $R_1$ , etc.

lengths and angles derived from them. The procedure also provides information on the vibrational amplitudes of the atoms.

## 19.4 Neutron and electron diffraction

**Key point** Neutrons generated in a nuclear reactor and then slowed to thermal velocities have wavelengths similar to those of X-rays and may also be used for diffraction studies of solids.

According to the de Broglie relation (eqn 7.16,  $\lambda = h/p$ ), particles have wavelengths and may therefore undergo diffraction. Neutrons generated in a nuclear reactor and then slowed to thermal velocities have wavelengths similar to those of X-rays and may also be used for diffraction studies. For instance, a neutron generated in a reactor and slowed to thermal velocities by repeated collisions with a moderator (such as graphite) until it is travelling at about  $4 \text{ km s}^{-1}$  has a wavelength of about 100 pm. In practice, a range of wavelengths occurs in a neutron beam, but a monochromatic beam can be selected by diffraction from a crystal, such as a single crystal of germanium.

### Example 19.4 Calculating the typical wavelength of thermal neutrons

Calculate the typical wavelength of neutrons that have reached thermal equilibrium with their surroundings at 373 K.

**Method** We need to relate the wavelength to the temperature. There are two linking steps. First, the de Broglie relation expresses the wavelength in terms of the linear momentum. Then the linear momentum can be expressed in terms of the kinetic energy, the mean value of which is given in terms of the temperature by the equipartition theorem (see Section 16.3).

**Answer** From the equipartition principle, we know that the mean translational kinetic energy of a neutron at a temperature  $T$  travelling in the  $x$ -direction is  $E_k = \frac{1}{2}kT$ . The kinetic energy is also equal to  $p^2/2m$ , where  $p$  is the momentum of the neutron and  $m$  is its mass. Hence,  $p = (mkT)^{1/2}$ . It follows from the de Broglie relation  $\lambda = h/p$  that the neutron's wavelength is

$$\lambda = \frac{h}{(mkT)^{1/2}}$$

Therefore, at 373 K,

$$\begin{aligned} \lambda &= \frac{6.626 \times 10^{-34} \text{ J s}}{\{(1.675 \times 10^{-27} \text{ kg}) \times (1.381 \times 10^{-23} \text{ J K}^{-1}) \times (373 \text{ K})\}^{1/2}} \\ &= \frac{6.626 \times 10^{-34} \text{ J s}}{(1.675 \times 1.381 \times 373 \times 10^{-50})^{1/2} (\text{kg}^2 \text{ m}^2 \text{ s}^{-2})^{1/2}} \\ &= 2.26 \times 10^{-10} \text{ m} = 226 \text{ pm} \end{aligned}$$

where we have used  $1 \text{ J} = 1 \text{ kg m}^2 \text{ s}^{-2}$ .

**Self-test 19.6** Calculate the temperature needed for the average wavelength of the neutrons to be 100 pm. [ $1.90 \times 10^3 \text{ K}$ ]

Neutron diffraction differs from X-ray diffraction in two main respects. First, the scattering of neutrons is a nuclear phenomenon. Neutrons pass through the extra-nuclear electrons of atoms and interact with the nuclei through the 'strong force' that is responsible for binding nucleons together. As a result, the intensity with which neutrons are scattered is independent of the number of electrons and neighbouring

elements in the periodic table may scatter neutrons with markedly different intensities. Neutron diffraction can be used to distinguish atoms of elements such as Ni and Co that are present in the same compound and to study order–disorder phase transitions in FeCo. A second difference is that neutrons possess a magnetic moment due to their spin. This magnetic moment can couple to the magnetic fields of atoms or ions in a crystal (if the ions have unpaired electrons) and modify the diffraction pattern. One consequence is that neutron diffraction is well suited to the investigation of magnetically ordered lattices in which neighbouring atoms may be of the same element but have different orientations of their electronic spin (Fig. 19.26).

Electrons accelerated from rest through a potential difference of 40 kV have wavelengths of about 6 pm, and so are also suitable for diffraction studies. However, their main application is to the study of surfaces.

## 19.5 Metallic solids

**Key points** (a) Many elemental metals have close-packed structures with coordination number 12; close-packed structures are commonly either cubic (ccp) or hexagonal (hcp). (b) The departure from close packing suggests that such factors as specific covalent bonding between neighbouring atoms influence the structure of a solid.

We now turn to the information that has been obtained from these various diffraction measurements. The bonding within a solid may be of various kinds. Simplest of all (in principle) are elemental metals, where electrons are delocalized over arrays of identical cations and bind them together into a rigid but ductile and malleable whole. Most metallic elements crystallize in one of three simple forms, two of which can be explained in terms of hard spheres packing together in the closest possible arrangement.

### (a) Close packing

Figure 19.27 shows a **close-packed** layer of identical spheres, one with maximum utilization of space. A close-packed three-dimensional structure is obtained by stacking such close-packed layers on top of one another. However, this stacking can be done in different ways, which result in close-packed **polytypes**, or structures that are identical in two dimensions (the close-packed layers) but differ in the third dimension.

In all polytypes, the spheres of the second close-packed layer lie in the depressions of the first layer (Fig. 19.28). The third layer may be added in either of two ways. In one, the spheres are placed so that they reproduce the first layer (Fig. 19.29a), to give an ABA pattern of layers. Alternatively, the spheres may be placed over the gaps in the

**Fig. 19.27** The first layer of close-packed spheres used to build a three-dimensional close-packed structure.

**Fig. 19.28** The second layer of close-packed spheres occupies the dips of the first layer. The two layers are the AB component of the close-packed structure.

**Fig. 19.26** If the spins of atoms at lattice points are orderly, as in this material, where the spins of one set of atoms are aligned antiparallel to those of the other set, neutron diffraction detects two interpenetrating simple cubic lattices on account of the magnetic interaction of the neutron with the atoms, but X-ray diffraction would see only a single bcc lattice.

**Fig. 19.29** (a) The third layer of close-packed spheres might occupy the dips lying directly above the spheres in the first layer, resulting in an ABA structure, which corresponds to hexagonal close-packing. (b) Alternatively, the third layer might lie in the dips that are not above the spheres in the first layer, resulting in an ABC structure, which corresponds to cubic close-packing.

**Fig. 19.30** A fragment of the structure shown in Fig. 19.29 revealing the (a) hexagonal (b) cubic symmetry. The tints on the spheres are the same as for the layers in Fig. 19.29.

**Fig. 19.31** The calculation of the packing fraction of a ccp unit cell.

**Table 19.2** The crystal structures of some elements

| Structure           | Element                                                        |
|---------------------|----------------------------------------------------------------|
| hcp*                | Be, Cd, Co, He, Mg, Sc, Ti, Zn                                 |
| fcc* (ccp, cubic F) | Ag, Al, Ar, Au, Ca, Cu, Kr, Ne, Ni, Pd, Pb, Pt, Rh, Rn, Sr, Xe |
| bcc (cubic I)       | Ba, Cs, Cr, Fe, K, Li, Mn, Mo, Rb, Na, Ta, W, V                |
| cubic P             | Po                                                             |

\* Close-packed structures.

first layer (Fig. 19.29b), so giving an ABC pattern. Two polytypes are formed if the two stacking patterns are repeated in the vertical direction. If the ABA pattern is repeated, to give the sequence of layers ABABAB . . . , the spheres are **hexagonally close-packed** (hcp). Alternatively, if the ABC pattern is repeated, to give the sequence ABCABC . . . , the spheres are **cubic close-packed** (ccp). We can see the origins of these names by referring to Fig. 19.30. The cubic close-packed (ccp) structure belongs to the cubic P Bravais lattice, from which one can construct a face-centred cubic (fcc) unit cell. It is also possible to have random sequences of layers; however, the hcp and ccp polytypes are the most important. Table 19.2 lists some elements possessing these structures.

The compactness of close-packed structures is indicated by their **coordination number**, the number of atoms immediately surrounding any selected atom, which is 12 in all cases. Another measure of their compactness is the **packing fraction**, the fraction of space occupied by the spheres, which is 0.740 (see the following *Justification*). That is, in a close-packed solid of identical hard spheres, only 26.0 per cent of the volume is empty space. The fact that many metals are close-packed accounts for their high densities.

**Justification 19.3** *The packing fraction*

To calculate a packing fraction of a ccp structure, we first calculate the volume of a unit cell, and then calculate the total volume of the spheres that fully or partially occupy it. The first part of the calculation is a straightforward exercise in geometry. The second part involves counting the fraction of spheres that occupy the cell.

Refer to Fig. 19.31. Because a diagonal of any face passes completely through one sphere and halfway through two other spheres, its length is  $4R$ . The length of a side is therefore  $8^{1/2}R$  and the volume of the unit cell is  $8^{3/2}R^3$ . Because each cell contains the equivalent of  $6 \times \frac{1}{2} + 8 \times \frac{1}{8} = 4$  spheres, and the volume of each sphere is  $\frac{4}{3}\pi R^3$ , the total occupied volume is  $\frac{16}{3}\pi R^3$ . The fraction of space occupied is therefore  $\frac{16}{3}\pi R^3 / 8^{3/2}R^3 = \frac{16}{3}\pi / 8^{3/2}$ , or 0.740. Because an hcp structure has the same coordination number, its packing fraction is the same. The packing fractions of structures that are not close-packed are calculated similarly (see Exercises 19.20 and 19.21).

### (b) Less closely packed structures

As shown in Table 19.2, a number of common metals adopt structures that are less than close-packed. The departure from close packing suggests that factors such as specific covalent bonding between neighbouring atoms are beginning to influence the structure and impose a specific geometrical arrangement. One such arrangement results in a cubic I (bcc, for body-centred cubic) structure, with one sphere at the centre of a cube formed by eight others. The coordination number of a bcc structure is only 8, but there are six more atoms not much further away than the eight nearest neighbours. The packing fraction of 0.68 is not much smaller than the value for a close-packed structure (0.74), and shows that about two-thirds of the available space is actually occupied.

## 19.6 Ionic solids

**Key points** (a) Representative ionic structures include the caesium-chloride, rock-salt, and zinc-blende structures. The radius-ratio rule may be used cautiously to predict which of these three structures is likely. (b) The lattice enthalpy is the change in enthalpy accompanying the complete separation of the components of the solid. The lattice enthalpy is expressed by the Born–Mayer equation. Experimental values of the lattice enthalpy are obtained by using a Born–Haber cycle.

Two questions arise when we consider ionic solids: the relative locations adopted by the ions and the energetics of the resulting structure.

### (a) Structure

When crystals of compounds of monatomic ions (such as NaCl and MgO) are modelled by stacks of hard spheres it is essential to allow for the different ionic radii (typically with the cations smaller than the anions) and different charges. The **coordination number** of an ion is the number of nearest neighbours of opposite charge; the structure itself is characterized as having  $(n_+, n_-)$ -coordination, where  $n_+$  is the coordination number of the cation and  $n_-$  that of the anion.

Even if, by chance, the ions have the same size, the problems of ensuring that the unit cells are electrically neutral makes it impossible to achieve 12-coordinate close-packed ionic structures. As a result, ionic solids are generally less dense than metals. The best packing that can be achieved is the (8,8)-coordinate **caesium-chloride structure** in which each cation is surrounded by eight anions and each anion is surrounded by eight cations (Fig. 19.32). In this structure, an ion of one charge occupies the centre of a cubic unit cell with eight counter ions at its corners. The structure is adopted by CsCl itself and also by CaS, CsCN (with some distortion), and CsAu.

When the radii of the ions differ more than in CsCl, even eight-coordinate packing cannot be achieved. One common structure adopted is the (6,6)-coordinate **rock-salt structure** typified by NaCl (Fig. 19.33). In this structure, each cation is surrounded by six anions and each anion is surrounded by six cations. The rock-salt structure can be pictured as consisting of two interpenetrating slightly expanded cubic F (fcc) arrays, one composed of cations and the other of anions. This structure is adopted by NaCl itself and also by several other MX compounds, including KBr, AgCl, MgO, and ScN.

The switch from the caesium-chloride structure to the rock-salt structure is related to the value of the **radius ratio**,  $\gamma$ :

$$\gamma = \frac{r_{\text{smaller}}}{r_{\text{larger}}}$$

Definition of  
the radius ratio

[19.12]

**Fig. 19.32** The caesium-chloride structure consists of two interpenetrating simple cubic arrays of ions, one of cations and the other of anions, so that each cube of ions of one kind has a counter ion at its centre.

**Fig. 19.33** The rock-salt (NaCl) structure consists of two mutually interpenetrating slightly expanded face-centred cubic arrays of ions. The entire assembly shown here is the unit cell.

**Fig. 19.34** The structure of the sphalerite form of ZnS showing the location of the Zn ions in the tetrahedral holes formed by the array of S ions. (There is an S ion at the centre of the cube inside the tetrahedron of Zn ions.)

**Table 19.3\*** Ionic radii,  $r/\text{pm}$

|                 |                                |
|-----------------|--------------------------------|
| Na <sup>+</sup> | 102 (6 <sup>†</sup> ), 116 (8) |
| K <sup>+</sup>  | 138 (6), 151 (8)               |
| F <sup>-</sup>  | 128 (2), 131 (4)               |
| Cl <sup>-</sup> | 181 (close packing)            |

\* More values are given in the Data section.

† Coordination number.

The two radii are those of the larger and smaller ions in the crystal. The **radius-ratio rule**, which is derived by considering the geometrical problem of packing the maximum number of hard spheres of one radius around a hard sphere of a different radius, can be summarized as follows:

| Radius ratio                           | Structural type  |
|----------------------------------------|------------------|
| $\gamma < 2^{1/2} - 1 = 0.414$         | Sphalerite       |
| $2^{1/2} - 1 = 0.414 < \gamma < 0.732$ | Rock-salt        |
| $\gamma > 3^{1/2} - 1 = 0.732$         | Caesium-chloride |

The sphalerite (or zinc-blende) structure is shown in Fig. 19.34. The deviation of a structure from that expected on the basis of the radius-ratio rule is often taken to be an indication of a shift from ionic towards covalent bonding; however, a major source of unreliability is the arbitrariness of ionic radii and their variation with coordination number.

Ionic radii are derived from the distance between centres of adjacent ions in a crystal. However, we need to apportion the total distance between the two ions by defining the radius of one ion and then inferring the radius of the other ion. One scale that is widely used is based on the value 140 pm for the radius of the O<sup>2-</sup> ion (Table 19.3). Other scales are also available (such as one based on F<sup>-</sup> for discussing halides), and it is essential not to mix values from different scales. Because ionic radii are so arbitrary, predictions based on them must be viewed cautiously.

### (b) Energetics

The **lattice energy** of a solid is the difference in potential energy of the ions packed together in a solid and widely separated as a gas. The lattice energy is always positive; a high lattice energy indicates that the ions interact strongly with one another to give a tightly bonded solid. The **lattice enthalpy**,  $\Delta H_L$ , is the change in standard molar enthalpy for the process

and its equivalent for other charge types and stoichiometries. The lattice enthalpy is equal to the lattice energy at  $T = 0$ ; at normal temperatures they differ by only a few kilojoules per mole, and the difference is normally neglected.

Each ion in a solid experiences electrostatic attractions from all the other oppositely charged ions and repulsions from all the other like-charged ions. The total Coulombic potential energy is the sum of all the electrostatic contributions. Each cation is surrounded by anions, and there is a large negative contribution from the attraction of the opposite charges. Beyond those nearest neighbours, there are cations that contribute a positive term to the total potential energy of the central cation. There is also a negative contribution from the anions beyond those cations, a positive contribution from the cations beyond them, and so on to the edge of the solid. These repulsions and attractions become progressively weaker as the distance from the central ion increases, but the net outcome of all these contributions is a lowering of energy.

First, consider a simple one-dimensional model of a solid consisting of a long line of uniformly spaced alternating cations and anions, with  $d$  the distance between their centres, the sum of the ionic radii (Fig. 19.35). If the charge numbers of the ions have the same absolute value (+1 and -1, or +2 and -2, for instance), then  $z_1 = +z$ ,  $z_2 = -z$ , and  $z_1 z_2 = -z^2$ . The potential energy of the central ion is calculated by summing all the terms, with negative terms representing attractions to oppositely charged ions and positive terms representing repulsions from like-charged ions. Suppose the central ion is a cation; then the potential energy of its interaction with ions extending in a line to the right is

**Fig. 19.35** A line of alternating cations and ions used in the calculation of the Madelung constant in one dimension.

$$\begin{aligned}
 E_p(\text{cation}) &= \frac{1}{4\pi\epsilon_0} \times \left( -\frac{z^2 e^2}{d} + \frac{z^2 e^2}{2d} - \frac{z^2 e^2}{3d} + \frac{z^2 e^2}{4d} - \dots \right) \\
 &= -\frac{z^2 e^2}{4\pi\epsilon_0 d} \left( 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots \right) \\
 &= -\frac{z^2 e^2}{4\pi\epsilon_0 d} \times \ln 2
 \end{aligned}$$

We have used the relation  $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots = \ln 2$ . Next, we multiply  $E_p$  by 2 to obtain the total energy arising from interactions on each side of the ion to obtain

$$E_p(\text{cation}) = -2 \ln 2 \times \frac{z^2 e^2}{4\pi\epsilon_0 d}$$

with  $d = r_{\text{cation}} + r_{\text{anion}}$ . This energy is negative, corresponding to a net attraction. The same expression applies to the potential energy of the neighbouring anion,  $E_p(\text{anion})$ . The total potential energy per mole of ion pairs is therefore

$$E_p = \frac{1}{2} N_A \{E_p(\text{cation}) + E_p(\text{anion})\} = -2 \ln 2 \times \frac{z^2 N_A e^2}{4\pi\epsilon_0 d}$$

We have introduced the factor of  $\frac{1}{2}$  to avoid double counting the interaction (Jack with Jill, Jill with Jack, etc.). This calculation can be extended to three-dimensional arrays of ions with different charges:

$$E_p = -A \times \frac{|z_A z_B| N_A e^2}{4\pi\epsilon_0 d} \quad \text{Potential energy in terms of the Madelung constant} \quad (19.13)$$

The factor  $A$  is a positive numerical constant called the **Madelung constant**; its value depends on how the ions are arranged about one another. For ions arranged in the same way as in sodium chloride,  $A = 1.748$ . Table 19.4 lists Madelung constants for other common structures.

There are also repulsions arising from the overlap of the atomic orbitals of the ions and the role of the Pauli principle. These repulsions are taken into account by supposing that, because wavefunctions decay exponentially with distance at large distances from the nucleus, and repulsive interactions depend on the overlap of orbitals, the repulsive contribution to the potential energy has the form

$$E_p^* = N_A C' e^{-d/d^*} \quad (19.14)$$

with  $C'$  and  $d^*$  constants; the latter is commonly taken to be 34.5 pm. The total potential energy is the sum of  $E_p$  and  $E_p^*$  and passes through a minimum when  $d(E_p + E_p^*)/dd = 0$  (Fig. 19.36). A short calculation leads to the following expression for the minimum total potential energy (see Problem 19.27):

$$E_{p,\min} = -\frac{N_A |z_A z_B| e^2}{4\pi\epsilon_0 d} \left( 1 - \frac{d^*}{d} \right) A \quad \text{Born-Mayer equation} \quad (19.15)$$

This expression is called the **Born-Mayer equation**. Provided we ignore zero-point contributions to the energy, we can identify the negative of this potential energy with the lattice energy. We see that large lattice energies are expected when the ions are highly charged (so  $|z_A z_B|$  is large) and small (so  $d$  is small).

Experimental values of the lattice enthalpy (the enthalpy, rather than the energy) are obtained by using a **Born-Haber cycle**, a closed path of transformations starting and ending at the same point, one step of which is the formation of the solid compound

**Table 19.4** Madelung constants

| Structural type  | $A$   |
|------------------|-------|
| Caesium chloride | 1.763 |
| Fluorite         | 2.519 |
| Rock salt        | 1.748 |
| Rutile           | 2.408 |
| Sphalerite       | 1.638 |
| Wurtzite         | 1.641 |

**Fig. 19.36** The contributions to the total potential energy of an ionic crystal.

**Table 19.5\*** Lattice enthalpies at 298 K,  $\Delta H_L/(\text{kJ mol}^{-1})$

|      |      |
|------|------|
| NaF  | 787  |
| NaBr | 751  |
| MgO  | 3850 |
| MgS  | 3406 |

\* More values are given in the Data section.

**Fig. 19.38** A fragment of the structure of diamond. Each C atom is tetrahedrally bonded to four neighbours. This framework-like structure results in a rigid crystal.

from a gas of widely separated ions. A typical cycle, for potassium chloride, is shown in Fig. 19.37. It consists of the following steps (for convenience, starting at the elements):

|                                                        | $\Delta H/(\text{kJ mol}^{-1})$                                                |
|--------------------------------------------------------|--------------------------------------------------------------------------------|
| 1. Sublimation of K(s)                                 | +89 [dissociation enthalpy of K(s)]                                            |
| 2. Dissociation of $\frac{1}{2} \text{Cl}_2(\text{g})$ | +122 [ $\frac{1}{2} \times$ dissociation enthalpy of $\text{Cl}_2(\text{g})$ ] |
| 3. Ionization of K(g)                                  | +418 [ionization enthalpy of K(g)]                                             |
| 4. Electron attachment to Cl(g)                        | −349 [electron gain enthalpy of Cl(g)]                                         |
| 5. Formation of solid from gas                         | − $\Delta H_L/(\text{kJ mol}^{-1})$                                            |
| 6. Decomposition of compound                           | +437 [negative of enthalpy of formation of KCl(s)]                             |

Because the sum of these enthalpy changes is equal to zero, we can infer from

$$89 + 122 + 418 - 349 - \Delta H_L/(\text{kJ mol}^{-1}) + 437 = 0$$

that  $\Delta H_L = +717 \text{ kJ mol}^{-1}$ . Some lattice enthalpies obtained in this way are listed in Table 19.5. As can be seen from the data, the trends in values are in general accord with the predictions of the Born–Mayer equation. Agreement is typically taken to imply that the ionic model of bonding is valid for the substance; disagreement implies that there is a covalent contribution to the bonding. It is important, though, to be cautious, because numerical agreement might be coincidental.

## 19.7 Molecular solids and covalent networks

**Key points** A covalent network solid is a solid in which covalent bonds in a definite spatial orientation link the atoms in a network extending through the crystal. A molecular solid is a solid consisting of discrete molecules held together by van der Waals interactions and, in certain cases, hydrogen bonding.

X-ray diffraction studies of solids reveal a huge amount of information, including interatomic distances, bond angles, stereochemistry, and vibrational parameters. In this section we can do no more than hint at the diversity of types of solids found when molecules pack together or atoms link together in extended networks.

In **covalent network solids**, covalent bonds in a definite spatial orientation link the atoms in a network extending through the crystal. The demands of directional bonding, which have only a small effect on the structures of many metals, now override the geometrical problem of packing spheres together, and elaborate and extensive structures may be formed. Examples include silicon, red phosphorus, boron nitride, and—very importantly—diamond, graphite, and carbon nanotubes, which we discuss in detail.

Diamond and graphite are two *allotropes*, distinct forms of an element that differ in the way that atoms are linked, of carbon. In diamond each  $\text{sp}^3$ -hybridized carbon is bonded tetrahedrally to its four neighbours (Fig. 19.38). The network of strong C–C bonds is repeated throughout the crystal and, as a result, diamond is the hardest known substance.

In graphite,  $\sigma$  bonds between  $\text{sp}^2$ -hybridized carbon atoms form hexagonal rings which, when repeated throughout a plane, give rise to graphene sheets (Fig. 19.39). Because the sheets can slide against each other when impurities are present, graphite is used widely as a lubricant.

Carbon nanotubes are thin cylinders of carbon atoms that are both mechanically strong and highly conducting (see *Impact I19.2*). They are synthesized by condensing

**Fig. 19.39** Graphite consists of flat planes of hexagons of carbon atoms lying above one another. (a) The arrangement of carbon atoms in a sheet; (b) the relative arrangement of neighbouring sheets. When impurities are present, the planes can slide over one another easily.

a carbon plasma either in the presence or absence of a catalyst. The simplest structural motif is called a *single-walled nanotube* (SWNT) and is shown in Fig. 19.40. In a SWNT,  $sp^2$ -hybridized carbon atoms form hexagonal rings reminiscent of the structure of the carbon sheets found in graphite. The tubes have diameters between 1 and 2 nm and lengths of several micrometres. The features shown in Fig. 19.40 have been confirmed by direct visualization with scanning tunnelling microscopy (*Impact I8.2*). A *multi-walled nanotube* (MWNT) consists of several concentric SWNTs and its diameter varies between 2 and 25 nm.

**Molecular solids**, which are the subject of the overwhelming majority of modern structural determinations, are held together by van der Waals interactions and, in certain cases, hydrogen bonding (Chapter 17). The observed crystal structure is Nature's solution to the problem of condensing objects of various shapes into an aggregate of minimum energy (actually, for  $T > 0$ , of minimum Gibbs energy). The prediction of the structure is a very difficult task, but software specifically designed to explore interaction energies can now make reasonably reliable predictions. The problem is made more complicated by the role of hydrogen bonds, which in some cases dominate the crystal structure, as in ice (Fig. 19.41), but in others (for example, in phenol) distort a structure that is determined largely by the van der Waals interactions.

**Fig. 19.40** In a single-walled nanotube (SWNT),  $sp^2$ -hybridized carbon atoms form hexagonal rings that grow as tubes with diameters between 1 and 2 nm and lengths of several micrometres.

## IMPACT ON BIOCHEMISTRY

### 119.1 X-ray crystallography of biological macromolecules

X-ray crystallography is the deployment of X-ray diffraction techniques for the determination of the location of all the atoms in molecules as complicated as biopolymers. Bragg's law helps us understand the features of one of the most seminal X-ray images of all, the characteristic X-shaped pattern obtained by Rosalind Franklin and Maurice Wilkins from strands of DNA and used by James Watson and Francis Crick in their construction of the double-helix model of DNA (Fig. 19.42). To interpret this image by using Bragg's law we have to be aware that it was obtained by using a fibre consisting of many DNA molecules oriented with their axes parallel to the axis of the fibre, with X-rays incident from a perpendicular direction. All the molecules in the fibre are parallel (or nearly so), but are randomly distributed in the perpendicular directions; as a result, the diffraction pattern exhibits the periodic structure parallel to the fibre axis superimposed on a general background of scattering from the distribution of molecules in the perpendicular directions.

There are two principal features in Fig. 19.42: the strong 'meridional' scattering upward and downward by the fibre and the X-shaped distribution at smaller scattering angles. Because scattering through large angles occurs for closely spaced features (from  $\lambda = 2d \sin \theta$ , if  $d$  is small, then  $\theta$  must be large to preserve the equality), we can

**Fig. 19.41** A fragment of the crystal structure of ice (ice-I). Each O atom is at the centre of a tetrahedron of four O atoms at a distance of 276 pm. The central O atom is attached by two short O–H bonds to two H atoms and by two long hydrogen bonds to the H atoms of two of the neighbouring molecules. Overall, the structure consists of planes of hexagonal puckered rings of  $H_2O$  molecules (like the chair form of cyclohexane).

**Fig. 19.42** The X-ray diffraction pattern obtained from a fibre of B-DNA. The black dots are the reflections, the points of maximum constructive interference, that are used to determine the structure of the molecule. (Adapted from an illustration that appears in J.P. Glusker and K.N. Trueblood, *Crystal structure analysis: A primer*. Oxford University Press (1972).)

**Fig. 19.43** The origin of the X pattern characteristic of diffraction by a helix. (a) A helix can be thought of as consisting of an array of planes at an angle  $\alpha$  together with an array of planes at an angle  $-\alpha$ . (b) The diffraction spots from one set of planes appear at an angle  $\alpha$  to the vertical, giving one leg of the X, and those of the other set appear at an angle  $-\alpha$ , giving rise to the other leg of the X. The lower half of the X appears because the helix has up–down symmetry in this arrangement. (c) The sequence of spots outward along a leg of the X corresponds to first-, second-, ... order diffraction ( $n = 1, 2, \dots$ ).

infer that the meridional scattering arises from closely spaced components and that the inner X-shaped pattern arises from features with a longer periodicity. Because the meridional pattern occurs at a distance of about 10 times that of the innermost spots of the X-pattern, the large-scale structure is about 10 times bigger than the small-scale structure. From the geometry of the instrument, the wavelength of the radiation, and Bragg's law, we can infer that the periodicity of the small-scale feature is 340 pm whereas that of the large-scale feature is 3400 pm (that is, 3.4 nm).

To see that the cross is characteristic of a helix, look at Fig. 19.43. Each turn of the helix defines two planes, one orientated at an angle  $\alpha$  to the horizontal and the other at  $-\alpha$ . As a result, to a first approximation, a helix can be thought of as consisting of an array of planes at an angle  $\alpha$  together with an array of planes at an angle  $-\alpha$  with a separation within each set determined by the pitch of the helix. Thus, a DNA molecule is like two arrays of planes, each set corresponding to those treated in the derivation of Bragg's law, with a perpendicular separation  $d = p \cos \alpha$ , where  $p$  is the pitch of the helix, each canted at the angles  $\pm\alpha$  to the horizontal. The diffraction spots from one set of planes therefore occur at an angle  $\alpha$  to the vertical, giving one leg of the X, and those of the other set occur at an angle  $-\alpha$ , giving rise to the other leg of the X. The experimental arrangement has up–down symmetry, so the diffraction pattern repeats to produce the lower half of the X. The sequence of spots outward along a leg corresponds to first-, second-, ... order diffraction ( $n = 1, 2, \dots$  in eqn 19.4). Therefore from the X-ray pattern, we see at once that the molecule is helical and we can measure the angle  $\alpha$  directly, and find  $\alpha = 40^\circ$ . Finally, with the angle  $\alpha$  and the pitch  $p$  determined, we can determine the radius  $r$  of the helix from  $\tan \alpha = p/r$ , from which it follows that  $r = (3.4 \text{ nm})/(\tan 40^\circ) = 4.1 \text{ nm}$ .

To derive the relation between the helix and the cross-like pattern we have ignored the detailed structure of the helix, the fact that it is a periodic array of nucleotide bases, not a smooth wire. In Fig. 19.44 we represent the bases by points, and see that there is an additional periodicity of separation  $h$ , forming planes that are perpendicular to the axis to the molecule (and the fibre). These planes give rise to the strong meridional

**Fig. 19.44** The effect of the internal structure of the helix on the X-ray diffraction pattern. (a) The residues of the macromolecule are represented by points. (b) Parallel planes passing through the residues are perpendicular to the axis of the molecule. (c) The planes give rise to strong diffraction with an angle that allows us to determine the layer spacing  $h$  from  $\lambda = 2h \sin \theta$ .

diffraction with an angle that allows us to determine the layer spacing from Bragg's law in the form  $\lambda = 2h \sin \theta$  as  $h = 340$  pm.

The success of modern biochemistry in explaining such processes as DNA replication, protein biosynthesis, and enzyme catalysis is a direct result of developments in preparatory, instrumental, and computational procedures that have led to the determination of large numbers of structures of biological macromolecules by techniques based on X-ray diffraction. Most work is now done not on fibres but on crystals, in which the large molecules lie in orderly ranks. But even so crystallography yields only a static picture of biological structure and does not lend insight into changes that accompany biological processes. Therefore, information from crystallographic and spectroscopic studies is considered together to describe biochemical reactions.

## The properties of solids

In this section we consider how the bulk properties of solids, particularly their mechanical, electrical, optical, and magnetic properties, stem from the properties of their constituent atoms. The rational fabrication of modern materials depends crucially on an understanding of this link.

### 19.8 Mechanical properties

**Key points** The mechanical properties of a solid are discussed in terms of the relationship between stress, the applied force divided by the area to which it is applied, and strain, the distortion of a sample resulting from an applied stress. The response of a solid to an applied stress is summarized by the Young's modulus, the bulk modulus, the shear modulus, and Poisson's ratio.

The fundamental concepts for the discussion of the mechanical properties of solids are stress and strain. The **stress** on an object is the applied force divided by the area to which it is applied. The **strain** is the resulting distortion of the sample. The general field of the relations between stress and strain is called **rheology**.

Stress may be applied in a number of different ways. Thus, **uniaxial stress** is a simple compression or extension in one direction (Fig. 19.45); **hydrostatic stress** is a stress applied simultaneously in all directions, as in a body immersed in a fluid. A **pure shear** is a stress that tends to push opposite faces of the sample in opposite directions. A sample subjected to a small stress typically undergoes **elastic deformation** in the sense that it recovers its original shape when the stress is removed. For low stresses, the strain is linearly proportional to the stress. The response becomes nonlinear at high stresses but may remain elastic. Above a certain threshold, the strain becomes **plastic** in the sense that recovery does not occur when the stress is removed. Plastic deformation

**Fig. 19.45** Types of stress applied to a body. (a) Uniaxial stress, (b) shear stress, (c) hydrostatic pressure.

**Fig. 19.46** (a) Normal stress and the resulting strain. (b) Shear stress. Poisson's ratio indicates the extent to which a body changes shape when subjected to a uniaxial stress.

occurs when bond breaking takes place and, in pure metals, typically takes place through the agency of dislocations. Brittle solids, such as ionic solids, exhibit sudden fracture as the stress focused by cracks causes them to spread catastrophically.

The response of a solid to an applied stress is commonly summarized by a number of coefficients of proportionality known as 'moduli':

$$E = \frac{\text{normal stress}}{\text{normal strain}} \quad \begin{array}{|l|} \hline \text{Definition of} \\ \text{Young's modulus} \\ \hline \end{array} \quad [19.16a]$$

$$K = \frac{\text{pressure}}{\text{fractional change in volume}} \quad \begin{array}{|l|} \hline \text{Definition of} \\ \text{bulk modulus} \\ \hline \end{array} \quad [19.16b]$$

$$G = \frac{\text{shear stress}}{\text{shear strain}} \quad \begin{array}{|l|} \hline \text{Definition of} \\ \text{shear modulus} \\ \hline \end{array} \quad [19.16c]$$

where 'normal stress' refers to stretching and compression of the material, as shown in Fig. 19.46a and 'shear stress' refers to the stress depicted in Fig. 19.46b. The bulk modulus is the inverse of the isothermal compressibility,  $\kappa_T$ , first encountered in Section 2.11 (eqn 2.43,  $\kappa_T = -(\partial V/\partial p)_T/V$ ). A third ratio, called **Poisson's ratio**, indicates how the sample changes its shape:

$$\nu_p = \frac{\text{transverse strain}}{\text{normal strain}} \quad \begin{array}{|l|} \hline \text{Definition of} \\ \text{Poisson's ratio} \\ \hline \end{array} \quad [19.17]$$

The moduli are interrelated:

$$G = \frac{E}{2(1 + \nu_p)} \quad K = \frac{E}{3(1 - 2\nu_p)} \quad \begin{array}{|l|} \hline \text{Relations between} \\ \text{the moduli} \\ \hline \end{array} \quad (19.18)$$

We can use thermodynamic arguments to discover the relation of the moduli to the molecular properties of the solid. Thus, in the following *Justification*, we show that, if neighbouring molecules interact by a Lennard-Jones potential, then the bulk modulus and the compressibility of the solid are related to the Lennard-Jones parameter  $\epsilon$  (the depth of the potential well) by

$$K = \frac{8N_A\epsilon}{V_m} \quad \kappa_T = \frac{V_m}{8N_A\epsilon} \quad (19.19)$$

We see that the bulk modulus is large (the solid stiff) if the potential well represented by the Lennard-Jones potential is deep and the solid is dense (its molar volume small).

#### **Justification 19.4** *The relation between compressibility and molecular interactions*

We begin by writing an expression for  $K$  from the definition of  $\kappa_T$  (eqn 2.43,  $\kappa_T = -(\partial U/\partial p)_T/V$ ), but in terms of the variation of the internal energy  $U$  with the volume  $V$ . To do so, we note that the thermodynamic relation  $p = -(\partial A/\partial V)_T$ , which comes from the relation  $dA = -pdV - SdT$  at constant temperature, becomes  $p = -(\partial U/\partial V)_T$  at  $T = 0$  (because  $A = U - TS$ ). Therefore, at  $T = 0$ ,

$$K = \frac{1}{\kappa_T} = -\frac{V}{(\partial V/\partial p)_T} = -V \left( \frac{\partial p}{\partial V} \right)_T = V \left( \frac{\partial^2 U}{\partial V^2} \right)_T$$

This expression shows that the bulk modulus (and through eqn 19.18, the other two moduli) depends on the curvature of a plot of the internal energy against volume. To develop this conclusion, we note that the variation of internal energy with volume can be expressed in terms of its variation with a lattice parameter,  $R$ , such as the length of the side of a unit cell:

$$\frac{\partial U}{\partial V} = \frac{\partial U}{\partial R} \frac{\partial R}{\partial V}$$

and so

$$\frac{\partial^2 U}{\partial V^2} = \frac{\partial U}{\partial R} \frac{\partial^2 R}{\partial V^2} + \frac{\partial^2 U}{\partial V \partial R} \frac{\partial R}{\partial V} = \frac{\partial U}{\partial R} \frac{\partial^2 R}{\partial V^2} + \frac{\partial^2 U}{\partial R^2} \left( \frac{\partial R}{\partial V} \right)^2$$

To calculate  $K$  at the equilibrium volume of the sample, we set  $R = R_0$  and recognize that  $\partial U / \partial R = 0$  at equilibrium, so

$$K = V \left( \frac{\partial^2 U}{\partial R^2} \right)_{T,0} \left( \frac{\partial R}{\partial V} \right)_{T,0}^2$$

where the 0 denotes that the derivatives are evaluated at the equilibrium dimensions of the unit cell by setting  $R = R_0$  after the derivative has been calculated. At this point we can write  $V = aR^3$ , where  $a$  is a constant that depends on the crystal structure, which implies that  $\partial R / \partial V = 1/(3aR^2)$ . Then, if the internal energy is given by a pair-wise Lennard-Jones (12,6)-potential (eqn 17.33) we can write

$$\left( \frac{\partial^2 U}{\partial R^2} \right)_{T,0} = \frac{72nN_A \epsilon}{R_0^2} \quad (19.20)$$

where  $n$  is the amount of substance in the sample of volume  $V_0$ . It then follows that

$$K = \frac{72nN_A \epsilon}{9aR_0^3} = \frac{8nN_A \epsilon}{V_0} = \frac{8N_A \epsilon}{V_m}$$

where we have used  $V_m = V_0/n$ , which is the first of eqn 19.19. Its reciprocal is  $\kappa_T$ . To obtain the result in eqn 19.20, we have used the fact that, at equilibrium,  $R = R_0$  and  $\sigma^6/R_0^6 = \frac{1}{2}$  where  $\sigma$  is the scale parameter for the intermolecular potential ( $r_0$  in eqn 17.33).

The typical behaviour of a solid under stress is illustrated in Fig. 19.47. For small strains, the stress–strain relation is a Hooke’s law of force, with the strain directly proportional to the stress. For larger strains, though, dislocations begin to play a major role and the strain becomes plastic in the sense that the sample does not recover its original shape when the stress is removed (recall Fig. 18.10).

The differing rheological characteristics of metals can be traced to the presence of **slip planes**, which are planes of atoms that under stress may slip or slide relative to one another. The slip planes of a ccp structure are the close-packed planes, and careful inspection of a unit cell shows that there are eight sets of slip planes in different directions. As a result, metals with cubic close-packed structures, like copper, are malleable: they can easily be bent, flattened, or pounded into shape. In contrast, a hexagonal close-packed structure has only one set of slip planes; and metals with hexagonal close packing, like zinc or cadmium, tend to be brittle.

## 19.9 Electrical properties

**Key points** Electronic conductors are classified as metallic conductors or semiconductors according to the temperature dependence of their conductivities. An insulator is a semiconductor with a very low electrical conductivity. (a) According to the band theory, electrons occupy molecular orbitals formed from the overlap of atomic orbitals. Full bands are called valence bands and empty bands are called conduction bands. (b) The occupation of the orbitals in a solid is given by the Fermi–Dirac distribution. (c) Semiconductors are classified as p-type or n-type according to whether conduction is due to holes in the valence band or electrons in the conduction band.

**Fig. 19.47** At small strains, a body obeys Hooke’s law (stress proportional to strain) and is elastic (recovers its shape when the stress is removed). At high strains, the body is no longer elastic, may yield and become plastic. At even higher strains, the solid fails (at its limiting tensile strength) and finally fractures.

**Fig. 19.48** The variation of the electrical conductivity of a substance with temperature is the basis of its classification as a metallic conductor, a semiconductor, or a superconductor. We shall see in Chapter 20 that conductivity is expressed in siemens per metre ( $\text{S m}^{-1}$  or, as here,  $\text{S cm}^{-1}$ ), where  $1 \text{ S} = 1 \Omega^{-1}$  (the resistance is expressed in ohms,  $\Omega$ ).

**Fig. 19.49** The formation of a band of  $N$  molecular orbitals by successive addition of  $N$  atoms to a line. Note that the band remains of finite width as  $N$  becomes infinite and, although it looks continuous, it consists of  $N$  different orbitals.

We shall confine attention to electronic conductivity, but note that some ionic solids display ionic conductivity. Two types of solid are distinguished by the temperature dependence of their electrical conductivity (Fig. 19.48):

A **metallic conductor** is a substance with a conductivity that decreases as the temperature is raised.

A **semiconductor** is a substance with a conductivity that increases as the temperature is raised.

A semiconductor generally has a lower conductivity than that typical of metals, but the magnitude of the conductivity is not the criterion of the distinction. It is conventional to classify semiconductors with very low electrical conductivities, such as most synthetic polymers, as **insulators**. We shall use this term, but it should be appreciated that it is one of convenience rather than one of fundamental significance. A **superconductor** is a solid that conducts electricity without resistance.

### (a) The formation of bands

The central aspect of solids that determines their electrical properties is the distribution of their electrons. There are two models of this distribution. In one, the **nearly free-electron approximation**, the valence electrons are assumed to be trapped in a box with a periodic potential, with low energy corresponding to the locations of cations. In the **tight-binding approximation**, the valence electrons are assumed to occupy molecular orbitals delocalized throughout the solid. The latter model is more in accord with the discussion in the foregoing chapters, and we confine our attention to it.

We shall consider a one-dimensional solid, which consists of a single, infinitely long line of atoms. At first sight, this model may seem too restrictive and unrealistic. However, not only does it give us the concepts we need to understand conductivity in three-dimensional, macroscopic samples of metals and semiconductors, it is also the starting point for the description of long and thin structures, such as the carbon nanotubes discussed earlier in the chapter.

Suppose that each atom has one  $s$  orbital available for forming molecular orbitals. We can construct the LCAO-MOs of the solid by adding  $N$  atoms in succession to a line, and then infer the electronic structure using the building-up principle. One atom contributes one  $s$  orbital at a certain energy (Fig. 19.49). When a second atom is brought up it overlaps the first and forms bonding and antibonding orbitals. The third atom overlaps its nearest neighbour (and only slightly the next-nearest) and, from these three atomic orbitals, three molecular orbitals are formed: one is fully bonding, one fully antibonding, and the intermediate orbital is nonbonding between neighbours. The fourth atom leads to the formation of a fourth molecular orbital. At this stage, we can begin to see that the general effect of bringing up successive atoms is to spread the range of energies covered by the molecular orbitals, and also to fill in the range of energies with more and more orbitals (one more for each atom). When  $N$  atoms have been added to the line, there are  $N$  molecular orbitals covering a band of energies of finite width, and the Hückel secular determinant (Section 10.6) is

$$\begin{vmatrix} \alpha - E & \beta & 0 & 0 & 0 & \cdots & 0 \\ \beta & \alpha - E & \beta & 0 & 0 & \cdots & 0 \\ 0 & \beta & \alpha - E & \beta & 0 & \cdots & 0 \\ 0 & 0 & \beta & \alpha - E & \beta & \cdots & 0 \\ 0 & 0 & 0 & \beta & \alpha - E & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & \cdots & \alpha - E \end{vmatrix} = 0$$

where  $\beta$  is now the (s,s) resonance integral. The theory of determinants applied to such a symmetrical example as this (technically a ‘tridiagonal determinant’) leads to the following expression for the roots:

$$E_k = \alpha + 2\beta \cos \frac{k\pi}{N+1} \quad k = 1, 2, \dots, N \quad (19.21)$$

When  $N$  is infinitely large, the difference between neighbouring energy levels (the energies corresponding to  $k$  and  $k+1$ ) is infinitely small, but, as we show in the following *Justification*, the band still has finite width overall:

$$E_N - E_1 \rightarrow -4\beta \quad \text{as} \quad N \rightarrow \infty \quad (19.22)$$

We can think of this band as consisting of  $N$  different molecular orbitals, the lowest-energy orbital ( $k=1$ ) being fully bonding, and the highest-energy orbital ( $k=N$ ) being fully antibonding between adjacent atoms (Fig. 19.50). Similar bands form in three-dimensional solids.

**Justification 19.5** *The width of a band*

The energy of the level with  $k=1$  is

$$E_1 = \alpha + 2\beta \cos \frac{\pi}{N+1}$$

As  $N$  becomes infinite, the cosine term becomes  $\cos 0 = 1$ . Therefore, in this limit

$$E_1 = \alpha + 2\beta$$

When  $k$  has its maximum value of  $N$ ,

$$E_N = \alpha + 2\beta \cos \frac{N\pi}{N+1}$$

As  $N$  approaches infinity, we can ignore the 1 in the denominator, and the cosine term becomes  $\cos \pi = -1$ . Therefore, in this limit  $E_N = \alpha - 2\beta$ . The difference between the upper and lower energies of the band is therefore  $4\beta$ .

The band formed from overlap of s orbitals is called the **s band**. If the atoms have p orbitals available, the same procedure leads to a **p band** (as shown in the upper half of Fig. 19.50). If the atomic p orbitals lie higher in energy than the s orbitals, then the p band lies higher than the s band, and there may be a **band gap**, a range of energies to which no orbital corresponds. However, the s and p bands may also be contiguous or even overlap (as is the case for the 3s and 3p bands in magnesium).

**(b) The occupation of orbitals**

Now consider the electronic structure of a solid formed from atoms each able to contribute one electron (for example, the alkali metals). There are  $N$  atomic orbitals and therefore  $N$  molecular orbitals packed into an apparently continuous band. There are  $N$  electrons to accommodate.

At  $T=0$ , only the lowest  $\frac{1}{2}N$  molecular orbitals are occupied (Fig. 19.51), and the HOMO is called the **Fermi level**. However, unlike in molecules, there are empty orbitals very close in energy to the Fermi level, so it requires hardly any energy to excite the uppermost electrons. Some of the electrons are therefore very mobile and give rise to electrical conductivity.

At temperatures above absolute zero, electrons can be excited by the thermal motion of the atoms. The population,  $P$ , of the orbitals is given by the **Fermi–Dirac**

**Fig. 19.50** The overlap of s orbitals gives rise to an s band and the overlap of p orbitals gives rise to a p band. In this case, the s and p orbitals of the atoms are so widely spaced that there is a band gap. In many cases the separation is less and the bands overlap.

**Fig. 19.51** When  $N$  electrons occupy a band of  $N$  orbitals, it is only half full and the electrons near the Fermi level (the top of the filled levels) are mobile.

**Fig. 19.52** The Fermi–Dirac distribution, which gives the population of the levels at a temperature  $T$ . The high-energy tail decays exponentially towards zero. The curves are labelled with the value of  $\mu/kT$ . The tinted grey region shows the occupation of levels at  $T = 0$ .

**InterActivity** Express the population  $P$  as a function of the variables  $(E - \mu)/\mu$  and  $\mu/kT$  and then display the set of curves shown in Fig. 19.52 as a single surface.

**Fig. 19.53** (a) When  $2N$  electrons are present, the band is full and the material is an insulator at  $T = 0$ . (b) At temperatures above  $T = 0$ , electrons populate the levels of the upper *conduction band* and the solid is a semiconductor.

**distribution**, a version of the Boltzmann distribution that takes into account the effect of the Pauli principle:

$$P = \frac{1}{e^{(E-\mu)/kT} + 1} \quad \text{The Fermi–Dirac distribution} \quad (19.23)$$

The quantity  $\mu$  is the **chemical potential**, which in this context is the energy of the level for which  $P = \frac{1}{2}$  (note that the chemical potential decreases as the temperature increases). The chemical potential in eqn 19.23 has the dimensions of energy, not energy per mole. The shape of the Fermi–Dirac distribution is shown in Fig. 19.52. For energies well above  $\mu$ , the 1 in the denominator can be neglected, and then

$$P \approx e^{-(E-\mu)/kT} \quad (19.24)$$

The population now resembles a Boltzmann distribution, decaying exponentially with increasing energy. The higher the temperature, the longer the exponential tail.

The electrical conductivity of a metallic solid decreases with increasing temperature even though more electrons are excited into empty orbitals. This apparent paradox is resolved by noting that the increase in temperature causes more vigorous thermal motion of the atoms, so collisions between the moving electrons and an atom are more likely. That is, the electrons are scattered out of their paths through the solid, and are less efficient at transporting charge.

### (c) Insulators and semiconductors

When each atom provides two electrons, the  $2N$  electrons fill the  $N$  orbitals of the  $s$  band. The Fermi level now lies at the top of the band (at  $T = 0$ ), and there is a gap before the next band begins (Fig. 19.53). As the temperature is increased, the tail of the Fermi–Dirac distribution extends across the gap, and electrons leave the lower band, which is called the **valence band**, and populate the empty orbitals of the upper band, which is called the **conduction band**. As a consequence of electron promotion, positively charged ‘holes’ are left in the valence band. The holes and promoted electrons are now mobile, and the solid is an electrical conductor. In fact, it is a semiconductor, because the electrical conductivity depends on the number of electrons that are promoted across the gap, and that number increases as the temperature is raised. If the gap is large, though, very few electrons will be promoted at ordinary temperatures and the conductivity will remain close to zero, resulting in an insulator. Thus, the conventional distinction between an insulator and a semiconductor is related to the size of the band gap and is not an absolute distinction like that between a metal (incomplete bands at  $T = 0$ ) and a semiconductor (full bands at  $T = 0$ ).

Figure 19.53 depicts conduction in an **intrinsic semiconductor**, in which semiconduction is a property of the band structure of the pure material. Examples of intrinsic semiconductors include silicon and germanium. A **compound semiconductor** is an intrinsic semiconductor that is a combination of different elements, such as GaN, CdS, and many d-metal oxides. An **extrinsic semiconductor** is one in which charge carriers are present as a result of the replacement of some atoms (to the extent of about  $1$  in  $10^9$ ) by **dopant** atoms, the atoms of another element. If the dopants can trap electrons, they withdraw electrons from the filled band, leaving holes which allow the remaining electrons to move (Fig. 19.54a). This procedure gives rise to **p-type semiconductivity**, the  $p$  indicating that the holes are positive relative to the electrons in the band. An example is silicon doped with indium. We can picture the semiconduction as arising from the transfer of an electron from a Si atom to a neighbouring In atom. The electrons at the top of the silicon valence band are now mobile, and carry current through the solid. Alternatively, a dopant might carry excess electrons (for

example, phosphorus atoms introduced into germanium), and these additional electrons occupy otherwise empty bands, giving **n-type semiconductivity**, where n denotes the negative charge of the carriers (Fig. 19.54b).

Now we consider the properties of a **p–n junction**, the interface of a p-type and n-type semiconductor. Consider the application of a ‘reverse bias’ to the junction, in the sense that a negative electrode is attached to the p-type semiconductor and a positive electrode is attached to the n-type semiconductor (Fig. 19.55a). Under these conditions, the positively charged holes in the p-type semiconductor are attracted to the negative electrode and the negatively charged electrons in the n-type semiconductor are attracted to the positive electrode. As a consequence, charge does not flow across the junction. Now consider the application of a ‘forward bias’ to the junction, in the sense that the positive electrode is attached to the p-type semiconductor and the negative electrode is attached to the n-type semiconductor (Fig. 19.55b). Now charge flows across the junction, with electrons in the n-type semiconductor moving toward the positive electrode and holes moving in the opposite direction. It follows that a p–n junction affords a great deal of control over the magnitude and direction of current through a material. This control is essential for the operation of transistors and diodes, which are key components of modern electronic devices.

As electrons and holes move across a p–n junction under forward bias, they recombine and release energy. However, as long as the forward bias continues to be applied, the flow of charge from the electrodes to the semiconductors will replenish them with electrons and holes, so the junction will sustain a current. In some solids, the energy of electron–hole recombination is released as heat and the device becomes warm. This is the case for silicon semiconductors, and is one reason why computers need efficient cooling systems.

## IMPACT ON NANOSCIENCE

### 19.2 Nanowires

We have already remarked throughout the text that research on nanometre-sized materials is motivated by the possibility that they will form the basis for cheaper and smaller electronic devices. The synthesis of *nanowires*, nanometre-sized atomic assemblies that conduct electricity, is a major step in the fabrication of nanodevices. An important type of nanowire is based on carbon nanotubes, which, like graphite, can conduct electrons through delocalized  $\pi$  molecular orbitals that form from unhybridized 2p orbitals on carbon. Recent studies have shown a correlation between structure and conductivity in single-walled nanotubes (SWNTs) that does not occur in graphite. The SWNT in Fig. 19.40 is a semiconductor. If the hexagons are rotated by  $90^\circ$  about their sixfold axis, the resulting SWNT is a metallic conductor.

Carbon nanotubes are promising building blocks not only because they have useful electrical properties but also because they have unusual mechanical properties. For example, an SWNT has a Young’s modulus that is approximately five times larger and a tensile strength that is approximately 375 times larger than that of steel.

Silicon nanowires can be made by focusing a pulsed laser beam on to a solid target composed of silicon and iron. The laser ejects Fe and Si atoms from the surface of the target, forming a vapour that can condense into liquid  $\text{FeSi}_n$  nanoclusters at sufficiently low temperatures. The phase diagram for this complex mixture shows that solid silicon and liquid  $\text{FeSi}_n$  coexist at temperatures higher than 1473 K. Hence, it is possible to precipitate solid silicon from the mixture if the experimental conditions are controlled to maintain the  $\text{FeSi}_n$  nanoclusters in a liquid state that is supersaturated with silicon. It is observed that the silicon precipitate consists of nanowires with diameters of about 10 nm and lengths greater than 1  $\mu\text{m}$ .

**Fig. 19.54** (a) A dopant with fewer electrons than its host can form a narrow band that accepts electrons from the valence band. The holes in the band are mobile and the substance is a p-type semiconductor. (b) A dopant with more electrons than its host forms a narrow band that can supply electrons to the conduction band. The electrons it supplies are mobile and the substance is an n-type semiconductor.

**Fig. 19.55** A p–n junction under (a) reverse bias, (b) forward bias.

**Fig. 19.56** Germanium nanowires fabricated on to a silicon surface by molecular beam epitaxy. (Reproduced with permission from T. Ogino *et al.*, *Acc. Chem. Res.* 32, 447 (1999).)

Nanowires are also fabricated by *molecular beam epitaxy* (MBE), in which gaseous atoms or molecules are sprayed on to a crystalline surface in an ultra-high vacuum chamber. The result is formation of highly ordered structures. Through careful control of the chamber temperature and of the spraying process, it is possible to deposit thin films on to a surface or to create nanometre-sized assemblies with specific shapes. For example, Fig. 19.56 shows an AFM image of germanium nanowires on a silicon surface. The wires are about 2 nm high, 10–32 nm wide, and 10–600 nm long.

Direct manipulation of atoms on a surface also leads to the formation of nanowires. The Coulomb attraction between an atom and the tip of an STM can be exploited to move atoms along a surface, arranging them into patterns, such as wires.

## 19.10 Optical properties

**Key points** (a) The optical properties of molecular solids can be understood in terms of the formation and migration of excitons. (b) The spectroscopic properties of metallic conductors and semiconductors can be understood in terms of the light-induced promotion of electrons from valence bands to conduction band. (c) Nonlinear optical phenomena arise from changes in the optical properties of a material in the presence of intense electromagnetic radiation.

In this section, we explore the consequences of interactions between electromagnetic radiation and solids. Our focus will be on the origins of phenomena that inform the design of useful devices, such as lasers and light-emitting diodes.

### (a) Light absorption by excitons in molecular solids

From the discussion in earlier chapters, we are already familiar with the factors that determine the energy and intensity of light absorbed by atoms and molecules in the gas phase and in solution. Now we consider the effects on the electronic absorption spectrum of bringing atoms or molecules together into a solid.

Consider an electronic excitation of a molecule (or an ion) in a crystal. If the excitation corresponds to the removal of an electron from one orbital of a molecule and its elevation to an orbital of higher energy, then the excited state of the molecule can be envisaged as the coexistence of an electron and a hole. This electron–hole pair, the particle-like **exciton**, migrates from molecule to molecule in the crystal (Fig. 19.57). Exciton formation causes spectral lines to shift, split, and change intensity.

The electron and the hole jump together from molecule to molecule as they migrate. A migrating excitation of this kind is called a **Frenkel exciton**. The electron and hole can also be on different molecules, but in each other's vicinity. A migrating excitation of this kind, which is now spread over several molecules (more usually ions), is a **Wannier exciton**.

Frenkel excitons are more common in molecular solids. Their migration implies that there is an interaction between the species that constitute the crystal, for otherwise the excitation on one unit could not move to another. This interaction affects the energy levels of the system. The strength of the interaction governs the rate at which an exciton moves through the crystal: a strong interaction results in fast migration, and a vanishingly small interaction leaves the exciton localized on its original molecule. The specific mechanism of interaction that leads to exciton migration is the interaction between the transition dipole moments of the excitation. Thus, an electric dipole transition in a molecule is accompanied by a shift of charge, and the transient dipole exerts a force on an adjacent molecule. The latter responds by shifting its charge. This process continues and the excitation migrates through the crystal.

The energy shift arising from the interaction between transition dipoles can be understood in terms of their electrostatic interaction. An all-parallel arrangement of

**Fig. 19.57** The electron–hole pair shown on the left can migrate through a solid lattice as the excitation hops from molecule to molecule. The mobile excitation is called an exciton.

the dipoles (Fig. 19.58a) is energetically unfavourable, so the absorption occurs at a higher frequency than in the isolated molecule. Conversely, a head-to-tail alignment of transient dipoles (Fig. 19.58b) is energetically favourable, and the transition occurs at a lower frequency than in the isolated molecules.

#### • A brief illustration

Recall from Section 17.5 that the potential energy of interaction between two parallel dipoles  $\mu_1$  and  $\mu_2$  separated by a distance  $r$  is  $V = \mu_1\mu_2(1 - 3\cos^2\theta)/4\pi\epsilon_0r^3$ , where the angle  $\theta$  is defined in (1). We see that  $\theta = 0^\circ$  for a head-to-tail alignment and  $\theta = 90^\circ$  for a parallel alignment. It follows that  $V < 0$  (an attractive interaction) for  $0^\circ \leq \theta < 54.74^\circ$ ,  $V = 0$  when  $\theta = 54.74^\circ$  (for then  $1 - 3\cos^2\theta = 0$ ), and  $V > 0$  (a repulsive interaction) for  $54.74^\circ < \theta \leq 90^\circ$ . This result is expected on the basis of qualitative arguments. In a head-to-tail arrangement, the interaction between the region of partial positive charge in one molecule with the region of partial negative charge in the other molecule is attractive. By contrast, in a parallel arrangement, the molecular interaction is repulsive because of the close approach of regions of partial charge with the same sign. •

It follows from this discussion that, when  $0^\circ \leq \theta < 54.74^\circ$ , the frequency of exciton absorption is lower than the corresponding absorption frequency for the isolated molecule (a *red shift* in the spectrum of the solid with respect to that of the isolated molecule). Conversely, when  $54.74^\circ < \theta \leq 90^\circ$ , the frequency of exciton absorption is higher than the corresponding absorption frequency for the isolated molecule (a *blue shift* in the spectrum of the solid with respect to that of the isolated molecule). In the special case  $\theta = 54.74^\circ$ , the solid and the isolated molecule have absorption lines at the same frequency.

If there are  $N$  molecules per unit cell, there are  $N$  exciton bands in the spectrum (if all of them are allowed). The splitting between the bands is the **Davydov splitting**. To understand the origin of the splitting, consider the case  $N = 2$  with the molecules arranged as in Fig. 19.59 and suppose that the transition dipoles are along the length of the molecules. The radiation stimulates the collective excitation of the transition dipoles that are in-phase between neighbouring unit cells. Within each unit cell the transition dipoles may be arrayed in the two different ways shown in the illustration. Since the two orientations correspond to different interaction energies, with interaction being repulsive in one and attractive in the other, the two transitions appear in the spectrum at two bands of different frequencies. The Davydov splitting is determined by the energy of interaction between the transition dipoles within the unit cell.

#### (b) Light absorption by metals and semiconductors

Now we turn our attention to metallic conductors and semiconductors. Again we need to consider the consequences of interactions between particles, in this case atoms, which are now so strong that we need to abandon arguments based primarily on van der Waals interactions in favour of a full molecular orbital treatment, the band model of Section 19.9.

Consider Fig. 19.51, which shows bands in an idealized metallic conductor. The absorption of light can excite electrons from the occupied levels to the unoccupied levels. There is a near continuum of unoccupied energy levels above the Fermi level, so we expect to observe absorption over a wide range of frequencies. In metals, the bands are sufficiently wide that radiation from the radiofrequency to the middle of the ultraviolet region of the electromagnetic spectrum is absorbed (many metals are transparent to very high-frequency radiation, such as X-rays and  $\gamma$ -rays). Because this range of absorbed frequencies includes the entire visible spectrum, we expect that all

**Fig. 19.58** (a) The alignment of transition dipoles (the gold arrows) is energetically unfavourable, and the exciton absorption is shifted to higher energy (higher frequency). (b) The alignment is energetically favourable for a transition in this orientation, and the exciton band occurs at lower frequency than in the isolated molecules.

**Fig. 19.59** When the transition moments within a unit cell may lie in different relative directions, as depicted in (a) and (b), the energies of the transitions are shifted and give rise to the two bands labelled (a) and (b) in the spectrum. The separation of the bands is the Davydov splitting.

metals should appear black. However, we know that metals are shiny (that is, they reflect light) and some are coloured (that is, they absorb light of only certain wavelengths), so we need to extend our model.

To explain the shiny appearance of a smooth metal surface, we need to realize that the absorbed energy can be re-emitted very efficiently as light, with only a small fraction of the energy being released to the surroundings as heat. Because the atoms near the surface of the material absorb most of the radiation, emission also occurs primarily from the surface. In essence, if the sample is excited with visible light, then visible light will be reflected from the surface, accounting for the lustre of the material.

The perceived colour of a metal depends on the frequency range of reflected light which, in turn, depends on the frequency range of light that can be absorbed and, by extension, on the band structure. Silver reflects light with nearly equal efficiency across the visible spectrum because its band structure has many unoccupied energy levels that can be populated by absorption of, and depopulated by emission of, visible light. On the other hand, copper has its characteristic colour because it has relatively fewer unoccupied energy levels that can be excited with violet, blue, and green light. The material reflects at all wavelengths, but more light is emitted at lower frequencies (corresponding to yellow, orange, and red). Similar arguments account for the colours of other metals, such as the yellow of gold.

Finally, consider semiconductors. We have already seen that promotion of electrons from the valence to the conduction band of a semiconductor can be the result of thermal excitation, if the band gap  $E_g$  is comparable to the energy that can be supplied by heating. In some materials, the band gap is very large and electron promotion can occur only by excitation with electromagnetic radiation. However, we see from Fig. 19.53 that there is a frequency  $\nu_{\min} = E_g/h$  below which light absorption cannot occur. Above this frequency threshold, a wide range of frequencies can be absorbed by the material, as in a metal.

#### • A brief illustration

The semiconductor cadmium sulfide (CdS) has a band gap energy of 2.4 eV (equivalent to 0.38 aJ). It follows that the minimum electronic absorption frequency is

$$\nu_{\min} = \frac{3.8 \times 10^{-19} \text{ J}}{6.626 \times 10^{-34} \text{ J s}} = 5.8 \times 10^{14} \text{ s}^{-1}$$

This frequency,  $5.8 \times 10^{14} \text{ Hz}$ , corresponds to a wavelength of 517 nm (green light; see Table 13.1). Lower frequencies, corresponding to yellow, orange, and red, are not absorbed and consequently CdS appears yellow-orange. •

**Self-test 19.7** Predict the colours of the following materials, given their band-gap energies (in parentheses): GaAs (1.43 eV), HgS (2.1 eV), and ZnS (3.6 eV).

[Black, red, and colourless]

### (c) Nonlinear optical phenomena

Nonlinear optical phenomena arise from changes in the optical properties of a material in the presence of an intense electric field from electromagnetic radiation. Here we explore two phenomena that not only can be studied conveniently with intense laser beams but are commonly used in the laboratory to modify the output of lasers for specific experiments, such as those described in Section 13.6.

In **frequency doubling**, or **second harmonic generation**, an intense laser beam is converted to radiation with twice (and in general a multiple) of its initial frequency as it passes through a suitable material. It follows that frequency doubling and tripling of a Nd–YAG laser, which emits radiation at 1064 nm (see *Further information 19.1*), produce green light at 532 nm and ultraviolet radiation at 355 nm, respectively.

We can account for frequency doubling by examining how a substance responds nonlinearly to incident radiation of frequency  $\omega = 2\pi\nu$ . Radiation of a particular frequency arises from oscillations of an electric dipole at that frequency and the incident electric field  $\mathcal{E}$  induces an electric dipole of magnitude  $\mu$ , in the substance. At low light intensity, most materials respond linearly, in the sense that  $\mu = \alpha\mathcal{E}$ , where  $\alpha$  is the polarizability (see Section 17.2). To allow for nonlinear response by some materials at high light intensity, we can write

$$\mu = \alpha\mathcal{E} + \frac{1}{2}\beta\mathcal{E}^2 + \dots \quad (19.25)$$

The induced dipole moment in terms of the hyperpolarizability

where the coefficient  $\beta$  is the **hyperpolarizability** of the material. The nonlinear term  $\beta\mathcal{E}^2$  can be expanded as follows if we suppose that the incident electric field is  $\mathcal{E}_0 \cos \omega t$ :

$$\beta\mathcal{E}^2 = \beta\mathcal{E}_0^2 \cos^2 \omega t = \frac{1}{2}\beta\mathcal{E}_0^2 (1 + \cos 2\omega t) \quad (19.26)$$

Hence, the nonlinear term contributes an induced electric dipole that oscillates at the frequency  $2\omega$  and that can act as a source of radiation of that frequency. Common materials that can be used for frequency doubling in laser systems include crystals of potassium dihydrogenphosphate ( $\text{KH}_2\text{PO}_4$ ), lithium niobate ( $\text{LiNbO}_3$ ), and  $\beta$ -barium borate ( $\beta\text{-BaB}_2\text{O}_4$ ).

Another important nonlinear optical phenomenon is the **optical Kerr effect**, which arises from a change in refractive index of a well chosen medium, the **Kerr medium**, when it is exposed to intense laser pulses. Because a beam of light changes direction when it passes from a region of one refractive index to a region with a different refractive index, changes in refractive index result in the self-focusing of an intense laser pulse as it travels through the Kerr medium (Fig. 19.60).

The optical Kerr effect is used as a mechanism of mode-locking lasers (Section 13.6c). A Kerr medium is included in the cavity and next to it is a small aperture. The procedure makes use of the fact that the **gain**, the growth in intensity, of a frequency component of the radiation in the cavity is very sensitive to amplification and, once a particular frequency begins to grow, it can quickly dominate. When the power inside the cavity is low, a portion of the photons will be blocked by the aperture, creating a significant loss. A spontaneous fluctuation in intensity—a bunching of photons—may begin to turn on the optical Kerr effect and the changes in the refractive index of the Kerr medium will result in a **Kerr lens**, which is the self-focusing of the laser beam. The bunch of photons can pass through and travel to the far end of the cavity, amplifying as it goes. The Kerr lens immediately disappears (if the medium is well chosen), but is re-created when the intense pulse returns from the mirror at the far end. In this way, that particular bunch of photons may grow to considerable intensity because it alone is stimulating emission in the cavity. Sapphire is an example of a Kerr medium that facilitates the mode-locking of titanium sapphire lasers, resulting in very short laser pulses of duration in the femtosecond range.

In addition to being useful laboratory tools, nonlinear optical materials are also finding many applications in the telecommunications industry, which is becoming ever more reliant on optical signals transmitted through optical fibres to carry voice and data. Judicious use of nonlinear phenomena leads to more ways in which the properties of optical signals, and hence the information they carry, can be manipulated.

**Fig. 19.60** An illustration of the Kerr effect. An intense laser beam is focused inside a Kerr medium and passes through a small aperture in the laser cavity. This effect may be used to mode-lock a laser, as explained in the text.

#### A brief comment

The refractive index,  $n_r$ , of the medium, the ratio of the speed of light in a vacuum,  $c$ , to its speed  $c'$  in the medium:  $n_r = c/c'$ . A beam of light changes direction ('bends') when it passes from a region of one refractive index to a region with a different refractive index.

## 19.11 Magnetic properties

**Key points** (a) A diamagnetic material moves out of a magnetic field; a paramagnetic material moves into a magnetic field. The Curie law describes the temperature dependence of the molar magnetic susceptibility. (b) Ferromagnetism is the cooperative alignment of electron spins in a material; antiferromagnetism results from alternating spin orientations in a material. (c) Temperature-independent paramagnetism arises from induced electron currents in a molecule.

The magnetic properties of metallic solids and semiconductors depend strongly on the band structures of the material. Here we confine our attention largely to magnetic properties that stem from collections of individual centres (molecules or ions, such as d-metal complexes). Much of the discussion applies to liquid and gas phase samples as well as to solids.

## (a) Magnetic susceptibility

The magnetic and electric properties of molecules and solids are analogous. For instance, some molecules and ions possess permanent magnetic dipole moments, and an applied magnetic field can induce a magnetic moment, with the result that the entire solid sample becomes magnetized. The analogue of the electric polarization,  $P$ , is the **magnetization**,  $\mathcal{M}$ , the average molecular magnetic dipole moment multiplied by the number density of magnetic centres in the sample. The magnetization induced by a field of strength  $\mathcal{H}$  is proportional to  $\mathcal{H}$ , and we write

$$\mathcal{M} = \chi \mathcal{H} \quad \begin{array}{l} \text{Definition of the} \\ \text{magnetization} \end{array} \quad [19.27]$$

where  $\chi$  is the dimensionless **volume magnetic susceptibility**. A closely related quantity is the **molar magnetic susceptibility**,  $\chi_m$ :

$$\chi_m = \chi V_m \quad \begin{array}{l} \text{Definition of the molar} \\ \text{magnetic susceptibility} \end{array} \quad [19.28]$$

where  $V_m$  is the molar volume of the substance (we shall soon see why it is sensible to introduce this quantity). The **magnetic flux density**,  $\mathcal{B}$ , is related to the applied field strength and the magnetization by

$$\mathcal{B} = \mu_0(\mathcal{H} + \mathcal{M}) = \mu_0(1 + \chi)\mathcal{H} \quad \begin{array}{l} \text{Definition of the} \\ \text{magnetic flux density} \end{array} \quad [19.29]$$

where  $\mu_0$  is the vacuum permeability,  $\mu_0 = 4\pi \times 10^{-7} \text{ J C}^{-2} \text{ m}^{-1} \text{ s}^2$ . The magnetic flux density can be thought of as the density of magnetic lines of force permeating the medium. This density is increased if  $\mathcal{M}$  adds to  $\mathcal{H}$  (when  $\chi > 0$ ), but the density is decreased if  $\mathcal{M}$  opposes  $\mathcal{H}$  (when  $\chi < 0$ ). Materials for which  $\chi$  is positive are called **paramagnetic**. Those for which  $\chi$  is negative are called **diamagnetic**.

Just as polar molecules with a permanent electric dipole moment of magnitude  $\mu$  in fluid phases contribute a term proportional to  $\mu^2/3kT$  to the electric polarization of a medium (eqn 17.15), so molecules and ions with a permanent magnetic dipole moment of magnitude  $m$  contribute to the magnetization an amount proportional to  $m^2/3kT$ . However, unlike for polar molecules, this contribution to the magnetization is obtained even for paramagnetic species trapped in solids, because the direction of the spin of the electrons is typically not coupled to the orientation of the molecular framework and so contributes even when the nuclei are stationary. An applied field can also induce a magnetic moment by stirring up currents in the electron distribution like those responsible for the chemical shift in NMR (Section 14.5). The constant

of proportionality between the induced moment and the applied field is called the **magnetizability**,  $\xi$  (xi), and the magnetic analogue of eqn 17.15 is

$$\chi = \mathcal{N}\mu_0 \left( \xi + \frac{m^2}{3kT} \right) \quad (19.30)$$

We can now see why it is convenient to introduce  $\chi_m$ , because the product of the number density  $\mathcal{N}$  and the molar volume is Avogadro's constant,  $N_A$ :

$$\mathcal{N}V_m = \frac{NV_m}{V} = \frac{nN_A V_m}{nV_m} = N_A \quad (19.31)$$

Hence

$$\chi_m = N_A \mu_0 \left( \xi + \frac{m^2}{3kT} \right) \quad (19.32)$$

and the density dependence of the susceptibility (which occurs in eqn 19.30 via  $\mathcal{N} = N_A \chi / M$ ) has been eliminated. The expression for  $\chi_m$  is in agreement with the empirical **Curie law**:

$$\chi_m = A + \frac{C}{T} \quad \text{Curie law} \quad (19.33)$$

with  $A = N_A \mu_0 \xi$  and  $C = N_A \mu_0 m^2 / 3k$ . As indicated above, and in contrast to electric moments, this expression applies to solids as well as fluid phases.

The magnetic susceptibility is traditionally measured with a **Gouy balance**. This instrument consists of a sensitive balance from which the sample hangs in the form of a narrow cylinder and lies between the poles of a magnet. If the sample is paramagnetic, it is drawn into the field, and its apparent weight is greater than when the field is off. A diamagnetic sample tends to be expelled from the field and appears to weigh less when the field is turned on. The balance is normally calibrated against a sample of known susceptibility. The modern version of the determination makes use of a **superconducting quantum interference device** (SQUID, Fig. 19.61). A SQUID takes advantage of the quantization of magnetic flux and the property of current loops in superconductors that, as part of the circuit, include a weakly conducting link through which electrons must tunnel. The current that flows in the loop in a magnetic field depends on the value of the magnetic flux, and a SQUID can be exploited as a very sensitive magnetometer.

Table 19.6 lists some experimental values. A typical paramagnetic volume susceptibility is about  $10^{-3}$ , and a typical diamagnetic volume susceptibility is about  $(- )10^{-5}$ . The permanent magnetic moment can be extracted from susceptibility measurements by plotting  $\chi$  against  $1/T$ .

**Fig. 19.61** The arrangement used to measure magnetic susceptibility with a SQUID. The sample is moved upwards in small increments and the potential difference across the SQUID is measured.

**Table 19.6\*** Magnetic susceptibilities at 298 K

|                                         | $\chi/10^{-6}$ | $\chi_m/(10^{-10} \text{ m}^3 \text{ mol}^{-1})$ |

\* More values are given in the *Data section*.

**(b) The permanent magnetic moment**

The permanent magnetic moment of a magnetic centre arises from any unpaired electron spins. We saw in Section 14.1 that the magnitude of the magnetic moment of an electron is proportional to the magnitude of the spin angular momentum,  $\{s(s+1)\}^{1/2}\hbar$

$$\mu = g_e \{s(s+1)\}^{1/2} \mu_B \quad \mu_B = \frac{e\hbar}{2m_e} \quad (19.34)$$

where  $g_e = 2.0023$  (see Section 14.1). If there are several unpaired electron spins in each molecule or ion, they combine to a total spin  $S$ , and then  $s(s+1)$  should be replaced by  $S(S+1)$ . It follows that the spin contribution to the molar magnetic susceptibility is

$$\chi_m = \frac{N_A g_e^2 \mu_0 \mu_B^2 S(S+1)}{3kT} \quad \text{Spin contribution} \quad (19.35)$$

This expression shows that the susceptibility is positive, so the spin magnetic moments contribute to the paramagnetic susceptibilities of materials. The contribution decreases with increasing temperature because the thermal motion randomizes the spin orientations. In practice, a contribution to the paramagnetism also arises from the orbital angular momenta of electrons: we have discussed the spin-only contribution.

**• A brief illustration**

Consider a complex salt with three unpaired electrons per complex cation at 298 K, of mass density  $3.24 \text{ g cm}^{-3}$ , and molar mass  $200 \text{ g mol}^{-1}$ . First note that

$$\frac{N_A g_e^2 \mu_0 \mu_B^2}{3k} = 6.3001 \times 10^{-6} \text{ m}^3 \text{ K}^{-1} \text{ mol}^{-1}$$

Consequently,

$$\chi_m = 6.3001 \times 10^{-6} \times \frac{S(S+1)}{T/K} \text{ m}^3 \text{ mol}^{-1}$$

Substitution of the data with  $S = \frac{3}{2}$  gives  $\chi_m = 7.9 \times 10^{-8} \text{ m}^3 \text{ mol}^{-1}$ . Note that the density is not needed at this stage. To obtain the volume magnetic susceptibility, the molar susceptibility is divided by the molar volume  $V_m = M/\rho$ , where  $\rho$  is the mass density. In this illustration,  $V_m = 61.7 \text{ cm}^3 \text{ mol}^{-1}$ , so  $\chi = 1.3 \times 10^{-3}$ . •

**Fig. 19.62** (a) In a paramagnetic material, the electron spins are aligned at random in the absence of an applied magnetic field. (b) In a ferromagnetic material, the electron spins are locked into a parallel alignment over large domains. (c) In an antiferromagnetic material, the electron spins are locked into an antiparallel arrangement. The latter two arrangements survive even in the absence of an applied field.

At low temperatures, some paramagnetic solids make a phase transition to a state in which large domains of spins align with parallel orientations. This cooperative alignment gives rise to a very strong magnetization and is called **ferromagnetism** (Fig. 19.62). In other cases, the cooperative effect leads to alternating spin orientations: the spins are locked into a low-magnetization arrangement to give an **antiferromagnetic phase**. The ferromagnetic phase has a nonzero magnetization in the absence of an applied field, but the antiferromagnetic phase has a zero magnetization because the spin magnetic moments cancel. The ferromagnetic transition occurs at the **Curie temperature**, and the antiferromagnetic transition occurs at the **Néel temperature**.

**(c) Induced magnetic moments**

An applied magnetic field induces the circulation of electronic currents. These currents give rise to a magnetic field that usually opposes the applied field, so the substance is diamagnetic. In a few cases the induced field augments the applied field, and the substance is then paramagnetic.

The great majority of molecules and ions with no unpaired electron spins are diamagnetic. In these cases, the induced electron currents occur within the orbitals

that are occupied in its ground state. In the few cases in which species are paramagnetic despite having no unpaired electrons, the induced electron currents flow in the opposite direction because they can make use of unoccupied orbitals that lie close to the HOMO in energy. This orbital paramagnetism can be distinguished from spin paramagnetism by the fact that it is temperature-independent: this is why it is called **temperature-independent paramagnetism (TIP)**.

We can summarize these remarks as follows. All molecules and ions have a diamagnetic component to their susceptibility, but it is dominated by spin paramagnetism if unpaired electrons are present. In a few cases (where there are low-lying excited states) TIP is strong enough to make the species paramagnetic even though their electrons are paired.

## 19.12 Superconductors

---

**Key points** Superconductors conduct electricity without resistance below a critical temperature  $T_c$ . Type I superconductors show abrupt loss of superconductivity when an applied magnetic field exceeds a critical value  $\mathcal{H}_c$ . Type II superconductors show a gradual loss of superconductivity and diamagnetism with increasing magnetic field.

---

The resistance to flow of electrical current of a normal metallic conductor decreases smoothly with temperature but never vanishes. However, certain solids known as **superconductors** conduct electricity without resistance below a critical temperature,  $T_c$ . Following the discovery in 1911 that mercury is a superconductor below 4.2 K, the boiling point of liquid helium, physicists and chemists made slow but steady progress in the discovery of superconductors with higher values of  $T_c$ . Metals, such as tungsten, mercury, and lead, tend to have  $T_c$  values below about 10 K. Intermetallic compounds, such as  $\text{Nb}_3\text{X}$  ( $\text{X} = \text{Sn}, \text{Al}, \text{or Ge}$ ), and alloys, such as  $\text{Nb/Ti}$  and  $\text{Nb/Zr}$ , have intermediate  $T_c$  values ranging between 10 K and 23 K. In 1986, **high-temperature superconductors (HTSC)** were discovered. Several **ceramics**, inorganic powders that have been fused and hardened by heating to a high temperature, containing oxocuprate motifs,  $\text{Cu}_m\text{O}_n$ , are now known with  $T_c$  values well above 77 K, the boiling point of the inexpensive refrigerant liquid nitrogen. For example,  $\text{HgBa}_2\text{Ca}_2\text{Cu}_2\text{O}_8$  has  $T_c = 153$  K.

Superconductors have unique magnetic properties as well. Some superconductors, classed as **Type I**, show abrupt loss of superconductivity when an applied magnetic field exceeds a critical value  $\mathcal{H}_c$  characteristic of the material. It is observed that the value of  $\mathcal{H}_c$  depends on temperature and  $T_c$  as

$$\mathcal{H}_c(T) = \mathcal{H}_c(0) \left( 1 - \frac{T^2}{T_c^2} \right) \quad (19.36)$$

where  $\mathcal{H}_c(0)$  is the value of  $\mathcal{H}_c$  as  $T \rightarrow 0$ . Type I superconductors are also completely diamagnetic below  $\mathcal{H}_c$ , meaning that no magnetic field lines penetrate into the material. This complete exclusion of a magnetic field in a material is known as the **Meissner effect**, which can be visualized by the levitation of a superconductor above a magnet. **Type II** superconductors, which include the HTSCs, show a gradual loss of superconductivity and diamagnetism with increasing magnetic field.

There is a degree of periodicity in the elements that exhibit superconductivity. The metals iron, cobalt, nickel, copper, silver, and gold do not display superconductivity, nor do the alkali metals. It is observed that, for simple metals, ferromagnetism and superconductivity never coexist, but in some of the oxocuprate superconductors ferromagnetism and superconductivity can coexist. One of the most widely studied oxocuprate superconductors  $\text{YBa}_2\text{Cu}_3\text{O}_7$  (informally known as ‘123’ on account of the proportions of the metal atoms in the compound) has the structure shown in Fig. 19.63. The square-pyramidal  $\text{CuO}_5$  units arranged as two-dimensional layers and

**Fig. 19.63** Structure of the  $\text{YBa}_2\text{Cu}_3\text{O}_7$  superconductor. (a) Metal atom positions. (b) The polyhedra show the positions of oxygen atoms and indicate that the metal ions are in square-planar and square-pyramidal coordination environments.

**Fig. 19.64** The formation of a Cooper pair. One electron distorts the crystal lattice and the second electron has a lower energy if it goes to that region. These electron–lattice interactions effectively bind the two electrons into a pair.

the square planar  $\text{CuO}_4$  units arranged in sheets are common structural features of oxocuprate HTSCs.

The mechanism of superconduction is well-understood for low-temperature materials but there is as yet no settled explanation of high-temperature superconductivity. The central concept of low-temperature superconduction is the existence of a **Cooper pair**, a pair of electrons that exists on account of the indirect electron–electron interactions fostered by the nuclei of the atoms in the lattice. Thus, if one electron is in a particular region of a solid, the nuclei there move toward it to give a distorted local structure (Fig. 19.64). Because that local distortion is rich in positive charge, it is favourable for a second electron to join the first. Hence, there is a virtual attraction between the two electrons, and they move together as a pair. The local distortion can be easily disrupted by thermal motion of the ions in the solid, so the virtual attraction occurs only at very low temperatures. A Cooper pair undergoes less scattering than an individual electron as it travels through the solid because the distortion caused by one electron can attract back the other electron should it be scattered out of its path in a collision. Because the Cooper pair is stable against scattering, it can carry charge freely through the solid, and hence give rise to superconduction.

The Cooper pairs responsible for low-temperature superconductivity are likely to be important in HTSCs, but the mechanism for pairing is hotly debated. There is evidence implicating the arrangement of  $\text{CuO}_5$  layers and  $\text{CuO}_4$  sheets in the mechanism of high-temperature superconduction. It is believed that movement of electrons along the linked  $\text{CuO}_4$  units accounts for superconductivity, whereas the linked  $\text{CuO}_5$  units act as ‘charge reservoirs’ that maintain an appropriate number of electrons in the superconducting layers.

Superconductors can sustain large currents and, consequently, are excellent materials for the high-field magnets used in modern NMR spectroscopy (Chapter 14). However, the potential uses of superconducting materials are not limited to the field to chemical instrumentation. For example, HTSCs with  $T_c$  values near ambient temperature would be very efficient components of an electrical power transmission system, in which energy loss due to electrical resistance would be minimized. The appropriate technology is not yet available, but research in this area of materials science is active.

## Checklist of key equations

| Property                                                   | Equation                                                             | Comment                                      |

## Further information

### Further information 19.1 Solid state lasers and light-emitting diodes

Here we explore the further consequences of light emission in solids, focusing our attention on ionic crystals and semiconductors used in the design of lasers and light-emitting diodes. In Chapter 13 we discussed the conditions under which a material can become a laser and it would be helpful to review those concepts.

The **neodymium laser** is an example of a four-level laser, in which the laser transition terminates in a state other than the ground state of the laser material (Fig. 19.65). In one form it consists of  $\text{Nd}^{3+}$  ions at low concentration in yttrium aluminium garnet (YAG, specifically  $\text{Y}_3\text{Al}_5\text{O}_{12}$ ), and is then known as a **Nd-YAG laser**. The population inversion results from pumping a majority of the  $\text{Nd}^{3+}$  ions into an excited state by using an intense flash from another source, followed by a radiationless transition to another excited state. The pumping flash need not be monochromatic because the upper level actually consists of several states spanning a band of frequencies. A neodymium laser operates at a number of wavelengths in the

**Fig. 19.65** The transitions involved in a neodymium laser. The laser action takes place between the  $^4\text{F}$  and  $^4\text{I}$  excited states.

infrared, the band at 1064 nm being most common. The transition at 1064 nm is very efficient and the laser is capable of substantial power output, either in continuous or pulsed (by Q-switching or mode-locking as discussed in Section 13.6c) modes of operation.

The **titanium sapphire laser** consists of  $\text{Ti}^{3+}$  ions at low concentration in a crystal of sapphire ( $\text{Al}_2\text{O}_3$ ). The electronic absorption spectrum of  $\text{Ti}^{3+}$  ion in sapphire is very similar to that shown in Fig. 13.13, with a broad absorption band centred at around 500 nm that arises from vibronically allowed d–d transitions of the  $\text{Ti}^{3+}$  ion in an octahedral environment provided by oxygen atoms of the host lattice. As a result, the emission spectrum of  $\text{Ti}^{3+}$  in sapphire is also broad and laser action occurs over a wide range of wavelengths (Fig. 19.66). Therefore, the titanium sapphire laser is an example of a **vibronic laser**, in which the laser transitions originate from vibronic transitions in the laser medium. The titanium sapphire laser is usually pumped by another laser, such as a Nd–YAG laser or an argon-ion laser (*Further information 13.1*), and can be operated in either a continuous or pulsed fashion. Mode-locked titanium sapphire lasers produce energetic (20 mJ to 1 J) and very short (20–100 fs,  $1 \text{ fs} = 10^{-15} \text{ s}$ ) pulses. When considered together with broad wavelength tunability (700–1000 nm), these features of the titanium sapphire laser justify its wide use in modern spectroscopy and photochemistry.

The unique electrical properties of p–n junctions between semiconductors can be put to good use in optical devices. In some materials, most notably gallium arsenide, GaAs, energy from electron–hole recombination is released not as heat but is carried away by photons as electrons move across the junction under forward bias. Practical **light-emitting diodes** of this kind are widely used in electronic displays. The wavelength of emitted light depends on the band gap of the semiconductor. Gallium arsenide itself emits infrared light, but the band gap is widened by incorporating phosphorus, and a material of composition approximately  $\text{GaAs}_{0.6}\text{P}_{0.4}$  emits light in the red region of the spectrum.

A light-emitting diode is not a laser, because no resonance cavity and stimulated emission are involved. In **diode lasers**, light emission due to electron–hole recombination is employed as the basis of laser action. The population inversion can be sustained by sweeping away the electrons that fall into the holes of the p-type semiconductor, and

**Fig. 19.66** The transitions involved in a titanium sapphire laser. The laser medium consists of sapphire ( $\text{Al}_2\text{O}_3$ ) doped with  $\text{Ti}^{3+}$  ions. Monochromatic light from a pump laser induces a  ${}^2\text{E} \leftarrow {}^2\text{T}_2$  transition in a  $\text{Ti}^{3+}$  ion that resides in a site with octahedral symmetry. After radiationless vibrational excitation in the  ${}^2\text{E}$  state, laser emission occurs from a very large number of closely spaced vibronic states of the medium. As a result, the titanium sapphire laser emits radiation over a broad spectrum that spans from about 700 nm to about 1000 nm.

a resonant cavity can be formed by using the high refractive index of the semiconducting material and cleaving single crystals so that the light is trapped by the abrupt variation of refractive index. One widely used material is  $\text{Ga}_{1-x}\text{Al}_x\text{As}$ , which produces infrared laser radiation and is widely used in compact-disc (CD) players.

High-power diode lasers are also used to pump other lasers. One example is the pumping of Nd:YAG lasers by  $\text{Ga}_{0.91}\text{Al}_{0.09}\text{As}/\text{Ga}_{0.7}\text{Al}_{0.3}\text{As}$  diode lasers. The Nd:YAG laser is often used to pump yet another laser, such as a Ti:sapphire laser. As a result, it is now possible to construct a laser system for steady-state or time-resolved spectroscopy entirely out of solid-state components.

## Discussion questions

- 19.1** Describe the relationship between the space lattice and unit cell.
- 19.2** Explain how planes of lattice points are labelled.
- 19.3** Describe the procedure for identifying the type and size of a cubic unit cell.
- 19.4** What is meant by a systematic absence? How do they arise?
- 19.5** Explain the general features of the X-ray diffraction pattern of a helical molecule. How would the pattern change as the pitch of the helix is increased?
- 19.6** Describe what is meant by ‘scattering factor’. How is it related to the number of electrons in the atoms scattering X-rays?
- 19.7** Describe the phase problem and explain how it may be overcome.
- 19.8** Describe the structures of elemental metallic solids in terms of the packing of hard spheres. To what extent is the hard-sphere model inaccurate?
- 19.9** Describe the caesium-chloride and rock-salt structures in terms of the occupation of holes in expanded close-packed lattices.
- 19.10** Explain how metallic conductors and semiconductors are identified and explain their electrical and optical properties in terms of band theory.
- 19.11** Describe the characteristics of the Fermi–Dirac distribution. Why is it appropriate to call the parameter  $\mu$  a chemical potential?
- 19.12** Explain the origin of Davydov splitting in the exciton bands of a crystal.
- 19.13** To what extent are the electric and magnetic properties of molecules analogous? How do they differ?

## Exercises

- 19.1(a)** Equivalent lattice points within the unit cell of a Bravais lattice have identical surroundings. What points within a face-centred cubic unit cell are equivalent to the point  $(\frac{1}{2}, 0, 0)$ ?
- 19.1(b)** Equivalent lattice points within the unit cell of a Bravais lattice have identical surroundings. What points within a body-centred cubic unit cell are equivalent to the point  $(\frac{1}{2}, 0, \frac{1}{2})$ ?
- 19.2(a)** Find the Miller indices of the planes that intersect the crystallographic axes at the distances  $(2a, 3b, 2c)$  and  $(2a, 2b, \infty c)$ .
- 19.2(b)** Find the Miller indices of the planes that intersect the crystallographic axes at the distances  $(1a, 3b, -c)$  and  $(2a, 3b, 4c)$ .
- 19.3(a)** Calculate the separations of the planes  $\{111\}$ ,  $\{211\}$ , and  $\{100\}$  in a crystal in which the cubic unit cell has side 432 pm.
- 19.3(b)** Calculate the separations of the planes  $\{121\}$ ,  $\{221\}$ , and  $\{244\}$  in a crystal in which the cubic unit cell has side 523 pm.
- 19.4(a)** The glancing angle of a Bragg reflection from a set of crystal planes separated by 99.3 pm is  $20.85^\circ$ . Calculate the wavelength of the X-rays.
- 19.4(b)** The glancing angle of a Bragg reflection from a set of crystal planes separated by 128.2 pm is  $19.76^\circ$ . Calculate the wavelength of the X-rays.
- 19.5(a)** What are the values of  $2\theta$  of the first three diffraction lines of bcc iron (atomic radius 126 pm) when the X-ray wavelength is 58 pm?
- 19.5(b)** What are the values of  $2\theta$  of the first three diffraction lines of fcc gold (atomic radius 144 pm) when the X-ray wavelength is 154 pm?
- 19.6(a)** Copper  $K_\alpha$  radiation consists of two components of wavelengths 154.433 pm and 154.051 pm. Calculate the separation of the diffraction lines arising from the two components in a powder diffraction pattern recorded in a circular camera of radius 5.74 cm (with the sample at the centre) from planes of separation 77.8 pm.
- 19.6(b)** A synchrotron source produces X-radiation at a range of wavelengths. Consider two components of wavelengths 95.401 and 96.035 pm. Calculate the separation of the diffraction lines arising from the two components in a powder diffraction pattern recorded in a circular camera of radius 5.74 cm (with the sample at the centre) from planes of separation 82.3 pm.
- 19.7(a)** What is the value of the scattering factor in the forward direction for  $\text{Br}^-$ ?
- 19.7(b)** What is the value of the scattering factor in the forward direction for  $\text{Mg}^{2+}$ ?
- 19.8(a)** The compound  $\text{Rb}_3\text{TlF}_6$  has a tetragonal unit cell with dimensions  $a = 651$  pm and  $c = 934$  pm. Calculate the volume of the unit cell.
- 19.8(b)** Calculate the volume of the hexagonal unit cell of sodium nitrate, for which the dimensions are  $a = 1692.9$  pm and  $c = 506.96$  pm.
- 19.9(a)** The orthorhombic unit cell of  $\text{NiSO}_4$  has the dimensions  $a = 634$  pm,  $b = 784$  pm, and  $c = 516$  pm, and the density of the solid is estimated as  $3.9 \text{ g cm}^{-3}$ . Determine the number of formula units per unit cell and calculate a more precise value of the density.
- 19.9(b)** An orthorhombic unit cell of a compound of molar mass  $135.01 \text{ g mol}^{-1}$  has the dimensions  $a = 589$  pm,  $b = 822$  pm, and  $c = 798$  pm. The density of the solid is estimated as  $2.9 \text{ g cm}^{-3}$ . Determine the number of formula units per unit cell and calculate a more precise value of the density.
- 19.10(a)** The unit cells of  $\text{SbCl}_3$  are orthorhombic with dimensions  $a = 812$  pm,  $b = 947$  pm, and  $c = 637$  pm. Calculate the spacing,  $d$ , of the  $\{411\}$  planes.
- 19.10(b)** An orthorhombic unit cell has dimensions  $a = 679$  pm,  $b = 879$  pm, and  $c = 860$  pm. Calculate the spacing,  $d$ , of the  $\{322\}$  planes.
- 19.11(a)** A substance known to have a cubic unit cell gives reflections with Cu  $K_\alpha$  radiation (wavelength 154 pm) at glancing angles  $19.4^\circ$ ,  $22.5^\circ$ ,  $32.6^\circ$ , and  $39.4^\circ$ . The reflection at  $32.6^\circ$  is known to be due to the  $\{220\}$  planes. Index the other reflections.
- 19.11(b)** A substance known to have a cubic unit cell gives reflections with radiation of wavelength 137 pm at the glancing angles  $10.7^\circ$ ,  $13.6^\circ$ ,  $17.7^\circ$ , and  $21.9^\circ$ . The reflection at  $17.7^\circ$  is known to be due to the  $\{111\}$  planes. Index the other reflections.
- 19.12(a)** Potassium nitrate crystals have orthorhombic unit cells of dimensions  $a = 542$  pm,  $b = 917$  pm, and  $c = 645$  pm. Calculate the glancing angles for the  $\{100\}$ ,  $\{010\}$ , and  $\{111\}$  reflections using Cu  $K_\alpha$  radiation (154 pm).
- 19.12(b)** Calcium carbonate crystals in the form of aragonite have orthorhombic unit cells of dimensions  $a = 574.1$  pm,  $b = 796.8$  pm, and  $c = 495.9$  pm. Calculate the glancing angles for the  $\{100\}$ ,  $\{010\}$ , and  $\{111\}$  reflections using radiation of wavelength 83.42 pm (from aluminium).
- 19.13(a)** Copper(I) chloride forms cubic crystals with four formula units per unit cell. The only reflections present in a powder photograph are those with either all even indices or all odd indices. What is the (Bravais) lattice type of the unit cell?
- 19.13(b)** A powder diffraction photograph from tungsten shows lines which index as  $\{110\}$ ,  $\{200\}$ ,  $\{211\}$ ,  $\{220\}$ ,  $\{310\}$ ,  $\{222\}$ ,  $\{321\}$ ,  $\{400\}$ , ... Identify the (Bravais) lattice type of the unit cell.
- 19.14(a)** The coordinates, in units of  $a$ , of the atoms in a body-centred cubic lattice are  $(0,0,0)$ ,  $(0,1,0)$ ,  $(0,0,1)$ ,  $(0,1,1)$ ,  $(1,0,0)$ ,  $(1,1,0)$ ,  $(1,0,1)$ , and  $(1,1,1)$ . Calculate the structure factors  $F_{hkl}$  when all the atoms are identical.
- 19.14(b)** The coordinates, in units of  $a$ , of the atoms in a body-centred cubic lattice are  $(0,0,0)$ ,  $(0,1,0)$ ,  $(0,0,1)$ ,  $(0,1,1)$ ,  $(1,0,0)$ ,  $(1,1,0)$ ,  $(1,0,1)$ ,  $(1,1,1)$ , and  $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ . Calculate the structure factors  $F_{hkl}$  when all the atoms are identical.
- 19.15(a)** In an X-ray investigation, the following structure factors were determined (with  $F_{-h00} = F_{h00}$ )
- | $h$       | 0  | 1   | 2 | 3  | 4 | 5  | 6 | 7  | 8 | 9  |
|-----------|----|-----|---|----|---|----|---|----|---|----|
| $F_{h00}$ | 10 | -10 | 8 | -8 | 6 | -6 | 4 | -4 | 2 | -2 |
- Construct the electron density along the corresponding direction.
- 19.15(b)** In an X-ray investigation, the following structure factors were determined (with  $F_{-h00} = F_{h00}$ )
- | $h$       | 0  | 1  | 2 | 3 | 4 | 5 | 6 | 7 | 8  | 9  |
|-----------|----|----|---|---|---|---|---|---|----|----|
| $F_{h00}$ | 10 | 10 | 4 | 4 | 6 | 6 | 8 | 8 | 10 | 10 |
- Construct the electron density along the corresponding direction.
- 19.16(a)** Construct the Patterson synthesis from the information in Exercise 19.15a.
- 19.16(b)** Construct the Patterson synthesis from the information in Exercise 19.15b.
- 19.17(a)** In a Patterson synthesis, the spots correspond to the lengths and directions of the vectors joining the atoms in a unit cell. Sketch the pattern that would be obtained for a planar, triangular isolated  $\text{BF}_3$  molecule.
- 19.17(b)** In a Patterson synthesis, the spots correspond to the lengths and directions of the vectors joining the atoms in a unit cell. Sketch the pattern that would be obtained from the C atoms in an isolated benzene molecule.

**19.18(a)** What velocity should neutrons have if they are to have wavelength 50 pm?

**19.18(b)** What velocity should neutrons have if they are to have wavelength 105 pm?

**19.19(a)** Calculate the wavelength of neutrons that have reached thermal equilibrium by collision with a moderator at 300 K.

**19.19(b)** Calculate the wavelength of neutrons that have reached thermal equilibrium by collision with a moderator at 380 K.

**19.20(a)** Calculate the packing fraction for close packed cylinders.

**19.20(b)** Calculate the packing fraction for equilateral triangular rods stacked as shown in (2).

2

**19.21(a)** Calculate the packing fractions of (a) a primitive cubic unit cell, (b) a bcc unit cell, (c) an fcc unit cell composed of identical hard spheres.

**19.21(b)** Calculate the atomic packing fraction for a side-centred C cubic unit cell.

**19.22(a)** Verify that the radius ratios for sixfold coordination is 0.414.

**19.22(b)** Verify that the radius ratios for eightfold coordination is 0.732.

**19.23(a)** From the data in Table 19.3 determine the radius of the smallest cation that can have (a) sixfold and (b) eightfold coordination with the  $O^{2-}$  ion.

**19.23(b)** From the data in Table 19.3 determine the radius of the smallest cation that can have (a) sixfold and (b) eightfold coordination with the  $K^+$  ion.

**19.24(a)** Is there an expansion or a contraction as titanium transforms from hcp to body-centred cubic? The atomic radius of titanium is 145.8 pm in hcp but 142.5 pm in bcc.

**19.24(b)** Is there an expansion or a contraction as iron transforms from hcp to bcc? The atomic radius of iron is 126 in hcp but 122 pm in bcc.

**19.25(a)** Calculate the lattice enthalpy of CaO from the following data:

|                                                           | $\Delta H/(\text{kJ mol}^{-1})$ |
|-----------------------------------------------------------|---------------------------------|
| Sublimation of Ca(s)                                      | +178                            |
| Ionization of Ca(g) to $\text{Ca}^{2+}(\text{g})$         | +1735                           |
| Dissociation of $\text{O}_2(\text{g})$                    | +249                            |
| Electron attachment to O(g)                               | -141                            |
| Electron attachment to $\text{O}^-(\text{g})$             | +844                            |
| Formation of CaO(s) from Ca(s) and $\text{O}_2(\text{g})$ | -635                            |

**19.25(b)** Calculate the lattice enthalpy of  $\text{MgBr}_2$  from the following data:

|                                                                               | $\Delta H/(\text{kJ mol}^{-1})$ |
|-------------------------------------------------------------------------------|---------------------------------|
| Sublimation of Mg(s)                                                          | +148                            |
| Ionization of Mg(g) to $\text{Mg}^{2+}(\text{g})$                             | +2187                           |
| Vaporization of $\text{Br}_2(\text{l})$                                       | +31                             |

**19.28(b)** Is gallium-doped germanium a p-type or n-type semiconductor?

**19.29(a)** The promotion of an electron from the valence band into the conduction band in pure  $\text{TiO}_2$  by light absorption requires a wavelength of less than 350 nm. Calculate the energy gap in electronvolts between the valence and conduction bands.

**19.29(b)** The band gap in silicon is 1.12 eV. Calculate the minimum frequency of electromagnetic radiation that results in promotion of electrons from the valence to the conduction band.

**19.30(a)** The magnetic moment of  $\text{CrCl}_3$  is  $3.81 \mu_B$ . How many unpaired electrons does the Cr atom possess?

**19.30(b)** The magnetic moment of  $\text{Mn}^{2+}$  in its complexes is typically  $5.3 \mu_B$ . How many unpaired electrons does the ion possess?

**19.31(a)** Calculate the molar susceptibility of benzene given that its volume susceptibility is  $-7.2 \times 10^{-7}$  and its density  $0.879 \text{ g cm}^{-3}$  at  $25^\circ\text{C}$ .

**19.31(b)** Calculate the molar susceptibility of cyclohexane given that its volume susceptibility is  $-7.9 \times 10^{-7}$  and its density  $811 \text{ kg m}^{-3}$  at  $25^\circ\text{C}$ .

**19.32(a)** Data on a single crystal of  $\text{MnF}_2$  give  $\chi_m = 0.1463 \text{ cm}^3 \text{ mol}^{-1}$  at 294.53 K. Determine the effective number of unpaired electrons in this compound and compare your result with the theoretical value.

**19.32(b)** Data on a single crystal of  $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$  give  $\chi_m = 6.00 \times 10^{-8} \text{ m}^3 \text{ mol}^{-1}$  at 298 K. Determine the effective number of unpaired electrons in this compound and compare your result with the theoretical value.

**19.33(a)** Estimate the spin-only molar susceptibility of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  at  $25^\circ\text{C}$ .

**19.33(b)** Estimate the spin-only molar susceptibility of  $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$  at 298 K.

**19.34(a)** Lead has  $T_c = 7.19 \text{ K}$  and  $\mathcal{H}_c = 63.9 \text{ kA m}^{-1}$ . At what temperature does lead become superconducting in a magnetic field of  $20 \text{ kA m}^{-1}$ ?

**19.34(b)** Tin has  $T_c = 3.72 \text{ K}$  and  $\mathcal{H}_c = 25 \text{ kA m}^{-1}$ . At what temperature does tin become superconducting in a magnetic field of  $15 \text{ kA m}^{-1}$ ?

## Problems\*

## Numerical problems

**19.1** In the early days of X-ray crystallography there was an urgent need to know the wavelengths of X-rays. One technique was to measure the diffraction angle from a mechanically ruled grating. Another method was to estimate the separation of lattice planes from the measured density of a crystal. The density of NaCl is  $2.17 \text{ g cm}^{-3}$  and the (100) reflection using  $\text{Pd K}\alpha$  radiation occurred at  $6.0^\circ$ . Calculate the wavelength of the X-rays.

**19.2** The element polonium crystallizes in a cubic system. Bragg reflections, with X-rays of wavelength 154 pm, occur at  $\sin \theta = 0.225, 0.316$ , and  $0.388$  from the (100), (110), and (111) sets of planes. The separation between the sixth and seventh lines observed in the powder diffraction pattern is larger than between the fifth and sixth lines. Is the unit cell simple, body-centred, or face-centred? Calculate the unit cell dimension.

**19.3** Elemental silver reflects X-rays of wavelength 154.18 pm at angles of  $19.076^\circ, 22.171^\circ$ , and  $32.256^\circ$ . However, there are no other reflections at angles of less than  $33^\circ$ . Assuming a cubic unit cell, determine its type and dimension. Calculate the density of silver.

**19.4** In their book *X-rays and crystal structures* (which begins 'It is now two years since Dr. Laue conceived the idea . . .') the Braggs give a number of simple examples of X-ray analysis. For instance, they report that the reflection from (100) planes in KCl occurs at  $5^\circ 23'$ , but for NaCl it occurs at  $6^\circ 0'$  for X-rays of the same wavelength. If the side of the NaCl unit cell is 564 pm, what is the side of the KCl unit cell? The densities of KCl and NaCl are  $1.99 \text{ g cm}^{-3}$  and  $2.17 \text{ g cm}^{-3}$ , respectively. Do these values support the X-ray analysis?

**19.5** Calculate the coefficient of thermal expansion of diamond given that the (111) reflection shifts from  $22^\circ 2' 25''$  to  $21^\circ 57' 59''$  on heating a crystal from 100 K to 300 K and 154.0562 pm X-rays are used.

**19.6** The carbon–carbon bond length in diamond is 154.45 pm. If diamond were considered to be a close-packed structure of hard spheres with radii equal to half the bond length, what would be its expected density? The diamond lattice is face-centred cubic and its actual density is  $3.516 \text{ g cm}^{-3}$ . Can you explain the discrepancy?

**19.7** The volume of a monoclinic unit cell is  $abc \sin \beta$ . Naphthalene has a monoclinic unit cell with two molecules per cell and sides in the ratio 1.377:1:1.436. The angle  $\beta$  is  $122^\circ 49'$  and the density of the solid is  $1.152 \text{ g cm}^{-3}$ . Calculate the dimensions of the cell.

**19.8‡** B.A. Bovenzi and G.A. Pearse, Jr. (*J. Chem. Soc. Dalton Trans.* 2793–8 (1997)) synthesized coordination compounds of the tridentate ligand pyridine-2,6-diamidoxime ( $\text{C}_7\text{H}_9\text{N}_5\text{O}_2$ ). The compound that they isolated from the reaction of the ligand with  $\text{CuSO}_4(\text{aq})$  did not contain a  $[\text{Cu}(\text{C}_7\text{H}_9\text{N}_5\text{O}_2)_2]^{2+}$  complex cation as expected. Instead, X-ray diffraction analysis revealed a linear polymer of formula  $[\text{Cu}(\text{Cu}(\text{C}_7\text{H}_9\text{N}_5\text{O}_2)(\text{SO}_4) \cdot 2\text{H}_2\text{O})_n]$ , which features bridging sulfate groups. The unit cell was primitive monoclinic with  $a = 1.0427 \text{ nm}$ ,  $b = 0.8876 \text{ nm}$ ,  $c = 1.3777 \text{ nm}$ , and  $\beta = 93.254^\circ$ . The mass density of the crystals is  $2.024 \text{ g cm}^{-3}$ . How many monomer units are there per unit cell?

**19.9‡** D. Sellmann *et al.* (*Inorg. Chem.* 36, 1397 (1997)) describe the synthesis and reactivity of the ruthenium nitrido compound  $[\text{N}(\text{C}_4\text{H}_9)_4][\text{Ru}(\text{N})(\text{S}_2\text{C}_6\text{H}_4)_2]$ . The ruthenium complex anion has the two 1,2-benzenedithiolate ligands (3) at the base of a rectangular pyramid and the nitrido ligand at the apex. Compute the mass density of the compound given that it crystallizes into an orthorhombic unit cell with  $a = 3.6881 \text{ nm}$ ,  $b = 0.9402 \text{ nm}$ , and  $c = 1.7652 \text{ nm}$  and eight formula units per cell. Replacing

the ruthenium with an osmium results in a compound with the same crystal structure and a unit cell with a volume less than 1 per cent larger. Estimate the mass density of the osmium analogue.

**19.10** The unit cell dimensions of NaCl, KCl, NaBr, and KBr, all of which crystallize in face-centred cubic lattices, are 562.8 pm, 627.7 pm, 596.2 pm, and 658.6 pm, respectively. In each case, anion and cation are in contact along an edge of the unit cell. Do the data support the contention that ionic radii are constants independent of the counterion?

**19.11** The powder diffraction patterns of (a) tungsten, (b) copper obtained in a camera of radius 28.7 mm are shown in Fig. 19.67. Both were obtained with 154 pm X-rays and the scales are marked. Identify the unit cell in each case, and calculate the lattice spacing. Estimate the metallic radii of W and Cu.

Fig. 19.67

**19.12** Genuine pearls consist of concentric layers of calcite crystals ( $\text{CaCO}_3$ ) in which the trigonal axes are oriented along the radii. The nucleus of a cultured pearl is a piece of mother-of-pearl that has been worked into a sphere on a lathe. The oyster then deposits concentric layers of calcite on the central seed. Suggest an X-ray method for distinguishing between real and cultured pearls.

**19.13** The structures of crystalline macromolecules may be determined by X-ray diffraction techniques by methods similar to those for smaller molecules. Fully crystalline polyethylene has its chains aligned in an orthorhombic unit cell of dimensions  $740 \text{ pm} \times 493 \text{ pm} \times 253 \text{ pm}$ . There are two repeating  $\text{CH}_2\text{CH}_2$  units per unit cell. Calculate the theoretical density of fully crystalline polyethylene. The actual density ranges from  $0.92$  to  $0.95 \text{ g cm}^{-3}$ .

**19.14** The scattering of electrons or neutrons from a pair of nuclei separated by a distance  $R_{ij}$  and orientated at a definite angle to the incident beam can be calculated. When the molecule consists of a number of atoms, we sum over the contribution from all pairs, and find that the total intensity has an angular variation given by the *Wierl equation*:

$$I(\theta) = \sum_{i,j} f_i f_j \frac{\sin s R_{ij}}{s R_{ij}} \quad s = \frac{4\pi}{\lambda} \sin \frac{1}{2} \theta$$

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp and Carmen Giunta.

where  $\lambda$  is the wavelength of the electrons in the beam and  $\theta$  is the scattering angle. The *electron scattering factor*,  $f$ , is a measure of the intensity of the electron scattering powers of the atoms. (a) Predict from the Wierl equation the positions of the first maximum and first minimum in the neutron and electron diffraction patterns of a  $\text{Br}_2$  molecule obtained with neutrons of wavelength 78 pm and electrons of wavelength 4.0 pm. (b) Use the Wierl equation to predict the appearance of the 10.0 keV electron diffraction pattern of  $\text{CCl}_4$  with an (as yet) undetermined C–Cl bond length but of known tetrahedral symmetry. Take  $f_{\text{Cl}} = 17f$  and  $f_{\text{C}} = 6f$  and note that  $R(\text{Cl}, \text{Cl}) = (8/3)^{1/2} R(\text{C}, \text{Cl})$ . Plot  $I/f^2$  against positions of the maxima that occurred at  $3^\circ 10'$ ,  $5^\circ 22'$ , and  $7^\circ 54'$  and minima that occurred at  $1^\circ 46'$ ,  $4^\circ 6'$ ,  $6^\circ 40'$ , and  $9^\circ 10'$ . What is the C–Cl bond length in  $\text{CCl}_4$ ?

**19.15** Aided by the Born–Mayer equation for the lattice enthalpy and a Born–Haber cycle, show that formation of  $\text{CaCl}$  is an exothermic process (the sublimation enthalpy of  $\text{Ca}(\text{s})$  is  $176 \text{ kJ mol}^{-1}$ ). Show that an explanation for the nonexistence of  $\text{CaCl}$  can be found in the reaction enthalpy for the reaction  $2\text{CaCl}(\text{s}) \rightarrow \text{Ca}(\text{s}) + \text{CaCl}_2$ .

**19.16** In an intrinsic semiconductor, the band gap is so small that the Fermi–Dirac distribution results in some electrons populating the conduction band. It follows from the exponential form of the Fermi–Dirac distribution that the conductance  $G$ , the inverse of the resistance (with units of siemens,  $1 \text{ S} = 1 \Omega^{-1}$ ), of an intrinsic semiconductor should have an Arrhenius-like temperature dependence, shown in practice to have the form  $G = G_0 e^{-E_g/2kT}$ , where  $E_g$  is the band gap. The conductance of a sample of germanium varied with temperature as indicated below. Estimate the value of  $E_g$ .

|              |        |       |      |
|--------------|--------|-------|------|
| $T/\text{K}$ | 312    | 354   | 420  |
| $G/\text{S}$ | 0.0847 | 0.429 | 2.86 |

**19.17†** J.J. Dannenberg, *et al.* (*J. Phys. Chem.* **100**, 9631 (1996)) carried out theoretical studies of organic molecules consisting of chains of unsaturated four-membered rings. The calculations suggest that such compounds have large numbers of unpaired spins, and that they should therefore have unusual magnetic properties. For example, the lowest-energy state of the five-ring compound  $\text{C}_{22}\text{H}_{14}$  (4) is computed to have  $S = 3$ , but the energies of  $S = 2$  and  $S = 4$  structures are each predicted to be  $50 \text{ kJ mol}^{-1}$  higher in energy. Compute the molar magnetic susceptibility of these three low-lying levels at 298 K. Estimate the molar susceptibility at 298 K if each level is present in proportion to its Boltzmann factor (effectively assuming that the degeneracy is the same for all three of these levels).

4

**19.18†** P.G. Radaelli *et al.* (*Science* **265**, 380 (1994)) report the synthesis and structure of a material that becomes superconducting at temperatures below 45 K. The compound is based on a layered compound  $\text{Hg}_2\text{Ba}_2\text{YCu}_2\text{O}_{8-\delta}$ , which has a tetragonal unit cell with  $a = 0.38606 \text{ nm}$  and  $c = 2.8915 \text{ nm}$ ; each unit cell contains two formula units. The compound is made superconducting by partially replacing Y by Ca, accompanied by a change in unit cell volume by less than 1 per cent. Estimate the Ca content  $x$  in superconducting  $\text{Hg}_2\text{Ba}_2\text{Y}_{1-x}\text{Ca}_x\text{Cu}_2\text{O}_{7.55}$  given that the mass density of the compound is  $7.651 \text{ g cm}^{-3}$ .

### Theoretical problems

**19.19** Show that the separation of the  $(hkl)$  planes in an orthorhombic crystal with sides  $a$ ,  $b$ , and  $c$  is given by eqn 19.3.

**19.20** Show that the volume of a triclinic unit cell of sides  $a$ ,  $b$ , and  $c$  and angles  $\alpha$ ,  $\beta$ , and  $\gamma$  is

$$V = abc(1 - \cos^2 \alpha - \cos^2 \beta - \cos^2 \gamma + 2 \cos \alpha \cos \beta \cos \gamma)^{1/2}$$

Use this expression to derive expressions for monoclinic and orthorhombic unit cells. For the derivation, it may be helpful to use the result from vector analysis that  $V = \mathbf{a} \cdot \mathbf{b} \times \mathbf{c}$  and to calculate  $V^2$  initially.

**19.21** Use mathematical software to draw a graph of the scattering factor  $f$  against  $(\sin \theta)/\lambda$  for an atom of atomic number  $Z$  for which  $\rho(r) = 3Z/4\pi R^3$  for  $0 \leq r \leq R$  and  $\rho(r) = 0$  for  $r > R$ , with  $R$  a parameter that represents the radius of the atom. Explore how  $f$  varies with  $Z$  and  $R$ .

**19.22** Calculate the scattering factor for a hydrogenic atom of atomic number  $Z$  in which the single electron occupies (a) the 1s orbital, (b) the 2s orbital. Radial wavefunctions are given in Table 9.1. Plot  $f$  as a function of  $(\sin \theta)/\lambda$ . *Hint.* Interpret  $4\pi\rho(r)r^2$  as the radial distribution function  $P(r)$  of eqn 9.18.

**19.23** Explore how the scattering factor of Problem 19.22 changes when the actual 1s wavefunction of a hydrogenic atom is replaced by a Gaussian function.

**19.24** Rods of elliptical cross-section with semi-major and -minor axes  $a$  and  $b$  are close-packed as shown in (5). What is the packing fraction? Draw a graph of the packing fraction against the eccentricity  $\varepsilon$  of the ellipse. For an ellipse with semi-major axis  $a$  and semi-minor axis  $b$ ,  $\varepsilon = (1 - b^2/a^2)^{1/2}$ .

5

**19.25** The coordinates of the four I atoms in the unit cell of  $\text{KIO}_4$  are  $(0,0,0)$ ,  $(0, \frac{1}{2}, \frac{1}{2})$ ,  $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ ,  $(\frac{1}{2}, 0, \frac{3}{4})$ . By calculating the phase of the I reflection in the structure factor, show that the I atoms contribute no net intensity to the  $(114)$  reflection.

**19.26** The coordinates, in units of  $a$ , of the A atoms, with scattering factor  $f_A$ , in a cubic lattice are  $(0,0,0)$ ,  $(0,1,0)$ ,  $(0,0,1)$ ,  $(0,1,1)$ ,  $(1,0,0)$ ,  $(1,1,0)$ ,  $(1,0,1)$ , and  $(1,1,1)$ . There is also a B atom, with scattering factor  $f_B$ , at  $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ . Calculate the structure factors  $F_{hkl}$  and predict the form of the powder diffraction pattern when (a)  $f_A = f$ ,  $f_B = 0$ , (b)  $f_B = \frac{1}{2}f_A$ , and (c)  $f_A = f_B = f$ .

**19.27** Derive the Born–Mayer equation (eqn 19.15) by calculating the energy at which  $d(E_p + E_p^*)/dd = 0$ , with  $E_p$  and  $E_p^*$  given by eqns 19.13 and 19.14, respectively.

**19.28** For an isotropic substance, the moduli and Poisson's ratio may be expressed in terms of two parameters  $\lambda$  and  $\mu$  called the *Lamé constants*:

$$E = \frac{\mu(3\lambda + 2\mu)}{\lambda + \mu} \quad K = \frac{3\lambda + 2\mu}{3} \quad G = \mu \quad \nu_p = \frac{\lambda}{2(\lambda + \mu)}$$

Use the Lamé constants to confirm the relations between  $G$ ,  $K$ , and  $E$  given in eqn 19.18.

**19.29** When energy levels in a band form a continuum, the density of states  $\rho(E)$ , the number of levels in an energy range divided by the width of the range, may be written as  $\rho(E) = dk/dE$ , where  $dk$  is the change in the quantum number  $k$  and  $dE$  is the energy change. (a) Use eqn 19.21 to show that

$$\rho(E) = -\frac{(N+1)/2\pi\beta}{\left\{1 - \left(\frac{E - \alpha}{2\beta}\right)^2\right\}^{1/2}}$$

Fig. 19.68

where  $k$ ,  $N$ ,  $\alpha$ , and  $\beta$  have the meanings described in Section 19.9. (b) Use the expression above to show that  $\rho(E)$  becomes infinite as  $E$  approaches  $\alpha \pm 2\beta$ . That is, show that the density of states increases towards the edges of the bands in a one-dimensional metallic conductor.

**19.30** The treatment in Problem 19.29 applies only to one-dimensional solids. In three dimensions, the variation of density of states is more like that shown in Fig. 19.68. Account for the fact that in a three-dimensional solid the greatest density of states lies near the centre of the band and the lowest density at the edges.

**19.31** Here we investigate quantitatively the spectra of molecular solids. We begin by considering a dimer, with each monomer having a single transition with transition dipole moment  $\mu_{\text{mon}}$  and wavenumber  $\bar{\nu}_{\text{mon}}$ . We assume that the ground state wavefunctions are not perturbed as a result of dimerization, and then write the dimer excited state wavefunctions  $\psi_i$  as linear combinations of the excited state wavefunctions  $\psi_1$  and  $\psi_2$  of the monomer:  $\psi_i = c_j \psi_1 + c_k \psi_2$ . Now we write the hamiltonian matrix with diagonal elements set to the energy between the excited and ground state of the monomer (which, expressed as a wavenumber, is simply  $\bar{\nu}_{\text{mon}}$ ), and off-diagonal elements corresponding to the energy of interaction between the transition dipoles. Using the arrangement discussed in (1), we write this interaction energy (as a wavenumber) as:

$$\beta = \frac{\mu_{\text{mon}}^2}{4\pi\epsilon_0 h c r^3} (1 - 3 \cos^2 \theta)$$

It follows that the hamiltonian matrix is

$$\hat{H} = \begin{pmatrix} \bar{\nu}_{\text{mon}} & \beta \\ \beta & \bar{\nu}_{\text{mon}} \end{pmatrix}$$

The eigenvalues of the matrix are the dimer transition wavenumbers  $\bar{\nu}_1$  and  $\bar{\nu}_2$ . The eigenvectors are the wavefunctions for the excited states of the dimer

and have the form  $\begin{pmatrix} c_j \\ c_k \end{pmatrix}$ . (a) The intensity of absorption of incident radiation

is proportional to the square of the transition dipole moment (Section 9.3). The monomer transition dipole moment is  $\mu_{\text{mon}} = \int \psi_1^* \hat{\mu} \psi_0 d\tau = \int \psi_2^* \hat{\mu} \psi_0 d\tau$ , where  $\psi_0$  is the wavefunction of the monomer ground state. Assume that the dimer ground state may also be described by  $\psi_0$  and show that the transition dipole moment  $\mu_i$  of each dimer transition is given by  $\mu_i = \mu_{\text{mon}}(c_j + c_k)$ .

**19.32** (a) Consider a dimer of monomers with  $\mu_{\text{mon}} = 4.00 \text{ D}$ ,  $\bar{\nu}_{\text{mon}} = 25\,000 \text{ cm}^{-1}$ , and  $r = 0.5 \text{ nm}$ . How do the transition wavenumbers  $\bar{\nu}_1$  and  $\bar{\nu}_2$  vary with the angle  $\theta$ ? The relative intensities of the dimer transitions may be estimated by calculating the ratio  $\mu_2^2/\mu_1^2$ . How does this ratio vary with the angle  $\theta$ ? (c) Now expand the treatment given above to a chain of  $N$  monomers ( $N = 5, 10, 15$ , and  $20$ ), with  $\mu_{\text{mon}} = 4.00 \text{ D}$ ,  $\bar{\nu}_{\text{mon}} = 25\,000 \text{ cm}^{-1}$ , and  $r = 0.5 \text{ nm}$ . For simplicity, assume that  $\theta = 0$  and that only nearest neighbours interact with interaction energy  $V$ . For example the hamiltonian matrix for the case  $N = 4$  is

$$\hat{H} = \begin{pmatrix} \bar{\nu}_{\text{mon}} & V & 0 & 0 \\ V & \bar{\nu}_{\text{mon}} & V & 0 \\ 0 & V & \bar{\nu}_{\text{mon}} & V \\ 0 & 0 & V & \bar{\nu}_{\text{mon}} \end{pmatrix}$$

How does the wavenumber of the lowest energy transition vary with size of the chain? How does the transition dipole moment of the lowest energy transition vary with the size of the chain?

**19.33** Show that if a substance responds nonlinearly to two sources of radiation, one of frequency  $\omega_1$  and the other of frequency  $\omega_2$ , then it may give rise to radiation of the sum and difference of the two frequencies. This nonlinear optical phenomenon is known as *frequency mixing* and is used to expand the wavelength range of lasers in laboratory applications, such as spectroscopy and photochemistry.

**19.34** The magnetizability,  $\xi$ , and the volume and molar magnetic susceptibilities can be calculated from the wavefunctions of molecules. For instance, the magnetizability of a hydrogenic atom is given by the expression  $\xi = -(e^2/6m_e)\langle r^2 \rangle$ , where  $\langle r^2 \rangle$  is the (expectation) mean value of  $r^2$  in the atom. Calculate  $\xi$  and  $\chi_m$  for the ground state of a hydrogenic atom.

**19.35** Nitrogen dioxide, a paramagnetic compound, is in equilibrium with its dimer, dinitrogen tetroxide, a diamagnetic compound. Derive an expression in terms of the equilibrium constant,  $K$ , for the dimerization to show how the molar susceptibility varies with the pressure of the sample. Suggest how the susceptibility might be expected to vary as the temperature is changed at constant pressure.

**19.36** An NO molecule has thermally accessible electronically excited states. It also has an unpaired electron, and so may be expected to be paramagnetic. However, its ground state is not paramagnetic because the magnetic moment of the orbital motion of the unpaired electron almost exactly cancels the spin magnetic moment. The first excited state (at  $121 \text{ cm}^{-1}$ ) is paramagnetic because the orbital magnetic moment adds to, rather than cancels, the spin magnetic moment. The upper state has a magnetic moment of  $2\mu_B$ . Because the upper state is thermally accessible, the paramagnetic susceptibility of NO shows a pronounced temperature dependence even near room temperature. Calculate the molar paramagnetic susceptibility of NO and plot it as a function of temperature.

### Applications to: biochemistry and nanoscience

**19.37** Although the crystallization of large biological molecules may not be as readily accomplished as that of small molecules, their crystal lattices are no different. Tobacco seed globulin forms face-centred cubic crystals with unit cell dimension of  $12.3 \text{ nm}$  and a density of  $1.287 \text{ g cm}^{-3}$ . Determine its molar mass.

**19.38** What features in an X-ray diffraction pattern suggest a helical conformation for a biological macromolecule? Use Fig. 19.42 to deduce as much quantitative information as you can about the shape and size of a DNA molecule.

**19.39** A transistor is a semiconducting device that is commonly used either as a switch or an amplifier of electrical signals. Prepare a brief report on the design of a nanometre-sized transistor that uses a carbon nanotube as a component. A useful starting point is the work summarized by S.J. Tans *et al.* (*Nature* 393, 49 (1998)).

**19.40** The tip of a scanning tunnelling microscope can be used to move atoms on a surface. The movement of atoms and ions depends on their ability to leave one position and stick to another, and therefore on the energy changes that occur. As an illustration, consider a two-dimensional square lattice of univalent positive and negative ions separated by  $200 \text{ pm}$ , and consider a cation on top of this array. Calculate, by direct summation, its Coulombic interaction when it is in an empty lattice point directly above an anion.

## MATHEMATICAL BACKGROUND 7

## Fourier series and Fourier transforms

Some of the most versatile mathematical functions are the trigonometric functions sine and cosine. As a result, it is often very helpful to express a general function as a linear combination of these functions and then to carry out manipulations on the resulting series. Because sines and cosines have the form of waves, the linear combinations often have a straightforward physical interpretation. Throughout this discussion, the function  $f(x)$  is real.

### MB7.1 Fourier series

A *Fourier series* is a linear combination of sines and cosines that replicates a periodic function:

$$f(x) = \frac{1}{2}a_0 + \sum_{n=1}^{\infty} \left\{ a_n \cos \frac{2n\pi x}{L} + b_n \sin \frac{2n\pi x}{L} \right\} \quad (\text{MB7.1})$$

A periodic function is one that repeats periodically, such that  $f(x + 2L) = f(x)$  where  $2L$  is the period. Although it is perhaps not surprising that sines and cosines can be used to replicate continuous functions, it turns out that—with certain limitations—they can also be used to replicate discontinuous functions. The coefficients in eqn MB7.1 are found by making use of the orthogonality of the sine and cosine functions

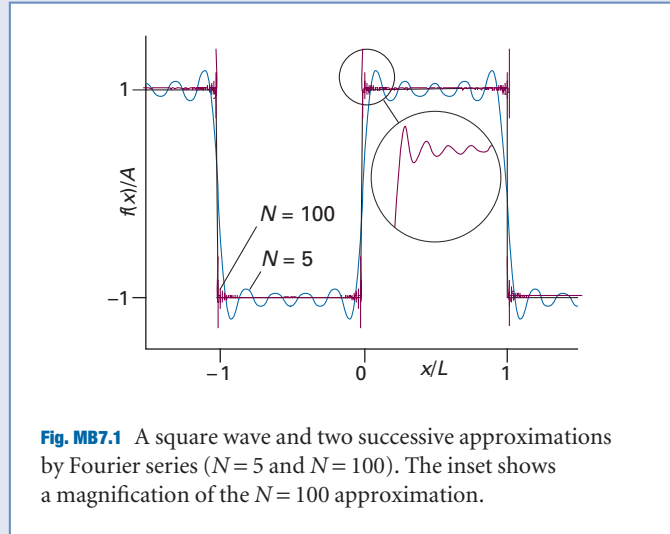

$$\int_{-L}^L \sin \frac{m\pi x}{L} \cos \frac{m\pi x}{L} dx = 0 \quad (\text{MB7.2a})$$

and the integrals

$$\begin{aligned} \int_{-L}^L \sin \frac{m\pi x}{L} \sin \frac{n\pi x}{L} dx &= \int_{-L}^L \cos \frac{m\pi x}{L} \cos \frac{n\pi x}{L} dx \\ &= L\delta_{mn} \end{aligned} \quad (\text{MB7.2b})$$

where  $\delta_{mn} = 1$  if  $m = n$  and 0 if  $m \neq n$ . Thus, multiplication of both sides of eqn MB7.1 by  $\cos(k\pi x/L)$  and integration from  $-L$  to  $L$  gives an expression for the coefficient  $a_k$ , and multiplication by  $\sin(k\pi x/L)$  and integration likewise gives an expression for  $b_k$ :

$$\begin{aligned} a_k &= \frac{1}{L} \int_{-L}^L f(x) \cos \frac{k\pi x}{L} dx & k = 0, 1, 2, \dots \\ b_k &= \frac{1}{L} \int_{-L}^L f(x) \sin \frac{k\pi x}{L} dx & k = 0, 1, 2, \dots \end{aligned} \quad (\text{MB7.3})$$

**Fig. MB7.1** A square wave and two successive approximations by Fourier series ( $N = 5$  and  $N = 100$ ). The inset shows a magnification of the  $N = 100$  approximation.

#### • A brief illustration

Figure MB7.1 shows a graph of a square wave of amplitude  $A$  that is periodic between  $-L$  and  $L$ . The mathematical form of the wave is

$$f(x) = \begin{cases} -A & -L \leq x \leq 0 \\ +A & 0 \leq x \leq L \end{cases}$$

The coefficients  $a$  are all zero because  $f(x)$  is antisymmetric ( $f(-x) = -f(x)$ ) whereas all the cosine functions are symmetric ( $\cos(-x) = \cos(x)$ ) and so cosine waves make no contribution to the sum. The coefficients  $b$  are obtained from

$$\begin{aligned} b_k &= \frac{1}{L} \int_{-L}^L f(x) \sin \frac{k\pi x}{L} dx \\ &= \frac{1}{L} \int_{-L}^0 (-A) \sin \frac{k\pi x}{L} dx + \frac{1}{L} \int_0^L A \sin \frac{k\pi x}{L} dx = \frac{2A}{k\pi} \{1 - (-1)^k\} \end{aligned}$$

The final expression has been formulated to acknowledge that the two integrals cancel when  $k$  is even but add together when  $k$  is odd. Therefore,

$$f(x) = \frac{2A}{\pi} \sum_{k=1}^N \frac{1 - (-1)^k}{k} \sin \frac{k\pi x}{L} = \frac{4A}{\pi} \sum_{n=1}^N \frac{1}{2n-1} \sin \frac{(2n-1)\pi x}{L} =$$

with  $N \rightarrow \infty$ . The sum over  $n$  is the same as the sum over  $k$ ; in the latter, terms with  $k$  even are all zero. This function is plotted in Fig. MB7.1 for two values of  $N$  to show how the series becomes more faithful to the original function as  $N$  increases. •

**Self-test MB7.1** Repeat the analysis for a saw-tooth wave,  $f(x) = Ax$  in the range  $-L \leq x < L$  and  $f(x + 2L) = f(x)$  elsewhere. Use graphing software to depict the result.

$$[f(x) = (2AL/\pi) \sum_{n=1}^{\infty} \{(-1)^{n+1}/n\} \sin(n\pi x/L), \text{ Fig. MB7.2}]$$

**Fig. MB7.2** A saw-tooth function and its representation as a Fourier series with two successive approximations ( $N = 5$  and  $N = 10$ ).

### MB7.2 Fourier transforms

The Fourier series in eqn MB7.1 can be expressed in a more succinct manner if we allow the coefficients to be complex numbers and make use of *de Moivre's relation*

$$e^{in\pi x/L} = \cos \frac{n\pi x}{L} + i \sin \frac{n\pi x}{L} \quad (\text{MB7.4})$$

for then we may write

$$f(x) = \sum_{n=-\infty}^{\infty} c_n e^{in\pi x/L} \quad c_n = \frac{1}{2L} \int_{-L}^L f(x) e^{-in\pi x/L} dx \quad (\text{MB7.5})$$

This complex formalism is well suited to the extension of this discussion to functions with periods that become infinite. If a period is infinite, we are effectively dealing with a non-periodic function, such as the decaying exponential function  $e^{-x}$ .

We write  $\delta k = \pi/L$  and consider the limit as  $L \rightarrow \infty$  and therefore  $\delta k \rightarrow 0$ : that is, eqn MB7.5 becomes

$$\begin{aligned} f(x) &= \lim_{L \rightarrow \infty} \sum_{n=-\infty}^{\infty} \left\{ \frac{1}{2L} \int_{-L}^L f(x') e^{-in\pi x'/L} dx' \right\} e^{in\pi x/L} \\ &= \lim_{\delta k \rightarrow 0} \sum_{n=-\infty}^{\infty} \left\{ \frac{\delta k}{2\pi} \int_{-\pi/\delta k}^{\pi/\delta k} f(x') e^{-in\delta k x'} dx' \right\} e^{in\delta k x} \quad (\text{MB7.6}) \\ &= \frac{1}{2\pi} \lim_{\delta k \rightarrow 0} \sum_{n=-\infty}^{\infty} \left\{ \int_{-\infty}^{\infty} f(x') e^{-in\delta k (x'-x)} dx' \right\} \delta k \end{aligned}$$

In the last line we have anticipated that the limits of the integral will become infinite. At this point we should recognize that a formal definition of an integral is the sum of the value of a function at a series of infinitely spaced points multiplied by the separation of each point (Fig. MB7.3):

$$\int_a^b F(k) dk = \lim_{\delta k \rightarrow 0} \sum_{n=-\infty}^{\infty} F(n\delta k) \delta k \quad (\text{MB7.7})$$

**Fig. MB7.3** The formal definition of an integral as the sum of the value of a function at a series of infinitely spaced points multiplied by the separation of each point.

Exactly this form appears on the right-hand side of eqn MB7.6, so we can write that equation as

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \tilde{f}(k) e^{ikx} dk \quad \text{where} \quad \tilde{f}(k) = \int_{-\infty}^{\infty} f(x') e^{-ikx'} dx' \quad (\text{MB7.8})$$

(At this stage we can drop the prime on  $x$ .) We call the function  $\tilde{f}(k)$  the *Fourier transform* of  $f(x)$ ; the original function  $f(x)$  is the *inverse Fourier transform* of  $\tilde{f}(k)$ .

#### • A brief illustration

The Fourier transform of the symmetrical exponential function  $f(x) = e^{-a|x|}$  is

$$\begin{aligned} \tilde{f}(k) &= \int_{-\infty}^{\infty} e^{-a|x|} e^{-ikx} dx \\ &= \int_{-\infty}^0 e^{ax-ikx} dx + \int_0^{\infty} e^{-ax-ikx} dx \\ &= \frac{1}{a-ik} + \frac{1}{a+ik} = \frac{2a}{a^2+k^2} \end{aligned}$$

The original function and its Fourier transform are drawn in Fig. MB7.4. •

**Self-test MB7.2** Evaluate the Fourier transform of the Gaussian function  $e^{-a^2 x^2}$ .

$$[\tilde{f}(k) = (\pi/a^2)^{1/2} e^{-k^2/4a^2}]$$

The physical interpretation of eqn MB7.8 is that  $f(x)$  is expressed as a superposition of harmonic (sine and cosine) functions of wavelength  $\lambda = 2\pi/k$ , and that the weight of each

**Fig. MB7.4** (a) The symmetrical exponential function  $f(x) = e^{-a|x|}$  and (b) its Fourier transform for two values of the decay constant  $a$ . Note how the function with the more rapid decay has a Fourier transform richer in short-wavelength (high  $k$ ) components.

constituent function is given by the Fourier transform at the corresponding value of  $k$ . This interpretation is consistent with the calculation in the *brief illustration*. As we see from Fig. MB7.4, when the exponential function falls away rapidly, the Fourier

transform is extended to high values of  $k$ , corresponding to a significant contribution from short-wavelength waves. When the exponential function decays only slowly, the most significant contributions to the superposition come from long-wavelength components, which is reflected in the Fourier transform, with its predominance of small- $k$  contributions in this case. In general, a slowly varying function has a Fourier transform with significant contributions from small- $k$  components.

### MB7.3 The convolution theorem

A final point concerning the properties of Fourier transforms is the *convolution theorem*, which states that, if a function is the ‘convolution’ of two other functions, that is if

$$F(x) = \int_{-\infty}^{\infty} f_1(x')f_2(x-x')dx' \quad (\text{MB7.9a})$$

then the Fourier transform of  $F(x)$  is the product of the Fourier transforms of its component functions:

$$\tilde{F}(k) = \tilde{f}_1(k)\tilde{f}_2(k) \quad (\text{MB7.9b})$$

#### • A brief illustration

If  $F(x)$  is the convolution of two Gaussian functions,

$$F(x) = \int_{-\infty}^{\infty} e^{-a^2x'^2} e^{-b^2(x-x')^2} dx'$$

then from Self-test MB7.2 we can immediately write its transform as

$$\tilde{F}(k) = \left(\frac{\pi}{a^2}\right)^{1/2} e^{-k^2/4a^2} \left(\frac{\pi}{b^2}\right)^{1/2} e^{-k^2/4b^2} = \frac{\pi}{ab} e^{-(k^2/4)(1/a^2+1/b^2)} \bullet$$

## PART 3 Change

Part 3 considers the processes by which change occurs. We prepare the ground for a discussion of the rates of reactions by considering the motion of molecules in gases and in liquids. Then we establish the precise meaning of reaction rate, and see how the overall rate, and the complex behaviour of some reactions, may be expressed in terms of elementary steps and the atomic events that take place when molecules meet. Of enormous importance in both industry and biology is the control of reaction rates by catalysis, which we discuss in the last chapter of the text.

# Molecules in motion

# 20

One of the simplest types of molecular motion to describe is the random motion of molecules of a perfect gas. We see that a simple theory accounts for the pressure of a gas and the rates at which molecules and energy migrate through gases. Molecular mobility is particularly important in liquids. Another simple kind of motion is the largely uniform motion of ions in solution in the presence of an electric field. Molecular and ionic motion have common features and, by considering them from a more general viewpoint, we derive expressions that govern the migration of properties through matter. One of the most useful consequences of this general approach is the formulation of the diffusion equation, which is an equation that shows how matter and energy spread through media of various kinds. Finally, we build a simple model for all types of molecular motion, in which the molecules migrate in a series of small steps, and see that it accounts for many of the properties of migrating molecules in both gases and condensed phases.

This chapter provides techniques for discussing the motion of all kinds of particles in all kinds of fluids. We set the scene by considering a simple type of motion, that of molecules in a perfect gas, and go on to see that molecular motion in liquids shows a number of similarities. We shall concentrate on the **transport properties** of a substance, its ability to transfer matter, energy, or some other property from one place to another. Four examples of transport properties are

**Diffusion**, the migration of matter down a concentration gradient.

**Thermal conduction**, the migration of energy down a temperature gradient.

**Electric conduction**, the migration of electric charge up or down an electrical potential gradient.

**Viscosity**, the migration of linear momentum down a velocity gradient.

It is convenient to include in the discussion **effusion**, the emergence of a gas from a container through a small hole.

## Molecular motion in gases

Here we present the kinetic model of a perfect gas as a starting point for the discussion of its transport properties. In the **kinetic model** of gases we assume that the only contribution to the energy of the gas is from the kinetic energies of the molecules. The kinetic model is one of the most remarkable—and arguably most beautiful—models in physical chemistry for, from a set of very slender assumptions, powerful quantitative conclusions can be deduced.

## 20.1 The kinetic model of gases

**Key points** The kinetic model of a gas considers only the contribution to the energy from the kinetic energies of the molecules. (a) Important results from the model include expressions for the pressure and the root mean square speed. The Maxwell distribution of speeds gives the fraction of molecules that have speeds in a specified range. (b) The collision frequency is the number of collisions made by a molecule in an interval divided by the length of the interval. (c) The mean free path is the average distance a molecule travels between collisions.

The kinetic model is based on three assumptions:

1. The gas consists of molecules of mass  $m$  in ceaseless random motion.
2. The size of the molecules is negligible, in the sense that their diameters are much smaller than the average distance travelled between collisions.
3. The molecules interact only through brief, infrequent, and elastic collisions.

An **elastic collision** is a collision in which the total translational kinetic energy of the molecules is conserved.

### (a) Pressure and molecular speeds

From the very economical assumptions of the kinetic model, we show in the following *Justification* that the pressure and volume of the gas are related by

$$pV = \frac{1}{3}nMc^2 \quad \text{The pressure of a perfect gas according to the kinetic model} \quad (20.1)^{\circ}$$

where  $M = mN_A$ , the molar mass of the molecules, and  $c$  is the **root mean square speed** of the molecules, the square root of the mean of the squares of the speeds,  $v$ , of the molecules:

$$c = \langle v^2 \rangle^{1/2} \quad \text{Definition of the root mean square speed} \quad [20.2]$$

**Fig. 20.1** The pressure of a gas arises from the impact of its molecules on the walls. In an elastic collision of a molecule with a wall perpendicular to the  $x$ -axis, the  $x$ -component of velocity is reversed but the  $y$ - and  $z$ -components are unchanged.

**Fig. 20.2** A molecule will reach the wall on the right within an interval  $\Delta t$  if it is within a distance  $v_x \Delta t$  of the wall and travelling to the right.

#### Justification 20.1 The pressure of a gas according to the kinetic model

Consider the arrangement in Fig. 20.1. When a particle of mass  $m$  that is travelling with a component of velocity  $v_x$  parallel to the  $x$ -axis collides with the wall on the right and is reflected, its linear momentum (the product of its mass and its velocity) changes from  $mv_x$  before the collision to  $-mv_x$  after the collision (when it is travelling in the opposite direction). The  $x$ -component of momentum therefore changes by  $2mv_x$  on each collision (the  $y$ - and  $z$ -components are unchanged). Many molecules collide with the wall in an interval  $\Delta t$ , and the total change of momentum is the product of the change in momentum of each molecule multiplied by the number of molecules that reach the wall during the interval.

Because a molecule with velocity component  $v_x$  can travel a distance  $v_x \Delta t$  along the  $x$ -axis in an interval  $\Delta t$ , all the molecules within a distance  $v_x \Delta t$  of the wall will strike it if they are travelling towards it (Fig. 20.2). It follows that, if the wall has area  $A$ , then all the particles in a volume  $A \times v_x \Delta t$  will reach the wall (if they are travelling towards it). The number density of particles is  $nN_A/V$ , where  $n$  is the total amount of molecules in the container of volume  $V$  and  $N_A$  is Avogadro's constant, so the number of molecules in the volume  $Av_x \Delta t$  is  $(nN_A/V) \times Av_x \Delta t$ .

At any instant, half the particles are moving to the right and half are moving to the left. Therefore, the average number of collisions with the wall during the interval  $\Delta t$

is  $\frac{1}{2}nN_AAv_x\Delta t/V$ . The total momentum change in that interval is the product of this number and the change  $2mv_x$ :

$$\text{Momentum change} = \frac{nN_AAv_x\Delta t}{2V} \times 2mv_x = \frac{nmAN_Av_x^2\Delta t}{V} = \frac{nMAv_x^2\Delta t}{V}$$

where  $M = mN_A$ .

Next, to find the force, we calculate the rate of change of momentum, which is this change of momentum divided by the interval  $\Delta t$  during which it occurs:

$$\text{Rate of change of momentum} = \frac{nMAv_x^2}{V}$$

This rate of change of momentum is equal to the force (by Newton's second law of motion). It follows that the pressure, the force divided by the area, is

$$\text{Pressure} = \frac{nMv_x^2}{V}$$

Not all the molecules travel with the same velocity, so the detected pressure,  $p$ , is the average (denoted  $\langle \cdot \cdot \rangle$ ) of the quantity just calculated:

$$p = \frac{nM\langle v_x^2 \rangle}{V}$$

This expression already resembles the perfect gas equation of state.

To write an expression of the pressure in terms of the root mean square speed,  $c$ , we begin by writing the speed of a single molecule,  $v$ , as  $v = v_x^2 + v_y^2 + v_z^2$ . Because the root-mean-square speed,  $c$ , is defined as  $c = \langle v^2 \rangle^{1/2}$  (eqn 20.2), it follows that

$$c^2 = \langle v^2 \rangle = \langle v_x^2 \rangle + \langle v_y^2 \rangle + \langle v_z^2 \rangle$$

However, because the molecules are moving randomly, all three averages are the same. It follows that  $c^2 = 3\langle v_x^2 \rangle$ . Equation 20.1 follows immediately by substituting  $\langle v_x^2 \rangle = \frac{1}{3}c^2$  into  $p = nM\langle v_x^2 \rangle/V$ .

Equation 20.1 is one of the key results of the kinetic model. We see that, if the root mean square speed of the molecules depends only on the temperature, then at constant temperature

$$pV = \text{constant}$$

which is the content of Boyle's law (Section 1.2). Moreover, for eqn 20.1 to be the equation of state of a perfect gas, its right-hand side must be equal to  $nRT$ . It follows that the root mean square speed of the molecules in a gas at a temperature  $T$  must be

$$c = \left( \frac{3RT}{M} \right)^{1/2} \quad \boxed{\text{Root mean square speed in a perfect gas}} \quad (20.3)^\circ$$

We can conclude that the root mean square speed of the molecules of a gas is proportional to the square root of the temperature and inversely proportional to the square root of the molar mass. That is, the higher the temperature, the higher the root mean square speed of the molecules, and, at a given temperature, heavy molecules travel more slowly than light molecules.

### • A brief illustration

The root mean square speed of  $\text{N}_2$  molecules ( $M = 28.02 \text{ g mol}^{-1}$ ) at 298 K is found from eqn 20.3 to be

$$c = \left( \frac{3 \times 8.3145 \text{ J K}^{-1} \text{ mol}^{-1} \times 298 \text{ K}}{28.02 \times 10^{-3} \text{ kg mol}^{-1}} \right)^{1/2} = 515 \text{ m s}^{-1}$$

Sound waves are pressure waves, and for them to propagate the molecules of the gas must move to form regions of high and low pressure. Therefore, we should expect the speed of sound in air to be approximately  $500 \text{ m s}^{-1}$ . The experimental value is  $340 \text{ m s}^{-1}$ . •

Equation 20.3 is an expression for the mean square speed of molecules. However, in an actual gas the speeds of individual molecules span a wide range, and the collisions in the gas continually redistribute the speeds among the molecules. Before a collision, a molecule may be travelling rapidly, but after a collision it may be accelerated to a very high speed, only to be slowed again by the next collision. The fraction of molecules that have speeds in the range  $v$  to  $v + dv$  is proportional to the width of the range, and is written  $f(v)dv$ , where  $f(v)$  is called the **distribution of speeds**. Note that, in common with other distribution functions,  $f(v)$  acquires physical significance only after it is multiplied by the range of speeds of interest.

The precise form of  $f$  for molecules of a gas at a temperature  $T$  was derived by J.C. Maxwell, and is

$$f(v) = 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} v^2 e^{-Mv^2/2RT} \quad \text{Maxwell distribution of speeds} \quad (20.4)$$

This expression is called the **Maxwell distribution of speeds** and is derived in the following *Justification*. Let's consider its features, which are also shown pictorially in Fig. 20.3:

**Fig. 20.3** The distribution of molecular speeds with temperature and molar mass. Note that the most probable speed (corresponding to the peak of the distribution) increases with temperature and with decreasing molar mass, and simultaneously the distribution becomes broader.

**InterActivity** (a) Plot different distributions by keeping the molar mass constant at  $100 \text{ g mol}^{-1}$  and varying the temperature of the sample between 200 K and 2000 K. (b) Use mathematical software or the *Living graph* applet from the text's web site to evaluate numerically the fraction of molecules with speeds in the range  $100 \text{ m s}^{-1}$  to  $200 \text{ m s}^{-1}$  at 300 K and 1000 K. (c) Based on your observations, provide a molecular interpretation of temperature.

1. Equation 20.4 includes a decaying exponential function, the term  $e^{-Mv^2/2RT}$ . Its presence implies that the fraction of molecules with very high speeds will be very small because  $e^{-x^2}$  becomes very small when  $x^2$  is large.

2. The factor  $M/2RT$  multiplying  $v^2$  in the exponent is large when the molar mass,  $M$ , is large, so the exponential factor goes most rapidly towards zero when  $M$  is large. That is, heavy molecules are unlikely to be found with very high speeds.

3. The opposite is true when the temperature,  $T$ , is high: then the factor  $M/2RT$  in the exponent is small, so the exponential factor falls towards zero relatively slowly as  $v$  increases. In other words, a greater fraction of the molecules can be expected to have high speeds at high temperatures than at low temperatures.

4. A factor  $v^2$  (the term before the  $e$ ) multiplies the exponential. This factor goes to zero as  $v$  goes to zero, so the fraction of molecules with very low speeds will also be very small.

5. The remaining factors (the term in parentheses in eqn 20.4 and the  $4\pi$ ) simply ensure that, when we add together the fractions over the entire range of speeds from zero to infinity, then we get 1.

To use eqn 20.4 to calculate the fraction of molecules in a given narrow range of speeds,  $\Delta v$ , we evaluate  $f(v)$  at the speed of interest, then multiply it by the width of the range of speeds of interest, that is, we form  $f(v)\Delta v$ . To use the distribution to calculate the fraction in a range of speeds that is too wide to be treated as infinitesimal, we evaluate the integral:

$$\text{Fraction in the range } v_1 \text{ to } v_2 = \int_{v_1}^{v_2} f(v) dv \quad (20.5)$$

This integral is the area under the graph of  $f$  as a function of  $v$  and, except in special cases, has to be evaluated numerically by using mathematical software (Fig. 20.4).

**Justification 20.2** *The Maxwell distribution of speeds*

The Boltzmann distribution is a key result of physical chemistry; it was introduced in *Fundamentals F.5* and treated fully in Section 15.1. It implies that the fraction of molecules with velocity components  $v_x$ ,  $v_y$ ,  $v_z$  is proportional to an exponential function of their kinetic energy,  $E_k$ , which is

$$E_k = \frac{1}{2}mv_x^2 + \frac{1}{2}mv_y^2 + \frac{1}{2}mv_z^2$$

Therefore, we can use the relation  $a^{x+y+z+\dots} = a^x a^y a^z \dots$  to write

$$f = K e^{-E_k/kT} = K e^{-(\frac{1}{2}mv_x^2 + \frac{1}{2}mv_y^2 + \frac{1}{2}mv_z^2)/kT} = K e^{-mv_x^2/2kT} e^{-mv_y^2/2kT} e^{-mv_z^2/2kT}$$

where  $K$  is a constant of proportionality (at constant temperature) and  $f dv_x dv_y dv_z$  is the fraction of molecules in the velocity range  $v_x$  to  $v_x + dv_x$ ,  $v_y$  to  $v_y + dv_y$ , and  $v_z$  to  $v_z + dv_z$ . We see that the fraction factorizes into three factors, one for each axis, and we can write  $f = f(v_x)f(v_y)f(v_z)$  with

$$f(v_x) = K^{1/3} e^{-mv_x^2/2kT}$$

and likewise for the two other directions.

To determine the constant  $K$ , we note that a molecule must have a velocity somewhere in the range  $-\infty < v_x < \infty$ , so

$$\int_{-\infty}^{\infty} f(v_x) dv_x = 1$$

Substitution of the expression for  $f(v_x)$  then gives

$$1 = K^{1/3} \int_{-\infty}^{\infty} e^{-mv_x^2/2kT} dv_x = K^{1/3} \left( \frac{2\pi kT}{m} \right)^{1/2}$$

where we have used the standard integral

$$\int_{-\infty}^{\infty} e^{-ax^2} dx = \left( \frac{\pi}{a} \right)^{1/2}$$

Therefore,  $K = (m/2\pi kT)^{3/2} = (M/2\pi RT)^{3/2}$ , where  $M$  is the molar mass of the molecules. At this stage we know that

$$f(v_x) = \left( \frac{M}{2\pi RT} \right)^{1/2} e^{-Mv_x^2/2RT} \quad (20.6)$$

The probability that a molecule has a velocity in the range  $v_x$  to  $v_x + dv_x$ ,  $v_y$  to  $v_y + dv_y$ ,  $v_z$  to  $v_z + dv_z$  is the product of these individual probabilities:

$$f(v_x)f(v_y)f(v_z)dv_x dv_y dv_z = \left( \frac{M}{2\pi RT} \right)^{3/2} e^{-Mv^2/2RT} dv_x dv_y dv_z$$

where  $v^2 = v_x^2 + v_y^2 + v_z^2$ . The probability  $f(v)dv$  that the molecules have a speed in the range  $v$  to  $v + dv$  regardless of direction is the sum of the probabilities that the velocity lies in any of the volume elements  $dv_x dv_y dv_z$  forming a spherical shell of radius  $v$  and thickness  $dv$  (Fig. 20.5). The sum of the volume elements on the right-hand side of the last equation is the volume of this shell,  $4\pi v^2 dv$ . Therefore, the probability that it is in a volume element  $dv_x dv_y dv_z$  at a distance  $v$  from the origin

$$f(v) = 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} v^2 e^{-Mv^2/2RT}$$

as given in eqn 20.4.

**Fig. 20.4** To calculate the probability that a molecule will have a speed in the range  $v_1$  to  $v_2$ , we integrate the distribution between those two limits; the integral is equal to the area of the curve between the limits, as shown shaded here.

**Fig. 20.5** To evaluate the probability that a molecule has a speed in the range  $v$  to  $v + dv$ , we evaluate the total probability that the molecule will have a speed that is anywhere on the surface of a sphere of radius  $v = (v_x^2 + v_y^2 + v_z^2)^{1/2}$  by summing the probabilities that it is in a volume element  $dv_x dv_y dv_z$  at a distance  $v$  from the origin.

**Example 20.1** Calculating the mean speed of molecules in a gas

What is the mean speed,  $\bar{c}$ , of  $\text{N}_2$  molecules in air at  $25^\circ\text{C}$ ?

**Method** A mean speed is calculated by multiplying each speed by the fraction of molecules that have that speed, and then adding all the products together. When the speed varies over a continuous range, the sum is replaced by an integral. To employ this approach here, we note that the fraction of molecules with a speed in the range  $v$  to  $v + dv$  is  $f(v)dv$ , so the product of this fraction and the speed is  $vf(v)dv$ . The mean speed,  $\bar{c}$ , is obtained by evaluating the integral

$$\bar{c} = \int_{-\infty}^{\infty} vf(v)dv$$

with  $f(v)$  given in eqn 20.4.

**Answer** The integral required is

$$\begin{aligned}\bar{c} &= 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} \int_0^{\infty} v^3 e^{-Mv^2/2RT} dv \\ &= 4\pi \left( \frac{M}{2\pi RT} \right)^{3/2} \times \frac{1}{2} \left( \frac{2RT}{M} \right)^2 = \left( \frac{8RT}{\pi M} \right)^{1/2}\end{aligned}$$

where we have used the standard result from tables of integrals (or software) that

$$\int_0^{\infty} x^3 e^{-ax^2} dx = \frac{1}{2a^2}$$

Substitution of the data then gives

$$\bar{c} = \left( \frac{8 \times (8.3141 \text{ J K}^{-1} \text{ mol}^{-1}) \times (298 \text{ K})}{\pi \times (28.02 \times 10^{-3} \text{ kg mol}^{-1})} \right)^{1/2} = 475 \text{ m s}^{-1}$$

where we have used  $1 \text{ J} = 1 \text{ kg m}^2 \text{ s}^{-2}$ .

**Self-test 20.1** Evaluate the root mean square speed of the molecules by integration. You will need the integral

$$\int_0^{\infty} x^4 e^{-ax^2} dx = \frac{3}{8} \left( \frac{\pi}{a^5} \right)^{1/2} \quad [c = (3RT/M)^{1/2}, 515 \text{ m s}^{-1}]$$

As shown in Example 20.1, we can use the Maxwell distribution to evaluate the mean speed,  $\bar{c}$ , of the molecules in a gas:

$$\bar{c} = \left( \frac{8RT}{\pi M} \right)^{1/2} \quad \text{Mean speed} \quad (20.7)$$

We can identify the **most probable speed**,  $c^*$ , by differentiating  $f$  with respect to  $v$  and looking for the value of  $v$  at which the derivative is zero (other than at  $v = 0$  and  $v = \infty$ ):

$$c^* = \left( \frac{2RT}{M} \right)^{1/2} \quad \text{Most probable speed} \quad (20.8)$$

Figure 20.6 summarizes these results. Note that the mean speed is the value of  $v$  that divides the distribution into two equal areas.

**Fig. 20.6** A summary of the conclusions that can be deduced from the Maxwell distribution for molecules of molar mass  $M$  at a temperature  $T$ :  $c^*$  is the most probable speed,  $\bar{c}$  is the mean speed, and  $c$  is the root mean square speed.

The **relative mean speed**,  $\bar{c}_{\text{rel}}$ , the mean speed with which one molecule approaches another, can also be calculated from the distribution:

$$\bar{c}_{\text{rel}} = 2^{1/2} \bar{c} \quad \text{Relative mean speed} \quad (20.9)$$

This result is much harder to derive, but the diagram in Fig. 20.7 should help to show that it is plausible. The last result can also be generalized to the relative mean speed of two dissimilar molecules of masses  $m_A$  and  $m_B$ :

$$\bar{c}_{\text{rel}} = \left( \frac{8kT}{\pi\mu} \right)^{1/2} \quad \mu = \frac{m_A m_B}{m_A + m_B} \quad \text{Relative mean speed} \quad (20.10)$$

Note that the molecular masses (not the molar masses) and Boltzmann's constant,  $k = R/N_A$ , appear in this expression; the quantity  $\mu$  is called the **reduced mass** of the molecules. Equation 20.10 turns into eqn 20.9 when the molecules are identical (that is,  $m_A = m_B = m$ , so  $\mu = \frac{1}{2}m$ ).

### (b) The collision frequency

A qualitative picture of the events taking place in a gas was first described in Section 1.2. The kinetic model enables us to make that picture more quantitative. In particular, it enables us to calculate the frequency with which molecular collisions occur and the distance a molecule travels on average between collisions.

We count a 'hit' whenever the centres of two molecules come within a distance  $d$  of each other, where  $d$ , the **collision diameter**, is of the order of the actual diameters of the molecules (for impenetrable hard spheres  $d$  is the diameter). As we show in the following *Justification*, we can use kinetic model to deduce that the **collision frequency**,  $z$ , the number of collisions made by one molecule divided by the time interval during which the collisions are counted, when there are  $N$  molecules in a volume  $V$  is

$$z = \sigma \bar{c}_{\text{rel}} \mathcal{N} \quad \text{Collision frequency} \quad (20.11a)^{\circ}$$

with  $\mathcal{N} = N/V$  and  $\bar{c}_{\text{rel}}$  given in eqn 20.10. The area  $\sigma = \pi d^2$  is called the **collision cross-section** of the molecules. Some typical collision cross-sections are given in Table 20.1. In terms of the pressure

$$z = \frac{\sigma \bar{c}_{\text{rel}} p}{kT} \quad \text{Collision frequency in terms of the pressure} \quad (20.11b)^{\circ}$$

#### Justification 20.3 Using the kinetic model to calculate the collision frequency

When a molecule travels through a gas it sweeps out a 'collision tube' of area  $\sigma = \pi d^2$  and length  $\lambda = \bar{c}_{\text{rel}} \Delta t$  where  $\bar{c}_{\text{rel}}$  is the relative velocity and  $\Delta t$  is the interval before the first collision (Fig. 20.8). There is one molecule in this tube of volume  $\sigma \lambda$ , so the number density is  $1/\sigma \lambda = 1/\sigma \bar{c}_{\text{rel}} \Delta t$ . This number density must be equal to the bulk number density,  $\mathcal{N} = N/V = p/kT$ , so from  $p/kT = 1/\sigma \bar{c}_{\text{rel}} \Delta t$  we can infer that  $\Delta t = kT/\sigma \bar{c}_{\text{rel}} p$ . The collision frequency,  $z$ , is the inverse of the time between collisions, so  $z = 1/\Delta t = \sigma \bar{c}_{\text{rel}} p/kT$ , as in eqn 20.11b.

Equation 20.11a shows that, at constant volume (and therefore constant number density), the collision frequency increases with increasing temperature. The reason

**Fig. 20.7** A simplified version of the argument to show that the relative mean speed of molecules in a gas is related to the mean speed. When the molecules are moving in the same direction, the relative mean speed is zero; it is  $2v$  when the molecules are approaching each other. A typical mean direction of approach is from the side, and the mean speed of approach is then  $2^{1/2}v$ . The last direction of approach is the most characteristic, so the mean speed of approach can be expected to be about  $2^{1/2}v$ . This value is confirmed by more detailed calculation.

#### A brief comment

The reduced mass arises whenever relative motion of two particles is encountered. It also occurs in the hydrogen atom when considering the relative motion of the electron and nucleus (Section 9.1) and in the description of the vibration of a diatomic molecule (Section 12.8).

**Table 20.1\*** Collision cross-sections

|                        | $\sigma/\text{nm}^2$ |
|------------------------|----------------------|
| $\text{C}_6\text{H}_6$ | 0.88                 |
| $\text{CO}_2$          | 0.52                 |
| He                     | 0.21                 |
| $\text{N}_2$           | 0.43                 |

\* More values are given in the *Data section*.

**Fig. 20.8** The calculation of the collision frequency and the mean free path in the kinetic theory of gases.

for this increase is that the relative mean speed increases with temperature (eqns 20.9 and 20.10). Equation 20.11b shows that, at constant temperature, the collision frequency is proportional to the pressure. Such a proportionality is plausible for, the greater the pressure, the greater the number density of molecules in the sample, and the rate at which they encounter one another is greater even though their average speed remains the same. For an  $\text{N}_2$  molecule in a sample at 1 atm and  $25^\circ\text{C}$ ,  $z \approx 5 \times 10^9 \text{ s}^{-1}$ , so a given molecule collides about  $5 \times 10^9$  times each second. We are beginning to appreciate the timescale of events in gases.

### (c) The mean free path

Once we have the collision frequency, we can calculate the **mean free path**,  $\lambda$  (lambda), the average distance a molecule travels between collisions. As implied by the derivation in *Justification 20.3*

$$\lambda = \bar{c}_{\text{rel}} \Delta t = \frac{\bar{c}_{\text{rel}}}{z} \quad \text{Mean free path} \quad (20.12)$$

Substitution of the expression for  $z$  in eqn 20.11b gives

$$\lambda = \frac{kT}{\sigma p} \quad \text{Mean free path in terms of the pressure} \quad (20.13)$$

Doubling the pressure reduces the mean free path by half. A typical mean free path in nitrogen gas at 1 atm is 70 nm, or about  $10^3$  molecular diameters. Although the temperature appears in eqn 20.13, in a sample of constant volume, the pressure is proportional to  $T$ , so  $T/p$  remains constant when the temperature is increased. Therefore, the mean free path is independent of the temperature in a sample of gas in a container of fixed volume. The distance between collisions is determined by the number of molecules present in the given volume, not by the speed at which they travel.

In summary, a typical gas ( $\text{N}_2$  or  $\text{O}_2$ ) at 1 atm and  $25^\circ\text{C}$  can be thought of as a collection of molecules travelling with a mean speed of about  $500 \text{ m s}^{-1}$ . Each molecule makes a collision within about 1 ns, and between collisions it travels about  $10^3$  molecular diameters. The kinetic model of gases is valid (and the gas behaves nearly perfectly) if the diameter of the molecules is much smaller than the mean free path ( $d \ll \lambda$ ), for then the molecules spend most of their time far from one another.

## IMPACT ON ASTROPHYSICS

### 120.1 The Sun as a ball of perfect gas

The kinetic model of gases is valid when the size of the particles is negligible compared with their mean free path. It may seem absurd, therefore, to expect the kinetic model and, as a consequence, the perfect gas law, to be applicable to the dense matter of stellar interiors. In the Sun, for instance, the density at its centre is 1.50 times that of liquid water and comparable to that of water about halfway to its surface. However, we have to realize that the state of matter is that of a *plasma*, in which the electrons have been stripped from the atoms of hydrogen and helium that make up the bulk of the matter of stars. As a result, the particles making up the plasma have diameters comparable to those of nuclei, or about 10 fm. Therefore, a mean free path of only 0.1 pm satisfies the criterion for the validity of the kinetic theory and the perfect gas law. We can therefore use  $pV = nRT$  as the equation of state for the stellar interior. Although the Coulombic interaction between charged particles is strong, at the high temperatures of stellar interiors the kinetic energy of the charged particles is very much greater and so 'kinetic-energy only' is a tolerable approximation.

As for any perfect gas, the pressure in the interior of the Sun is related to the mass density,  $\rho = m/V$ , by  $p = \rho RT/M$ . Atoms are stripped of their electrons in the interior of stars so, if we suppose that the interior consists of ionized hydrogen atoms, the mean molar mass is one-half the molar mass of hydrogen, or  $0.5 \text{ g mol}^{-1}$  (the mean of the molar mass of  $\text{H}^+$  and  $\text{e}^-$ , the latter being virtually 0). Halfway to the centre of the Sun, the temperature is 3.6 MK and the mass density is  $1.20 \text{ g cm}^{-3}$  (slightly denser than water); so the pressure there works out as  $7.2 \times 10^{13} \text{ Pa}$ , or about 720 million atmospheres.

We can combine this result with the expression for the pressure from the kinetic model (eqn 20.1). Because the total kinetic energy of the particles is  $E_k = \frac{1}{2} Nmc^2$ , we can write  $p = \frac{2}{3} E_k/V$ . That is, the pressure of the plasma is related to the *kinetic energy density*,  $\rho_k = E_k/V$ , the kinetic energy of the molecules in a region divided by the volume of the region, by  $p = \frac{2}{3} \rho_k$ . It follows that the kinetic energy density halfway to the centre of the Sun is about  $0.11 \text{ GJ cm}^{-3}$ . In contrast, on a warm day ( $25^\circ\text{C}$ ) on Earth, the (translational) kinetic energy density of our atmosphere is only  $0.15 \text{ J cm}^{-3}$ .

## 20.2 Collisions with walls and surfaces

**Key point** The collision flux,  $Z_W$ , is the number of collisions with an area in a given time interval divided by the area and the duration of the interval.

The key result for accounting for transport in the gas phase (and in Chapter 23 for the discussion of surface chemistry) is the rate at which molecules strike an area, which may be an imaginary area embedded in the gas, or part of a real wall. The **collision flux**,  $Z_W$ , is the number of collisions with the area in a given time interval divided by the area and the duration of the interval. The **collision frequency**, the number of hits per second, is obtained by multiplication of the collision flux by the area of interest. We show in the following *Justification* that the collision flux is

$$Z_W = \frac{p}{(2\pi mkT)^{1/2}} \quad \text{Collision flux} \quad (20.14)^\circ$$

When  $p = 100 \text{ kPa}$  (1.00 bar) and  $T = 300 \text{ K}$ ,  $Z_W \approx 3 \times 10^{23} \text{ cm}^{-2} \text{ s}^{-1}$  for  $\text{O}_2$ .

### Justification 20.4 The collision flux

Consider a wall of area  $A$  perpendicular to the  $x$ -axis (as in Fig. 20.2). If a molecule has  $v_x > 0$  (that is, it is travelling in the direction of positive  $x$ ), then it will strike the wall within an interval  $\Delta t$  if it lies within a distance  $v_x \Delta t$  of the wall. Therefore, all molecules in the volume  $Av_x \Delta t$ , and with positive  $x$ -component of velocities, will strike the wall in the interval  $\Delta t$ . The total number of collisions in this interval is therefore the volume  $Av_x \Delta t$  multiplied by the number density,  $\mathcal{N}$ , of molecules. However, to take account of the presence of a range of velocities in the sample, we must sum the result over all the positive values of  $v_x$  weighted by the probability distribution of velocities (eqn 20.6):

$$\text{Number of collisions} = \mathcal{N} A \Delta t \int_0^\infty v_x f(v_x) dx$$

The collision flux is the number of collisions divided by  $A$  and  $\Delta t$ , so

$$Z_W = \mathcal{N} \int_0^\infty v_x f(v_x) dx$$

Then, using the velocity distribution in eqn 20.6,

$$\int_0^\infty v_x f(v_x) dv_x = \left( \frac{m}{2\pi kT} \right)^{1/2} \int_0^\infty v_x e^{-mv_x^2/2kT} dv_x = \left( \frac{kT}{2\pi m} \right)^{1/2}$$

where we have used the standard integral

$$\int_0^\infty x e^{-ax^2} dx = \frac{1}{2a}$$

Therefore,

$$Z_W = \mathcal{N} \left( \frac{kT}{2\pi m} \right)^{1/2} = \frac{1}{4} \bar{c} \mathcal{N} \quad (20.15)^\circ$$

where we have used eqn 20.7 in the form  $\bar{c} = (8kT/\pi m)^{1/2}$ , which implies that  $\frac{1}{4}\bar{c} = (kT/2\pi m)^{1/2}$ . Substitution of  $\mathcal{N} = nN_A/V = p/kT$  gives eqn 20.14.

### 20.3 The rate of effusion

**Key points** Effusion is the emergence of a gas from a container through a small hole. Graham's law of effusion states that the rate of effusion is inversely proportional to the square root of the molar mass.

The essential empirical observations on effusion are summarized by **Graham's law of effusion**, which states that the rate of effusion is inversely proportional to the square root of the molar mass. The basis of this result is that, as remarked above, the mean speed of molecules is inversely proportional to  $M^{1/2}$ , so the rate at which they strike the area of the hole is also inversely proportional to  $M^{1/2}$ . However, by using the expression for the rate of collisions, we can obtain a more detailed expression for the rate of effusion and hence use effusion data more effectively.

When a gas at a pressure  $p$  and temperature  $T$  is separated from a vacuum by a small hole, the rate of escape of its molecules is equal to the rate at which they strike the area of the hole (which is given by eqn 20.14). Therefore, for a hole of area  $A_0$ ,

$$\text{Rate of effusion} = Z_W A_0 = \frac{pA_0}{(2\pi mkT)^{1/2}} = \frac{pA_0 N_A}{(2\pi MRT)^{1/2}} \quad \text{Rate of effusion} \quad (20.16)^\circ$$

where, in the last step, we have used  $R = N_A k$  and  $M = mN_A$ . This rate is inversely proportional to  $M^{1/2}$ , in accord with Graham's law.

Equation 20.16 is the basis of the **Knudsen method** for the determination of the vapour pressures of liquids and solids, particularly of substances with very low vapour pressures. Thus, if the vapour pressure of a sample is  $p$ , and it is enclosed in a cavity with a small hole, then the rate of loss of mass from the container is proportional to  $p$ .

#### Example 20.2 Calculating the vapour pressure from a mass loss

Caesium (m.p. 29°C, b.p. 686°C) was introduced into a container and heated to 500°C. When a hole of diameter 0.50 mm was opened in the container for 100 s, a mass loss of 385 mg was measured. Calculate the vapour pressure of liquid caesium at 500 K.

**Method** The pressure of vapour is constant inside the container despite the effusion of atoms because the hot liquid metal replenishes the vapour. The rate of effusion is therefore constant, and given by eqn 20.16. To express the rate in terms of mass, multiply the number of atoms that escape by the mass of each atom.

**Answer** The mass loss  $\Delta m$  in an interval  $\Delta t$  is related to the collision flux by

$$\Delta m = Z_W A_0 m \Delta t$$

where  $A_0$  is the area of the hole and  $m$  is the mass of one atom. It follows that

$$Z_W = \frac{\Delta m}{A_0 m \Delta t}$$

Because  $Z_W$  is related to the pressure by eqn 20.14, we can write

$$p = \left( \frac{2\pi RT}{M} \right)^{1/2} \frac{\Delta m}{A_0 \Delta t}$$

Because  $M = 132.9 \text{ g mol}^{-1}$ , substitution of the data gives  $p = 8.7 \text{ kPa}$  (using  $1 \text{ Pa} = 1 \text{ N m}^{-2} = 1 \text{ J m}^{-1}$ ), or 65 Torr.

**Self-test 20.2** How long would it take 1.0 g of Cs atoms to effuse out of the oven under the same conditions? [260 s]

## 20.4 Transport properties of a perfect gas

**Key points** (a) Flux is the quantity of a property passing through a given area in a given time interval divided by the area and the duration of the interval. Diffusion is the migration of matter down a concentration gradient. Fick's first law of diffusion states that the flux of matter is proportional to the concentration gradient. Thermal conduction is the migration of energy down a temperature gradient and the flux of energy is proportional to the temperature gradient. Viscosity is the migration of linear momentum down a velocity gradient and the flux of momentum is proportional to the velocity gradient. (b) The coefficients of diffusion, thermal conductivity, and viscosity of a perfect gas are proportional to the product of the mean free path and mean speed.

Transport properties are commonly expressed in terms of a number of 'phenomenological' equations, or equations that are empirical summaries of experimental observations. These phenomenological equations apply to all kinds of properties and media. In the following sections, we introduce the equations for the general case and then show how to calculate the parameters that appear in them.

### (a) The phenomenological equations

The rate of migration of a property is measured by its **flux**,  $J$ , the quantity of that property passing through a given area in a given time interval divided by the area and the duration of the interval. If matter is flowing (as in diffusion), we speak of a **matter flux** of so many molecules per square metre per second; if the property is energy (as in thermal conduction), then we speak of the **energy flux** and express it in joules per square metre per second, and so on. To calculate the total quantity of each property transferred through a given area  $A$  in a given time interval  $\Delta t$ , we multiply the flux by the area and the time interval, and form  $J A \Delta t$ .

Experimental observations on transport properties show that the flux of a property is usually proportional to the first derivative of some other related property. For example, the flux of matter diffusing parallel to the  $z$ -axis of a container is found to be proportional to the first derivative of the concentration:

$$J(\text{matter}) \propto \frac{d\mathcal{N}}{dz} \quad \text{Fick's first law of diffusion} \quad (20.17)$$

**Fig. 20.9** The flux of particles down a concentration gradient. Fick's first law states that the flux of matter (the number of particles passing through an imaginary window in a given interval divided by the area of the window and the length of the interval) is proportional to the density gradient at that point.

where  $\mathcal{N}$  is the number density of particles with units number per metre cubed ( $\text{m}^{-3}$ ). The SI units of  $J$  are number per metre squared per second ( $\text{m}^{-2} \text{s}^{-1}$ ). The proportionality of the flux of matter to the concentration gradient is sometimes called **Fick's first law of diffusion**: the law implies that diffusion will be faster when the concentration varies steeply with position than when the concentration is nearly uniform. There is no net flux if the concentration is uniform ( $d\mathcal{N}/dz = 0$ ). Similarly, the rate of thermal conduction (the flux of the energy associated with thermal motion) is found to be proportional to the temperature gradient:

$$J(\text{energy}) \propto \frac{dT}{dz} \quad \boxed{\text{Flux of energy}} \quad (20.18)$$

The SI units of this flux are joules per metre squared per second ( $\text{J m}^{-2} \text{s}^{-1}$ ).

A positive value of  $J$  signifies a flux towards positive  $z$ ; a negative value of  $J$  signifies a flux towards negative  $z$ . Because matter flows down a concentration gradient, from high concentration to low concentration,  $J$  is positive if  $d\mathcal{N}/dz$  is negative (Fig. 20.9). Therefore, the coefficient of proportionality in eqn 20.17 must be negative, and we write it  $-D$ :

$$J(\text{matter}) = -D \frac{d\mathcal{N}}{dz} \quad \boxed{\text{Fick's first law in terms of the diffusion coefficient}} \quad (20.19)$$

The constant  $D$  is called the **diffusion coefficient**; its SI units are metre squared per second ( $\text{m}^2 \text{s}^{-1}$ ). Energy migrates down a temperature gradient, and the same reasoning leads to

$$J(\text{energy}) = -\kappa \frac{dT}{dz} \quad \boxed{\text{Flux of energy in terms of the coefficient of thermal conductivity}} \quad (20.20)$$

where  $\kappa$  is the **coefficient of thermal conductivity**. The SI units of  $\kappa$  are joules per kelvin per metre per second ( $\text{J K}^{-1} \text{m}^{-1} \text{s}^{-1}$ ). Some experimental values are given in Table 20.2.

To see the connection between the flux of momentum and the viscosity, consider a fluid in a state of **Newtonian flow**, which can be imagined as occurring by a series of layers moving past one another (Fig. 20.10). The layer next to the wall of the vessel is stationary, and the velocity of successive layers varies linearly with distance,  $z$ , from the wall. Molecules ceaselessly move between the layers and bring with them the  $x$ -component of linear momentum they possessed in their original layer. A layer is retarded by molecules arriving from a more slowly moving layer because they have a low momentum in the  $x$ -direction. A layer is accelerated by molecules arriving from a more rapidly moving layer. We interpret the net retarding effect as the fluid's viscosity.

Because the retarding effect depends on the transfer of the  $x$ -component of linear momentum into the layer of interest, the viscosity depends on the flux of this  $x$ -component in the  $z$ -direction. The flux of the  $x$ -component of momentum is proportional to  $dv_x/dz$  because there is no net flux when all the layers move at the same velocity. We can therefore write

$$J(x\text{-component of momentum}) = -\eta \frac{dv_x}{dz} \quad \boxed{\text{Momentum flux in terms of the coefficient of viscosity}} \quad (20.21)$$

The constant of proportionality,  $\eta$ , is the **coefficient of viscosity** (or simply 'the viscosity'). Its units are kilograms per metre per second ( $\text{kg m}^{-1} \text{s}^{-1}$ ). Viscosities are often reported in poise (P), where  $1 \text{ P} = 10^{-1} \text{ kg m}^{-1} \text{s}^{-1}$ . Some experimental values are given in Table 20.2.

**Table 20.2\*** Transport properties of gases at 1 atm

|                 | $\kappa/(\text{J K}^{-1} \text{m}^{-1} \text{s}^{-1})$ | $\eta/\mu\text{P}^\dagger$ |       |

**(b) The transport parameters**

As shown in *Further information 20.1* and summarized in Table 20.3, the kinetic model leads to expressions for the diffusional parameters of a perfect gas. The diffusion coefficient, for instance, is

$$D = \frac{1}{3}\lambda\bar{c} \quad \text{Diffusion coefficient of a perfect gas} \quad (20.22)^\circ$$

As usual, we need to consider the significance of this expression:

1. The mean free path,  $\lambda$ , decreases as the pressure is increased (eqn 20.13), so  $D$  decreases with increasing pressure and, as a result, the gas molecules diffuse more slowly.
2. The mean speed,  $\bar{c}$ , increases with the temperature (eqn 20.7), so  $D$  also increases with temperature. As a result, molecules in a hot sample diffuse more quickly than those in a cool sample (for a given concentration gradient).
3. Because the mean free path increases when the collision cross-section of the molecules decreases (eqn 20.13), the diffusion coefficient is greater for small molecules than for large molecules.

Similarly, according to the kinetic model of gases, the thermal conductivity of a perfect gas A having molar concentration  $[A]$  is given by the expression

$$\kappa = \frac{1}{3}\lambda\bar{c}C_{V,m}[A] \quad \text{Coefficient of thermal conductivity of a perfect gas} \quad (20.23)^\circ$$

where  $C_{V,m}$  is the molar heat capacity at constant volume. To interpret this expression, we note that:

1. Because  $\lambda$  is inversely proportional to the pressure, and hence inversely proportional to the molar concentration of the gas, the thermal conductivity is independent of the pressure.
2. The thermal conductivity is greater for gases with a high heat capacity because a given temperature gradient then corresponds to a greater energy gradient.

The physical reason for the pressure independence of  $\kappa$  is that the thermal conductivity can be expected to be large when many molecules are available to transport the energy, but the presence of so many molecules limits their mean free path and they cannot carry the energy over a great distance. These two effects balance. The thermal conductivity is indeed found experimentally to be independent of the pressure, except

**Fig. 20.10** The viscosity of a fluid arises from the transport of linear momentum. In this illustration the fluid is undergoing Newtonian (laminar) flow, and particles bring their initial momentum when they enter a new layer. If they arrive with high  $x$ -component of momentum they accelerate the layer; if with low  $x$ -component of momentum they retard the layer.

when the pressure is very low, when  $\kappa \propto p$ . At low pressures  $\lambda$  exceeds the dimensions of the apparatus, and the distance over which the energy is transported is determined by the size of the container and not by the other molecules present. The flux is still proportional to the number of carriers, but the length of the journey no longer depends on  $\lambda$ , so  $\kappa \propto [A]$ , which implies that  $\kappa \propto p$ .

Finally, the kinetic model leads to the following expression for the viscosity (see *Further information 20.1*):

$$\eta = \frac{1}{3} M \lambda \bar{c} [A] \quad \text{Coefficient of viscosity of a perfect gas} \quad (20.24)^{\circ}$$

where  $[A]$  is the molar concentration of the gas molecules and  $M$  is their molar mass. We can interpret this expression as follows:

1. Because  $\lambda \propto 1/p$  (eqn 20.13) and  $[A] \propto p$ , it follows that  $\eta \propto \bar{c}$ , independent of  $p$ . That is, the viscosity is independent of the pressure.
2. Because  $\bar{c} \propto T^{1/2}$  (eqn 20.7),  $\eta \propto T^{1/2}$ . That is, the viscosity of a gas *increases* with temperature.

The physical reason for the pressure independence of the viscosity is the same as for the thermal conductivity: more molecules are available to transport the momentum, but they carry it less far on account of the decrease in mean free path. The increase of viscosity with temperature is explained when we remember that at high temperatures the molecules travel more quickly, so the flux of momentum is greater. By contrast, as we shall see in Section 20.5, the viscosity of a liquid *decreases* with increase in temperature because intermolecular interactions must be overcome.

## Molecular motion in liquids

We outlined what is currently known about the structure of simple liquids in Section 16.6. Here we consider a particularly simple type of motion through a liquid, that of an ion, and see that the information that motion provides can be used to infer the behaviour of uncharged species too.

### 20.5 Experimental results

**Key point** Molecular motion in liquids can be studied by NMR, EPR, inelastic neutron scattering, and viscosity measurements.

The motion of molecules in liquids can be studied experimentally by a variety of methods. Relaxation time measurements in NMR and EPR (Chapter 14) can be interpreted in terms of the mobilities of the molecules, and have been used to show that big molecules in viscous fluids typically rotate in a series of small (about  $5^\circ$ ) steps, whereas small molecules in nonviscous fluids typically jump through about 1 radian ( $57^\circ$ ) in each step. Another important technique is **inelastic neutron scattering**, in which the energy neutrons collect or discard as they pass through a sample is interpreted in terms of the motion of its particles. The same technique is used to examine the internal dynamics of macromolecules.

More mundane than these experiments are viscosity measurements (Table 20.4). For a molecule to move in a liquid, it must acquire at least a minimum energy to escape from its neighbours. The probability that a molecule has at least an energy  $E_a$  is proportional to  $e^{-E_a/RT}$ , so the mobility of the molecules in the liquid should follow

**Table 20.4\*** Viscosities of liquids at 298 K

<sup>†</sup> The viscosity of water corresponds to 0.891 cP.

this type of temperature dependence. Because the coefficient of viscosity,  $\eta$ , is inversely proportional to the mobility of the particles, we should expect that

$$\eta \propto e^{E_a/RT} \quad (20.25)$$

(Note the positive sign of the exponent.) This expression implies that the viscosity should decrease sharply with increasing temperature. Such a variation is found experimentally, at least over reasonably small temperature ranges (Fig. 20.11). The activation energy typical of viscosity is comparable to the mean potential energy of intermolecular interactions.

One problem with the interpretation of viscosity measurements is that the change in density of the liquid as it is heated makes a pronounced contribution to the temperature variation of the viscosity. Thus, the temperature dependence of viscosity at constant volume, when the density is constant, is much less than that at constant pressure. The intermolecular interactions between the molecules of the liquid govern the magnitude of  $E_a$ , but the problem of calculating it is immensely difficult and still largely unsolved. At low temperatures, the viscosity of water decreases as the pressure is increased. This behaviour is consistent with the rupture of hydrogen bonds.

## 20.6 The conductivities of electrolyte solutions

**Key points** The conductance is the inverse of resistance. Kohlrausch's law describes the concentration dependence of the molar conductivity of a strong electrolyte (a substance that dissociates fully into ions in solution).

Further insight into the nature of molecular motion can be obtained by studying the motion of ions in solution, for ions can be dragged through the solvent by the application of a potential difference between two electrodes immersed in the sample. By studying the transport of charge through electrolyte solutions it is possible to build up a picture of the events that occur in them and, in some cases, to extrapolate the conclusions to species that have zero charge, that is, to neutral molecules.

The fundamental measurement used to study the motion of ions is that of the electrical resistance,  $R$ , of the solution. The **conductance**,  $G$ , of a solution is the inverse of its resistance  $R$ :  $G = 1/R$ . As resistance is expressed in ohms,  $\Omega$ , the conductance of a sample is expressed in  $\Omega^{-1}$ . The reciprocal ohm used to be called the mho, but its official designation is now the siemens, S, and  $1 \text{ S} = 1 \Omega^{-1} = 1 \text{ C V}^{-1} \text{ s}^{-1}$ . The conductance of a sample decreases with its length  $l$  and increases with its cross-sectional area  $A$ . We therefore write

$$G = \frac{\kappa A}{l} \quad \text{Conductance of a solution} \quad (20.26)$$

where  $\kappa$  is the **conductivity**. With the conductance in siemens and the dimensions in metres, it follows that the SI units of  $\kappa$  are siemens per metre ( $\text{S m}^{-1}$ ).

The conductivity of a solution depends on the number of ions present, and it is normal to introduce the **molar conductivity**,  $\Lambda_m$ , which is defined as

$$\Lambda_m = \frac{\kappa}{c} \quad \text{Definition of molar conductivity of a solution} \quad [20.27]$$

where  $c$  is the molar concentration of the added electrolyte. The SI unit of molar conductivity is siemens metre-squared per mole ( $\text{S m}^2 \text{ mol}^{-1}$ ), and typical values are about  $10 \text{ mS m}^2 \text{ mol}^{-1}$  (where  $1 \text{ mS} = 10^{-3} \text{ S}$ ).

The molar conductivity is found to vary with the concentration. One reason for this variation is that the number of ions in the solution might not be proportional to the

**Fig. 20.11** The experimental temperature dependence of the viscosity of water. As the temperature is increased, more molecules are able to escape from the potential wells provided by their neighbours, and so the liquid becomes more fluid. A plot of  $\ln \eta$  against  $1/T$  is a straight line (over a small range) with positive slope.

concentration of the electrolyte. For instance, the concentration of ions in a solution of a weak acid depends on the concentration of the acid in a complicated way, and doubling the concentration of the acid added does not double the number of ions. Secondly, because ions interact strongly with one another, the conductivity of a solution is not exactly proportional to the number of ions present.

In an extensive series of measurements during the nineteenth century, Friedrich Kohlrausch showed that at low concentrations the molar conductivities of strong electrolytes (substances that are fully dissociated into ions in solution) vary linearly with the square root of the concentration:

$$\Lambda_m = \Lambda_m^\circ - \mathcal{K}c^{1/2} \quad \text{Kohlrausch's law} \quad (20.28)$$

This variation is called **Kohlrausch's law**. The constant  $\Lambda_m^\circ$  is the **limiting molar conductivity**, the molar conductivity in the limit of zero concentration (when the ions are effectively infinitely far apart and do not interact with one another). The constant  $\mathcal{K}$  is found to depend more on the stoichiometry of the electrolyte (that is, whether it is of the form MA, or  $M_2A$ , etc.) than on its specific identity. In due course we shall see that the  $c^{1/2}$  dependence arises from interactions between ions: when charge is conducted ionically, ions of one charge are moving past the ions of interest and retard its progress.

Kohlrausch was also able to establish experimentally that  $\Lambda_m^\circ$  can be expressed as the sum of contributions from its individual ions. If the limiting molar conductivity of the cations is denoted  $\lambda_+$  and that of the anions  $\lambda_-$ , then his **law of the independent migration of ions** states that

$$\Lambda_m^\circ = \nu_+ \lambda_+ + \nu_- \lambda_- \quad \text{Law of independent migration of ions} \quad (20.29)^\circ$$

where  $\nu_+$  and  $\nu_-$  are the numbers of cations and anions per formula unit of electrolyte (for example,  $\nu_+ = \nu_- = 1$  for HCl, NaCl, and  $\text{CuSO}_4$ , but  $\nu_+ = 1$ ,  $\nu_- = 2$  for  $\text{MgCl}_2$ ).

## 20.7 The mobilities of ions

**Key points** (a) The drift speed is the terminal speed when an accelerating force is balanced by the viscous drag. The Grotthuss mechanism describes the motion of a proton in water as resulting from rearrangement of bonds in a group of water molecules. (b) The ionic conductivity is the contribution of ions of one type to the molar conductivity of a solution. (c) The Debye–Hückel–Onsager theory explains the concentration dependence of the molar conductivity of a strong electrolyte in terms of ionic interactions.

To interpret conductivity measurements we need to know why ions move at different rates, why they have different molar conductivities, and why the molar conductivities of strong electrolytes decrease with the square root of the molar concentration. The central idea in this section is that, although the motion of an ion remains largely random, the presence of an electric field biases its motion, and the ion undergoes net migration through the solution.

### (a) The drift speed

When the potential difference between two electrodes a distance  $l$  apart is  $\Delta\phi$ , the ions in the solution between them experience a uniform electric field of magnitude

$$\mathcal{E} = \frac{\Delta\phi}{l} \quad (20.30)$$

**Table 20.5\*** Ionic mobilities in water at 298 K

\* More values are given in the *Data section*.

In such a field, an ion of charge  $ze$  experiences a force of magnitude

$$\mathcal{F} = zeE = \frac{ze\Delta\phi}{l} \quad (20.31)$$

(In this chapter we disregard the sign of the charge number and so avoid notational complications.) A cation responds to the application of the field by accelerating towards the negative electrode and an anion responds by accelerating towards the positive electrode. However, this acceleration is short-lived. As the ion moves through the solvent it experiences a frictional retarding force,  $\mathcal{F}_{\text{fric}}$ , proportional to its speed. If we assume that the Stokes's relation formula (eqn 18.31) for a sphere of radius  $a$  and speed  $s$  applies even on a microscopic scale (and independent evidence from magnetic resonance suggests that it often gives at least the right order of magnitude), then we can write this retarding force as

$$\mathcal{F}_{\text{fric}} = fs \quad f = 6\pi\eta a \quad \text{Frictional retarding force} \quad (20.32)$$

The two forces act in opposite directions, and the ions quickly reach a terminal speed, the **drift speed**, when the accelerating force is balanced by the viscous drag. The net force is zero when

$$s = \frac{zeE}{f} \quad \text{Drift speed} \quad (20.33)$$

It follows that the drift speed of an ion is proportional to the strength of the applied field. We write

$$s = uE \quad \text{Definition of ionic mobility} \quad [20.34]$$

where  $u$  is called the **mobility** of the ion (Table 20.5). Comparison of eqns 20.33 and 20.34 and use of eqn 20.32 shows that

$$u = \frac{ze}{f} = \frac{ze}{6\pi\eta a} \quad \text{Ionic mobility in terms of viscosity} \quad (20.35)$$

### • A brief illustration

For an order of magnitude estimate we can take  $z = 1$  and  $a$  the radius of an ion such as  $\text{Cs}^+$  (which might be typical of a smaller ion plus its hydration sphere), which is 170 pm. For the viscosity, we use  $\eta = 1.0 \text{ cP}$  ( $1.0 \times 10^{-3} \text{ kg m}^{-1} \text{ s}^{-1}$ , Table 20.4). Then  $u \approx 5 \times 10^{-8} \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1}$ . This value means that, when there is a potential difference of 1 V across a solution of length 1 cm (so  $\mathcal{E} = 100 \text{ V m}^{-1}$ ), the drift speed is typically about  $5 \mu\text{m s}^{-1}$ . That speed might seem slow, but not when expressed on a molecular scale, for it corresponds to an ion passing about  $10^4$  solvent molecules per second. •

**Fig. 20.12** A highly schematic diagram showing the effective motion of a proton in water.

Because the drift speed governs the rate at which charge is transported, we might expect the conductivity to decrease with increasing solution viscosity and ion size. Experiments confirm these predictions for bulky ions (such as  $R_4N^+$  and  $RCO_2^-$ ) but not for small ions. For example, the molar conductivities of the alkali metal ions increase from  $Li^+$  to  $Cs^+$  (Table 20.5) even though the ionic radii increase. The paradox is resolved when we realize that the radius  $a$  in the Stokes formula is the **hydrodynamic radius** (or ‘Stokes radius’) of the ion, its effective radius in the solution taking into account all the  $H_2O$  molecules it carries in its hydration sphere. Small ions give rise to stronger electric fields than large ones (the electric field at the surface of a sphere of radius  $r$  is proportional to  $ze/r^2$  and it follows that the smaller the radius the stronger the field), so small ions are more extensively solvated than big ions. Thus, an ion of small ionic radius may have a large hydrodynamic radius because it drags many solvent molecules through the solution as it migrates. The hydrating  $H_2O$  molecules are often very labile, however, and NMR and isotope studies have shown that the exchange between the coordination sphere of the ion and the bulk solvent is very rapid.

The proton, although it is very small, has a very high molar conductivity (Table 20.5)! Proton and  $^{17}O$ -NMR show that the times characteristic of protons hopping from one molecule to the next are about 1.5 ps, which is comparable to the time that inelastic neutron scattering shows it takes a water molecule to reorientate through about 1 rad (1 to 2 ps). According to the **Grotthuss mechanism**, there is an effective motion of a proton that involves the rearrangement of bonds in a group of water molecules (Fig. 20.12). The model is consistent with the observation that the molar conductivity of protons increases as the pressure is raised, for increasing pressure ruptures the hydrogen bonds in water. The mobility of  $NH_4^+$  is also anomalous and presumably occurs by an analogous mechanism.

### (b) Mobility and conductivity

Ionic mobilities provide a link between measurable and theoretical quantities. As a first step we establish in the following *Justification* the following relation between an ion’s mobility and its molar conductivity:

$$\lambda_{\pm} = zu_{\pm} F$$

Relation between  
ionic mobility and  
molar conductivity

(20.36)<sup>o</sup>

where  $F$  is Faraday’s constant ( $F = N_A e$ ).

**Fig. 20.13** In the calculation of the current, all the cations within a distance  $s_+ \Delta t$  (that is, those in the volume  $s_+ A \Delta t$ ) will pass through the area  $A$ . The anions in the corresponding volume on the other side of the window will also contribute to the current similarly.

#### Justification 20.5 The relation between ionic mobility and molar conductivity

To keep the calculation simple, we ignore signs in the following, and concentrate on the magnitudes of quantities: the direction of ion flux can always be decided by common sense.

Consider a solution of a fully dissociated strong electrolyte at a molar concentration  $c$ . Let each formula unit give rise to  $v_+$  cations of charge  $z_+ e$  and  $v_-$  anions of charge  $z_- e$ . The molar concentration of each type of ion is therefore  $vc$  (with  $v = v_+$  or  $v_-$ ), and the number density of each type is  $vcN_A$ . The number of ions of one kind that pass through an imaginary window of area  $A$  during an interval  $\Delta t$  is equal to the number within the distance  $s \Delta t$  (Fig. 20.13), and therefore to the number in the volume  $s \Delta t A$ . (The same argument was used in Section 20.1 in the discussion of the pressure of a gas.) The number of ions of that kind in this volume is equal to  $s \Delta t A vcN_A$ . The flux through the window (the number of this type of ion passing through the window divided by the area of the window and the duration of the interval) is therefore

$$J(\text{ions}) = \frac{s \Delta t A vcN_A}{A \Delta t} = s vcN_A$$

Each ion carries a charge  $ze$ , so the flux of charge is

$$J(\text{charge}) = zsvceN_A = szvcF$$

Because  $s = u\mathcal{E}$ , the flux is

$$J(\text{charge}) = zuvcF\mathcal{E}$$

The current,  $I$ , through the window due to the ions we are considering is the charge flux times the area:

$$I = JA = zuvcF\mathcal{E}A$$

Because the electric field is the potential gradient,  $\Delta\phi/l$ , we can write

$$I = \frac{zuvcFA\Delta\phi}{l} \quad (20.37)$$

Current and potential difference are related by Ohm's law,  $\Delta\phi = IR$ , so it follows that

$$I = \frac{\Delta\phi}{R} = G\Delta\phi = \frac{\kappa A\Delta\phi}{l}$$

where we have used eqn 20.26 in the form  $\kappa = Gl/A$ . Note that the proportionality of current to potential difference ( $I \propto \Delta\phi$ ) is another example of a phenomenological flux equation like those introduced in Section 20.4. Comparison of the last two expressions gives  $\kappa = zuvcF$ . Division by the molar concentration of ions,  $vc$ , then results in eqn 20.36 for cations ( $u_+$ ) and anions ( $u_-$ ).

Equation 20.36 applies to the cations and to the anions. Therefore, for the solution itself in the limit of zero concentration (when there are no interionic interactions),

$$\Lambda_m^\circ = (z_+u_+v_+ + z_-u_-v_-)F \quad (20.38)^\circ$$

For a symmetrical  $z:z$  electrolyte (for example,  $\text{CuSO}_4$  with  $z = 2$ ), this equation simplifies to

$$\Lambda_m^\circ = z(u_+ + u_-)F \quad (20.39)^\circ$$

#### • A brief illustration

Earlier, we estimated the typical ionic mobility as  $5 \times 10^{-8} \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1}$ ; so, with  $z = 1$  for both the cation and anion, we can estimate that a typical limiting molar conductivity should be about  $10 \text{ mS m}^2 \text{ mol}^{-1}$ , in accord with experiment. The experimental value for KCl, for instance, is  $15 \text{ mS m}^2 \text{ mol}^{-1}$ . •

#### (c) Ion–ion interactions

The remaining problem is to account for the  $c^{1/2}$  dependence of the Kohlrausch law (eqn 20.28). In Section 5.13 we saw something similar: the activity coefficients of ions at low concentrations also depend on  $c^{1/2}$  and depend on their charge type rather than their specific identities. That  $c^{1/2}$  dependence was explained in terms of the properties of the ionic atmosphere around each ion, and we can suspect that the same explanation applies here too.

To accommodate the effect of motion, we need to modify the picture of an ionic atmosphere as a spherical haze of charge. Because the ions forming the atmosphere do not adjust to the moving ion immediately, the atmosphere is incompletely formed in front of the moving ion and incompletely decayed behind the ion (Fig. 20.14). The overall effect is the displacement of the centre of charge of the atmosphere a short distance behind the moving ion. Because the two charges are opposite, the result is a retardation of the moving ion. This reduction of the ions' mobility is called the

**Fig. 20.14** (a) In the absence of an applied field, the ionic atmosphere is spherically symmetric, but (b) when a field is present it is distorted and the centres of negative and positive charge no longer coincide. The attraction between the opposite charges retards the motion of the central ion.

**Fig. 20.15** The dependence of molar conductivities on the square root of the ionic strength, and comparison (dotted lines) with the dependence predicted by the Debye–Hückel–Onsager theory.

**Table 20.6\*** Debye–Hückel–Onsager coefficients for (1,1)-electrolytes at 298 K

| Solvent   | $A/(\text{mS m}^2 \text{ mol}^{-1}/(\text{mol dm}^{-3})^{1/2})$ | $B/(\text{mol dm}^{-3})^{-1/2}$ |
|-----------|-----------------------------------------------------------------|---------------------------------|
| Methanol  | 15.61                                                           | 0.923                           |
| Propanone | 32.8                                                            | 1.63                            |
| Water     | 6.02                                                            | 0.229                           |

\* More values are given in the Data section.

**relaxation effect.** A confirmation of the picture is obtained by observing the conductivities of ions at high frequencies, which are greater than at low frequencies: the atmosphere does not have time to follow the rapidly changing direction of motion of the ion, and its effect averages to zero.

The ionic atmosphere has another effect on the motion of the ions. We have seen that the moving ion experiences a viscous drag. When the ionic atmosphere is present this drag is enhanced because the ionic atmosphere moves in an opposite direction to the central ion. The enhanced viscous drag, which is called the **electrophoretic effect**, reduces the mobility of the ions, and hence also reduces their conductivities.

The quantitative formulation of these effects is far from simple, but the **Debye–Hückel–Onsager theory** is an attempt to obtain quantitative expressions at about the same level of sophistication as the Debye–Hückel theory itself. The theory leads to a Kohlrausch-like expression in which

$$\mathcal{K} = A + B\Lambda_m^0 \quad (20.40a)$$

with

$$A \propto \frac{z^2}{\eta T^{1/2}} \quad B \propto \frac{z^3}{T^{3/2}} \quad (20.40b)$$

See Table 20.6 for some values of  $A$  and  $B$ . The slopes of the conductivity curves are predicted to depend on the charge type of the electrolyte, in accord with the Kohlrausch law, and some comparisons between theory and experiment are shown in Fig. 20.15. The agreement is quite good at very low ionic strengths, corresponding to very low molar concentrations (less than about  $10^{-3}$  M, depending on the charge type).

## IMPACT ON BIOCHEMISTRY

### 120.2 Ion channels

Controlled transport of molecules and ions across biological membranes is at the heart of a number of key cellular processes, such as the transmission of nerve impulses, the transfer of glucose into red blood cells, and the synthesis of ATP by oxidative phosphorylation (*Impact I6.1*). Here we examine some of the ways in which ions cross the alien environment of the lipid bilayer.

The thermodynamic tendency to transport an ion through the membrane is partially determined by a concentration gradient (more precisely, an activity gradient) across the membrane, which results in a difference in molar Gibbs energy between the inside and the outside of the cell, and a transmembrane potential gradient, which is due to the different potential energy of the ions on each side of the bilayer. There is a tendency, called **passive transport**, for a species to move spontaneously down concentration and membrane potential gradients. It is also possible to move a species against these gradients, but now the flow is not spontaneous and must be driven by an exergonic process, such as the hydrolysis of ATP. This process is called **active transport**.

The transport of ions into or out of a cell needs to be mediated (that is, facilitated by other species) because the hydrophobic environment of the membrane is inhospitable to ions. There are two mechanisms for ion transport: mediation by a carrier molecule and transport through a ‘channel former’, a protein that creates a hydrophilic pore through which the ion can pass. An example of a channel former is the polypeptide gramicidin A, which increases the membrane permeability to cations such as  $\text{H}^+$ ,  $\text{K}^+$ , and  $\text{Na}^+$ .

**Ion channels** are proteins that effect the movement of specific ions down a membrane potential gradient. They are highly selective, so there is a channel protein for  $\text{Ca}^{2+}$ , another for  $\text{Cl}^-$ , and so on. The opening of the gate may be triggered by potential differences between the two sides of the membrane or by the binding of an ‘effector molecule’ to a specific receptor site on the channel.

Ions such as  $\text{H}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Ca}^{2+}$  are often transported actively across membranes by integral proteins called **ion pumps**. Ion pumps are molecular machines that work by adopting conformations that are permeable to one ion but not others depending on the state of phosphorylation of the protein. Because protein phosphorylation requires dephosphorylation of ATP, the conformational change that opens or closes the pump is endergonic and requires the use of energy stored during metabolism.

The structures of a number of channel proteins have been obtained by the now traditional X-ray diffraction techniques described in Chapter 19. Information about the flow of ions across channels and pumps is supplied by the **patch clamp technique**. One of many possible experimental arrangements is shown in Fig. 20.16. With mild suction, a ‘patch’ of membrane from a whole cell or a small section of a broken cell can be attached tightly to the tip of a micropipette filled with an electrolyte solution and containing an electronic conductor, the so-called ‘patch electrode’. A potential difference (the ‘clamp’) is applied between the patch electrode and an intracellular electronic conductor in contact with the cytosol of the cell. If the membrane is permeable to ions at the applied potential difference, a current flows through the completed circuit. Using narrow micropipette tips with diameters of less than  $1\ \mu\text{m}$ , ion currents of a few picoamperes ( $1\ \text{pA} = 10^{-12}\ \text{A}$ ) have been measured across sections of membranes containing only one ion channel protein.

A detailed picture of the mechanism of action of ion channels has emerged from analysis of patch clamp data and structural data. Here we focus on the  $\text{K}^+$  ion channel protein, which, like all other mediators of ion transport, spans the membrane bilayer (Fig. 20.17). The pore through which ions move has a length of  $3.4\ \text{nm}$  and is divided into two regions: a wide region with a length of  $2.2\ \text{nm}$  and diameter of  $1.0\ \text{nm}$  and a narrow region with a length of  $1.2\ \text{nm}$  and diameter of  $0.3\ \text{nm}$ . The narrow region is called the ‘selectivity filter’ of the  $\text{K}^+$  ion channel because it allows only  $\text{K}^+$  ions to pass.

Filtering is a subtle process that depends on ionic size and the thermodynamic tendency of an ion to lose its hydrating water molecules. Upon entering the selectivity filter, the  $\text{K}^+$  ion is stripped of its hydrating shell and is then gripped by carbonyl groups of the protein. Dehydration of the  $\text{K}^+$  ion is endergonic ( $\Delta_{\text{dehyd}}G^\circ = +203\ \text{kJ mol}^{-1}$ ), but is driven by the energy of interaction between the ion and the protein. The  $\text{Na}^+$  ion, though smaller than the  $\text{K}^+$  ion, does not pass through the selectivity filter of the  $\text{K}^+$  ion channel because interactions with the protein are not sufficient to compensate for the high Gibbs energy of dehydration of  $\text{Na}^+$  ( $\Delta_{\text{dehyd}}G^\circ = +301\ \text{kJ mol}^{-1}$ ). More specifically, a dehydrated  $\text{Na}^+$  ion is too small and cannot be held tightly by the protein carbonyl groups, which are positioned for ideal interactions with the larger  $\text{K}^+$  ion. In its hydrated form, the  $\text{Na}^+$  ion is too large (larger than a dehydrated  $\text{K}^+$  ion), does not fit in the selectivity filter, and does not cross the membrane.

Though very selective, a  $\text{K}^+$  ion channel can still let other ions pass through. For example,  $\text{K}^+$  and  $\text{Tl}^+$  ions have similar radii and Gibbs energies of dehydration, so  $\text{Tl}^+$

**Fig. 20.16** A representation of the patch clamp technique for the measurement of ionic currents through membranes in intact cells. A section of membrane containing an ion channel is in tight contact with the tip of a micropipette containing an electrolyte solution and the patch electrode. An intracellular electronic conductor is inserted into the cytosol of the cell and the two conductors are connected to a power supply and current measuring device.

**Fig. 20.17** A schematic representation of the cross-section of a membrane-spanning  $\text{K}^+$  ion channel protein. The bulk of the protein is shown in light shades of grey. The pore through which ions move is divided into two regions: a wide region with a length of  $2.2\ \text{nm}$  and diameter of  $1.0\ \text{nm}$ , and a narrow region, the *selectivity filter*, with a length of  $1.2\ \text{nm}$  and diameter of  $0.3\ \text{nm}$ . The selectivity filter has a number of carbonyl groups (shown in dark green) that grip  $\text{K}^+$  ions. As explained in the text, electrostatic repulsions between two bound  $\text{K}^+$  ions ‘encourage’ ionic movement through the selectivity filter and across the membrane.

can cross the membrane. As a result,  $\text{Ti}^+$  is a neurotoxin because it replaces  $\text{K}^+$  in many neuronal functions.

The efficiency of transfer of  $\text{K}^+$  ions through the channel can also be explained by structural features of the protein. For efficient transport to occur, a  $\text{K}^+$  ion must enter the protein, but then must not be allowed to remain inside for very long so that, as one  $\text{K}^+$  ion enters the channel from one side, another  $\text{K}^+$  ion leaves from the opposite side. An ion is lured into the channel by water molecules about halfway through the length of the membrane. Consequently, the thermodynamic cost of moving an ion from an aqueous environment to the less hydrophilic interior of the protein is minimized. The ion is ‘encouraged’ to leave the protein by electrostatic interactions in the selectivity filter, which can bind two  $\text{K}^+$  ions simultaneously, usually with a bridging water molecule. Electrostatic repulsion prevents the ions from binding too tightly, minimizing the residence time of an ion in the selectivity filter, and maximizing the transport rate.

## Diffusion

We are now in a position to extend the discussion of ionic motion to cover the migration of neutral molecules and of ions in the absence of an applied electric field. We shall do this by expressing ion motion in a more general way than hitherto, and will then discover that the same equations apply even when the charge on the particles is zero.

### 20.8 The thermodynamic view

**Key points** The thermodynamic force represents the spontaneous tendency of molecules to disperse as a consequence of the Second Law. (a) Fick’s first law of diffusion can be deduced by considering the thermodynamic force and viscous drag of a solution. (b) The diffusion coefficient and the ionic mobility are related by the Einstein relation. (c) The Stokes–Einstein equation relates the diffusion coefficient to the frictional force.

We saw in Part 1 that, at constant temperature and pressure, the maximum non-expansion work that can be done per mole when a substance moves from a location where its chemical potential is  $\mu$  to a location where its chemical potential is  $\mu + d\mu$  is  $dw = d\mu$ . In a system in which the chemical potential depends on the position  $x$ ,

$$dw = d\mu = \left( \frac{\partial \mu}{\partial x} \right)_{p,T} dx \quad (20.41)$$

We also saw in Chapter 2 (Table 2.1) that, in general, work can always be expressed in terms of an opposing force (which here we write  $\mathcal{F}$ ), and that

$$dw = -\mathcal{F} dx \quad (20.42)$$

By comparing these two expressions, we see that the slope of the chemical potential can be interpreted as an effective force per mole of molecules. We write this **thermodynamic force** as

$$\mathcal{F} = - \left( \frac{\partial \mu}{\partial x} \right)_{p,T} \quad \text{Definition of the thermodynamic force} \quad [20.43]$$

There is not necessarily a real force pushing the particles down the slope of the chemical potential. As we shall see, the force may represent the spontaneous tendency of the

molecules to disperse as a consequence of the Second Law and the hunt for maximum entropy.

**(a) Fick's first law of diffusion**

In a solution in which the activity of the solute is  $a$ , the chemical potential is

$$\mu = \mu^\ominus + RT \ln a$$

If the solution is not uniform the activity depends on the position and we can write

$$\mathcal{F} = -RT \left( \frac{\partial \ln a}{\partial x} \right)_{p,T} \quad (20.44)$$

If the solution is ideal,  $a$  may be replaced by the molar concentration  $c$ , and then

$$\mathcal{F} = -\frac{RT}{c} \left( \frac{\partial c}{\partial x} \right)_{p,T} \quad (20.45)^\circ$$

where we have also used the relation  $d \ln y/dx = (1/y)(dy/dx)$ .

**Example 20.3** Calculating the thermodynamic force

Suppose the concentration of a solute decays exponentially along the length of a container. Calculate the thermodynamic force on the solute at 25°C given that the concentration falls to half its value in 10 cm.

**Method** According to eqn 20.45, the thermodynamic force is calculated by differentiating the concentration with respect to distance. Therefore, write an expression for the variation of the concentration with distance, and then differentiate it.

**Answer** The concentration varies with position as

$$c = c_0 e^{-x/\lambda}$$

where  $\lambda$  is the decay constant. Therefore,

$$\frac{dc}{dx} = -\frac{c}{\lambda}$$

Equation 20.45 then implies that

$$\mathcal{F} = \frac{RT}{\lambda}$$

We know that the concentration falls to  $\frac{1}{2}c_0$  at  $x = 10$  cm, so we can find  $\lambda$  from  $\frac{1}{2} = e^{-(10 \text{ cm})/\lambda}$ . That is  $\lambda = (10 \text{ cm}/\ln 2)$ . It follows that

$$\mathcal{F} = (8.3145 \text{ J K}^{-1} \text{ mol}^{-1}) \times (298 \text{ K}) \times \ln 2 / (1.0 \times 10^{-1} \text{ m}) = 17 \text{ kN mol}^{-1}$$

where we have used  $1 \text{ J} = 1 \text{ N m}$ .

**Self-test 20.3** Calculate the thermodynamic force on the molecules of molar mass  $M$  in a vertical tube in a gravitational field on the surface of the Earth, and evaluate  $\mathcal{F}$  for molecules of molar mass  $100 \text{ g mol}^{-1}$ . Comment on its magnitude relative to that just calculated.

[ $\mathcal{F} = -Mg$ ,  $-0.98 \text{ N mol}^{-1}$ ; the force arising from the concentration gradient greatly dominates that arising from the gravitational gradient.]

In Section 20.4 we saw that Fick's first law of diffusion (that the particle flux is proportional to the concentration gradient) could be deduced from the kinetic model of gases. We shall now show that it can be deduced more generally and that it applies to the diffusion of species in condensed phases too.

We suppose that the flux of diffusing particles is motion in response to a thermodynamic force arising from a concentration gradient. The particles reach a steady drift speed,  $s$ , when the thermodynamic force,  $\mathcal{F}$ , is matched by the viscous drag. This drift speed is proportional to the thermodynamic force, and we write  $s \propto \mathcal{F}$ . However, the particle flux,  $J$ , is proportional to the drift speed, and the thermodynamic force is proportional to the concentration gradient,  $dc/dx$ . The chain of proportionalities ( $J \propto s$ ,  $s \propto \mathcal{F}$ , and  $\mathcal{F} \propto dc/dx$ ) implies that  $J \propto dc/dx$ , which is the content of Fick's law.

### (b) The Einstein relation

If we divide both sides of eqn 20.19 by Avogadro's constant, thereby converting numbers into amounts (numbers of moles), then Fick's law becomes

$$J = -D \frac{dc}{dx} \quad \text{Fick's first law in terms of the concentration gradient} \quad (20.46)$$

In this expression,  $D$  is the diffusion coefficient and  $dc/dx$  is the slope of the molar concentration. The flux is related to the drift speed by

$$J = sc \quad (20.47)$$

This relation follows from the argument that we have used several times before. Thus, all particles within a distance  $s\Delta t$ , and therefore in a volume  $s\Delta tA$ , can pass through a window of area  $A$  in an interval  $\Delta t$ . Hence, the amount of substance that can pass through the window in that interval is  $s\Delta tAc$ . Therefore,

$$sc = -D \frac{dc}{dx}$$

If now we express  $dc/dx$  in terms of  $\mathcal{F}$  by using eqn 20.45, we find

$$s = -\frac{D}{c} \frac{dc}{dx} = \frac{D\mathcal{F}}{RT} \quad (20.48)$$

Therefore, once we know the effective force and the diffusion coefficient,  $D$ , we can calculate the drift speed of the particles (and vice versa) whatever the origin of the force.

There is one case where we already know the drift speed and the effective force acting on a particle: an ion in solution has a drift speed  $s = uE$  when it experiences a force  $ezE$  from an electric field of strength  $E$  (so  $\mathcal{F} = N_A ezE = zFE$ ). Therefore, substituting these known values into eqn 20.48 gives

$$uE = \frac{zFE D}{RT}$$

and hence

$$u = \frac{zFD}{RT} \quad (20.49)$$

This equation rearranges into the very important result known as the **Einstein relation** between the diffusion coefficient and the ionic mobility:

$$D = \frac{uRT}{zF} \quad \text{Einstein relation} \quad (20.50)^{\circ}$$

On inserting the typical value  $u = 5 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ , we find  $D \approx 1 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$  at  $25^\circ\text{C}$  as a typical value of the diffusion coefficient of an ion in water.

### (c) The Stokes–Einstein equation

Equations 20.35 ( $u = ez/f$ ) and 20.49 relate the mobility of an ion to the frictional force and to the diffusion coefficient, respectively. We can combine the two expressions into the Stokes–Einstein equation:

$$D = \frac{kT}{f} \quad \text{Stokes–Einstein equation} \quad (20.51)$$

If the frictional force is described by Stokes's relation (eqn 18.31), then we also obtain a relation between the diffusion coefficient and the viscosity of the medium:

$$D = \frac{kT}{6\pi\eta a} \quad (20.52)$$

An important feature of eqn 20.51 (and of its special case, eqn 20.52) is that it makes no reference to the charge of the diffusing species. Therefore, the equation also applies in the limit of vanishingly small charge, that is, it also applies to neutral molecules. Consequently, we may use viscosity measurements to estimate the diffusion coefficients for electrically neutral molecules in solution (Table 20.7). It must not be forgotten, however, that both equations depend on the assumption that the viscous drag is proportional to the speed.

#### Example 20.4 Interpreting the mobility of an ion

Use the experimental value of the mobility to evaluate the diffusion coefficient, the limiting molar conductivity, and the hydrodynamic radius of a sulfate ion in aqueous solution.

**Method** The starting point is the mobility of the ion, which is given in Table 20.5. The diffusion coefficient can then be determined from the Einstein relation, eqn 20.50. The ionic conductivity is related to the mobility by eqn 20.36. To estimate the hydrodynamic radius,  $a$ , of the ion, use the Stokes–Einstein relation to find  $f$  and the Stokes law to relate  $f$  to  $a$ .

**Answer** From Table 20.5, the mobility of  $\text{SO}_4^{2-}$  is  $8.29 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ . It follows from eqn 20.50 that

$$D = \frac{uRT}{zF} = 1.1 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$$

From eqn 20.36 it follows that

$$\lambda_- = zu_-F = 16 \text{ mS m}^2 \text{ mol}^{-1}$$

Finally, from  $f = 6\pi\eta a$  using  $0.891 \text{ cP}$  (or  $8.91 \times 10^{-4} \text{ kg m}^{-1} \text{ s}^{-1}$ ) for the viscosity of water (Table 20.4):

$$a = \frac{kT}{6\pi\eta D} = 220 \text{ pm}$$

The bond length in  $\text{SO}_4^{2-}$  is  $144 \text{ pm}$ , so the radius calculated here is plausible and consistent with a small degree of solvation.

**Self-test 20.4** Repeat the calculation for the  $\text{NH}_4^+$  ion.

[ $1.96 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ ,  $7.4 \text{ mS m}^2 \text{ mol}^{-1}$ ,  $125 \text{ pm}$ ]

**Table 20.7\*** Diffusion coefficients at  $298 \text{ K}$

|                        | $D/(10^{-9} \text{ m}^2 \text{ s}^{-1})$ |
|------------------------|------------------------------------------|
| $\text{H}^+$ in water  | 9.31                                     |
| $\text{I}_2$ in hexane | 4.05                                     |
| $\text{Na}^+$ in water | 1.33                                     |
| Sucrose in water       | 0.522                                    |

\* More values are given in the *Data section*.

## 20.9 The diffusion equation

**Key points** The diffusion equation is a relation between the rate of change of concentration at a point and the spatial variation of the concentration at that point. (a) The generalized diffusion equation takes into account the combined effects of diffusion and convection. (b) The diffusion equation is a second-order differential equation with respect to space and a first-order differential equation with respect to time. Its solution requires specification of two boundary conditions for the spatial dependence and an initial condition for the time dependence.

We now turn to the discussion of time-dependent diffusion processes, where we are interested in the spreading of inhomogeneities with time. One example is the temperature of a metal bar that has been heated at one end: if the source of heat is removed, then the bar gradually settles down into a state of uniform temperature. When the source of heat is maintained and the bar is connected at the far end to a thermal sink, it settles down into a steady state of nonuniform temperature. Another example (and one more relevant to chemistry) is the concentration distribution in a solvent to which a solute is added. We shall focus on the description of the diffusion of particles, but similar arguments apply to the diffusion of physical properties, such as temperature. Our aim is to obtain an equation for the rate of change of the concentration of particles in an inhomogeneous region.

The central equation of this section is the **diffusion equation**, also called ‘Fick’s second law of diffusion’, which relates the rate of change of concentration at a point to the spatial variation of the concentration at that point:

$$\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2} \quad \text{Diffusion equation} \quad (20.53)$$

We show in the following *Justification* that the diffusion equation follows from Fick’s first law of diffusion.

**Fig. 20.18** The net flux in a region is the difference between the flux entering from the region of high concentration (on the left) and the flux leaving to the region of low concentration (on the right).

### Justification 20.6 The diffusion equation

Consider a thin slab of cross-sectional area  $A$  that extends from  $x$  to  $x + l$  (Fig. 20.18). Let the concentration at  $x$  be  $c$  at the time  $t$ . The amount (number of moles) of particles that enter the slab in the infinitesimal interval  $dt$  is  $JAdt$ , so the rate of increase in molar concentration inside the slab (which has volume  $Al$ ) on account of the flux from the left is

$$\frac{\partial c}{\partial t} = \frac{JAdt}{Al dt} = \frac{J}{l}$$

There is also an outflow through the right-hand window. The flux through that window is  $J'$ , and the rate of change of concentration that results is

$$\frac{\partial c}{\partial t} = -\frac{J'Adt}{Al dt} = -\frac{J'}{l}$$

The net rate of change of concentration is therefore

$$\frac{\partial c}{\partial t} = \frac{J - J'}{l}$$

Each flux is proportional to the concentration gradient at the window. So, by using Fick’s first law, we can write

$$J - J' = -D \frac{\partial c}{\partial x} + D \frac{\partial c'}{\partial x} = -D \frac{\partial c}{\partial x} + D \frac{\partial}{\partial x} \left\{ c + \left( \frac{\partial c}{\partial x} \right) l \right\} = Dl \frac{\partial^2 c}{\partial x^2}$$

When this relation is substituted into the expression for the rate of change of concentration in the slab, we get eqn 20.53.

The diffusion equation shows that the rate of change of concentration is proportional to the curvature (more precisely, to the second derivative) of the concentration with respect to distance. If the concentration changes sharply from point to point (if the distribution is highly wrinkled) then the concentration changes rapidly with time. Where the curvature is positive (a dip, Fig. 20.19), the change in concentration is positive; the dip tends to fill. Where the curvature is negative (a heap), the change in concentration is negative; the heap tends to spread. If the curvature is zero, then the concentration is constant in time. If the concentration decreases linearly with distance, then the concentration at any point is constant because the inflow of particles is exactly balanced by the outflow.

The diffusion equation can be regarded as a mathematical formulation of the intuitive notion that there is a natural tendency for the wrinkles in a distribution to disappear. More succinctly: Nature abhors a wrinkle.

**Fig. 20.19** Nature abhors a wrinkle. The diffusion equation tells us that peaks in a distribution (regions of negative curvature) spread and troughs (regions of positive curvature) fill in.

### (a) Diffusion with convection

The transport of particles arising from the motion of a streaming fluid is called **convection**. If for the moment we ignore diffusion, then the flux of particles through an area  $A$  in an interval  $\Delta t$  when the fluid is flowing at a velocity  $v$  can be calculated in the way we have used several times before (by counting the particles within a distance  $v\Delta t$ ), and is

$$J = \frac{cAv\Delta t}{A\Delta t} = cv \quad \text{Convective flux} \quad (20.54)$$

This  $J$  is called the **convective flux**. The rate of change of concentration in a slab of thickness  $l$  and area  $A$  is, by the same argument as before and assuming that the velocity does not depend on the position,

$$\frac{\partial c}{\partial t} = \frac{J - J'}{l} = \left\{ c - \left[ c + \left( \frac{\partial c}{\partial x} \right) l \right] \right\} \frac{v}{l} = -v \frac{\partial c}{\partial x} \quad (20.55)$$

When both diffusion and convection occur, the total change of concentration in a region is the sum of the two effects, and the **generalized diffusion equation** is

$$\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2} - v \frac{\partial c}{\partial x} \quad \text{Generalized diffusion equation} \quad (20.56)$$

A further refinement, which is important in chemistry, is the possibility that the concentrations of particles may change as a result of reaction. When reactions are included in eqn 20.56 (Section 22.2), we get a powerful differential equation for discussing the properties of reacting, diffusing, convecting systems and which is the basis of reactor design in chemical industry and of the utilization of resources in living cells.

### (b) Solutions of the diffusion equation

The diffusion equation, eqn 20.53, is a second-order differential equation with respect to space and a first-order differential equation with respect to time. Therefore, we must specify two boundary conditions for the spatial dependence and a single initial condition for the time dependence.

As an illustration, consider a solvent in which the solute is initially coated on one surface of the container (for example, a layer of sugar on the bottom of a deep beaker of water). The single initial condition is that at  $t = 0$  all  $N_0$  particles are concentrated on the  $yz$ -plane (of area  $A$ ) at  $x = 0$ . The two boundary conditions are derived from the requirements (1) that the concentration must everywhere be finite and (2) that the total amount (number of moles) of particles present is  $n_0$  (with  $n_0 = N_0/N_A$ ) at all

**Fig. 20.20** The concentration profiles above a plane from which a solute is diffusing. The curves are plots of eqn 20.57 and are labelled with different values of  $Dt$ . The units of  $Dt$  and  $x$  are arbitrary, but are related so that  $Dt/x^2$  is dimensionless. For example, if  $x$  is in metres,  $Dt$  would be in metres<sup>2</sup>; so, for  $D = 10^{-9} \text{ m}^2 \text{ s}^{-1}$ ,  $Dt = 0.1 \text{ m}^2$  corresponds to  $t = 10^8 \text{ s}$ .

**interActivity** Generate a family of curves similar to that shown in Fig. 20.20 but by using eqn 20.58, which describes diffusion in three dimensions.

times. These requirements imply that the flux of particles is zero at the top and bottom surfaces of the system. Under these conditions it is found that

$$c(x,t) = \frac{n_0}{A(\pi Dt)^{1/2}} e^{-x^2/4Dt} \quad (20.57)$$

as may be verified by direct substitution. Figure 20.20 shows the shape of the concentration distribution at various times, and it is clear that the concentration spreads and tends to uniformity.

Another useful result is for a localized concentration of solute in a three-dimensional solvent (a sugar lump suspended in a large flask of water). The concentration of diffused solute is spherically symmetrical and at a radius  $r$  is

$$c(r,t) = \frac{n_0}{8(\pi Dt)^{3/2}} e^{-r^2/4Dt} \quad (20.58)$$

Other chemically (and physically) interesting arrangements, such as transport of substances across biological membranes can be treated. In many cases the solutions are more cumbersome.

The solutions of the diffusion equation are useful for experimental determinations of diffusion coefficients. In the **capillary technique**, a capillary tube, open at one end and containing a solution, is immersed in a well-stirred larger quantity of solvent, and the change of concentration in the tube is monitored. The solute diffuses from the open end of the capillary at a rate that can be calculated by solving the diffusion equation with the appropriate boundary conditions, so  $D$  may be determined. In the **diaphragm technique**, the diffusion occurs through the capillary pores of a sintered glass diaphragm separating the well-stirred solution and solvent. The concentrations are monitored and then related to the solutions of the diffusion equation corresponding to this arrangement. Diffusion coefficients may also be measured by laser light scattering techniques and by NMR.

## 20.10 Diffusion probabilities

**Key point** Diffusion is a very slow process.

The solutions of the diffusion equation can be used to predict the concentration of particles (or the value of some other physical quantity, such as the temperature in a nonuniform system) at any location. We can also use them to calculate the net distance through which the particles diffuse in a given time.

### Example 20.5 Calculating the net distance of diffusion

Calculate the net distance travelled on average by particles in a time  $t$  if they have a diffusion constant  $D$ .

**Method** We need to calculate the probability that a particle will be found at a certain distance from the origin, and then calculate the average distance travelled by weighting each distance by that probability.

**Answer** The number of particles in a slab of thickness  $dx$  and area  $A$  at  $x$ , where the molar concentration is  $c$ , is  $cAN_A dx$ . The probability that any of the  $N_0 = n_0 N_A$  particles is in the slab is therefore  $cAN_A dx/N_0$ . If the particle is in the slab, it has travelled a distance  $x$  from the origin. Therefore, the mean distance travelled by all the particles is the sum of each  $x$  weighted by the probability of its occurrence:

$$\langle x \rangle = \int_0^\infty \frac{xcAN_A}{N_0} dx = \frac{1}{(\pi Dt)^{1/2}} \int_0^\infty x e^{-x^2/4Dt} dx = 2 \left( \frac{Dt}{\pi} \right)^{1/2}$$

where we have used the same standard integral as that used in *Justification 20.4*.

**Self-test 20.5** Derive an expression for the root mean square distance travelled by diffusing particles in a time  $t$ .  $[\langle x^2 \rangle^{1/2} = (2Dt)^{1/2}]$

As shown in Example 20.5, the average distance travelled by a diffusing particle in a time  $t$  is

$$\langle x \rangle = 2 \left( \frac{Dt}{\pi} \right)^{1/2} \quad (20.59)$$

and the root mean square distance travelled in the same time is

$$\langle x^2 \rangle^{1/2} = (2Dt)^{1/2} \quad (20.60)$$

The latter is a valuable measure of the spread of particles when they can diffuse in both directions from the origin (for then  $\langle x \rangle = 0$  at all times). The root mean square distance travelled by particles with a typical diffusion coefficient ( $D = 5 \times 10^{-10} \text{ m}^2 \text{ s}^{-1}$ ) is illustrated in Fig. 20.21, which shows how long it takes for diffusion to increase the net distance travelled on average to about 1 cm in an unstirred solution. The graph shows that diffusion is a very slow process (which is why solutions are stirred, to encourage mixing by convection).

## 20.11 The statistical view

**Key points** Diffusion can be described mathematically with a random walk model. The Einstein–Smoluchowski equation relates the diffusion coefficient to the parameters used in the formulation of the random walk model.

An intuitive picture of diffusion is of the particles moving in a series of small steps and gradually migrating from their original positions. We shall explore this idea using a model in which the particles can jump through a distance  $\lambda$  in a time  $\tau$ . The total distance travelled by a particle in a time  $t$  is therefore  $t\lambda/\tau$ . However, the particle will not necessarily be found at that distance from the origin. The direction of each step may be different, and the net distance travelled must take the changing directions into account.

If we simplify the discussion by allowing the particles to travel only along a straight line (the  $x$ -axis), and for each step (to the left or the right) to be through the same distance  $\lambda$ , then we obtain the **one-dimensional random walk**. The same model was used in the discussion of a one-dimensional random coil in Section 18.1. We can use the result (eqn 18.1) established there by substituting  $N = t/\tau$  for the total number of steps and  $n = x/\lambda$  for the displacement from the origin, and obtain

$$P = \left( \frac{2\tau}{\pi t} \right)^{1/2} e^{-x^2 \tau / 2t \lambda^2} \quad (20.61)$$

The differences of detail between eqns 20.57 and 20.61 arise from the fact that in the present calculation the particles can migrate in either direction from the origin. Moreover, they can be found only at discrete points separated by  $\lambda$  instead of being anywhere on a continuous line. The fact that the two expressions are so similar suggests that diffusion can indeed be interpreted as the outcome of a large number of steps in random directions.

We can now relate the coefficient  $D$  to the step length  $\lambda$  and the rate at which the jumps occur. Thus, by comparing the two exponents in eqns 20.59 and 20.63 we can immediately write down the **Einstein–Smoluchowski equation**:

$$D = \frac{\lambda^2}{2\tau} \quad \text{Einstein–Smoluchowski equation} \quad (20.62)$$

**Fig. 20.21** The root mean square distance covered by particles with  $D = 5 \times 10^{-10} \text{ m}^2 \text{ s}^{-1}$ . Note the great slowness of diffusion.

### • A brief illustration

Suppose that a  $\text{SO}_4^{2-}$  ion jumps through its own diameter each time it makes a move in an aqueous solution; then, because  $D = 1.1 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$  and  $a = 220 \text{ pm}$  (as deduced from mobility measurements), it follows from  $\lambda = 2a$  that  $\tau = 88 \text{ ps}$ . Because  $\tau$  is the time for one jump, the ion makes  $1 \times 10^{10}$  jumps per second. •

The Einstein–Smoluchowski equation is the central connection between the microscopic details of particle motion and the macroscopic parameters relating to diffusion (for example, the diffusion coefficient and, through the Stokes–Einstein relation, the viscosity). It also brings us back full circle to the properties of the perfect gas. For if we interpret  $\lambda/\tau$  as  $\bar{c}$ , the mean speed of the molecules, and interpret  $\lambda$  as a mean free path, then we can recognize in the Einstein–Smoluchowski equation exactly the same expression as we obtained from the kinetic model of gases, eqn 20.22. That is, the diffusion of a perfect gas is a random walk with an average step size equal to the mean free path.

## Checklist of key equations

| Property                                             | Equation                                                                      | Comment       |
|------------------------------------------------------|-------------------------------------------------------------------------------|---------------|
| Pressure of a perfect gas from the kinetic model     | $pV = \frac{1}{3}nMc^2$                                                       | Kinetic model |
| Maxwell distribution of speeds                       | $f(v) = 4\pi(M/2\pi RT)^{3/2}v^2e^{-Mv^2/2RT}$                                |               |
| Root mean square speed in a perfect gas              | $c = \langle v^2 \rangle^{1/2} = (3RT/M)^{1/2}$                               | Kinetic model |
| Mean speed in a perfect gas                          | $\bar{c} = (8RT/\pi M)^{1/2}$                                                 | Kinetic model |
| Most probable speed in a perfect gas                 | $c^* = (2RT/M)^{1/2}$                                                         | Kinetic model |
| Relative mean speed in a perfect gas                 | $\bar{c}_{\text{rel}} = 2^{1/2}\bar{c}$                                       | Kinetic model |
| The collision frequency in a perfect gas             | $z = \sigma\bar{c}_{\text{rel}}\mathcal{N}$ , $\sigma = \pi d^2$              | Kinetic model |
| Mean free path in a perfect gas                      | $\lambda = \bar{c}_{\text{rel}}/z$                                            |               |
| Collision flux                                       | $Z_W = p/(2\pi mkT)^{1/2}$                                                    |               |
| Rate of effusion                                     | $Z_W A_0 = pA_0 N_A/(2\pi MRT)^{1/2}$                                         |               |
| Fick's first law of diffusion                        | $J(\text{matter}) = -D \text{d}\mathcal{N}/\text{d}z$                         |               |
| Flux of energy                                       | $J(\text{energy}) = -\kappa \text{d}T/\text{d}z$                              |               |
| Flux of momentum                                     | $J(x\text{-component of momentum}) = -\eta \text{d}v_x/\text{d}z$             |               |
| Diffusion coefficient of a perfect gas               | $D = \frac{1}{3}\lambda\bar{c}$                                               |               |
| Coefficient of thermal conductivity of a perfect gas | $\kappa = \frac{1}{3}\lambda\bar{c}C_{V,m}[A]$                                |               |
| Coefficient of viscosity of a perfect gas            | $\eta = \frac{1}{3}M\lambda\bar{c}[A]$                                        |               |
| Conductance                                          | $G = \kappa A/l$                                                              |               |
| Molar conductivity                                   | $\Lambda_m = \kappa/c$                                                        |               |
| Kohlrausch's law                                     | $\Lambda_m = \Lambda_m^\circ - \mathcal{K}c^{1/2}$                            |               |
| Law of independent migration of ions                 | $\Lambda_m^\circ = \nu_+ \lambda_+ + \nu_- \lambda_-$                         |               |
| Drift speed                                          | $s = uE$ , $u = ze/6\pi\eta a$                                                |               |
| Ionic conductivity                                   | $\lambda_\pm = zu_\pm F$                                                      |               |
| Einstein relation                                    | $D = uRT/zF$                                                                  |               |
| Stokes–Einstein equation                             | $D = kT/f$                                                                    |               |
| Diffusion equation                                   | $\partial c/\partial t = D\partial^2 c/\partial x^2$                          |               |
| Generalized diffusion equation                       | $\partial c/\partial t = D\partial^2 c/\partial x^2 - v\partial c/\partial x$ |               |
| Einstein–Smoluchowski equation                       | $D = \lambda^2/2\tau$                                                         |               |

## Further information

### Further information 20.1 The transport characteristics of a perfect gas

In this *Further information* section, we derive expressions for the diffusion characteristics (specifically, the diffusion coefficient, the thermal conductivity, and the viscosity) of a perfect gas on the basis of the kinetic molecular theory.

#### (a) The diffusion coefficient, $D$

Consider the arrangement depicted in Fig. 20.22. On average, the molecules passing through the area  $A$  at  $z = 0$  have travelled about one mean free path  $\lambda$  since their last collision. Therefore, the number density where they originated is  $\mathcal{N}(z)$  evaluated at  $z = -\lambda$ . This number density is approximately

$$\mathcal{N}(-\lambda) = \mathcal{N}(0) - \lambda \left( \frac{d\mathcal{N}}{dz} \right)_0 \quad (20.63)$$

where we have used a Taylor expansion of the form  $f(x) = f(0) + (df/dx)_0 x + \dots$  truncated after the second term. The average number of impacts on the imaginary window of area  $A_0$  during an interval  $\Delta t$  is  $Z_W A_0 \Delta t$ , with  $Z_W = \frac{1}{4} \mathcal{N} \bar{c}$  (eqn 20.15). Therefore, the flux from left to right,  $J(L \rightarrow R)$ , arising from the supply of molecules on the left, is

$$J(L \rightarrow R) = \frac{\frac{1}{4} A_0 \mathcal{N}(-\lambda) \bar{c} \Delta t}{A_0 \Delta t} = \frac{1}{4} \mathcal{N}(-\lambda) \bar{c} \quad (20.64)$$

There is also a flux of molecules from right to left. On average, the molecules making the journey have originated from  $z = +\lambda$  where the number density is  $\mathcal{N}(\lambda)$ . Therefore,

$$J(L \leftarrow R) = -\frac{1}{4} \mathcal{N}(\lambda) \bar{c} \quad (20.65)$$

**Fig. 20.22** The calculation of the rate of diffusion of a gas considers the net flux of molecules through a plane of area  $A$  as a result of arrivals from on average a distance  $\lambda$  away in each direction, where  $\lambda$  is the mean free path.

The average number density at  $z = +\lambda$  is approximately

$$\mathcal{N}(\lambda) = \mathcal{N}(0) + \lambda \left( \frac{d\mathcal{N}}{dz} \right)_0 \quad (20.66)$$

The net flux is

$$\begin{aligned} J_z &= J(L \rightarrow R) + J(L \leftarrow R) \\ &= \frac{1}{4} \bar{c} \left\{ \left[ \mathcal{N}(0) - \lambda \left( \frac{d\mathcal{N}}{dz} \right)_0 \right] - \left[ \mathcal{N}(0) + \lambda \left( \frac{d\mathcal{N}}{dz} \right)_0 \right] \right\} \\ &= -\frac{1}{2} \bar{c} \lambda \left( \frac{d\mathcal{N}}{dz} \right)_0 \end{aligned} \quad (20.67)$$

This equation shows that the flux is proportional to the first derivative of the concentration, in agreement with Fick's law.

At this stage it looks as though we can pick out a value of the diffusion coefficient by comparing eqns 20.19 and 20.67, so obtaining  $D = \frac{1}{2} \lambda \bar{c}$ . It must be remembered, however, that the calculation is quite crude, and is little more than an assessment of the order of magnitude of  $D$ . One aspect that has not been taken into account is illustrated in Fig. 20.23, which shows that, although a molecule may have begun its journey very close to the window, it could have a long flight before it gets there. Because the path is long, the molecule is likely to collide before reaching the window, so it ought to be added to the graveyard of other molecules that have collided. To take this effect into account involves a lot of work, but the end result is the appearance of a factor of  $\frac{2}{3}$  representing the lower flux. The modification results in eqn 20.22.

#### (b) Thermal conductivity

According to the equipartition theorem (Section 16.3), each molecule carries an average energy  $\varepsilon = \frac{1}{2} kT$ , where  $\frac{1}{2}$  is a number of the order of 1.

**Fig. 20.23** One approximation ignored in the simple treatment is that some particles might make a long flight to the plane even though they are only a short perpendicular distance away, and therefore they have a higher chance of colliding during their journey.

For monatomic particles,  $v = \frac{3}{2}$ . When one molecule passes through the imaginary window, it transports that energy on average. We suppose that the number density is uniform but that the temperature is not. On average, molecules arrive from the left after travelling a mean free path from their last collision in a hotter region, and therefore with a higher energy. Molecules also arrive from the right after travelling a mean free path from a cooler region. The two opposing energy fluxes are therefore

$$\begin{aligned} J(L \rightarrow R) &= \frac{1}{4} \bar{c} \mathcal{N} \varepsilon(-\lambda) & \varepsilon(-\lambda) &= vk \left\{ T - \lambda \left( \frac{dT}{dz} \right)_0 \right\} \\ J(L \leftarrow R) &= \frac{1}{4} \bar{c} \mathcal{N} \varepsilon(+\lambda) & \varepsilon(+\lambda) &= vk \left\{ T + \lambda \left( \frac{dT}{dz} \right)_0 \right\} \end{aligned} \quad (20.68)$$

and the net flux is

$$J_z = J(L \rightarrow R) - J(L \leftarrow R) = -\frac{1}{2} vk \lambda \bar{c} \mathcal{N} \left( \frac{dT}{dz} \right)_0 \quad (20.69)$$

As before, we multiply by  $\frac{2}{3}$  to take long flight paths into account, and so arrive at

$$J_z = -\frac{1}{3} vk \lambda \bar{c} \mathcal{N} \left( \frac{dT}{dz} \right)_0 \quad (20.70)$$

The energy flux is proportional to the temperature gradient, as we wanted to show. Comparison of this equation with eqn 20.20 shows that

$$\kappa = \frac{1}{3} vk \lambda \bar{c} \mathcal{N} \quad (20.71)$$

Equation 20.23 then follows from  $C_{V,m} = vkN_A$  for a perfect gas, where  $[A]$  is the molar concentration of A. For this step, we use  $\mathcal{N} = N/V = nN_A/V = N_A[A]$ .

### (c) Viscosity

Molecules travelling from the right in Fig. 20.24 (from a fast layer to a slower one) transport a momentum  $mv_x(\lambda)$  to their new layer at  $z=0$ ; those travelling from the left transport  $mv_x(-\lambda)$  to it. If it is assumed that the density is uniform, the collision flux is  $\frac{1}{4}\bar{c}$ . Those arriving from the right on average carry a momentum

$$mv_x(\lambda) = mv_x(0) + m\lambda \left( \frac{dv_x}{dz} \right)_0 \quad (20.72a)$$

**Fig. 20.24** The calculation of the viscosity of a gas examines the net  $x$ -component of momentum brought to a plane from faster and slower layers on average a mean free path away in each direction.

Those arriving from the left bring a momentum

$$mv_x(-\lambda) = mv_x(0) - m\lambda \left( \frac{dv_x}{dz} \right)_0 \quad (20.72b)$$

The net flux of  $x$ -momentum in the  $z$ -direction is therefore

$$\begin{aligned} J &= \frac{1}{4} \bar{c} \left\{ \left[ mv_x(0) - m\lambda \left( \frac{dv_x}{dz} \right)_0 \right] - \left[ mv_x(0) + m\lambda \left( \frac{dv_x}{dz} \right)_0 \right] \right\} \\ &= -\frac{1}{2} \bar{c} m \lambda \left( \frac{dv_x}{dz} \right)_0 \end{aligned} \quad (20.73)$$

The flux is proportional to the velocity gradient, as we wished to show. Comparison of this expression with eqn 20.21, and multiplication by  $\frac{2}{3}$  in the normal way, leads to

$$\eta = \frac{1}{3} \bar{c} m \lambda \quad (20.74)$$

which can easily be converted into eqn 20.24 by using  $Nm = nM$  and  $[A] = n/V$ .

## Discussion questions

**20.1** Provide a molecular interpretation for each of the following processes: diffusion, thermal conduction, electric conduction, viscosity.

**20.2** Provide a molecular interpretation for the observation that the viscosity of a gas increases with temperature whereas the viscosity of a liquid decreases with increasing temperature.

**20.3** Discuss the mechanism of proton conduction in liquid water. How could this mechanism be tested?

**20.4** What is the nature of a thermodynamic force?

**20.5** Provide a molecular interpretation for the observation that mediated transport across a biological membrane leads to a maximum flux  $J_{\max}$  when the concentration of the transported species becomes very large.

**20.6** Discuss how nuclear magnetic resonance spectroscopy, inelastic neutron scattering, and dynamic light scattering may be used to measure the mobility of molecules in liquids.

## Exercises

**20.1(a)** Determine the ratios of (a) the mean speeds, (b) the mean kinetic energies of  $\text{H}_2$  molecules and Hg atoms at  $20^\circ\text{C}$ .

**20.1(b)** Determine the ratios of (a) the mean speeds, (b) the mean kinetic energies of He atoms and Hg atoms at  $25^\circ\text{C}$ .

**20.2(a)** A  $1.0\text{ dm}^3$  glass bulb contains  $1.0 \times 10^{23}$   $\text{H}_2$  molecules. If the pressure exerted by the gas is 100 kPa, what are (a) the temperature of the gas, (b) the root mean square speeds of the molecules? (c) Would the temperature be different if they were  $\text{O}_2$  molecules?

**20.2(b)** The best laboratory vacuum pump can generate a vacuum of about 1 nTorr. At  $25^\circ\text{C}$  and assuming that air consists of  $\text{N}_2$  molecules with a collision diameter of 395 pm, calculate (a) the mean speed of the molecules, (b) the mean free path, (c) the collision frequency in the gas.

**20.3(a)** Use the Maxwell distribution of speeds to estimate the fraction of  $\text{N}_2$  molecules at 500 K that have speeds in the range 290 to 300  $\text{m s}^{-1}$ .

**20.3(b)** Use the Maxwell distribution of speeds to estimate the fraction of  $\text{CO}_2$  molecules at 300 K that have speeds in the range 200 to 250  $\text{m s}^{-1}$ .

**20.4(a)** Find an expression for the root mean square deviation of the speed of molecules in a gas from its mean value,  $\Delta c = \{\langle c^2 \rangle - \langle c \rangle^2\}^{1/2}$ .

**20.4(b)** Find a relation between  $\langle c^2 \rangle^{1/2}$  and  $\langle c^4 \rangle^{1/4}$  for molecules in a gas at a temperature  $T$ .

**20.5(a)** At what pressure does the mean free path of argon at  $25^\circ\text{C}$  become comparable to the size of a  $1\text{ dm}^3$  vessel that contains it? Take  $\sigma = 0.36\text{ nm}^2$ .

**20.5(b)** At what pressure does the mean free path of argon at  $25^\circ\text{C}$  become comparable to the diameters of the atoms themselves?

**20.6(a)** At an altitude of 20 km the temperature is 217 K and the pressure 0.050 atm. What is the mean free path of  $\text{N}_2$  molecules? ( $\sigma = 0.43\text{ nm}^2$ .)

**20.6(b)** At an altitude of 15 km the temperature is 217 K and the pressure 12.1 kPa. What is the mean free path of  $\text{N}_2$  molecules? ( $\sigma = 0.43\text{ nm}^2$ .)

**20.7(a)** How many collisions does a single Ar atom make in 1.0 s when the temperature is  $25^\circ\text{C}$  and the pressure is (a) 10 atm, (b) 1.0 atm, (c) 1.0  $\mu\text{atm}$ ?

**20.7(b)** How many collisions per second does an  $\text{N}_2$  molecule make at an altitude of 15 km? (See Exercise 20.6b for data.)

**20.8(a)** Calculate the mean free path of molecules in air using  $\sigma = 0.43\text{ nm}^2$  at  $25^\circ\text{C}$  and (a) 10 atm, (b) 1.0 atm, (c) 1.0  $\mu\text{atm}$ .

**20.8(b)** Calculate the mean free path of carbon dioxide molecules using  $\sigma = 0.52\text{ nm}^2$  at  $25^\circ\text{C}$  and (a) 15 atm, (b) 1.0 bar, (c) 1.0 Torr.

**20.9(a)** A solid surface with dimensions  $2.5\text{ mm} \times 3.0\text{ mm}$  is exposed to argon gas at 90 Pa and 500 K. How many collisions do the Ar atoms make with this surface in 15 s?

**20.9(b)** A solid surface with dimensions  $3.5\text{ mm} \times 4.0\text{ cm}$  is exposed to helium gas at 111 Pa and 1500 K. How many collisions do the He atoms make with this surface in 10 s?

**20.10(a)** An effusion cell has a circular hole of diameter 2.50 mm. If the molar mass of the solid in the cell is  $260\text{ g mol}^{-1}$  and its vapour pressure is 0.835 Pa at 400 K, by how much will the mass of the solid decrease in a period of 2.00 h?

**20.10(b)** An effusion cell has a circular hole of diameter 3.00 mm. If the molar mass of the solid in the cell is  $300\text{ g mol}^{-1}$  and its vapour pressure is 0.224 Pa at 450 K, by how much will the mass of the solid decrease in a period of 24.00 h?

**20.11(a)** A solid compound of molar mass  $100\text{ g mol}^{-1}$  was introduced into a container and heated to  $400^\circ\text{C}$ . When a hole of diameter 0.50 mm was opened in the container for 400 s, a mass loss of 285 mg was measured. Calculate the vapour pressure of the compound at  $400^\circ\text{C}$ .

**20.11(b)** A solid compound of molar mass  $200\text{ g mol}^{-1}$  was introduced into a container and heated to  $300^\circ\text{C}$ . When a hole of diameter 0.50 mm was opened in the container for 500 s, a mass loss of 277 mg was measured. Calculate the vapour pressure of the compound at  $300^\circ\text{C}$ .

**20.12(a)** A manometer was connected to a bulb containing carbon dioxide under slight pressure. The gas was allowed to escape through a small pinhole, and the time for the manometer reading to drop from 75 cm to 50 cm was 52 s. When the experiment was repeated using nitrogen (for which  $M = 28.02\text{ g mol}^{-1}$ ) the same fall took place in 42 s. Calculate the molar mass of carbon dioxide.

**20.12(b)** A manometer was connected to a bulb containing nitrogen under slight pressure. The gas was allowed to escape through a small pinhole, and the time for the manometer reading to drop from 65.1 cm to 42.1 cm was 18.5 s. When the experiment was repeated using a fluorocarbon gas, the same fall took place in 82.3 s. Calculate the molar mass of the fluorocarbon.

**20.13(a)** A space vehicle of internal volume  $3.0\text{ m}^3$  is struck by a meteor and a hole of radius 0.10 mm is formed. If the oxygen pressure within the vehicle is initially 80 kPa and its temperature 298 K, how long will the pressure take to fall to 70 kPa?

**20.13(b)** A container of internal volume  $22.0\text{ m}^3$  was punctured, and a hole of radius 0.050 mm was formed. If the nitrogen pressure within the vehicle is initially 122 kPa and its temperature 293 K, how long will the pressure take to fall to 105 kPa?

**20.14(a)** Calculate the flux of energy arising from a temperature gradient of  $2.5\text{ K m}^{-1}$  in a sample of argon in which the mean temperature is 273 K.

**20.14(b)** Calculate the flux of energy arising from a temperature gradient of  $3.5\text{ K m}^{-1}$  in a sample of hydrogen in which the mean temperature is 260 K.

**20.15(a)** Use the experimental value of the thermal conductivity of neon (Table 20.2) to estimate the collision cross-section of Ne atoms at 273 K.

**20.15(b)** Use the experimental value of the thermal conductivity of nitrogen (Table 20.2) to estimate the collision cross-section of  $\text{N}_2$  molecules at 298 K.

**20.16(a)** In a double-glazed window, the panes of glass are separated by 5.0 cm. What is the rate of transfer of heat by conduction from the warm room ( $25^\circ\text{C}$ ) to the cold exterior ( $-10^\circ\text{C}$ ) through a window of area  $1.0\text{ m}^2$ ? What power of heater is required to make good the loss of heat?

**20.16(b)** Two sheets of copper of area  $1.50\text{ m}^2$  are separated by 10.0 cm. What is the rate of transfer of heat by conduction from the warm sheet ( $50^\circ\text{C}$ ) to the cold sheet ( $-10^\circ\text{C}$ ). What is the rate of loss of heat?

**20.17(a)** Use the experimental value of the coefficient of viscosity for neon (Table 20.2) to estimate the collision cross-section of Ne atoms at 273 K.

**20.17(b)** Use the experimental value of the coefficient of viscosity for nitrogen (Table 20.2) to estimate the collision cross-section of the molecules at 273 K.

**20.18(a)** Calculate the inlet pressure required to maintain a flow rate of  $9.5 \times 10^5\text{ dm}^3\text{ h}^{-1}$  of nitrogen at 293 K flowing through a pipe of length 8.50 m and diameter 1.00 cm. The pressure of gas as it leaves the tube is 1.00 bar. The volume of the gas is measured at that pressure.

**20.18(b)** Calculate the inlet pressure required to maintain a flow rate of  $8.70 \text{ cm}^3 \text{ s}^{-1}$  of nitrogen at 300 K flowing through a pipe of length 10.5 m and diameter 15 mm. The pressure of gas as it leaves the tube is 1.00 bar. The volume of the gas is measured at that pressure.

**20.19(a)** Calculate the viscosity of air at (a) 273 K, (b) 298 K, (c) 1000 K. Take  $\sigma \approx 0.40 \text{ nm}^2$ . (The experimental values are 173  $\mu\text{P}$  at 273 K, 182  $\mu\text{P}$  at 20°C, and 394  $\mu\text{P}$  at 600°C.)

**20.19(b)** Calculate the viscosity of benzene vapour at (a) 273 K, (b) 298 K, (c) 1000 K. Take  $\sigma \approx 0.88 \text{ nm}^2$ .

**20.20(a)** Calculate the thermal conductivities of (a) argon, (b) helium at 300 K and 1.0 mbar. Each gas is confined in a cubic vessel of side 10 cm, one wall being at 310 K and the one opposite at 295 K. What is the rate of flow of energy as heat from one wall to the other in each case?

**20.20(b)** Calculate the thermal conductivities of (a) neon, (b) nitrogen at 300 K and 15 mbar. Each gas is confined in a cubic vessel of side 15 cm, one wall being at 305 K and the one opposite at 295 K. What is the rate of flow of energy as heat from one wall to the other in each case?

**20.21(a)** Calculate the thermal conductivity of argon ( $C_{V,m} = 12.5 \text{ J K}^{-1} \text{ mol}^{-1}$ ,  $\sigma = 0.36 \text{ nm}^2$ ) at room temperature (20°C).

**20.21(b)** Calculate the thermal conductivity of nitrogen ( $C_{V,m} = 20.8 \text{ J K}^{-1} \text{ mol}^{-1}$ ,  $\sigma = 0.43 \text{ nm}^2$ ) at room temperature (20°C).

**20.22(a)** Calculate the diffusion constant of argon at 25°C and (a) 1.00 Pa, (b) 100 kPa, (c) 10.0 MPa. If a pressure gradient of  $0.10 \text{ atm cm}^{-1}$  is established in a pipe, what is the flow of gas due to diffusion?

**20.22(b)** Calculate the diffusion constant of nitrogen at 25°C and (a) 10.0 Pa, (b) 100 kPa, (c) 15.0 MPa. If a pressure gradient of  $0.20 \text{ bar m}^{-1}$  is established in a pipe, what is the flow of gas due to diffusion?

**20.23(a)** The mobility of a chloride ion in aqueous solution at 25°C is  $7.91 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ . Calculate the molar ionic conductivity.

**20.23(b)** The mobility of an acetate ion in aqueous solution at 25°C is  $4.24 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ . Calculate the molar ionic conductivity.

**20.24(a)** The mobility of a  $\text{Rb}^+$  ion in aqueous solution is  $7.92 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$  at 25°C. The potential difference between two electrodes placed in the solution is 35.0 V. If the electrodes are 8.00 mm apart, what is the drift speed of the  $\text{Rb}^+$  ion?

**20.24(b)** The mobility of a  $\text{Li}^+$  ion in aqueous solution is  $4.01 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$  at 25°C. The potential difference between two electrodes placed in the solution is 12.0 V. If the electrodes are 1.00 cm apart, what is the drift speed of the ion?

**20.25(a)** The limiting molar conductivities of  $\text{KCl}$ ,  $\text{KNO}_3$ , and  $\text{AgNO}_3$  are  $14.99 \text{ mS m}^2 \text{ mol}^{-1}$ ,  $14.50 \text{ mS m}^2 \text{ mol}^{-1}$ , and  $13.34 \text{ mS m}^2 \text{ mol}^{-1}$ , respectively (all at 25°C). What is the limiting molar conductivity of  $\text{AgCl}$  at this temperature?

**20.25(b)** The limiting molar conductivities of  $\text{NaI}$ ,  $\text{NaCH}_3\text{CO}_2$ , and  $\text{Mg}(\text{CH}_3\text{CO}_2)_2$  are  $12.69 \text{ mS m}^2 \text{ mol}^{-1}$ ,  $9.10 \text{ mS m}^2 \text{ mol}^{-1}$ , and  $18.78 \text{ mS m}^2 \text{ mol}^{-1}$ , respectively (all at 25°C). What is the limiting molar conductivity of  $\text{MgI}_2$  at this temperature?

**20.26(a)** At 25°C the molar ionic conductivities of  $\text{Li}^+$ ,  $\text{Na}^+$ , and  $\text{K}^+$  are  $3.87 \text{ mS m}^2 \text{ mol}^{-1}$ ,  $5.01 \text{ mS m}^2 \text{ mol}^{-1}$ , and  $7.35 \text{ mS m}^2 \text{ mol}^{-1}$ , respectively. What are their mobilities?

**20.26(b)** At 25°C the molar ionic conductivities of  $\text{F}^-$ ,  $\text{Cl}^-$ , and  $\text{Br}^-$  are  $5.54 \text{ mS m}^2 \text{ mol}^{-1}$ ,  $7.635 \text{ mS m}^2 \text{ mol}^{-1}$ , and  $7.81 \text{ mS m}^2 \text{ mol}^{-1}$ , respectively. What are their mobilities?

**20.27(a)** The mobility of a  $\text{NO}_3^-$  ion in aqueous solution at 25°C is  $7.40 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ . Calculate its diffusion coefficient in water at 25°C.

**20.27(b)** The mobility of a  $\text{CH}_3\text{CO}_2^-$  ion in aqueous solution at 25°C is  $4.24 \times 10^{-8} \text{ m}^2 \text{ s}^{-1} \text{ V}^{-1}$ . Calculate its diffusion coefficient in water at 25°C.

**20.28(a)** Suppose the concentration of a solute decays linearly along the length of a container. Calculate the thermodynamic force on the solute at 25°C and 10 cm and 20 cm given that the concentration falls to half its value in 10 cm.

**20.28(b)** Suppose the concentration of a solute increases as  $x^2$  along the length of a container. Calculate the thermodynamic force on the solute at 25°C and 8 cm and 16 cm given that the concentration falls to half its value in 8 cm.

**20.29(a)** Suppose the concentration of a solute follows a Gaussian distribution (proportional to  $e^{-x^2}$ ) along the length of a container. Calculate the thermodynamic force on the solute at 20°C and 5.0 cm given that the concentration falls to half its value in 5.0 cm.

**20.29(b)** Suppose the concentration of a solute follows a Gaussian distribution (proportional to  $e^{-x^2}$ ) along the length of a container. Calculate the thermodynamic force on the solute at 18°C and 10.0 cm given that the concentration falls to half its value in 10.0 cm.

**20.30(a)** The diffusion coefficient of  $\text{CCl}_4$  in heptane at 25°C is  $3.17 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ . Estimate the time required for a  $\text{CCl}_4$  molecule to have a root mean square displacement of 5.0 mm.

**20.30(b)** The diffusion coefficient of  $\text{I}_2$  in hexane at 25°C is  $4.05 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ . Estimate the time required for an iodine molecule to have a root mean square displacement of 1.0 cm.

**20.31(a)** Estimate the effective radius of a sucrose molecule in water at 25°C given that its diffusion coefficient is  $5.2 \times 10^{-10} \text{ m}^2 \text{ s}^{-1}$  and that the viscosity of water is 1.00 cP.

**20.31(b)** Estimate the effective radius of a glycine molecule in water at 25°C given that its diffusion coefficient is  $1.055 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$  and that the viscosity of water is 1.00 cP.

**20.32(a)** The diffusion coefficient for molecular iodine in benzene is  $2.13 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ . How long does a molecule take to jump through about one molecular diameter (approximately the fundamental jump length for translational motion)?

**20.32(b)** The diffusion coefficient for  $\text{CCl}_4$  in heptane is  $3.17 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ . How long does a molecule take to jump through about one molecular diameter (approximately the fundamental jump length for translational motion)?

**20.33(a)** What are the root mean square distances travelled by an iodine molecule in benzene and by a sucrose molecule in water at 25°C in 1.0 s?

**20.33(b)** About how long, on average, does it take for the molecules in Exercise 20.33a to drift to a point (a) 1.0 mm, (b) 1.0 cm from their starting points?

## Problems\*

## Numerical problems

**20.1** The speed of molecules can be measured with a rotating slotted-disc apparatus, which consists of five coaxial 5.0 cm diameter discs separated by 1.0 cm, the slots in their rims being displaced by  $2.0^\circ$  between neighbours. The relative intensities,  $I$ , of the detected beam of Kr atoms for two different temperatures and at a series of rotation rates were as follows:

| $v/\text{Hz}$     | 20    | 40    | 80    | 100   | 120   |
|-------------------|-------|-------|-------|-------|-------|
| $I(40\text{ K})$  | 0.846 | 0.513 | 0.069 | 0.015 | 0.002 |
| $I(100\text{ K})$ | 0.592 | 0.485 | 0.217 | 0.119 | 0.057 |

Find the distributions of molecular velocities,  $f(v_x)$ , at these temperatures, and check that they conform to the theoretical prediction for a one-dimensional system.

**20.2** Cars were timed by police radar as they passed in both directions below a bridge. Their velocities (kilometres per hour, numbers of cars in parentheses) to the east and west were as follows: 80 E (40), 85 E (62), 90 E (53), 95 E (12), 100 E (2); 80 W (38), 85 W (59), 90 W (50), 95 W (10), 100 W (2). What are (a) the mean velocity, (b) the mean speed, (c) the root mean square speed?

**20.3** A population consists of people of the following heights (in metres, numbers of individuals in brackets): 1.80 (1), 1.82 (2), 1.84 (4), 1.86 (7), 1.88 (10), 1.90 (15), 1.92 (9), 1.94 (4), 1.96 (0), 1.98 (1). What are (a) the mean height, (b) the root mean square height of the population?

**20.4** Calculate the ratio of the thermal conductivities of gaseous hydrogen at 300 K to gaseous hydrogen at 10 K. Be circumspect, and think about the modes of motion that are thermally active at the two temperatures.

**20.5** A Knudsen cell was used to determine the vapour pressure of germanium at  $1000^\circ\text{C}$ . During an interval of 7200 s the mass loss through a hole of radius 0.50 mm amounted to 43  $\mu\text{g}$ . What is the vapour pressure of germanium at  $1000^\circ\text{C}$ ? Assume the gas to be monatomic.

**20.6** An atomic beam is designed to function with (a) cadmium, (b) mercury. The source is an oven maintained at 380 K, there being a small slit of dimensions  $1.0\text{ cm} \times 1.0 \times 10^{-3}\text{ cm}$ . The vapour pressure of cadmium is 0.13 Pa and that of mercury is 12 Pa at this temperature. What is the atomic current (the number of atoms per second) in the beams?

**20.7** Conductivities are often measured by comparing the resistance of a cell filled with the sample to its resistance when filled with some standard solution, such as aqueous potassium chloride. The conductivity of water is  $76\text{ mS m}^{-1}$  at  $25^\circ\text{C}$  and the conductivity of  $0.100\text{ mol dm}^{-3}\text{ KCl(aq)}$  is  $1.1639\text{ S m}^{-1}$ . A cell had a resistance of  $33.21\ \Omega$  when filled with  $0.100\text{ mol dm}^{-3}\text{ KCl(aq)}$  and  $300.0\ \Omega$  when filled with  $0.100\text{ mol dm}^{-3}\text{ CH}_3\text{COOH(aq)}$ . What is the molar conductivity of acetic acid at that concentration and temperature?

**20.8** The resistances of a series of aqueous NaCl solutions, formed by successive dilution of a sample, were measured in a cell with cell constant (the constant  $C$  in the relation  $\kappa = C/R$ ) equal to  $0.2063\text{ cm}^{-1}$ . The following values were found:

| $c/(\text{mol dm}^{-3})$ | 0.00050 | 0.0010 | 0.0050 | 0.010 | 0.020 | 0.050 |
|--------------------------|---------|--------|--------|-------|-------|-------|
| $R/\Omega$               | 3314    | 1669   | 342.1  | 174.1 | 89.08 | 37.14 |

Verify that the molar conductivity follows the Kohlrausch law and find the limiting molar conductivity. Determine the coefficient  $\mathcal{K}$ . Use the value of  $\mathcal{K}$  (which should depend only on the nature, not the identity of the ions) and the

information that  $\lambda(\text{Na}^+) = 5.01\text{ mS m}^2\text{ mol}^{-1}$  and  $\lambda(\text{I}^-) = 7.68\text{ mS m}^2\text{ mol}^{-1}$  to predict (a) the molar conductivity, (b) the conductivity, (c) the resistance it would show in the cell, of  $0.010\text{ mol dm}^{-3}\text{ NaI(aq)}$  at  $25^\circ\text{C}$ .

**20.9** After correction for the water conductivity, the conductivity of a saturated aqueous solution of AgCl at  $25^\circ\text{C}$  was found to be  $0.1887\text{ mS m}^{-1}$ . What is the solubility of silver chloride at this temperature?

**20.10** What are the drift speeds of  $\text{Li}^+$ ,  $\text{Na}^+$ , and  $\text{K}^+$  in water when a potential difference of 10 V is applied across a 1.00-cm conductivity cell? How long would it take an ion to move from one electrode to the other? In conductivity measurements it is normal to use alternating current: what are the displacements of the ions in (a) centimetres, (b) solvent diameters, about 300 pm, during a half cycle of 1.0 kHz applied potential?

**20.11** The mobilities of  $\text{H}^+$  and  $\text{Cl}^-$  at  $25^\circ\text{C}$  in water are  $3.623 \times 10^{-7}\text{ m}^2\text{ s}^{-1}\text{ V}^{-1}$  and  $7.91 \times 10^{-8}\text{ m}^2\text{ s}^{-1}\text{ V}^{-1}$ , respectively. What proportion of the current is carried by the protons in  $10^{-3}\text{ M HCl(aq)}$ ? What fraction do they carry when the NaCl is added to the acid so that the solution is  $1.0\text{ mol dm}^{-3}$  in the salt? Note how concentration as well as mobility governs the transport of current.

**20.12** A dilute solution of potassium permanganate in water at  $25^\circ\text{C}$  was prepared. The solution was in a horizontal tube of length 10 cm, and at first there was a linear gradation of intensity of the purple solution from the left (where the concentration was  $0.100\text{ mol dm}^{-3}$ ) to the right (where the concentration was  $0.050\text{ mol dm}^{-3}$ ). What are the magnitude and sign of the thermodynamic force acting on the solute (a) close to the left face of the container, (b) in the middle, (c) close to the right face? Give the force per mole and force per molecule in each case.

**20.13** Estimate the diffusion coefficients and the effective hydrodynamic radii of the alkali metal cations in water from their mobilities at  $25^\circ\text{C}$ . Estimate the approximate number of water molecules that are dragged along by the cations. Ionic radii are given in Table 20.3.

**20.14** Nuclear magnetic resonance can be used to determine the mobility of molecules in liquids. A set of measurements on methane in carbon tetrachloride showed that its diffusion coefficient is  $2.05 \times 10^{-9}\text{ m}^2\text{ s}^{-1}$  at  $0^\circ\text{C}$  and  $2.89 \times 10^{-9}\text{ m}^2\text{ s}^{-1}$  at  $25^\circ\text{C}$ . Deduce what information you can about the mobility of methane in carbon tetrachloride.

**20.15** A concentrated sucrose solution is poured into a cylinder of diameter 5.0 cm. The solution consisted of 10 g of sugar in  $5.0\text{ cm}^3$  of water. A further  $1.0\text{ dm}^3$  of water is then poured very carefully on top of the layer, without disturbing the layer. Ignore gravitational effects, and pay attention only to diffusional processes. Find the concentration at 5.0 cm above the lower layer after a lapse of (a) 10 s, (b) 1.0 years.

**20.16** In a series of observations on the displacement of rubber latex spheres of radius  $0.212\ \mu\text{m}$ , the mean square displacements after selected time intervals were on average as follows:

| $t/\text{s}$                            | 30   | 60    | 90  | 120 |
|-----------------------------------------|------|-------|-----|-----|
| $10^{12}\langle x^2 \rangle/\text{m}^2$ | 88.2 | 113.5 | 128 | 144 |

These results were originally used to find the value of Avogadro's constant, but there are now better ways of determining  $N_A$ , so the data can be used to find another quantity. Find the effective viscosity of water at the temperature of this experiment ( $25^\circ\text{C}$ ).

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp, Carmen Giunta, and Marshall Cady.

**20.17‡** A.K. Srivastava *et al.* (*J. Chem. Eng. Data* **41**, 431 (1996)) measured the conductance of several salts in a binary solvent mixture of water and a dipolar aprotic solvent 1,3-dioxolan-2-one. They report the following conductances at 25°C in a solvent 80 per cent 1,3-dioxolan-2-one by mass:

NaI

|                                              |       |       |       |       |       |       |       |
|----------------------------------------------|-------|-------|-------|-------|-------|-------|-------|
| $c/(\text{mmol dm}^{-3})$                    | 32.02 | 20.28 | 12.06 | 8.64  | 2.85  | 1.24  | 0.83  |
| $\Lambda_m/(\text{S cm}^2 \text{ mol}^{-1})$ | 50.26 | 51.99 | 54.01 | 55.75 | 57.99 | 58.44 | 58.67 |

KI

|                                              |       |       |       |       |       |       |       |
|----------------------------------------------|-------|-------|-------|-------|-------|-------|-------|
| $c/(\text{mmol dm}^{-3})$                    | 17.68 | 10.8  | 87.19 | 2.67  | 1.28  | 0.83  | 0.19  |
| $\Lambda_m/(\text{S cm}^2 \text{ mol}^{-1})$ | 42.45 | 45.91 | 47.53 | 51.81 | 54.09 | 55.78 | 57.42 |

Calculate  $\Lambda_m^\circ$  for NaI and KI in this solvent and  $\lambda^\circ(\text{Na}) - \lambda^\circ(\text{K})$ . Compare your results to the analogous quantities in aqueous solution using Table 20.5 in the *Data section*.

**20.18‡** A. Fenghour *et al.* (*J. Phys. Chem. Ref. Data* **24**, 1649 (1995)) have compiled an extensive table of viscosity coefficients for ammonia in the liquid and vapour phases. Deduce the effective molecular diameter of  $\text{NH}_3$  based on each of the following vapour-phase viscosity coefficients: (a)  $\eta = 9.08 \times 10^{-6} \text{ kg m}^{-1} \text{ s}^{-1}$  at 270 K and 1.00 bar; (b)  $\eta = 1.749 \times 10^{-5} \text{ kg m}^{-1} \text{ s}^{-1}$  at 490 K and 10.0 bar.

**20.19‡** G. Bakale *et al.* (*J. Phys. Chem.* **100**, 12477 (1996)) measured the mobility of singly charged  $\text{C}_{60}^-$  ions in a variety of nonpolar solvents. In cyclohexane at 22°C, the mobility is  $1.1 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . Estimate the effective radius of the  $\text{C}_{60}^-$  ion. The viscosity of the solvent is  $0.93 \times 10^{-3} \text{ kg m}^{-1} \text{ s}^{-1}$ . *Comment.* The researchers interpreted the substantial difference between this number and the van der Waals radius of neutral  $\text{C}_{60}$  in terms of a solvation layer around the ion.

### Theoretical problems

**20.20** Start from the Maxwell–Boltzmann distribution and derive an expression for the most probable speed of a gas of molecules at a temperature  $T$ . Go on to demonstrate the validity of the equipartition conclusion that the average translational kinetic energy of molecules free to move in three dimensions is  $\frac{3}{2}kT$ .

**20.21** Consider molecules that are confined to move in a plane (a two-dimensional gas). Calculate the distribution of speeds and determine the mean speed of the molecules at a temperature  $T$ .

**20.22** A specially constructed velocity-selector accepts a beam of molecules from an oven at a temperature  $T$  but blocks the passage of molecules with a speed greater than the mean. What is the mean speed of the emerging beam, relative to the initial value, treated as a one-dimensional problem?

**20.23** What is the proportion of gas molecules having (a) more than, (b) less than the root mean square speed? (c) What are the proportions having speeds greater and smaller than the mean speed?

**20.24** Calculate the fractions of molecules in a gas that have a speed in a range  $\Delta v$  at the speed  $nc^*$  relative to those in the same range at  $c^*$  itself? This calculation can be used to estimate the fraction of very energetic molecules (which is important for reactions). Evaluate the ratio for  $n = 3$  and  $n = 4$ .

**20.25** Derive an expression that shows how the pressure of a gas inside an effusion oven (a heated chamber with a small hole in one wall) varies with time if the oven is not replenished as the gas escapes. Then show that  $t_{1/2}$ , the time required for the pressure to decrease to half its initial value, is independent of the initial pressure. *Hint.* Begin by setting up a differential equation relating  $dp/dt$  to  $p = NkT/V$ , and then integrating it.

**20.26** Confirm that eqn 20.57 is a solution of the diffusion equation with the correct initial value.

**20.27** Calculate the relation between  $\langle x^2 \rangle^{1/2}$  and  $\langle x^4 \rangle^{1/4}$  for diffusing particles at a time  $t$  if they have a diffusion constant  $D$ .

**20.28** The diffusion equation is valid when many elementary steps are taken in the time interval of interest, but the random walk calculation lets us discuss distributions for short times as well as for long. Use eqn 20.61 to calculate the probability of being six paces from the origin (that is, at  $x = 6\lambda$ ) after (a) four, (b) six, (c) twelve steps.

**20.29‡** A dilute solution of a weak (1,1)-electrolyte contains both neutral ion pairs and ions in equilibrium ( $\text{AB} \rightleftharpoons \text{A}^+ + \text{B}^-$ ). Prove that molar conductivities are related to the degree of ionization by the equations:

$$\frac{1}{\Lambda_m} = \frac{1}{\Lambda_m(\alpha)} + \frac{(1-\alpha)\Lambda_m^\circ}{\alpha^2\Lambda_m(\alpha)^2} \quad \Lambda_m(\alpha) = \lambda_+ + \lambda_- = \Lambda_m^\circ - \mathcal{K}(\alpha)^{1/2}$$

where  $\Lambda_m^\circ$  is the molar conductivity at infinite dilution and  $\mathcal{K}$  is the constant in Kohlrausch's law (eqn 20.28).

### Applications: to astrophysics and biochemistry

**20.30** Calculate the escape velocity (the minimum initial velocity that will take an object to infinity) from the surface of a planet of radius  $R$ . What is the value for (a) the Earth,  $R = 6.37 \text{ Mm}$ ,  $g = 9.81 \text{ m s}^{-2}$ , (b) Mars,  $R = 3.38 \text{ Mm}$ ,  $m_{\text{Mars}}/m_{\text{Earth}} = 0.108$ . At what temperatures do  $\text{H}_2$ ,  $\text{He}$ , and  $\text{O}_2$  molecules have mean speeds equal to their escape speeds? What proportion of the molecules have enough speed to escape when the temperature is (a) 240 K, (b) 1500 K? Calculations of this kind are very important in considering the composition of planetary atmospheres.

**20.31‡** Interstellar space is a medium quite different from the gaseous environments we commonly encounter on Earth. For instance, a typical density of the medium is about  $1 \text{ atom cm}^{-3}$  and that atom is typically H; the effective temperature due to stellar background radiation is about 10 000 K. Estimate the diffusion coefficient and thermal conductivity of H under these conditions. *Comment.* Energy is in fact transferred much more effectively by radiation.

**20.32** The principal components of the atmosphere of the Earth are diatomic molecules, which can rotate as well as translate. Given that the translational kinetic energy density of the atmosphere is  $0.15 \text{ J cm}^{-3}$ , what is the total kinetic energy density, including rotation?

**20.33‡** In the *standard model* of stellar structure (I. Nicholson, *The sun*. Rand McNally, New York (1982)), the interior of the Sun is thought to consist of 36 per cent H and 64 per cent He by mass, at a density of  $158 \text{ g cm}^{-3}$ . Both atoms are completely ionized. The approximate dimensions of the nuclei can be calculated from the formula  $r_{\text{nucleus}} = 1.4A^{1/3} \text{ fm}$ , where  $A$  is the mass number. The size of the free electron,  $r_e \approx 10^{-18} \text{ m}$ , is negligible compared to the size of the nuclei. (a) Calculate the excluded volume in  $1.0 \text{ cm}^3$  of the stellar interior and on that basis decide upon the applicability of the perfect gas law to this system. (b) The standard model suggests that the pressure in the stellar interior is  $2.5 \times 10^{11} \text{ atm}$ . Calculate the temperature of the Sun's interior based on the perfect gas model. The generally accepted standard model value is 16 MK. (c) Would a van der Waals type of equation (with  $a = 0$ ) give a better value for  $T$ ?

**20.34** Enrico Fermi, the great Italian scientist, was a master at making good approximate calculations based on little or no actual data. Hence, such calculations are often called 'Fermi calculations'. Do a Fermi calculation on how long it would take for a gaseous air-borne cold virus of molar mass 100 kg

$\text{mol}^{-1}$  to travel the distance between two conversing people 1.0 m apart by diffusion in still air.

**20.35** The diffusion coefficient of a particular kind of t-RNA molecule is  $D = 1.0 \times 10^{-11} \text{ m}^2 \text{ s}^{-1}$  in the medium of a cell interior. How long does it take molecules produced in the cell nucleus to reach the walls of the cell at a distance 1.0  $\mu\text{m}$ , corresponding to the radius of the cell?

**20.36†** In this problem, we examine a model for the transport of oxygen from air in the lungs to blood. First, show that, for the initial and boundary conditions  $c(x, t) = c(x, 0) = c_0$ , ( $0 < x < \infty$ ) and  $c(0, t) = c_s$ , ( $0 \leq t \leq \infty$ ) where  $c_0$  and  $c_s$  are constants, the concentration,  $c(x, t)$ , of a species is given by

$$c(x, t) = c_0 + (c_s - c_0) \{1 - \text{erf} \xi\} \quad \xi(x, t) = \frac{x}{(4Dt)^{1/2}}$$

where  $\text{erf} \xi$  is the error function and the concentration  $c(x, t)$  evolves by diffusion from the  $yz$ -plane of constant concentration, such as might occur if a condensed phase is absorbing a species from a gas phase. Now draw graphs of concentration profiles at several different times of your choice for the diffusion of oxygen into water at 298 K (when  $D = 2.10 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ ) on a spatial scale comparable to passage of oxygen from lungs through alveoli into the blood. Use  $c_0 = 0$  and set  $c_s$  equal to the solubility of oxygen in water. *Hint.* Use mathematical software.

Problems

This chapter is the first of a sequence that explores the rates of chemical reactions. The chapter begins with a discussion of the definition of reaction rate and outlines the techniques for its measurement. The results of such measurements show that reaction rates depend on the concentration of reactants (and products) in characteristic ways that can be expressed in terms of differential equations known as rate laws. The solutions of these equations are used to predict the concentrations of species at any time after the start of the reaction. The form of the rate law also provides insight into the series of elementary steps by which a reaction takes place. The key task in this connection is the construction of a rate law from a proposed mechanism and its comparison with experiment. Simple elementary steps have simple rate laws, and these rate laws can be combined together by invoking one or more approximations. These approximations include the concept of the rate-determining stage of a reaction, the steady-state concentration of a reaction intermediate, and the existence of a pre-equilibrium. We go on to consider examples of reaction mechanisms, focusing on polymerization reactions and photochemistry, in which reactions are initiated by light.

This chapter introduces the principles of **chemical kinetics**, the study of reaction rates, by showing how the rates of reactions may be measured and interpreted. The remaining chapters of this part of the text then develop this material in more detail and apply it to more complicated or more specialized cases. The rate of a chemical reaction might depend on variables under our control, such as the pressure, the temperature, and the presence of a catalyst, and we may be able to optimize the rate by the appropriate choice of conditions. The study of reaction rates also leads to an understanding of the **mechanisms** of reactions, their analysis into a sequence of elementary steps.

## Empirical chemical kinetics

The first steps in the kinetic analysis of reactions are to establish the stoichiometry of the reaction and identify any side reactions. The basic data of chemical kinetics are then the concentrations of the reactants and products at different times after a reaction has been initiated. The rates of most chemical reactions are sensitive to the temperature, so in conventional experiments the temperature of the reaction mixture must be held constant throughout the course of the reaction. This requirement puts severe demands on the design of an experiment. Gas-phase reactions, for instance, are often carried out in a vessel held in contact with a substantial block of metal. Liquid-phase reactions, including flow reactions, must be carried out in an efficient thermostat. Special efforts have to be made to study reactions at low temperatures, as in the study of the

kinds of reactions that take place in interstellar clouds. Thus, supersonic expansion of the reaction gas can be used to attain temperatures as low as 10 K. For work in the liquid phase and the solid phase, very low temperatures are often reached by flowing cold liquid or cold gas around the reaction vessel. Alternatively, the entire reaction vessel is immersed in a thermally insulated container filled with a cryogenic liquid, such as liquid helium (for work at around 4 K) or liquid nitrogen (for work at around 77 K). Non-isothermal conditions are sometimes employed. For instance, the shelf-life of an expensive pharmaceutical may be explored by slowly raising the temperature of a single sample.

## 21.1 Experimental techniques

**Key points** (a) The rates of chemical reactions are measured by using techniques that monitor the concentrations of species present in the reaction mixture. (b) Examples of experimental techniques include real-time and quenching procedures, flow and stopped-flow techniques, and flash photolysis.

The method used to monitor concentrations depends on the species involved and the rapidity with which their concentrations change. Many reactions reach equilibrium over periods of minutes or hours, and several techniques may then be used to follow the changing concentrations.

### (a) Monitoring the progress of a reaction

A reaction in which at least one component is a gas might result in an overall change in pressure in a system of constant volume, so its progress may be followed by recording the variation of pressure with time.

#### Example 21.1 Monitoring the variation in pressure

Predict how the total pressure varies during the gas-phase decomposition  $2\text{N}_2\text{O}_5(\text{g}) \rightarrow 4\text{NO}_2(\text{g}) + \text{O}_2(\text{g})$  in a constant-volume container.

**Method** The total pressure (at constant volume and temperature and assuming perfect gas behaviour) is proportional to the number of gas-phase molecules. Therefore, because each mole of  $\text{N}_2\text{O}_5$  gives rise to  $\frac{5}{2}$  mol of gas molecules, we can expect the pressure to rise to  $\frac{5}{2}$  times its initial value. To confirm this conclusion, express the progress of the reaction in terms of the fraction,  $\alpha$ , of  $\text{N}_2\text{O}_5$  molecules that have reacted.

**Answer** Let the initial pressure be  $p_0$  and the initial amount of  $\text{N}_2\text{O}_5$  molecules present be  $n$ . When a fraction  $\alpha$  of the  $\text{N}_2\text{O}_5$  molecules has decomposed, the amounts of the components in the reaction mixture are:

|         | $\text{N}_2\text{O}_5$ | $\text{NO}_2$ | $\text{O}_2$          | Total                      |
|---------|------------------------|---------------|-----------------------|----------------------------|
| Amount: | $n(1 - \alpha)$        | $2\alpha n$   | $\frac{1}{2}\alpha n$ | $n(1 + \frac{3}{2}\alpha)$ |

When  $\alpha = 0$  the pressure is  $p_0$ , so at any stage the total pressure is

$$p = (1 + \frac{3}{2}\alpha)p_0$$

When the reaction is complete, the pressure will have risen to  $\frac{5}{2}$  times its initial value.

**Self-test 21.1** Repeat the calculation for  $2\text{NOBr}(\text{g}) \rightarrow 2\text{NO}(\text{g}) + \text{Br}_2(\text{g})$ .

$$[p = (1 + \frac{1}{2}\alpha)p_0]$$

**Fig. 21.1** The arrangement used in the flow technique for studying reaction rates. The reactants are injected into the mixing chamber at a steady rate. The location of the spectrometer corresponds to different times after initiation.

**Fig. 21.2** In the stopped-flow technique the reagents are driven quickly into the mixing chamber by the driving syringes and then the time dependence of the concentrations is monitored.

**Fig. 21.3** A configuration used for time-resolved absorption spectroscopy, in which the same pulsed laser is used to generate a monochromatic pump pulse and, after continuum generation in a suitable liquid, a 'white' light probe pulse. The time delay between the pump and probe pulses may be varied by moving the motorized stage in the direction shown by the double arrow.

Spectrophotometry, the measurement of absorption of radiation in a particular spectral region, is widely applicable, and is especially useful when one substance in the reaction mixture has a strong characteristic absorption in a conveniently accessible region of the electromagnetic spectrum. For example, the progress of the reaction

can be followed by measuring the absorption of visible light by bromine. A reaction that changes the number or type of ions present in a solution may be followed by monitoring the electrical conductivity of the solution. The replacement of neutral molecules by ionic products can result in dramatic changes in the conductivity, as in the reaction

If hydrogen ions are produced or consumed, the reaction may be followed by monitoring the pH of the solution.

Other methods of determining composition include emission spectroscopy, mass spectrometry, gas chromatography, nuclear magnetic resonance, and electron paramagnetic resonance (for reactions involving radicals or paramagnetic d-metal ions).

### (b) Application of the techniques

In a **real-time analysis** the composition of the system is analysed while the reaction is in progress. Either a small sample is withdrawn or the bulk solution is monitored. In the **flow method** the reactants are mixed as they flow together in a chamber (Fig. 21.1). The reaction continues as the thoroughly mixed solutions flow through the outlet tube, and observation of the composition at different positions along the tube is equivalent to the observation of the reaction mixture at different times after mixing. The disadvantage of conventional flow techniques is that a large volume of reactant solution is necessary. This makes the study of fast reactions particularly difficult because to spread the reaction over a length of tube the flow must be rapid. This disadvantage is avoided by the **stopped-flow technique**, in which the reagents are mixed very quickly in a small chamber fitted with a syringe instead of an outlet tube (Fig. 21.2). The flow ceases when the plunger of the syringe reaches a stop, and the reaction continues in the mixed solutions. Observations, commonly using spectroscopic techniques such as ultraviolet–visible absorption, circular dichroism, and fluorescence emission, are made on the sample as a function of time. The technique allows for the study of reactions that occur on the millisecond to second timescale. The suitability of the stopped-flow method to the study of small samples means that it is appropriate for many biochemical reactions, and it has been widely used to study the kinetics of protein folding and enzyme action (see *Impact I16.1*).

Very fast reactions can be studied by **flash photolysis**, in which the sample is exposed to a brief flash of light that initiates the reaction and then the contents of the reaction chamber are monitored. The apparatus used for flash photolysis studies is based on the experimental design for **time-resolved spectroscopy**, in which reactions occurring on a picosecond or femtosecond timescale may be monitored by using electronic absorption or emission, infrared absorption, or Raman scattering. The spectra are recorded at a series of times following laser excitation. The laser pulse can initiate the reaction by forming a reactive species, such as an excited electronic state of a molecule, a radical, or an ion. We discuss examples of excited state reactions in Section 21.10.

The arrangement shown in Fig. 21.3 is often used to study ultrafast chemical reactions that can be initiated by light, such as the initial events of vision (*Impact I13.1*). A strong and short laser pulse, the *pump*, promotes a molecule A to an excited electronic

state  $A^*$  that can either emit a photon (as fluorescence or phosphorescence) or react with another species B to yield a product C:

Here  $[AB]$  denotes either an intermediate or an activated complex (see Section 21.5). The rates of appearance and disappearance of the various species are determined by observing time-dependent changes in the absorption spectrum of the sample during the course of the reaction. This monitoring is done by passing a weak pulse of white light, the *probe*, through the sample at different times after the laser pulse. Pulsed 'white' light can be generated directly from the laser pulse by the phenomenon of **continuum generation**, in which focusing an ultrafast laser pulse on a sample containing a liquid (such as water or carbon tetrachloride) or a solid (such as sapphire) results in an outgoing beam with a wide distribution of frequencies. A time delay between the strong laser pulse and the 'white' light pulse can be introduced by allowing one of the beams to travel a longer distance before reaching the sample. For example, a difference in travel distance of  $\Delta d = 3 \text{ mm}$  corresponds to a time delay  $\Delta t = \Delta d/c \approx 10 \text{ ps}$  between two beams, where  $c$  is the speed of light. The relative distances travelled by the two beams in Fig. 21.3 are controlled by directing the 'white' light beam to a motorized stage carrying a pair of mirrors.

Variations of the arrangement in Fig. 21.3 allow for the observation of fluorescence decay kinetics of  $A^*$  and time-resolved Raman spectra during the course of the reaction. The fluorescence lifetime of  $A^*$  can be determined by exciting A as before and measuring the decay of the fluorescence intensity after the pulse with a fast photodetector system. In this case, continuum generation is not necessary. Time-resolved resonance Raman spectra of A,  $A^*$ , B,  $[AB]$ , or C can be obtained by initiating the reaction with a strong laser pulse of a certain wavelength and then, some time later, irradiating the sample with another laser pulse that can excite the resonance Raman spectrum of the desired species. Also in this case continuum generation is not necessary. Instead, the Raman excitation beam may be generated in a dye laser (see *Further information 13.1*).

In contrast to real-time analysis, **quenching methods** are based on stopping, or quenching, the reaction after it has been allowed to proceed for a certain time. In this way the composition is analysed at leisure and reaction intermediates may be trapped. These methods are suitable only for reactions that are slow enough for there to be little reaction during the time it takes to quench the mixture. In the **chemical quench flow method**, the reactants are mixed in much the same way as in the flow method but the reaction is quenched by another reagent, such as solution of acid or base, after the mixture has travelled along a fixed length of the outlet tube. Different reaction times can be selected by varying the flow rate along the outlet tube. An advantage of the chemical quench flow method over the stopped-flow method is that spectroscopic fingerprints are not needed in order to measure the concentration of reactants and products. Once the reaction has been quenched, the solution may be examined by 'slow' techniques, such as gel electrophoresis, mass spectrometry, and chromatography. In the **freeze quench method**, the reaction is quenched by cooling the mixture within milliseconds and the concentrations of reactants, intermediates, and products are measured spectroscopically.

**Fig. 21.4** The definition of (instantaneous) rate as the slope of the tangent drawn to the curve showing the variation of concentration with time. For negative slopes, the sign is changed when reporting the rate, so all reaction rates are positive.

## 21.2 The rates of reactions

**Key points** (a) The instantaneous rate of a reaction is the slope of the tangent to the graph of concentration against time (expressed as a positive quantity). (b) A rate law is an expression for the reaction rate in terms of the concentrations of the species that occur in the overall chemical reaction. (c) For a rate law of the form  $v = k_r[A]^a[B]^b \dots$ , the rate constant is  $k_r$ , the order with respect to A is  $a$ , and the overall order is  $a + b + \dots$ . (d) The isolation method and the method of initial rates are often used in the determination of rate laws.

Reaction rates depend on the composition and the temperature of the reaction mixture. The next few sections look at these observations in more detail.

### (a) The definition of rate

Consider a reaction of the form  $A + 2B \rightarrow 3C + D$ , in which at some instant the molar concentration of a participant J is [J] and the volume of the system is constant. The instantaneous **rate of consumption** of one of the reactants at a given time is  $d[R]/dt$ , where R is A or B. This rate is a positive quantity (Fig. 21.4). The **rate of formation** of one of the products (C or D, which we denote P) is  $d[P]/dt$  (note the difference in sign). This rate is also positive.

It follows from the stoichiometry for the reaction  $A + 2B \rightarrow 3C + D$  that

$$\frac{d[D]}{dt} = \frac{1}{3} \frac{d[C]}{dt} = -\frac{d[A]}{dt} = -\frac{1}{2} \frac{d[B]}{dt}$$

so the rate of the reaction is related to the rates of change of concentration of products and reactants in several ways. The undesirability of having different rates to describe the same reaction is avoided by using the extent of reaction,  $\xi$  (xi, the quantity introduced in Section 6.1a):

$$\xi = \frac{n_J - n_{J,0}}{\nu_J} \quad \text{Definition of the extent of reaction} \quad [21.1]$$

where  $\nu_J$  is the stoichiometric number of species J, and defining the unique **rate of reaction**,  $v$ , as the rate of change of the extent of reaction:

$$v = \frac{1}{V} \frac{d\xi}{dt} \quad \text{Definition of the rate of reaction} \quad [21.2]$$

where  $V$  is the volume of the system. It follows that

$$v = \frac{1}{\nu_J} \times \frac{1}{V} \frac{dn_J}{dt} \quad (21.3a)$$

(Remember that  $\nu_J$  is negative for reactants and positive for products.) For a homogeneous reaction in a constant-volume system the volume  $V$  can be taken inside the differential and we use  $[J] = n_J/V$  to write

$$v = \frac{1}{\nu_J} \frac{d[J]}{dt} \quad (21.3b)$$

For a heterogeneous reaction, we use the (constant) surface area,  $A$ , occupied by the species in place of  $V$  and use  $\sigma_J = n_J/A$  to write

$$v = \frac{1}{\nu_J} \frac{d\sigma_J}{dt} \quad (21.3c)$$

In each case there is now a single rate for the entire reaction (for the chemical equation as written). With molar concentrations in moles per cubic decimetre and time in seconds, reaction rates of homogeneous reactions are reported in moles per cubic decimetre per second ( $\text{mol dm}^{-3} \text{s}^{-1}$ ) or related units. For gas-phase reactions, such as those taking place in the atmosphere, concentrations are often expressed in molecules per cubic centimetre ( $\text{molecules cm}^{-3}$ ) and rates in molecules per cubic centimetre per second ( $\text{molecules cm}^{-3} \text{s}^{-1}$ ). For heterogeneous reactions, rates are expressed in moles per square metre per second ( $\text{mol m}^{-2} \text{s}^{-1}$ ) or related units.

• **A brief illustration**

If the rate of formation of NO in the reaction  $2 \text{NOBr(g)} \rightarrow 2 \text{NO(g)} + \text{Br}_2\text{(g)}$  is reported as  $0.16 \text{ mmol dm}^{-3} \text{s}^{-1}$ , we use  $v_{\text{NO}} = +2$  to report that  $v = 0.080 \text{ mmol dm}^{-3} \text{s}^{-1}$ . Because  $v_{\text{NOBr}} = -2$  it follows that  $d[\text{NOBr}]/dt = -0.16 \text{ mmol dm}^{-3} \text{s}^{-1}$ . The rate of consumption of NOBr is therefore  $0.16 \text{ mmol dm}^{-3} \text{s}^{-1}$ , or  $9.6 \times 10^{16} \text{ molecules cm}^{-3} \text{s}^{-1}$ . •

**Self-test 21.2** The rate of change of molar concentration of  $\text{CH}_3$  radicals in the reaction  $2 \text{CH}_3\text{(g)} \rightarrow \text{CH}_3\text{CH}_3\text{(g)}$  was reported as  $d[\text{CH}_3]/dt = -1.2 \text{ mol dm}^{-3} \text{s}^{-1}$  under particular conditions. What is (a) the rate of reaction and (b) the rate of formation of  $\text{CH}_3\text{CH}_3$ ? [(a)  $0.60 \text{ mol dm}^{-3} \text{s}^{-1}$ , (b)  $0.60 \text{ mol dm}^{-3} \text{s}^{-1}$ ]

**(b) Rate laws and rate constants**

The rate of reaction is often found to be proportional to the concentrations of the reactants raised to a power. For example, the rate of a reaction may be proportional to the molar concentrations of two reactants A and B, so we write

$$v = k_r [\text{A}][\text{B}] \quad (21.4)$$

with each concentration raised to the first power. The coefficient  $k_r$  is called the **rate constant** for the reaction. The rate constant is independent of the concentrations but depends on the temperature. An experimentally determined equation of this kind is called the **rate law** of the reaction. More formally, a rate law is an equation that expresses the rate of reaction as a function of the concentrations of all the species present in the overall chemical equation for the reaction at some time:

$$v = f([\text{A}], [\text{B}], \dots)$$

Definition of the rate law in terms of the concentration

[21.5a]

For homogeneous gas-phase reactions, it is often more convenient to express the rate law in terms of partial pressures. In this case, we write

$$v = f(p_{\text{A}}, p_{\text{B}}, \dots)$$

Definition of the rate law in terms of the pressure

[21.5b]

The units of  $k_r$  are always such as to convert the product of concentrations into a rate expressed as a change in concentration divided by time. For example, if the rate law is the one shown in eqn 21.4, with concentrations expressed in  $\text{mol dm}^{-3}$ , then the units of  $k_r$  will be  $\text{dm}^3 \text{mol}^{-1} \text{s}^{-1}$  because

$$\text{dm}^3 \text{mol}^{-1} \text{s}^{-1} \times \text{mol dm}^{-3} \times \text{mol dm}^{-3} = \text{mol dm}^{-3} \text{s}^{-1}$$

In gas-phase studies, including studies of the processes taking place in the atmosphere, concentrations are commonly expressed in  $\text{molecules cm}^{-3}$ , so the rate constant for

the reaction above would be expressed in  $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ . We can use the approach just developed to determine the units of the rate constant from rate laws of any form. For example, the rate constant for a reaction with rate law of the form  $k_r[A]$  is commonly expressed in  $\text{s}^{-1}$ .

• **A brief illustration**

The rate constant for the reaction  $\text{O}(\text{g}) + \text{O}_3(\text{g}) \rightarrow 2 \text{O}_2(\text{g})$  is  $8.0 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  at 298 K. To express this rate constant in  $\text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ , we make use of

$$1 \text{ cm} = 10^{-2} \text{ m} = 10^{-2} \times 10 \text{ dm} = 10^{-1} \text{ dm}$$

$$1 \text{ mol} = 6.022 \times 10^{23} \text{ molecules, so } 1 \text{ molecule} = \frac{1 \text{ mol}}{6.022 \times 10^{23}}$$

It follows that

$$\begin{aligned} k_r &= 8.0 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} \\ &= 8.0 \times 10^{-15} (10^{-1} \text{ dm})^3 \left( \frac{1 \text{ mol}}{6.022 \times 10^{23}} \right)^{-1} \text{ s}^{-1} \\ &= 8.0 \times 10^{-15} \times 10^{-3} \times 6.022 \times 10^{23} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1} \\ &= 4.8 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1} \quad \bullet \end{aligned}$$

**Self-test 21.3** A reaction has a rate law of the form  $k_r[A]^2[B]$ . What are the units of the rate constant if the reaction rate is measured in  $\text{mol dm}^{-3} \text{ s}^{-1}$ ?

$[\text{dm}^6 \text{ mol}^{-2} \text{ s}^{-1}]$

The rate law of a reaction is determined experimentally, and cannot in general be inferred from the stoichiometry of the balanced chemical equation for the reaction. The reaction of hydrogen and bromine, for example, has a very simple stoichiometry,  $\text{H}_2(\text{g}) + \text{Br}_2(\text{g}) \rightarrow 2 \text{HBr}(\text{g})$ , but its rate law is complicated:

$$v = \frac{k_a[\text{H}_2][\text{Br}_2]^{3/2}}{[\text{Br}_2] + k_b[\text{HBr}]} \quad (21.6)$$

In certain cases the rate law does reflect the stoichiometry of the reaction, but that is either a coincidence or reflects a feature of the underlying reaction mechanism.

A practical application of a rate law is that, once we know the law and the value of the rate constant, we can predict the rate of reaction from the composition of the mixture. Moreover, as we shall see later, by knowing the rate law, we can go on to predict the composition of the reaction mixture at a later stage of the reaction. A rate law is also a guide to the mechanism of the reaction, for any proposed mechanism must be consistent with the observed rate law.

**(c) Reaction order**

Many reactions are found to have rate laws of the form

$$v = k_r[A]^a[B]^b \dots \quad (21.7)$$

The power to which the concentration of a species (a product or a reactant) is raised in a rate law of this kind is the **order** of the reaction with respect to that species. A reaction with the rate law in eqn 21.4 is **first-order** in A and first-order in B. The **overall order** of a reaction with a rate law like that in eqn 21.7 is the sum of the individual orders,  $a + b + \dots$ . The rate law in eqn 21.4 is therefore second-order overall.

A reaction need not have an integral order, and many gas-phase reactions do not. For example, a reaction having the rate law

$$v = k[A]^{1/2}[B] \quad (21.8)$$

is half-order in A, first-order in B, and three-halves-order overall. Some reactions obey a **zero-order rate law**, and therefore have a rate that is independent of the concentration of the reactant (so long as some is present). Thus, the catalytic decomposition of phosphine ( $\text{PH}_3$ ) on hot tungsten at high pressures has the rate law

$$v = k_r \quad (21.9)$$

The  $\text{PH}_3$  decomposes at a constant rate until it has almost entirely disappeared. Zero-order reactions typically occur when there is a bottle-neck of some kind in the mechanism, as in heterogeneous reactions when the surface is saturated regardless of how much reactant remains. Zero-order reactions are also found for a number of enzyme reactions when there is a large excess of reactant relative to the enzyme, and the amount of enzyme present governs the rate, not the amount of reactant.

When a rate law is not of the form in eqn 21.7, the reaction does not have an overall order and may not even have definite orders with respect to each participant. Thus, although eqn 21.6 shows that the reaction of hydrogen and bromine is first-order in  $\text{H}_2$ , the reaction has an indefinite order with respect to both  $\text{Br}_2$  and  $\text{HBr}$  and has no overall order.

These remarks point to three important questions:

- How do we identify the rate law and obtain the rate constant from the experimental data? We concentrate on this aspect in this chapter.
- How do we construct reaction mechanisms that are consistent with the rate law? We shall develop the techniques of doing so in Sections 21.8–10 and in Chapter 23.
- How do we account for the values of the rate constants and their temperature dependence? We shall see a little of what is involved in this chapter, but leave the details until Chapter 22.

#### (d) The determination of the rate law

The determination of a rate law is simplified by the **isolation method** in which the concentrations of all the reactants except one are in large excess. If B is in large excess, for example, then to a good approximation its concentration is constant throughout the reaction. Although the true rate law might be  $v = k_r[A][B]$ , we can approximate [B] by  $[B]_0$ , its initial value, and write

$$v = k'_r[A] \quad k'_r = k_r[B]_0 \quad (21.10)$$

which has the form of a first-order rate law. Because the true rate law has been forced into first-order form by assuming that the concentration of B is constant, eqn 21.10 is called a **pseudofirst-order rate law**. The dependence of the rate on the concentration of each of the reactants may be found by isolating them in turn (by having all the other substances present in large excess), and so constructing a picture of the overall rate law.

In the **method of initial rates**, which is often used in conjunction with the isolation method, the rate is measured at the beginning of the reaction for several different initial concentrations of reactants. We shall suppose that the rate law for a reaction with A isolated is  $v = k'_r[A]^a$ ; then its initial rate,  $v_0$ , is given by the initial values of the concentration of A, and we write  $v_0 = k'_r[A]_0^a$ . Taking (common) logarithms gives:

$$\log v_0 = \log k'_r + a \log [A]_0 \quad (21.11)$$

**Fig. 21.5** The plot of  $\log v_0$  against (a)  $\log[I]_0$  for a given  $[Ar]_0$ , and (b)  $\log[Ar]_0$  for a given  $[I]_0$ .

**A note on good practice** The units of  $k_r$  come automatically from the calculation, and are always such as to convert the product of concentrations to a rate in concentration/time (for example,  $\text{mol dm}^{-3} \text{s}^{-1}$ ).

For a series of initial concentrations, a plot of the logarithms of the initial rates against the logarithms of the initial concentrations of A should be a straight line with slope  $a$ .

#### Example 21.2 Using the method of initial rates

The recombination of iodine atoms in the gas phase in the presence of argon was investigated and the order of the reaction was determined by the method of initial rates. The initial rates of reaction of  $2 \text{I}(\text{g}) + \text{Ar}(\text{g}) \rightarrow \text{I}_2(\text{g}) + \text{Ar}(\text{g})$  were as follows:

|                                            |                           |                       |                       |                       |
|--------------------------------------------|---------------------------|-----------------------|-----------------------|-----------------------|
| $[I]_0 / (10^{-5} \text{ mol dm}^{-3})$    | 1.0                       | 2.0                   | 4.0                   | 6.0                   |
| $v_0 / (\text{mol dm}^{-3} \text{s}^{-1})$ | (a) $8.70 \times 10^{-4}$ | $3.48 \times 10^{-3}$ | $1.39 \times 10^{-2}$ | $3.13 \times 10^{-2}$ |
|                                            | (b) $4.35 \times 10^{-3}$ | $1.74 \times 10^{-2}$ | $6.96 \times 10^{-2}$ | $1.57 \times 10^{-1}$ |
|                                            | (c) $8.69 \times 10^{-3}$ | $3.47 \times 10^{-2}$ | $1.38 \times 10^{-1}$ | $3.13 \times 10^{-1}$ |

The Ar concentrations are (a)  $1.0 \text{ mmol dm}^{-3}$ , (b)  $5.0 \text{ mmol dm}^{-3}$ , and (c)  $10.0 \text{ mmol dm}^{-3}$ . Determine the orders of reaction with respect to the I and Ar atom concentrations and the rate constant.

**Method** Plot the logarithm of the initial rate,  $\log v_0$ , against  $\log[I]_0$  for a given concentration of Ar, and, separately, against  $\log[Ar]_0$  for a given concentration of I. The slopes of the two lines are the orders of reaction with respect to I and Ar, respectively. The intercepts with the vertical axis give  $\log k'_r$  and, by using eqn 21.10,  $k_r$ .

**Answer** The plots are shown in Fig. 21.5. The slopes are 2 and 1, respectively, so the (initial) rate law is  $v_0 = k_r [I]_0^2 [Ar]_0$ . This rate law signifies that the reaction is second-order in [I], first-order in [Ar], and third-order overall. The intercept corresponds to  $k_r = 9 \times 10^9 \text{ mol}^{-2} \text{dm}^6 \text{s}^{-1}$ .

**Self-test 21.4** The initial rate of a reaction depended on concentration of a substance J as follows:

|                                                     |     |     |    |     |
|-----------------------------------------------------|-----|-----|----|-----|
| $[J]_0 / (\text{mmol dm}^{-3})$                     | 5.0 | 8.2 | 17 | 30  |
| $v_0 / (10^{-7} \text{ mol dm}^{-3} \text{s}^{-1})$ | 3.6 | 9.6 | 41 | 130 |

Determine the order of the reaction with respect to J and calculate the rate constant.  
 $[2, 1.4 \times 10^{-2} \text{ dm}^3 \text{mol}^{-1} \text{s}^{-1}]$

The method of initial rates might not reveal the full rate law, for once the products have been generated they might participate in the reaction and affect its rate. For example, products participate in the synthesis of HBr, because eqn 21.6 shows that the full rate law depends on the concentration of HBr. To avoid this difficulty, the rate law should be fitted to the data throughout the reaction. The fitting may be done, in simple cases at least, by using a proposed rate law to predict the concentration of any component at any time, and comparing it with the data. A law should also be tested by observing whether the addition of products or, for gas-phase reactions, a change in the surface-to-volume ratio in the reaction chamber affects the rate.

### 21.3 Integrated rate laws

**Key points** An integrated rate law is an expression for the concentration of a reactant or product as a function of time. The half-life  $t_{1/2}$  of a reaction is the time it takes for the concentration of a species to fall to half its initial value. The time constant  $\tau$  is the time required for the concentration of a reactant to fall to  $1/e$  of its initial value.

Because rate laws are differential equations, we must integrate them if we want to find the concentrations as a function of time. Even the most complex rate laws may be integrated numerically. However, in a number of simple cases analytical solutions, known as **integrated rate laws**, are easily obtained, and prove to be very useful. We examine a few of these simple cases here.

### (a) First-order reactions

As shown in the following *Justification*, the integrated form of the first-order rate law

$$\frac{d[A]}{dt} = -k_r[A] \quad (21.12a)$$

is

$$\ln\left(\frac{[A]}{[A]_0}\right) = -k_r t \quad [A] = [A]_0 e^{-k_r t} \quad (21.12b)$$

 Integrated  
first-order  
rate law

where  $[A]_0$  is the initial concentration of A (at  $t = 0$ ).

#### Justification 21.1 First-order integrated rate law

First, we rearrange eqn 21.12a into

$$\frac{d[A]}{[A]} = -k_r dt$$

This expression can be integrated directly because  $k_r$  is a constant independent of  $t$ . Initially (at  $t = 0$ ) the concentration of A is  $[A]_0$ , and at a later time  $t$  it is  $[A]$ , so we make these values the limits of the integrals and write

$$\int_{[A]_0}^{[A]} \frac{d[A]}{[A]} = -k_r \int_0^t dt$$

Because the integral of  $1/x$  is  $\ln x$ , eqn 21.12b is obtained immediately.

Equation 21.12b shows that, if  $\ln([A]/[A]_0)$  is plotted against  $t$ , then a first-order reaction will give a straight line of slope  $-k_r$ . Some rate constants determined in this way are given in Table 21.1. The second expression in eqn 21.12b shows that in a first-order reaction the reactant concentration decreases exponentially with time with a rate determined by  $k_r$  (Fig. 21.6).

**Table 21.1\*** Kinetic data for first-order reactions

| Reaction                                                      | Phase                   | $\theta/^\circ\text{C}$ | $k_r/\text{s}^{-1}$   | $t_{1/2}$ |
|---------------------------------------------------------------|-------------------------|-------------------------|-----------------------|-----------|
| $2\text{N}_2\text{O}_5 \rightarrow 4\text{NO}_2 + \text{O}_2$ | g                       | 25                      | $3.38 \times 10^{-5}$ | 5.70 h    |
|                                                               | $\text{Br}_2(\text{l})$ | 25                      | $4.27 \times 10^{-5}$ | 4.51 h    |
| $\text{C}_2\text{H}_6 \rightarrow 2\text{CH}_3$               | g                       | 700                     | $5.36 \times 10^{-4}$ | 21.6 min  |

\* More values are given in the *Data section*.

**Fig. 21.6** The exponential decay of the reactant in a first-order reaction. The larger the rate constant, the more rapid the decay: here  $k_{r,\text{large}} = 3k_{r,\text{small}}$ .

**InterActivity** For a first-order reaction of the form  $A \rightarrow nB$  (with  $n$  possibly fractional), the concentration of the product varies with time as  $[B] = n[B]_0(1 - e^{-k_r t})$ . Plot the time dependence of  $[A]$  and  $[B]$  for the cases  $n = 0.5, 1$ , and  $2$ .

**Fig. 21.7** The determination of the rate constant of a first-order reaction: a straight line is obtained when  $\ln[A]/[A]_0$  (or, as here,  $\ln p/p_0$ ) is plotted against  $t$ ; the slope gives  $k_r$ .

**A note on good practice** Because the horizontal and vertical axes of graphs are labelled with pure numbers, the slope of a graph is always dimensionless. For a graph of the form  $y = b + mx$  we can write  $y = b + (m \text{ units})(x/\text{units})$ , where ‘units’ are the units of  $x$ , and identify the (dimensionless) slope with ‘ $m$  units’. Then  $m = \text{slope}/\text{units}$ . In the present case, because the graph shown here is a plot of  $\ln(p/p_0)$  against  $t/s$  (with ‘units’ = s) and  $k_r$  is the negative value of the slope of  $\ln(p/p_0)$  against  $t$  itself,  $k_r = -\text{slope}/s$ .

### Example 21.3 Analysing a first-order reaction

The variation in the partial pressure of azomethane with time was followed at 600 K, with the results given below. Confirm that the decomposition

is first-order in azomethane, and find the rate constant at 600 K.

|               |      |      |      |      |      |
|---------------|------|------|------|------|------|
| $t/s$         | 0    | 1000 | 2000 | 3000 | 4000 |
| $p/\text{Pa}$ | 10.9 | 7.63 | 5.32 | 3.71 | 2.59 |

**Method** As indicated in the text, to confirm that a reaction is first-order, plot  $\ln([A]/[A]_0)$  against time and expect a straight line. Because the partial pressure of a gas is proportional to its concentration (provided it can be treated as a perfect gas), an equivalent procedure is to plot  $\ln(p/p_0)$  against  $t$ . If a straight line is obtained, its slope can be identified with  $k_r$ .

**Answer** We draw up the following table:

|              |   |        |        |        |        |
|--------------|---|--------|--------|--------|--------|
| $t/s$        | 0 | 1000   | 2000   | 3000   | 4000   |
| $\ln(p/p_0)$ | 0 | -0.357 | -0.717 | -1.078 | -1.437 |

Figure 21.7 shows the plot of  $\ln(p/p_0)$  against  $t$ . The plot is straight, confirming a first-order reaction, and its slope is  $-3.6 \times 10^{-4}$ . Therefore,  $k_r = 3.6 \times 10^{-4} \text{ s}^{-1}$ .

**Self-test 21.5** In a particular experiment, it was found that the concentration of  $\text{N}_2\text{O}_5$  in liquid bromine varied with time as follows:

|                                               |       |       |       |       |       |
|-----------------------------------------------|-------|-------|-------|-------|-------|
| $t/s$                                         | 0     | 200   | 400   | 600   | 1000  |
| $[\text{N}_2\text{O}_5]/(\text{mol dm}^{-3})$ | 0.110 | 0.073 | 0.048 | 0.032 | 0.014 |

Confirm that the reaction is first-order in  $\text{N}_2\text{O}_5$  and determine the rate constant.  
 $[k_r = 2.1 \times 10^{-3} \text{ s}^{-1}]$

### (b) Half-lives and time constants

A useful indication of the rate of a first-order chemical reaction is the **half-life**,  $t_{1/2}$ , of a substance, the time taken for the concentration of a reactant to fall to half its initial value. The time for  $[A]$  to decrease from  $[A]_0$  to  $\frac{1}{2}[A]_0$  in a first-order reaction is given by eqn 21.12b as

$$k_r t_{1/2} = -\ln \left( \frac{\frac{1}{2}[A]_0}{[A]_0} \right) = -\ln \frac{1}{2} = \ln 2$$

Hence

$$t_{1/2} = \frac{\ln 2}{k_r} \quad \text{Half-life of a first-order reaction} \quad (21.13)$$

(Note that  $\ln 2 = 0.693$ .) The main point to note about this result is that, for a first-order reaction, the half-life of a reactant is independent of its initial concentration. Therefore, if the concentration of A at some *arbitrary* stage of the reaction is  $[A]$ , then it will have fallen to  $\frac{1}{2}[A]$  after a further interval of  $(\ln 2)/k_r$ . Some half-lives are given in Table 21.1.

Another indication of the rate of a first-order reaction is the **time constant**,  $\tau$  (tau), the time required for the concentration of a reactant to fall to  $1/e$  of its initial value. From eqn 21.12b it follows that

$$k_r \tau = -\ln \left( \frac{[A]_0/e}{[A]_0} \right) = -\ln \frac{1}{e} = 1$$

That is, the time constant of a first-order reaction is the reciprocal of the rate constant:

$$\tau = \frac{1}{k_r} \quad \text{Time constant of a first-order reaction} \quad (21.14)$$

### (c) Second-order reactions

We show in the following *Justification* that the integrated form of the second-order rate law

$$\frac{d[A]}{dt} = -k_r[A]^2 \quad (21.15a)$$

is either of the following two forms:

$$\frac{1}{[A]} - \frac{1}{[A]_0} = k_r t \quad \text{Integrated second-order rate law} \quad (21.15b)$$

$$[A] = \frac{[A]_0}{1 + k_r t [A]_0} \quad \text{Alternative form of the integrated rate law} \quad (21.15c)$$

where  $[A]_0$  is the initial concentration of A (at  $t = 0$ ).

#### Justification 21.2 Second-order integrated rate law

To integrate eqn 21.15a we rearrange it into

$$\frac{d[A]}{[A]^2} = -k_r dt$$

The concentration of A is  $[A]_0$  at  $t = 0$  and  $[A]$  at a general time  $t$  later. Therefore,

$$-\int_{[A]_0}^{[A]} \frac{d[A]}{[A]^2} = k_r \int_0^t dt$$

Because the integral of  $1/x^2$  is  $-1/x$ , we obtain eqn 21.15b by substitution of the limits

$$\frac{1}{[A]} \Big|_{[A]_0}^{[A]} = \frac{1}{[A]} - \frac{1}{[A]_0} = k_r t$$

We can then rearrange this expression into eqn 21.15c.

Equation 21.15b shows that to test for a second-order reaction we should plot  $1/[A]$  against  $t$  and expect a straight line. The slope of the graph is  $k_r$ . Some rate constants determined in this way are given in Table 21.2. The rearranged form, eqn 21.15c, lets us predict the concentration of A at any time after the start of the reaction. It shows that the concentration of A approaches zero more slowly than in a first-order reaction with the same initial rate (Fig. 21.8).

It follows from eqn 21.15b by substituting  $t = t_{1/2}$  and  $[A] = \frac{1}{2}[A]_0$  that the half-life of a species A that is consumed in a second-order reaction is

$$t_{1/2} = \frac{1}{k_r [A]_0} \quad \text{Half-life of a second-order reaction} \quad (21.16)$$

**Fig. 21.8** The variation with time of the concentration of a reactant in a second-order reaction. The grey lines are the corresponding decays in a first-order reaction with the same initial rate. For this illustration,  $k_{r,\text{large}} = 3k_{r,\text{small}}$ .

**interActivity** For a second-order reaction of the form  $A \rightarrow nB$  (with  $n$  possibly fractional), the concentration of the product varies with time as  $[B] = nk_r t [A]_0^2 / (1 + k_r t [A]_0)$ . Plot the time dependence of  $[A]$  and  $[B]$  for the cases  $n = 0.5, 1$ , and  $2$ .

**Table 21.2\*** Kinetic data for second-order reactions

| Reaction                                              | Phase                     | $\theta/^{\circ}\text{C}$ | $k_r/(\text{dm}^3 \text{mol}^{-1} \text{s}^{-1})$ |
|-------------------------------------------------------|---------------------------|---------------------------|---------------------------------------------------|
| $2 \text{NOBr} \rightarrow 2 \text{NO} + \text{Br}_2$ | g                         | 10                        | 0.80                                              |
| $2 \text{I} \rightarrow \text{I}_2$                   | g                         | 23                        | $7 \times 10^9$                                   |
| $\text{CH}_3\text{Cl} + \text{CH}_3\text{O}^-$        | $\text{CH}_3\text{OH(l)}$ | 20                        | $2.29 \times 10^{-6}$                             |

\* More values are given in the *Data section*.

Therefore, unlike a first-order reaction, the half-life of a substance in a second-order reaction varies with the initial concentration. A practical consequence of this dependence is that species that decay by second-order reactions (which includes some environmentally harmful substances) may persist in low concentrations for long periods because their half-lives are long when their concentrations are low. In general, for an  $n$ th-order reaction (with  $n > 1$ ) of the form  $\text{A} \rightarrow \text{products}$ , the half-life is related to the rate constant and the initial concentration of A by

$$t_{1/2} = \frac{2^{n-1} - 1}{(n-1)k_r[\text{A}]_0^{n-1}} \quad \text{Half-life of an } n\text{th-order reaction} \quad (21.17)$$

(See Problem 21.22.)

Another type of second-order reaction is one that is first-order in each of two reactants A and B:

$$\frac{d[\text{A}]}{dt} = -k_r[\text{A}][\text{B}] \quad (21.18)$$

Such a rate law cannot be integrated until we know how the concentration of B is related to that of A. For example, if the reaction is  $\text{A} + \text{B} \rightarrow \text{P}$ , where P denotes products, and the initial concentrations are  $[\text{A}]_0$  and  $[\text{B}]_0$ , then it is shown in the following *Justification* that, at a time  $t$  after the start of the reaction, the concentrations satisfy the relation

$$\ln \left( \frac{[\text{B}]/[\text{B}]_0}{[\text{A}]/[\text{A}]_0} \right) = ([\text{B}]_0 - [\text{A}]_0)k_r t \quad \text{Integrated rate law of a second-order reaction of the type } \text{A} + \text{B} \rightarrow \text{P} \quad (21.19)$$

Therefore, a plot of the expression on the left against  $t$  should be a straight line from which  $k_r$  can be obtained.

**Justification 21.3** Overall second-order rate law

It follows from the reaction stoichiometry that, when the concentration of A has fallen to  $[\text{A}]_0 - x$ , the concentration of B will have fallen to  $[\text{B}]_0 - x$  (because each A that disappears entails the disappearance of one B). It follows that

$$\frac{d[\text{A}]}{dt} = -k_r([\text{A}]_0 - x)([\text{B}]_0 - x)$$

Because  $[\text{A}] = [\text{A}]_0 - x$ , it follows that  $d[\text{A}]/dt = -dx/dt$  and the rate law may be written as

$$\frac{dx}{dt} = k_r([\text{A}]_0 - x)([\text{B}]_0 - x)$$

The initial condition is that  $x = 0$  when  $t = 0$ ; so the integration required is

$$\int_0^x \frac{dx}{([A]_0 - x)([B]_0 - x)} = k_r \int_0^t dt$$

The integral on the right is simply  $k_r t$ . The integral on the left is evaluated by using the method of partial fractions in which we write

$$\frac{1}{(a-x)(b-x)} = \frac{1}{b-a} \left( \frac{1}{a-x} - \frac{1}{b-x} \right)$$

It follows that

$$\int \frac{dx}{(a-x)(b-x)} = \frac{1}{b-a} \left[ \int \frac{dx}{a-x} - \int \frac{dx}{b-x} \right] = \frac{1}{b-a} \left[ \ln \frac{1}{a-x} - \ln \frac{1}{b-x} \right] + \text{constant}$$

and therefore that

$$\int_0^x \frac{dx}{([A]_0 - x)([B]_0 - x)} = \frac{1}{[B]_0 - [A]_0} \left\{ \ln \left( \frac{[A]_0}{[A]_0 - x} \right) - \ln \left( \frac{[B]_0}{[B]_0 - x} \right) \right\}$$

This expression can be simplified and rearranged into eqn 21.19 by combining the two logarithms by using  $\ln y - \ln z = \ln(y/z)$  and noting that  $[A] = [A]_0 - x$  and  $[B] = [B]_0 - x$ . Similar calculations may be carried out to find the integrated rate laws for other orders, and some are listed in Table 21.3.

**Table 21.3** Integrated rate laws

| Order      | Reaction                                | Rate law*                                                                                                                                                 | $t_{1/2}$                                 |
|------------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| 0          | $A \rightarrow P$                       | $v = k_r$<br>$k_r t = x$ for $0 \leq x \leq [A]_0$                                                                                                        | $[A]_0/2k_r$                              |
| 1          | $A \rightarrow P$                       | $v = k_r[A]$<br>$k_r t = \ln \frac{[A]_0}{[A]_0 - x}$                                                                                                     | $(\ln 2)/k_r$                             |
| 2          | $A \rightarrow P$                       | $v = k_r[A]^2$<br>$k_r t = \frac{x}{[A]_0([A]_0 - x)}$                                                                                                    | $1/k_r[A]_0$                              |

\*  $x = [P]$  and  $v = dx/dt$ .

## 21.4 Reactions approaching equilibrium

**Key points** (a) The equilibrium constant for a reaction is equal to the ratio of the forward and reverse rate constants. (b) In relaxation methods of kinetic analysis, the equilibrium position of a reaction is first shifted suddenly and then allowed to readjust to the equilibrium composition characteristic of the new conditions.

Because all the rate laws considered so far disregard the possibility that the reverse reaction is important, none of them describes the overall rate when the reaction is close to equilibrium. At that stage the products may be so abundant that the reverse reaction must be taken into account. In practice, however, most kinetic studies are made on reactions that are far from equilibrium, and the reverse reactions are unimportant.

## (a) First-order reactions close to equilibrium

We can explore the variation of the composition with time close to chemical equilibrium by considering the reaction in which A forms B and both forward and reverse reactions are first-order (as in some isomerizations). The scheme we consider is

The concentration of A is reduced by the forward reaction (at a rate  $k_r[\text{A}]$ ) but it is increased by the reverse reaction (at a rate  $k'_r[\text{B}]$ ). The net rate of change is therefore

$$\frac{d[\text{A}]}{dt} = -k_r[\text{A}] + k'_r[\text{B}] \quad (21.21)$$

If the initial concentration of A is  $[\text{A}]_0$ , and no B is present initially, then at all times  $[\text{A}] + [\text{B}] = [\text{A}]_0$ . Therefore,

$$\frac{d[\text{A}]}{dt} = -k_r[\text{A}] + k'_r([\text{A}]_0 - [\text{A}]) = -(k_r + k'_r)[\text{A}] + k'_r[\text{A}]_0 \quad (21.22)$$

The solution of this first-order differential equation (as may be checked by differentiation) is

$$[\text{A}] = \frac{k'_r + k_r e^{-(k_r + k'_r)t}}{k'_r + k_r} [\text{A}]_0 \quad (21.23)$$

Figure 21.9 shows the time dependence predicted by this equation.

As  $t \rightarrow \infty$ , the concentrations reach their equilibrium values, which are given by eqn 21.23 as:

$$[\text{A}]_{\text{eq}} = \frac{k'_r[\text{A}]_0}{k_r + k'_r} \quad [\text{B}]_{\text{eq}} = [\text{A}]_0 - [\text{A}]_{\text{eq}} = \frac{k_r[\text{A}]_0}{k_r + k'_r} \quad (21.24)$$

It follows that the equilibrium constant of the reaction is

$$K = \frac{[\text{B}]_{\text{eq}}}{[\text{A}]_{\text{eq}}} = \frac{k_r}{k'_r} \quad (21.25)$$

(This expression is only approximate because thermodynamically precise equilibrium constants are expressed in terms of activities, not concentrations.) Exactly the same conclusion can be reached—more simply, in fact—by noting that, at equilibrium, the forward and reverse rates must be the same, so

$$k_r[\text{A}]_{\text{eq}} = k'_r[\text{B}]_{\text{eq}} \quad (21.26)$$

This relation rearranges into eqn 21.25. The theoretical importance of eqn 21.25 is that it relates a thermodynamic quantity, the equilibrium constant, to quantities

**Fig. 21.9** The approach of concentrations to their equilibrium values as predicted by eqn 21.23 for a reaction  $\text{A} \rightleftharpoons \text{B}$  that is first-order in each direction, and for which  $k_r = 2k'_r$ .

**InterActivity** Set up the rate equations and plot the corresponding graphs for the approach to an equilibrium of the form  $\text{A} \rightleftharpoons 2\text{B}$ .

relating to rates. Its practical importance is that, if one of the rate constants can be measured, then the other may be obtained if the equilibrium constant is known.

For a more general reaction, the overall equilibrium constant can be expressed in terms of the rate constants for all the intermediate stages of the reaction mechanism:

$$K = \frac{k_a}{k'_a} \times \frac{k_b}{k'_b} \times \dots \quad \text{The equilibrium constant in terms of the rate constants} \quad (21.27)$$

where the  $k$ s are the rate constants for the individual steps and the  $k'$ s are those for the corresponding reverse steps.

### (b) Relaxation methods

The term **relaxation** denotes the return of a system to equilibrium. It is used in chemical kinetics to indicate that an externally applied influence has shifted the equilibrium position of a reaction, normally suddenly, and that the reaction is adjusting to the equilibrium composition characteristic of the new conditions (Fig. 21.10). We shall consider the response of reaction rates to a **temperature jump**, a sudden change in temperature. We know from Section 6.4 that the equilibrium composition of a reaction depends on the temperature (provided  $\Delta_r H^\circ$  is nonzero), so a shift in temperature acts as a perturbation on the system. One way of achieving a temperature jump is to discharge a capacitor through a sample made conducting by the addition of ions, but laser or microwave discharges can also be used. Temperature jumps of between 5 and 10 K can be achieved in about 1  $\mu$ s with electrical discharges. The high energy output of pulsed lasers (Section 13.6) is sufficient to generate temperature jumps of between 10 and 30 K within nanoseconds in aqueous samples. Some equilibria are also sensitive to pressure, and **pressure-jump techniques** may then also be used.

When a sudden temperature increase is applied to a simple  $A \rightleftharpoons B$  equilibrium that is first-order in each direction, we show in the following *Justification* that the composition relaxes exponentially to the new equilibrium composition:

$$x = x_0 e^{-t/\tau} \quad \frac{1}{\tau} = k_r + k'_r \quad \text{Relaxation after a temperature jump} \quad (21.28)$$

where  $x_0$  is the departure from equilibrium immediately after the temperature jump and  $x$  is the departure from equilibrium at the new temperature after a time  $t$ .

**Fig. 21.10** The relaxation to the new equilibrium composition when a reaction initially at equilibrium at a temperature  $T_1$  is subjected to a sudden change of temperature, which takes it to  $T_2$ .

#### Justification 21.4 Relaxation to equilibrium

When the temperature of a system at equilibrium is increased suddenly, the rate constants change from their earlier values to the new values  $k_r$  and  $k'_r$  characteristic of that temperature, but the concentrations of A and B remain for an instant at their old equilibrium values. As the system is no longer at equilibrium, it readjusts to the new equilibrium concentrations, which are now given by

$$k_r[A]_{\text{eq}} = k'_r[B]_{\text{eq}}$$

and it does so at a rate that depends on the new rate constants. We write the deviation of [A] from its new equilibrium value as  $x$ , so  $[A] = x + [A]_{\text{eq}}$  and  $[B] = [B]_{\text{eq}} - x$ . The concentration of A then changes as follows:

$$\frac{d[A]}{dt} = -k_r[A] + k'_r[B] = -k_r([A]_{\text{eq}} + x) + k'_r([B]_{\text{eq}} - x) = -(k_r + k'_r)x$$

because the two terms involving the equilibrium concentrations cancel. Because  $d[A]/dt = dx/dt$ , this equation is a first-order differential equation with the solution that resembles eqn 21.12b and is given in eqn 21.28.

Equation 21.28 shows that the concentrations of A and B relax into the new equilibrium at a rate determined by the sum of the two new rate constants. Because the equilibrium constant under the new conditions is  $K \approx k_r/k'_r$ , its value may be combined with the relaxation time measurement to find the individual  $k_r$  and  $k'_r$ .

**Example 21.4** *Analysing a temperature-jump experiment*

The equilibrium constant for the autoprotolysis of water,  $\text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}^+(\text{aq}) + \text{OH}^-(\text{aq})$ , is  $K_w = a(\text{H}^+)a(\text{OH}^-) = 1.008 \times 10^{-14}$  at 298 K. After a temperature-jump, the reaction returns to equilibrium with a relaxation time of 37  $\mu\text{s}$  at 298 K and  $\text{pH} \approx 7$ . Given that the forward reaction is first-order and the reverse is second-order overall, calculate the rate constants for the forward and reverse reactions.

**Method** We need to derive an expression for the relaxation time,  $\tau$  (the time constant for return to equilibrium), in terms of  $k_r$  (forward, first-order reaction) and  $k'_r$  (reverse, second-order reaction). We can proceed as above, but it will be necessary to make the assumption that the deviation from equilibrium ( $x$ ) is so small that terms in  $x^2$  can be neglected. Relate  $k_r$  and  $k'_r$  through the equilibrium constant, but be careful with units because  $K_w$  is dimensionless.

**Answer** The forward rate at the final temperature is  $k_r[\text{H}_2\text{O}]$  and the reverse rate is  $k'_r[\text{H}^+][\text{OH}^-]$ . The net rate of deprotonation of  $\text{H}_2\text{O}$  is

$$\frac{d[\text{H}_2\text{O}]}{dt} = -k_r[\text{H}_2\text{O}] + k'_r[\text{H}^+][\text{OH}^-]$$

We write  $[\text{H}_2\text{O}] = [\text{H}_2\text{O}]_{\text{eq}} + x$ ,  $[\text{H}^+] = [\text{H}^+]_{\text{eq}} - x$ , and  $[\text{OH}^-] = [\text{OH}^-]_{\text{eq}} - x$ , and obtain

$$\begin{aligned} \frac{dx}{dt} &= -\{k_r + k'_r([\text{H}^+]_{\text{eq}} + [\text{OH}^-]_{\text{eq}})\}x - k_r[\text{H}_2\text{O}]_{\text{eq}} + k'_r[\text{H}^+]_{\text{eq}}[\text{OH}^-]_{\text{eq}} + k'_r x^2 \\ &\approx -\{k_r + k'_r([\text{H}^+]_{\text{eq}} + [\text{OH}^-]_{\text{eq}})\}x \end{aligned}$$

where we have neglected the term in  $x^2$  because it is so small and have used the equilibrium condition  $k_r[\text{H}_2\text{O}]_{\text{eq}} = k'_r[\text{H}^+]_{\text{eq}}[\text{OH}^-]_{\text{eq}}$  to eliminate the terms that are independent of  $x$ . It follows that

$$\frac{1}{\tau} = k_r + k'_r([\text{H}^+]_{\text{eq}} + [\text{OH}^-]_{\text{eq}})$$

At this point we note that

$$K_w = a(\text{H}^+)a(\text{OH}^-) \approx ([\text{H}^+]_{\text{eq}}/c^\ominus)([\text{OH}^-]_{\text{eq}}/c^\ominus) = [\text{H}^+]_{\text{eq}}[\text{OH}^-]_{\text{eq}}/c^{\ominus 2}$$

with  $c^\ominus = 1 \text{ mol dm}^{-3}$ . For this electrically neutral system,  $[\text{H}^+] = [\text{OH}^-]$ , so the concentration of each type of ion is  $K_w^{1/2}c^\ominus$ , and hence

$$\frac{1}{\tau} = k_r + k'_r(K_w^{1/2}c^\ominus + K_w^{1/2}c^\ominus) = k'_r \left\{ \frac{k_r}{k'_r} + 2K_w^{1/2}c^\ominus \right\}$$

At this point we note that

$$\frac{k_r}{k'_r} = \frac{[\text{H}^+]_{\text{eq}}[\text{OH}^-]_{\text{eq}}}{[\text{H}_2\text{O}]_{\text{eq}}} = \frac{K_w c^{\ominus 2}}{[\text{H}_2\text{O}]_{\text{eq}}}$$

The molar concentration of pure water is  $55.6 \text{ mol dm}^{-3}$ , so  $[\text{H}_2\text{O}]_{\text{eq}}/c^\ominus = 55.6$ . If we write  $K = K_w/55.6 = 1.81 \times 10^{-16}$ , we obtain

$$\frac{1}{\tau} = k'_r \{K + 2K_w^{1/2}\} c^\ominus$$

**A note on good practice** Notice how we keep track of units through the use of  $c^\ominus$ :  $K$  and  $K_w$  are dimensionless,  $k'_r$  is expressed in  $\text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ , and  $k_r$  is expressed in  $\text{s}^{-1}$ .

Hence,

$$k_r' = \frac{1}{\tau(K + 2K_w^{1/2})c^\ominus} = \frac{1}{(3.7 \times 10^{-5} \text{ s}) \times (2.0 \times 10^{-7}) \times (1 \text{ mol dm}^{-3})} = 1.4 \times 10^{11} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

It follows that

$$k_r = k_r' K c^\ominus = 2.4 \times 10^{-5} \text{ s}^{-1}$$

The reaction is faster in ice, where  $k_r' = 8.6 \times 10^{12} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ .

**Self-test 21.6** Derive an expression for the relaxation time of a concentration when the reaction  $A + B \rightleftharpoons C + D$  is second-order in both directions.

$$[1/\tau = k_r([A] + [B])_{\text{eq}} + k_r'([C] + [D])_{\text{eq}}]$$

## 21.5 The temperature dependence of reaction rates

**Key points** (a) The temperature dependence of the rate constant of a reaction typically follows the Arrhenius equation. (b) The activation energy  $E_a$  is the minimum kinetic energy required for reaction during a molecular encounter. The pre-exponential factor  $A$  is a measure of the rate at which collisions occur irrespective of their energy.

The rate constants of most reactions increase as the temperature is raised. Many reactions in solution fall somewhere in the range spanned by the hydrolysis of methyl ethanoate (where the rate constant at 35°C is 1.82 times that at 25°C) and the hydrolysis of sucrose (where the factor is 4.13).

### (a) The Arrhenius parameters

It is found experimentally for many reactions that a plot of  $\ln k_r$  against  $1/T$  gives a straight line. This behaviour is normally expressed mathematically by introducing two parameters, one representing the intercept and the other the slope of the straight line, and writing the **Arrhenius equation**

$$\ln k_r = \ln A - \frac{E_a}{RT} \quad \text{Arrhenius equation} \quad (21.29)$$

The parameter  $A$ , which corresponds to the intercept of the line at  $1/T = 0$  (at infinite temperature, Fig. 21.11), is called the **pre-exponential factor** or the ‘frequency factor’. The parameter  $E_a$ , which is obtained from the slope of the line ( $-E_a/R$ ), is called the **activation energy**. Collectively the two quantities are called the **Arrhenius parameters** (Table 21.4).

**Table 21.4\*** Arrhenius parameters

| (1) First-order reactions                                          | $A/\text{s}^{-1}$                                 | $E_a/(\text{kJ mol}^{-1})$ |
|--------------------------------------------------------------------|---------------------------------------------------|----------------------------|
| $\text{CH}_3\text{NC} \rightarrow \text{CH}_3\text{CN}$            | $3.98 \times 10^{13}$                             | 160                        |
| $2 \text{ N}_2\text{O}_5 \rightarrow 4 \text{ NO}_2 + \text{O}_2$  | $4.94 \times 10^{13}$                             | 103.4                      |
| (2) Second-order reactions                                         | $A/(\text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1})$ | $E_a/(\text{kJ mol}^{-1})$ |
| $\text{OH} + \text{H}_2 \rightarrow \text{H}_2\text{O} + \text{H}$ | $8.0 \times 10^{10}$                              | 42                         |
| $\text{NaC}_2\text{H}_5\text{O} + \text{CH}_3\text{I}$ in ethanol  | $2.42 \times 10^{11}$                             | 81.6                       |

\* More values are given in the Data section.

**Fig. 21.11** A plot of  $\ln k_r$  against  $1/T$  is a straight line when the reaction follows the behaviour described by the Arrhenius equation (eqn 21.29). The slope gives  $-E_a/R$  and the intercept at  $1/T = 0$  gives  $\ln A$ .

**Fig. 21.12** The Arrhenius plot using the data in Example 21.5.

**A note on good practice** Note that  $A$  has the same units as  $k_r$ . In practice,  $A$  is obtained from one of the mid-range data values rather than using a lengthy extrapolation.

### Example 21.5 Determining the Arrhenius parameters

The rate of the second-order decomposition of acetaldehyde (ethanal,  $\text{CH}_3\text{CHO}$ ) was measured over the temperature range 700–1000 K, and the rate constants are reported below. Find  $E_a$  and  $A$ .

|                                                   |       |       |       |       |       |      |      |      |
|---------------------------------------------------|-------|-------|-------|-------|-------|------|------|------|
| $T/\text{K}$                                      | 700   | 730   | 760   | 790   | 810   | 840  | 910  | 1000 |
| $k_r/(\text{dm}^3 \text{mol}^{-1} \text{s}^{-1})$ | 0.011 | 0.035 | 0.105 | 0.343 | 0.789 | 2.17 | 20.0 | 145  |

**Method** According to eqn 21.29, the data can be analysed by plotting  $\ln(k_r/\text{dm}^3 \text{mol}^{-1} \text{s}^{-1})$  against  $1/(T/\text{K})$ , or more conveniently  $(10^3 \text{ K})/T$ , and getting a straight line. As explained in Example 21.3, we obtain the activation energy from the dimensionless slope by writing  $-E_a/R = \text{slope}/\text{units}$ , where in this case ‘units’ =  $1/(10^3 \text{ K})$ , so  $E_a = -\text{slope} \times R \times 10^3 \text{ K}$ . The intercept at  $1/T = 0$  is  $\ln(A/\text{dm}^3 \text{mol}^{-1} \text{s}^{-1})$ .

**Answer** We draw up the following table:

|                                                      |       |       |       |       |       |      |      |      |
|------------------------------------------------------|-------|-------|-------|-------|-------|------|------|------|
| $(10^3 \text{ K})/T$                                 | 1.43  | 1.37  | 1.32  | 1.27  | 1.23  | 1.19 | 1.10 | 1.00 |
| $\ln(k_r/\text{dm}^3 \text{mol}^{-1} \text{s}^{-1})$ | −4.51 | −3.35 | −2.25 | −1.07 | −0.24 | 0.77 | 3.00 | 4.98 |

Now plot  $\ln k_r$  against  $1/T$  (Fig. 21.12). The least-squares fit is to a line with slope  $-22.7$  and intercept  $27.7$ . Therefore,

$$E_a = 22.7 \times (8.3145 \text{ J K}^{-1} \text{mol}^{-1}) \times 10^3 \text{ K} = 189 \text{ kJ mol}^{-1}$$

$$A = e^{27.7} \text{ dm}^3 \text{mol}^{-1} \text{s}^{-1} = 1.1 \times 10^{12} \text{ dm}^3 \text{mol}^{-1} \text{s}^{-1}$$

### Self-test 21.7 Determine $A$ and $E_a$ from the following data:

|                                                   |                   |                   |                   |                   |                   |
|---------------------------------------------------|-------------------|-------------------|-------------------|-------------------|-------------------|
| $T/\text{K}$                                      | 300               | 350               | 400               | 450               | 500               |
| $k_r/(\text{dm}^3 \text{mol}^{-1} \text{s}^{-1})$ | $7.9 \times 10^6$ | $3.0 \times 10^7$ | $7.9 \times 10^7$ | $1.7 \times 10^8$ | $3.2 \times 10^8$ |

$[8 \times 10^{10} \text{ dm}^3 \text{mol}^{-1} \text{s}^{-1}, 23 \text{ kJ mol}^{-1}]$

The fact that  $E_a$  is given by the slope of the plot of  $\ln k_r$  against  $1/T$  means that, the higher the activation energy, the stronger the temperature dependence of the rate constant (that is, the steeper the slope). *A high activation energy signifies that the rate constant depends strongly on temperature.* If a reaction has zero activation energy, its rate is independent of temperature. In some cases the activation energy is negative, which indicates that the rate decreases as the temperature is raised. We shall see that such behaviour is a signal that the reaction has a complex mechanism.

The temperature dependence of some reactions is non-Arrhenius, in the sense that a straight line is not obtained when  $\ln k$  is plotted against  $1/T$ . However, it is still possible to define an activation energy at any temperature as

$$E_a = RT^2 \left( \frac{d \ln k_r}{dT} \right) \quad \text{Definition of the activation energy} \quad [21.30]$$

This definition reduces to the earlier one (as the slope of a straight line) for a temperature-independent activation energy. However, the definition in eqn 21.30 is more general than eqn 21.29, because it allows  $E_a$  to be obtained from the slope (at the temperature of interest) of a plot of  $\ln k_r$  against  $1/T$  even if the Arrhenius plot is not a straight line.

**(b) The interpretation of the parameters**

For the present chapter we shall regard the Arrhenius parameters as purely empirical quantities that enable us to discuss the variation of rate constants with temperature; however, it is useful to have an interpretation in mind. To find one, we begin by writing eqn 21.29 as

$$k_r = A e^{-E_a/RT} \quad \text{Alternative form of the Arrhenius equation} \quad (21.31)$$

Next, to interpret  $E_a$  we consider how the molecular potential energy changes in the course of a chemical reaction that begins with a collision between molecules of A and molecules of B (Fig. 21.13).

As the reaction event proceeds, A and B come into contact, distort, and begin to exchange or discard atoms. The **reaction coordinate** is the collection of motions, such as changes in interatomic distances and bond angles, that are directly involved in the formation of products from reactants. (The reaction coordinate is essentially a geometrical concept and quite distinct from the extent of reaction.) The potential energy rises to a maximum and the cluster of atoms that corresponds to the region close to the maximum is called the **activated complex**. After the maximum, the potential energy falls as the atoms rearrange in the cluster and reaches a value characteristic of the products. The climax of the reaction is at the peak of the potential energy, which corresponds to the activation energy  $E_a$ . Here two reactant molecules have come to such a degree of closeness and distortion that a small further distortion will send them in the direction of products. This crucial configuration is called the **transition state** of the reaction. Although some molecules entering the transition state might revert to reactants, if they pass through this configuration then it is inevitable that products will emerge from the encounter.

We also conclude from the preceding discussion that, for a reaction involving the collision of two molecules, *the activation energy is the minimum kinetic energy that reactants must have in order to form products*. For example, in a gas-phase reaction there are numerous collisions each second, but only a tiny proportion are sufficiently energetic to lead to reaction. The fraction of collisions with a kinetic energy in excess of an energy  $E_a$  is given by the Boltzmann distribution as  $e^{-E_a/RT}$ . We show in the following *Justification* that we can interpret the exponential factor in eqn 21.31 as the fraction of collisions that have enough kinetic energy to lead to reaction.

**Fig. 21.13** A potential energy profile for an exothermic reaction. The height of the barrier between the reactants and products is the activation energy of the reaction.

**A brief comment**

The terms *activated complex* and *transition state* are often used as synonyms; however, we shall preserve a distinction.

**Justification 21.5** *Interpreting the activation energy*

Suppose the energy levels available to the system form a uniform array of separation  $\epsilon$ . The Boltzmann distribution is

$$\frac{N_i}{N} = \frac{e^{-i\epsilon\beta}}{q} = (1 - e^{-\epsilon\beta})e^{-i\epsilon\beta}$$

where  $\beta = 1/kT$  and we have used the result in eqn 15.12 for the partition function  $q$ . The total number of molecules in states with energy of at least  $i_{\max}\epsilon$  is

$$\sum_{i=i_{\max}}^{\infty} N_i = \sum_{i=0}^{\infty} N_i - \sum_{i=0}^{i_{\max}-1} N_i = N - \frac{N}{q} \sum_{i=0}^{i_{\max}-1} e^{-i\epsilon\beta}$$

The sum of the finite geometrical series is

$$\sum_{i=0}^{i_{\max}-1} e^{-i\epsilon\beta} = \frac{1 - e^{-i_{\max}\epsilon\beta}}{1 - e^{-\epsilon\beta}} = q(1 - e^{-i_{\max}\epsilon\beta})$$

Therefore, the fraction of molecules in states with energy of at least  $\varepsilon_{\max} = i_{\max} \varepsilon$  is

$$\frac{\sum_{i=i_{\max}}^{\infty} N_i}{N} = 1 - (1 - e^{-i_{\max} \varepsilon \beta}) = e^{-i_{\max} \varepsilon \beta} = e^{-\varepsilon_{\max}/kT}$$

The calculation using translational states is more involved, and is presented in Section 22.4.

The pre-exponential factor is a measure of the rate at which collisions occur irrespective of their energy. Hence, the product of  $A$  and the exponential factor,  $e^{-E_a/RT}$ , gives the rate of *successful* collisions. We shall develop these remarks in Chapter 22 and see that they have their analogues for reactions that take place in liquids.

## Accounting for the rate laws

We now move on to the second stage of the analysis of kinetic data, their explanation in terms of a postulated reaction mechanism.

### 21.6 Elementary reactions

---

**Key points** The mechanism of reaction is the sequence of elementary steps involved in a reaction. The molecularity of an elementary reaction is the number of molecules coming together to react. An elementary unimolecular reaction has first-order kinetics; an elementary bimolecular reaction has second-order kinetics.

---

Most reactions occur in a sequence of steps called **elementary reactions**, each of which involves only a small number of molecules or ions. A typical elementary reaction is

Note that the phase of the species is not specified in the chemical equation for an elementary reaction, and the equation represents the specific process occurring to individual molecules. This equation, for instance, signifies that an H atom attacks a  $\text{Br}_2$  molecule to produce an HBr molecule and a Br atom. The **molecularity** of an elementary reaction is the number of molecules coming together to react in an elementary reaction. In a **unimolecular reaction**, a single molecule shakes itself apart or its atoms into a new arrangement, as in the isomerization of cyclopropane to propene. In a **bimolecular reaction**, a pair of molecules collide and exchange energy, atoms, or groups of atoms, or undergo some other kind of change. It is most important to distinguish molecularity from order:

- *reaction order* is an empirical quantity, and obtained from the experimental rate law;
- *molecularity* refers to an elementary reaction proposed as an individual step in a mechanism.

The rate law of a unimolecular elementary reaction is first-order in the reactant:

where P denotes products (several different species may be formed). A unimolecular reaction is first-order because the number of A molecules that decay in a short interval is proportional to the number available to decay. (Ten times as many decay in the same interval when there are initially 1000 A molecules as when there are only 100 present.) Therefore, the rate of decomposition of A is proportional to its molar concentration at any moment during the reaction.

An elementary bimolecular reaction has a second-order rate law:

A bimolecular reaction is second-order because its rate is proportional to the rate at which the reactant species meet, which in turn is proportional to their concentrations. Therefore, if we have evidence that a reaction is a single-step, bimolecular process, we can write down the rate law (and then go on to test it). Bimolecular elementary reactions are believed to account for many homogeneous reactions, such as the dimerizations of alkenes and dienes and reactions such as

(where 'alc' signifies alcohol solution). There is evidence that the mechanism of this reaction is a single elementary step

This mechanism is consistent with the observed rate law

$$v = k_r[\text{CH}_3\text{I}][\text{CH}_3\text{CH}_2\text{O}^-] \quad (21.35)$$

We shall see below how to combine a series of simple steps together into a mechanism and how to arrive at the corresponding rate law. For the present we emphasize that, *if the reaction is an elementary bimolecular process, then it has second-order kinetics, but if the kinetics are second-order, then the reaction might be complex*. The postulated mechanism can be explored only by detailed detective work on the system, and by investigating whether side products or intermediates appear during the course of the reaction. Detailed analysis of this kind was one of the ways, for example, in which the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightarrow 2 \text{HI}(\text{g})$  was shown to proceed by a complex mechanism. For many years the reaction had been accepted on good, but insufficiently meticulous evidence as a fine example of a simple bimolecular reaction,  $\text{H}_2 + \text{I}_2 \rightarrow \text{HI} + \text{HI}$ , in which atoms exchanged partners during a collision.

## 21.7 Consecutive elementary reactions

**Key points** (a) The concentration of a reaction intermediate rises to a maximum and then falls to zero whilst the concentration of the product rises from zero. (b) The rate-determining step is the slowest step in a reaction mechanism that controls the rate of the overall reaction. (c) In the steady-state approximation, it is assumed that the concentrations of all reaction intermediates remain constant and small throughout the reaction. (d) Provided a reaction has not reached equilibrium, the products of competing reactions are controlled by kinetics. (e) Pre-equilibrium is a state in which an intermediate is in equilibrium with the reactants and which arises when the rates of formation of the intermediate and its decay back into reactants are much faster than its rate of formation of products.

Some reactions proceed through the formation of an intermediate (I), as in the consecutive unimolecular reactions

An example is the decay of a radioactive family, such as

(The times are half-lives.) We can discover the characteristics of this type of reaction by setting up the rate laws for the net rate of change of the concentration of each substance.

### (a) The variation of concentrations with time

The rate of unimolecular decomposition of A is

$$\frac{d[A]}{dt} = -k_a[A] \quad (21.36)$$

and A is not replenished. The intermediate I is formed from A (at a rate  $k_a[A]$ ) but decays to P (at a rate  $k_b[I]$ ). The net rate of formation of I is therefore

$$\frac{d[I]}{dt} = k_a[A] - k_b[I] \quad (21.37)$$

The product P is formed by the unimolecular decay of I:

$$\frac{d[P]}{dt} = k_b[I] \quad (21.38)$$

We suppose that initially only A is present, and that its concentration is  $[A]_0$ .

The first of the rate laws, eqn 21.36, is an ordinary first-order decay, so we can write

$$[A] = [A]_0 e^{-k_a t} \quad (21.39)$$

When this equation is substituted into eqn 21.37, we obtain after rearrangement

$$\frac{d[I]}{dt} + k_b[I] = k_a[A]_0 e^{-k_a t} \quad (21.40)$$

This differential equation has a standard form (see *Mathematical background 4*) and, after setting  $[I]_0 = 0$ , the solution is

$$[I] = \frac{k_a}{k_b - k_a} (e^{-k_a t} - e^{-k_b t}) [A]_0 \quad (21.41)$$

At all times  $[A] + [I] + [P] = [A]_0$ , so it follows that

$$[P] = \left\{ 1 + \frac{k_a e^{-k_b t} - k_b e^{-k_a t}}{k_b - k_a} \right\} [A]_0 \quad (21.42)$$

The concentration of the intermediate I rises to a maximum and then falls to zero (Fig. 21.14). The concentration of the product P rises from zero towards  $[A]_0$ .

**Fig. 21.14** The concentrations of A, I, and P in the consecutive reaction scheme  $A \rightarrow I \rightarrow P$ . The curves are plots of eqns 21.39, 21.41, and 21.42 with  $k_a = 10k_b$ . If the intermediate I is in fact the desired product, it is important to be able to predict when its concentration is greatest; see Example 21.6.

**InterActivity** Use mathematical software, an electronic spreadsheet, or the applets found in the *Living graphs* section of the text's web site to investigate the effects on  $[A]$ ,  $[I]$ ,  $[P]$ , and  $t_{\max}$  of increasing the ratio  $k_a/k_b$  from 10 (as in Fig. 21.14) to 0.01. Compare your results with those shown in Fig. 21.16.

### Example 21.6 Analysing consecutive reactions

Suppose that in an industrial batch process a substance A produces the desired compound I, which goes on to decay to a worthless product C, each step of the reaction being first-order. At what time will I be present in greatest concentration?

**Method** The time dependence of the concentration of I is given by eqn 21.41. We can find the time at which  $[I]$  passes through a maximum,  $t_{\max}$ , by calculating  $d[I]/dt$  and setting the resulting rate equal to zero.

**Answer** It follows from eqn 21.41 that

$$\frac{d[I]}{dt} = -\frac{k_a[A]_0(k_a e^{-k_a t} - k_b e^{-k_b t})}{k_b - k_a}$$

This rate is equal to zero when  $k_a e^{-k_a t} = k_b e^{-k_b t}$ . Therefore,

$$t_{\max} = \frac{1}{k_a - k_b} \ln \frac{k_a}{k_b}$$

For a given value of  $k_a$ , as  $k_b$  increases both the time at which  $[I]$  is a maximum and the yield of  $I$  decrease.

**Self-test 21.8** Calculate the maximum concentration of  $I$  and justify the last remark.  
 $[[I]_{\max}/[A]_0 = (k_a/k_b)^c, c = k_b/(k_b - k_a)]$

### (b) The steady-state approximation

One feature of the calculation so far has probably not gone unnoticed: there is a considerable increase in mathematical complexity as soon as the reaction mechanism has more than a couple of steps. A reaction scheme involving many steps is nearly always unsolvable analytically, and alternative methods of solution are necessary. One approach is to integrate the rate laws numerically. An alternative approach, which continues to be widely used because it leads to convenient expressions and more readily digestible results, is to make an approximation.

The **steady-state approximation** (which is also widely called the **quasi-steady-state approximation**, QSSA, to distinguish it from a true steady state) assumes that, after an initial **induction period**, an interval during which the concentrations of intermediates,  $I$ , rise from zero, and during the major part of the reaction, the rates of change of concentrations of all reaction intermediates are negligibly small (Fig. 21.15):

$$\frac{d[I]}{dt} \approx 0 \quad (21.43)$$

This approximation greatly simplifies the discussion of reaction schemes. For example, when we apply the approximation to the consecutive first-order mechanism, we set  $d[I]/dt = 0$  in eqn 21.37, which then becomes  $k_a[A] - k_b[I] \approx 0$ . Then

$$[I] \approx (k_a/k_b)[A] \quad (21.44)$$

For this expression to be consistent with eqn 21.41, we require  $k_a/k_b \ll 1$  (so that, even though  $[A]$  does depend on the time, the dependence of  $[I]$  on the time is negligible). On substituting this value of  $[I]$  into eqn 21.38, that equation becomes

$$\frac{d[P]}{dt} = k_b[I] \approx k_a[A] \quad (21.45)$$

and we see that  $P$  is formed by a first-order decay of  $A$ , with a rate constant  $k_a$ , the rate constant of the slower, rate-determining, step. We can write down the solution of this equation at once by substituting the solution for  $[A]$ , eqn 21.39, and integrating:

$$[P] = k_a[A]_0 \int_0^t e^{-k_a t} dt = (1 - e^{-k_a t})[A]_0 \quad (21.46)$$

This is the same (approximate) result as before, eqn 21.42 (when  $k_b \gg k_a$ ), but much more quickly obtained. Figure 21.16 compares the approximate solutions found here with the exact solutions found earlier:  $k_b$  does not have to be very much bigger than  $k_a$  for the approach to be reasonably accurate.

**Fig. 21.15** The basis of the steady-state approximation. It is supposed that the concentrations of intermediates remain small and hardly change during most of the course of the reaction.

**Fig. 21.16** A comparison of the exact result for the concentrations of a consecutive reaction and the concentrations obtained by using the steady-state approximation (dotted lines) for  $k_b = 20k_a$ . (The curve for  $[A]$  is unchanged.)

**A note on good practice** Note that when writing the equation for an elementary reaction all the species are displayed individually; so we write  $A \rightarrow B + B$ , for instance, not  $A \rightarrow 2 B$ .

**Example 21.7** Using the steady-state approximation

Devise the rate law for the decomposition of  $N_2O_5$ ,

on the basis of the following mechanism:

**Method** First identify the intermediates (species that occur in the reaction steps but do not appear in the overall reaction) and write expressions for their net rates of formation. Then, all net rates of change of the concentrations of intermediates are set equal to zero and the resulting equations are solved algebraically.

**Answer** The intermediates are NO and  $NO_3$ ; the net rates of change of their concentrations are

$$\frac{d[NO]}{dt} = k_b[NO_2][NO_3] - k_c[NO][N_2O_5] \approx 0$$

$$\frac{d[NO_3]}{dt} = k_a[N_2O_5] - k'_a[NO_2][NO_3] - k_b[NO_2][NO_3] \approx 0$$

The net rate of change of concentration of  $N_2O_5$  is

$$\frac{d[N_2O_5]}{dt} = -k_a[N_2O_5] + k'_a[NO_2][NO_3] - k_c[NO][N_2O_5]$$

We use

$$k_b[NO_2][NO_3] - k_c[NO][N_2O_5] = 0$$

and

$$k_a[N_2O_5] - k'_a[NO_2][NO_3] - k_b[NO_2][NO_3] = 0$$

to write

$$[NO] = \frac{k_b[NO_2][NO_3]}{k_c[N_2O_5]}$$

$$[NO_3] = \frac{k_a[N_2O_5]}{(k'_a + k_b)[NO_2]}$$

and then substitute these expressions into that for  $d[N_2O_5]/dt$  to obtain

$$\frac{d[N_2O_5]}{dt} = -\frac{2k_a k_b [N_2O_5]}{k'_a + k_b}$$

**Self-test 21.9** Derive the rate law for the decomposition of ozone in the reaction  $2 O_3(g) \rightarrow 3 O_2(g)$  on the basis of the (incomplete) mechanism

$$[d[O_3]/dt = -2k_a k_b [O_3]^2 / (k'_a [O_2] + k_b [O_3])]$$

**(c) The rate-determining step**

Equation 21.46 shows that when  $k_b \gg k_a$  the formation of the final product P depends on only the *smaller* of the two rate constants. That is, the rate of formation of P depends on the rate at which I is formed, not on the rate at which I changes into P. For this reason, the step  $A \rightarrow I$  is called the ‘rate-determining step’ of the reaction. Its existence has been likened to building a six-lane highway up to a single-lane bridge: the traffic flow is governed by the rate of crossing the bridge. Similar remarks apply to more complicated reaction mechanisms, and in general the **rate-determining step** is the slowest step in a mechanism and controls the overall rate of the reaction. However, the rate-determining step is not just the slowest step: it must be slow *and* be a crucial gateway for the formation of products. If a faster reaction can also lead to products, then the slowest step is irrelevant because the slow reaction can then be sidestepped (Fig. 21.17).

The rate law of a reaction that has a rate-determining step can often be written down almost by inspection. If the first step in a mechanism is rate-determining, then the rate of the overall reaction is equal to the rate of the first step because all subsequent steps are so fast that once the first intermediate is formed it results immediately in the formation of products. Figure 21.18 shows the reaction profile for a mechanism in which the slowest step is the one with the highest activation energy. Once over the initial barrier, the intermediates cascade into products. However, a rate-determining step may also stem from the low concentration of a crucial reactant and need not correspond to the step with highest activation barrier.

**(d) Pre-equilibria**

From a simple sequence of consecutive reactions we now turn to a slightly more complicated mechanism in which an intermediate I reaches an equilibrium with the reactants A and B:

The rate constants are  $k_a$  and  $k'_a$  for the forward and reverse reactions of the equilibrium and  $k_b$  for the final step. This scheme involves a **pre-equilibrium**, in which an intermediate is in equilibrium with the reactants. A pre-equilibrium can arise when the rate of decay of the intermediate back into reactants is much faster than the rate at which it forms products; thus, the condition is possible when  $k'_a \gg k_b$  but not when  $k_b \gg k'_a$ . Because we assume that A, B, and I are in equilibrium, we can write

$$K = \frac{[I]}{[A][B]} \quad K = \frac{k_a}{k'_a} \quad (21.48)$$

In writing these equations, we are presuming that the rate of reaction of I to form P is too slow to affect the maintenance of the pre-equilibrium (see the example below). We are also ignoring the fact, as is commonly done, that the standard concentration  $c^\ominus$  should appear in the expression for  $K$  to ensure that it is dimensionless. The rate of formation of P may now be written:

$$\frac{d[P]}{dt} = k_b[I] = k_b K[A][B] \quad (21.49)$$

This rate law has the form of a second-order rate law with a composite rate constant:

$$\frac{d[P]}{dt} = k[A][B] \quad k = k_b K = \frac{k_a k_b}{k'_a} \quad (21.50)$$

**Fig. 21.17** In these diagrams of reaction schemes, heavy arrows represent fast steps and light arrows represent slow steps. (a) The first step is rate-determining; (b) the second step is rate-determining; (c) although one step is slow, it is not rate-determining because there is a fast route that circumvents it.

**Fig. 21.18** The reaction profile for a mechanism in which the first step (RDS) is rate-determining.

**Example 21.8** *Analysing a pre-equilibrium*

Repeat the pre-equilibrium calculation but without ignoring the fact that I is slowly leaking away as it forms P.

**Method** Begin by writing the net rates of change of the concentrations of the substances and then invoke the steady-state approximation for the intermediate I. Use the resulting expression to obtain the rate of change of the concentration of P.

**Answer** The net rates of change of P and I are

$$\frac{d[P]}{dt} = k_b[I]$$

$$\frac{d[I]}{dt} = k_a[A][B] - k'_a[I] - k_b[I] \approx 0$$

The second equation solves to

$$[I] \approx \frac{k_a[A][B]}{k'_a + k_b}$$

When we substitute this result into the expression for the rate of formation of P, we obtain

$$\frac{d[P]}{dt} \approx k_r[A][B] \quad k_r = \frac{k_a k_b}{k'_a + k_b}$$

This expression reduces to that in eqn 21.50 when the rate constant for the decay of I into products is much smaller than that for its decay into reactants,  $k_b \ll k'_a$ .

**Self-test 21.10** Show that the pre-equilibrium mechanism in which  $A + A \rightleftharpoons I$  ( $K$ ) followed by  $I + B \rightarrow P$  ( $k_b$ ) results in an overall third-order reaction.

$$[d[P]/dt = k_b K[A]^2[B]]$$

**(e) Kinetic and thermodynamic control of reactions**

In some cases reactants can give rise to a variety of products, as in nitrations of mono-substituted benzene, when various proportions of the *ortho*-, *meta*-, and *para*-substituted products are obtained, depending on the directing power of the original substituent. Suppose two products,  $P_1$  and  $P_2$ , are produced by the following competing reactions:

The relative proportion in which the two products have been produced at a given stage of the reaction (before it has reached equilibrium) is given by the ratio of the two rates, and therefore of the two rate constants:

$$\frac{[P_2]}{[P_1]} = \frac{k_2}{k_1} \quad (21.51)$$

This ratio represents the **kinetic control** over the proportions of products, and is a common feature of the reactions encountered in organic chemistry where reactants are chosen that facilitate pathways favouring the formation of a desired product. If a reaction is allowed to reach equilibrium, then the proportion of products is

determined by thermodynamic rather than kinetic considerations, and the ratio of concentrations is controlled by considerations of the standard Gibbs energies of all the reactants and products.

**Self-test 21.11** Two products are formed in reactions in which there is kinetic control of the ratio of products. The activation energy for the reaction leading to product 1 is greater than that leading to product 2. Will the ratio of product concentrations  $[P_1]/[P_2]$  increase or decrease if the temperature is raised?

[The ratio  $[P_1]/[P_2]$  will increase]

## Examples of reaction mechanisms

Many reactions take place by mechanisms that involve several elementary steps. Some take place at a useful rate only after absorption of light or if a catalyst is present. In the following sections we begin to see how to develop the ideas introduced so far to deal with these special kinds of reactions. We leave the study of catalysis to Chapter 23 and focus here on the kinetic analysis of a special class of reactions in the gas phase, polymerization kinetics, and photochemical reactions.

### 21.8 Unimolecular reactions

**Key points** (a) The Lindemann–Hinshelwood mechanism and the RRKM model of ‘unimolecular’ reactions account for the first-order kinetics of gas-phase reactions. (b) The overall activation energy of a reaction with a complex mechanism may be positive or negative.

A number of gas-phase reactions follow first-order kinetics, as in the isomerization of cyclopropane mentioned earlier:

The problem with the interpretation of first-order rate laws is that presumably a molecule acquires enough energy to react as a result of its collisions with other molecules. However, collisions are simple bimolecular events, so how can they result in a first-order rate law? First-order gas-phase reactions are widely called ‘unimolecular reactions’ because they also involve an elementary unimolecular step in which the reactant molecule changes into the product. This term must be used with caution, though, because the overall mechanism has bimolecular as well as unimolecular steps.

#### (a) The Lindemann–Hinshelwood mechanism

The first successful explanation of unimolecular reactions was provided by Frederick Lindemann in 1921 and then elaborated by Cyril Hinshelwood. In the **Lindemann–Hinshelwood mechanism** it is supposed that a reactant molecule A becomes energetically excited by collision with another A molecule in a bimolecular step (Fig. 21.19):

The energized molecule ( $\text{A}^*$ ) might lose its excess energy by collision with another molecule:

**Fig. 21.19** A representation of the Lindemann–Hinshelwood mechanism of unimolecular reactions. The species A is excited by collision with A, and the excited A molecule ( $\text{A}^*$ ) may either be deactivated by a collision with A or go on to decay by a unimolecular process to form products.

Alternatively, the excited molecule might shake itself apart and form products P. That is, it might undergo the unimolecular decay

If the unimolecular step is slow enough to be the rate-determining step, the overall reaction will have first-order kinetics, as observed. This conclusion can be demonstrated explicitly by applying the steady-state approximation to the net rate of formation of  $A^*$ :

$$\frac{d[A^*]}{dt} = k_a[A]^2 - k'_a[A][A^*] - k_b[A^*] \approx 0 \quad (21.56)$$

This equation solves to

$$[A^*] = \frac{k_a[A]^2}{k_b + k'_a[A]} \quad (21.57)$$

so the rate law for the formation of P is

$$\frac{d[P]}{dt} = k_b[A^*] = \frac{k_a k_b [A]^2}{k_b + k'_a[A]} \quad (21.58)$$

At this stage the rate law is not first-order. However, if the rate of deactivation by  $(A^*, A)$  collisions is much greater than the rate of unimolecular decay, in the sense that

$$k'_a[A^*][A] \gg k_b[A^*] \quad \text{or} \quad k'_a[A] \gg k_b$$

then we can neglect  $k_b$  in the denominator and obtain

$$\frac{d[P]}{dt} = k_r[A] \quad k_r = \frac{k_a k_b}{k'_a} \quad (21.59)$$

Equation 21.59 is a first-order rate law, as we set out to show.

The Lindemann–Hinshelwood mechanism can be tested because it predicts that, as the concentration (and therefore the partial pressure) of A is reduced, the reaction should switch to overall second-order kinetics. Thus, when  $k'_a[A] \ll k_b$ , the rate law in eqn 21.58 is

$$\frac{d[P]}{dt} \approx k_a[A]^2 \quad (21.60)$$

The physical reason for the change of order is that at low pressures the rate-determining step is the bimolecular formation of  $A^*$ . If we write the full rate law in eqn 21.58 as

$$\frac{d[P]}{dt} = k_r[A] \quad k_r = \frac{k_a k_b [A]}{k_b + k'_a[A]} \quad (21.61)$$

then the expression for the effective rate constant,  $k_r$ , can be rearranged to

$$\frac{1}{k_r} = \frac{k'_a}{k_a k_b} + \frac{1}{k_a[A]} \quad (21.62)$$

Hence, a test of the theory is to plot  $1/k_r$  against  $1/[A]$ , and to expect a straight line. This behaviour is observed often at low concentrations but deviations are common at high concentrations. In Chapter 22 we develop the description of the mechanism to take into account experimental results over a range of concentrations and pressures.

**(b) The activation energy of a composite reaction**

Although the rate of each step of a complex mechanism might increase with temperature and show Arrhenius behaviour, is that true of a composite reaction? To answer this question, we consider the high-pressure limit of the Lindemann–Hinshelwood mechanism as expressed in eqn 21.59. If each of the rate constants has an Arrhenius-like temperature dependence, we can use eqn 21.31 for each of them, and write

$$k_r = \frac{k_a k_b}{k'_a} = \frac{(A_a e^{-E_a(a)/RT})(A_b e^{-E_a(b)/RT})}{(A'_a e^{-E'_a(a)/RT})} \quad (21.63)$$

$$= \frac{A_a A_b}{A'_a} e^{-\{E_a(a) + E_a(b) - E'_a(a)\}/RT}$$

That is, the composite rate constant  $k$  has an Arrhenius-like form with activation energy

$$E_a = E_a(a) + E_a(b) - E'_a(a) \quad (21.64)$$

Provided  $E_a(a) + E_a(b) > E'_a(a)$ , the activation energy is positive and the rate increases with temperature. However, it is conceivable that  $E_a(a) + E_a(b) < E'_a(a)$  (Fig. 21.20), in which case the activation energy is negative and the rate will *decrease* as the temperature is raised. There is nothing remarkable about this behaviour: all it means is that the reverse reaction (corresponding to the deactivation of  $A^*$ ) is so sensitive to temperature that its rate increases sharply as the temperature is raised, and depletes the steady-state concentration of  $A^*$ . The Lindemann–Hinshelwood mechanism is an unlikely candidate for this type of behaviour because the deactivation of  $A^*$  has only a small activation energy, but there are reactions with analogous mechanisms in which a negative activation energy is observed.

When we examine the general rate law given in eqn 21.58, it is clear that the temperature dependence may be difficult to predict because each rate constant in the expression for  $k_r$  increases with temperature, and the outcome depends on whether the terms in the numerator dominate those in the denominator, or vice versa. The fact that so many reactions do show Arrhenius-like behaviour with positive activation energies suggests that their rate laws are in a ‘simple’ regime, like eqn 21.60 rather than eqn 21.58, and that the temperature dependence is dominated by the activation energy of the rate-determining stage.

**21.9 Polymerization kinetics**

**Key points** (a) In stepwise polymerization any two monomers in the reaction mixture can link together at any time. The longer a stepwise polymerization proceeds, the higher the average molar mass of the product. (b) In chain polymerization an activated monomer attacks another monomer and links to it. The slower the initiation of the chain, the higher the average molar mass of the polymer.

There are two major classes of polymerization processes and the average molar mass of the product varies with time in distinctive ways. In **stepwise polymerization** any two monomers present in the reaction mixture can link together at any time and growth of the polymer is not confined to chains that are already forming (Fig. 21.21). As a result, monomers are consumed early in the reaction and, as we shall see, the average molar mass of the product grows with time. In **chain polymerization** an activated monomer,  $M$ , attacks another monomer, links to it, then that unit attacks another monomer, and so on. The monomer is used up as it becomes linked to the growing chains (Fig. 21.22). High polymers are formed rapidly and only the yield, not the average molar mass, of the polymer is increased by allowing long reaction times.

**Fig. 21.20** For a reaction with a pre-equilibrium, there are three activation energies to take into account, two referring to the reversible steps of the pre-equilibrium and one for the final step. The relative magnitudes of the activation energies determine whether the overall activation energy is (a) positive or (b) negative.

**Fig. 21.21** In stepwise polymerization, growth can start at any pair of monomers, and so new chains begin to form throughout the reaction.

**Fig. 21.22** The process of chain polymerization. Chains grow as each chain acquires additional monomers.

**Fig. 21.23** The average chain length of a polymer as a function of the fraction of reacted monomers,  $p$ . Note that  $p$  must be very close to 1 for the chains to be long.

**InterActivity** Plot the variation of  $p$  with time for a range of  $k_t$  values of your choosing (take  $[A]_0 = 1.0 \text{ mol dm}^{-3}$ ).

### (a) Stepwise polymerization

Stepwise polymerization commonly proceeds by a condensation reaction, in which a small molecule (typically  $\text{H}_2\text{O}$ ) is eliminated in each step. Stepwise polymerization is the mechanism of production of polyamides, as in the formation of nylon-66:

Polyesters and polyurethanes are formed similarly (the latter without elimination). A polyester, for example, can be regarded as the outcome of the stepwise condensation of a hydroxyacid  $\text{HO}-\text{R}-\text{COOH}$ . We shall consider the formation of a polyester from such a monomer, and measure its progress in terms of the concentration of the  $-\text{COOH}$  groups in the sample (which we denote  $A$ ), for these groups gradually disappear as the condensation proceeds. Because the condensation reaction can occur between molecules containing any number of monomer units, chains of many different lengths can grow in the reaction mixture.

In the absence of a catalyst, we can expect the condensation to be overall second-order in the concentration of the  $-\text{OH}$  and  $-\text{COOH}$  (or  $A$ ) groups, and write

$$\frac{d[A]}{dt} = -k_t[\text{OH}][A] \quad (21.65a)$$

However, because there is one  $-\text{OH}$  group for each  $-\text{COOH}$  group, this equation is the same as

$$\frac{d[A]}{dt} = -k_t[A]^2 \quad (21.65b)$$

If we assume that the rate constant for the condensation is independent of the chain length, then  $k_t$  remains constant throughout the reaction. The solution of this rate law is given by eqn 21.15c, and is

$$[A] = \frac{[A]_0}{1 + k_t t [A]_0} \quad (21.66)$$

The fraction,  $p$ , of  $-\text{COOH}$  groups that have condensed at time  $t$  is, after application of eqn 21.66:

$$p = \frac{[A]_0 - [A]}{[A]_0} = \frac{k_t t [A]_0}{1 + k_t t [A]_0} \quad \text{Fraction of condensed groups} \quad (21.67)$$

Next, we calculate the **degree of polymerization**, which is defined as the average number of monomer residues per polymer molecule. This quantity is the ratio of the initial concentration of  $A$ ,  $[A]_0$ , to the concentration of end groups,  $[A]$ , at the time of interest, because there is one  $A$  group per polymer molecule. For example, if there were initially 1000  $A$  groups and there are now only 10, each polymer must be 100 units long on average. Because we can express  $[A]$  in terms of  $p$  (eqn 21.67), the average number of monomers per polymer molecule,  $\langle N \rangle$ , is

$$\langle N \rangle = \frac{[A]_0}{[A]} = \frac{1}{1 - p} \quad \text{Degree of polymerization} \quad (21.68a)$$

This result is illustrated in Fig. 21.23. When we express  $p$  in terms of the rate constant  $k_t$  (eqn 21.67), we find

$$\langle N \rangle = 1 + k_r t [A]_0$$

Degree of polymerization in terms of the rate constant

$$(21.68b)$$

The average length grows linearly with time. Therefore, the longer a stepwise polymerization proceeds, the higher the average molar mass of the product.

### (b) Chain polymerization

Many gas-phase reactions and liquid-phase polymerization reactions are **chain reactions**. In a chain reaction, a reaction intermediate produced in one step generates an intermediate in a subsequent step, then that intermediate generates another intermediate, and so on. The intermediates in a chain reaction are called **chain carriers**. In a **radical chain reaction** the chain carriers are radicals (species with unpaired electrons).

Chain polymerization occurs by addition of monomers to a growing polymer, often by a radical chain process. It results in the rapid growth of an individual polymer chain for each activated monomer. Examples include the addition polymerizations of ethene, methyl methacrylate, and styrene, as in

and subsequent reactions. The central feature of the kinetic analysis (which is summarized in the following *Justification*) is that the rate of polymerization is proportional to the square root of the initiator concentration:

$$v = k_r [I]^{1/2} [M] \quad (21.69)$$

#### Justification 21.6 The rate of chain polymerization

There are three basic types of reaction step in a chain polymerization process:

(a) Initiation:

where  $I$  is the initiator,  $R\cdot$  the radical  $I$  forms, and  $\cdot M_1$  a monomer radical. We have shown a reaction in which a radical is produced, but in some polymerizations the initiation step leads to the formation of an ionic chain carrier. The rate-determining step is the formation of the radicals  $R\cdot$  by homolysis of the initiator, so the rate of initiation is equal to the  $v_i$  given above.

(b) Propagation:

$\vdots$

If we assume that the rate of propagation is independent of chain size for sufficiently large chains, then we can use only the equation given above to describe the propagation process. Consequently, for sufficiently large chains, the rate of propagation is equal to the overall rate of polymerization.

Because this chain of reactions propagates quickly, the rate at which the total concentration of radicals grows is equal to the rate of the rate-determining initiation step. It follows that

$$\left( \frac{d[\cdot M]}{dt} \right)_{\text{production}} = 2fk_i [I] \quad (21.70)$$

where  $f$  is the fraction of radicals  $R\cdot$  that successfully initiate a chain.

(c) Termination:

In **mutual termination** two growing radical chains combine. In termination by **disproportionation** a hydrogen atom transfers from one chain to another, corresponding to the oxidation of the donor and the reduction of the acceptor. In **chain transfer**, a new chain initiates at the expense of the one currently growing.

Here we suppose that only mutual termination occurs. If we assume that the rate of termination is independent of the length of the chain, the rate law for termination is

$$v_t = k_t [\cdot M]^2$$

and the rate of change of radical concentration by this process is

$$\left( \frac{d[\cdot M]}{dt} \right)_{\text{depletion}} = -2k_t [\cdot M]^2$$

The steady-state approximation gives:

$$\frac{d[\cdot M]}{dt} = 2fk_i[I] - 2k_t[\cdot M]^2 = 0$$

The steady-state concentration of radical chains is therefore

$$[\cdot M] = \left( \frac{fk_i}{k_t} \right)^{1/2} [I]^{1/2} \quad (21.71)$$

Because the rate of propagation of the chains is the negative of the rate at which the monomer is consumed, we can write  $v_p = -d[M]/dt$  and

$$v_p = k_p [\cdot M][M] = k_p \left( \frac{fk_i}{k_t} \right)^{1/2} [I]^{1/2} [M] \quad (21.72)$$

This rate is also the rate of polymerization, which has the form of eqn 21.69.

The **kinetic chain length**,  $\nu$ , is the ratio of the number of monomer units consumed per activated centre produced in the initiation step:

$$\nu = \frac{\text{number of monomer units consumed}}{\text{number of activated centres produced}} \quad \boxed{\text{Definition of the kinetic chain length}} \quad [21.73a]$$

The kinetic chain length can be expressed in terms of the rate expressions in *Justification* 21.6. To do so, we recognize that monomers are consumed at the rate that chains propagate. Then,

$$\nu = \frac{\text{rate of propagation of chains}}{\text{rate of production of radicals}} \quad \boxed{\text{Definition of the kinetic chain length in terms of reaction rates}} \quad [21.73b]$$

By making the steady-state approximation, we set the rate of production of radicals equal to the termination rate. Therefore, we can write the expression for the kinetic chain length as

$$\nu = \frac{k_p [\cdot M][M]}{2k_t [\cdot M]^2} = \frac{k_p [M]}{2k_t [\cdot M]}$$

When we substitute the steady-state expression, eqn 21.71, for the radical concentration, we obtain

$$v = k_r[M][I]^{-1/2} \quad k_r = \frac{1}{2}k_p(fk_i k_t)^{-1/2} \quad (21.74)$$

Consider a polymer produced by a chain mechanism with mutual termination. In this case, the average number of monomers in a polymer molecule,  $\langle N \rangle$ , produced by the reaction is the sum of the numbers in the two combining polymer chains. The average number of units in each chain is  $v$ . Therefore,

$$\langle N \rangle = 2v = 2k_r[M][I]^{-1/2} \quad \text{Degree of polymerization in a chain process} \quad (21.75)$$

with  $k_r$  given in eqn 21.74. We see that, the slower the initiation of the chain (the smaller the initiator concentration and the smaller the initiation rate constant), the greater the kinetic chain length, and therefore the higher the average molar mass of the polymer. Some of the consequences of molar mass for polymers were explored in Chapter 18: now we have seen how we can exercise kinetic control over them.

## 21.10 Photochemistry

**Key points** (a) The primary quantum yield of a photochemical reaction is the number of reactant molecules producing specified primary products for each photon absorbed. (b) The observed lifetime of an excited state is related to the quantum yield and rate constant of emission. (c) A Stern–Volmer plot is used to analyse the kinetics of fluorescence quenching in solution. Collisional deactivation, electron transfer, and resonance energy transfer are common fluorescence quenching processes. (d) The efficiency of resonance energy transfer decreases with increasing separation between donor and acceptor molecules.

Many reactions can be initiated by the absorption of electromagnetic radiation by one of the mechanisms described in Chapter 13. The most important of all are the photochemical processes that capture the radiant energy of the Sun. Some of these reactions lead to the heating of the atmosphere during the daytime by absorption of ultraviolet radiation. Others include the absorption of visible radiation during photosynthesis (*Impact I21.1*). Without photochemical processes, the Earth would be simply a warm, sterile, rock. Table 21.5 summarizes common photochemical reactions.

Photochemical processes are initiated by the absorption of radiation by at least one component of a reaction mixture. In a **primary process**, products are formed directly from the excited state of a reactant. Examples include fluorescence (Section 13.4) and the *cis–trans* photoisomerization of retinal (Table 21.5, see also *Impact I13.1*). Products of a **secondary process** originate from intermediates that are formed directly from the excited state of a reactant.

Competing with the formation of photochemical products is a host of primary photophysical processes that can deactivate the excited state (Table 21.6). Therefore, it is important to consider the timescales of excited state formation and decay before describing the mechanisms of photochemical reactions. Electronic transitions caused by absorption of ultraviolet and visible radiation occur within  $10^{-16}$ – $10^{-15}$  s. We expect, then, that the upper limit for the rate constant of a first-order photochemical reaction is about  $10^{16}$  s<sup>-1</sup>. Fluorescence is slower than absorption, with typical lifetimes of  $10^{-12}$ – $10^{-6}$  s. Therefore, the excited singlet state can initiate very fast photochemical reactions in the femtosecond ( $10^{-15}$  s) to picosecond ( $10^{-12}$  s) timescale. Examples of such ultrafast reactions are the initial events of vision (*Impact I13.1*) and of photosynthesis. Typical intersystem crossing (ISC) and phosphorescence times

**Table 21.5** Examples of photochemical processes

| Process                        | General form                                      | Example                                                                                                                        |

| Singlet-singlet             | $S^* + S^* \rightarrow S^{**} + S$                                 |
| Triplet-triplet             | $T^* + T^* \rightarrow S^* + S$                                    |

<sup>†</sup> S denotes a singlet state, T a triplet state, and M is a third-body.

for large organic molecules are  $10^{-12}$ – $10^{-4}$  s and  $10^{-6}$ – $10^{-1}$  s, respectively. As a consequence, excited triplet states are photochemically important. Indeed, because phosphorescence decay is several orders of magnitude slower than most typical reactions, species in excited triplet states can undergo a very large number of collisions with other reactants before deactivation.

**(a) The primary quantum yield**

We shall see that the rates of deactivation of the excited state by radiative, non-radiative, and chemical processes determine the yield of product in a photochemical reaction. The **primary quantum yield**,  $\phi$ , is defined as the number of photophysical or photochemical events that lead to primary products divided by the number of photons absorbed by the molecule in the same interval:

$$\phi = \frac{\text{number of events}}{\text{number of photons absorbed}} \quad \text{Definition of the primary quantum yield} \quad [21.76a]$$

When we divide both the numerator and denominator of this expression by the time interval over which the events occurred, we see that the primary quantum yield is also the rate of radiation-induced primary events divided by the rate of photon absorption,  $I_{\text{abs}}$ :

$$\phi = \frac{\text{rate of process}}{\text{intensity of light absorbed}} = \frac{\nu}{I_{\text{abs}}} \quad \text{Definition of the primary quantum yield in terms of rates of processes} \quad [21.76b]$$

A molecule in an excited state must either decay to the ground state or form a photochemical product. Therefore, the total number of molecules deactivated by radiative processes, non-radiative processes, and photochemical reactions must be equal to the number of excited species produced by absorption of light. We conclude that the

sum of primary quantum yields  $\phi_i$  for *all* photophysical and photochemical events  $i$  must be equal to 1, regardless of the number of reactions involving the excited state. It follows that

$$\sum_i \phi_i = \sum_i \frac{v_i}{I_{\text{abs}}} = 1 \quad (21.77)$$

It follows that for an excited singlet state that decays to the ground state only via the photophysical processes described earlier in this section, we write

$$\phi_f + \phi_{\text{IC}} + \phi_p = 1$$

where  $\phi_f$ ,  $\phi_{\text{IC}}$ , and  $\phi_p$  are the quantum yields of fluorescence, internal conversion, and phosphorescence, respectively (intersystem crossing from the singlet to the triplet state is taken into account with the measurement of  $\phi_p$ ). The quantum yield of photon emission by fluorescence and phosphorescence is  $\phi_{\text{emission}} = \phi_f + \phi_p$ , which is less than 1. If the excited singlet state also participates in a primary photochemical reaction with quantum yield  $\phi_r$ , we write

$$\phi_f + \phi_{\text{IC}} + \phi_p + \phi_r = 1$$

We can now strengthen the link between reaction rates and primary quantum yield already established by eqns 21.76 and 21.77. By taking the constant  $I_{\text{abs}}$  out of the summation in eqn 21.77 and rearranging, we obtain  $I_{\text{abs}} = \sum_i v_i$ . Substituting this result into eqn 21.76b gives the general result

$$\phi = \frac{v}{\sum_i v_i} \quad (21.78)$$

Therefore, the primary quantum yield may be determined directly from the experimental rates of *all* photophysical and photochemical processes that deactivate the excited state.

### (b) Mechanism of decay of excited singlet states

Consider the formation and decay of an excited singlet state in the absence of a chemical reaction:

|                       |                              |                                        |
|-----------------------|------------------------------|----------------------------------------|
| Absorption:           | $S + h\nu_i \rightarrow S^*$ | $v_{\text{abs}} = I_{\text{abs}}$      |
| Fluorescence:         | $S^* \rightarrow S + h\nu_f$ | $v_f = k_f[S^*]$                       |
| Internal conversion:  | $S^* \rightarrow S$          | $v_{\text{IC}} = k_{\text{IC}}[S^*]$   |
| Intersystem crossing: | $S^* \rightarrow T^*$        | $v_{\text{ISC}} = k_{\text{ISC}}[S^*]$ |

in which S is an absorbing species,  $S^*$  an excited singlet state,  $T^*$  an excited triplet state, and  $h\nu_i$  and  $h\nu_f$  are the energies of the incident and fluorescent photons, respectively. From the methods developed earlier in this chapter and the rates of the steps that form and destroy the excited singlet state  $S^*$ , we write the rate of formation and decay of  $S^*$  as:

$$\text{Rate of formation of } [S^*] = I_{\text{abs}}$$

$$\text{Rate of decay of } [S^*] = -k_f[S^*] - k_{\text{ISC}}[S^*] - k_{\text{IC}}[S^*] = -(k_f + k_{\text{ISC}} + k_{\text{IC}})[S^*]$$

It follows that the excited state decays by a first-order process so, when the light is turned off, the concentration of  $S^*$  varies with time  $t$  as:

$$[S^*]_t = [S^*]_0 e^{-t/\tau_0} \quad (21.79)$$

where the **observed lifetime**,  $\tau_0$ , of the first excited singlet state is defined as:

$$\tau_0 = \frac{1}{k_f + k_{\text{ISC}} + k_{\text{IC}}} \quad \text{Definition of the observed lifetime of the excited singlet state} \quad [21.80]$$

We show in the following *Justification* that the quantum yield of fluorescence is

$$\phi_f = \frac{k_f}{k_f + k_{\text{ISC}} + k_{\text{IC}}} \quad \text{Quantum yield of fluorescence} \quad (21.81)$$

**Justification 21.7** *The quantum yield of fluorescence*

Most fluorescence measurements are conducted by illuminating a relatively dilute sample with a continuous and intense beam of light. It follows that  $[S^*]$  is small and constant, so we may invoke the steady-state approximation (Section 21.7) and write:

$$\frac{d[S^*]}{dt} = I_{\text{abs}} - k_f[S^*] - k_{\text{ISC}}[S^*] - k_{\text{IC}}[S^*] = I_{\text{abs}} - (k_f + k_{\text{ISC}} + k_{\text{IC}})[S^*] = 0$$

Consequently,

$$I_{\text{abs}} = (k_f + k_{\text{ISC}} + k_{\text{IC}})[S^*]$$

By using this expression and eqn 21.76b, the quantum yield of fluorescence is written as:

$$\phi_f = \frac{\nu_f}{I_{\text{abs}}} = \frac{k_f[S^*]}{(k_f + k_{\text{ISC}} + k_{\text{IC}})[S^*]}$$

which, by cancelling the  $[S^*]$ , simplifies to eqn 21.81.

The observed fluorescence lifetime can be measured by using a pulsed laser technique (Section 21.1). First, the sample is excited with a short light pulse from a laser using a wavelength at which S absorbs strongly. Then, the exponential decay of the fluorescence intensity after the pulse is monitored. From eqns 21.80 and 21.81, it follows that

$$\tau_0 = \frac{1}{k_f + k_{\text{ISC}} + k_{\text{IC}}} = \left( \frac{k_f}{k_f + k_{\text{ISC}} + k_{\text{IC}}} \right) \times \frac{1}{k_f} = \frac{\phi_f}{k_f} \quad (21.82)$$

• **A brief illustration**

In water, the fluorescence quantum yield and observed fluorescence lifetime of tryptophan are  $\phi_f = 0.20$  and  $\tau_0 = 2.6$  ns, respectively. It follows from eqn 21.82 that the fluorescence rate constant  $k_f$  is

$$k_f = \frac{\phi_f}{\tau_0} = \frac{0.20}{2.6 \times 10^{-9} \text{ s}} = 7.7 \times 10^7 \text{ s}^{-1} \quad \bullet$$

**(c) Quenching**

The shortening of the lifetime of the excited state by the presence of another species is called **quenching**. Quenching may be either a desired process, such as in energy or electron transfer, or an undesired side reaction that can decrease the quantum yield of a desired photochemical process. Quenching effects may be studied by monitoring the emission from the excited state that is involved in the photochemical reaction.

The addition of a quencher, Q, opens an additional channel for deactivation of  $S^*$ :

The **Stern–Volmer equation**, which is derived in the following *Justification*, relates the fluorescence quantum yields  $\phi_{f,0}$  and  $\phi_f$  measured in the absence and presence, respectively, of a quencher Q at a molar concentration [Q]:

$$\frac{\phi_{f,0}}{\phi_f} = 1 + \tau_0 k_Q [Q] \quad \text{Stern–Volmer equation} \quad (21.83)$$

This equation tells us that a plot of  $\phi_{f,0}/\phi_f$  against [Q] should be a straight line with slope  $\tau_0 k_Q$ . Such a plot is called a **Stern–Volmer plot** (Fig. 21.24). The method may also be applied to the quenching of phosphorescence.

**Justification 21.8** *The Stern–Volmer equation*

With the addition of quenching, the steady-state approximation for  $[S^*]$  now gives:

$$\frac{d[S^*]}{dt} = I_{\text{abs}} - (k_f + k_{\text{IC}} + k_{\text{ISC}} + k_Q[Q])[S^*] = 0$$

and the fluorescence quantum yield in the presence of the quencher is:

$$\phi_f = \frac{k_f}{k_f + k_{\text{ISC}} + k_{\text{IC}} + k_Q[Q]}$$

When  $[Q] = 0$ , the quantum yield is

$$\phi_{f,0} = \frac{k_f}{k_f + k_{\text{ISC}} + k_{\text{IC}}}$$

It follows that

$$\begin{aligned} \frac{\phi_{f,0}}{\phi_f} &= \left( \frac{k_f}{k_f + k_{\text{ISC}} + k_{\text{IC}}} \right) \times \left( \frac{k_f + k_{\text{ISC}} + k_{\text{IC}} + k_Q[Q]}{k_f} \right) \\ &= \frac{k_f + k_{\text{ISC}} + k_{\text{IC}} + k_Q[Q]}{k_f + k_{\text{ISC}} + k_{\text{IC}}} \\ &= 1 + \frac{k_Q}{k_f + k_{\text{ISC}} + k_{\text{IC}}} [Q] \end{aligned}$$

By using eqn 21.80, this expression simplifies to eqn 21.83.

Because the fluorescence intensity and lifetime are both proportional to the fluorescence quantum yield (specifically, from eqn 21.82,  $\tau_0 = \phi_f/k_f$ ), plots of  $I_{f,0}/I_f$  and  $\tau_0/\tau$  (where the subscript 0 indicates a measurement in the absence of quencher) against [Q] should also be linear with the same slope and intercept as those shown for eqn 21.83.

**Example 21.9** *Determining the quenching rate constant*

The molecule 2,2'-bipyridine (1, bpy) forms a complex with the  $\text{Ru}^{2+}$  ion. Ruthenium(II) tris-(2,2'-bipyridyl),  $\text{Ru}(\text{bpy})_3^{2+}$  (2), has a strong metal-to-ligand charge transfer (MLCT) transition (Section 13.3) at 450 nm. The quenching of the  $^*\text{Ru}(\text{bpy})_3^{2+}$  excited state by  $\text{Fe}(\text{OH}_2)_6^{3+}$  in acidic solution was monitored by measuring emission lifetimes at 600 nm. Determine the quenching rate constant for this reaction from the following data:

|                                                                 |   |      |      |      |      |
|-----------------------------------------------------------------|---|------|------|------|------|
| $[\text{Fe}(\text{OH}_2)_6^{3+}]/(10^{-4} \text{ mol dm}^{-3})$ | 0 | 1.6  | 4.7  | 7    | 9.4  |
| $\tau/(10^{-7} \text{ s})$                                      | 6 | 4.05 | 3.37 | 2.96 | 2.17 |

**Fig. 21.24** The format of a Stern–Volmer plot and the interpretation of the slope in terms of the rate constant for quenching and the observed fluorescence lifetime in the absence of quenching.

**1** 2,2'-Bipyridine (bpy)

**2**  $[\text{Ru}(\text{bpy})_3]^{2+}$

**Fig. 21.25** The Stern–Volmer plot of the data for Example 21.9.

**Method** Re-write the Stern–Volmer equation (eqn 21.83) for use with lifetime data; then fit the data to a straight line.

**Answer** Upon substitution of  $\tau_0/\tau$  for  $\phi_{f,0}/\phi_f$  in eqn 21.83 and after rearrangement, we obtain:

$$\frac{1}{\tau} = \frac{1}{\tau_0} + k_Q[Q] \quad (21.84)$$

Figure 21.25 shows a plot of  $1/\tau$  against  $[\text{Fe}^{3+}]$  and the results of a fit to eqn 21.84. The slope of the line is  $2.8 \times 10^9$ , so  $k_Q = 2.8 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . This example shows that measurements of emission lifetimes are preferred because they yield the value of  $k_Q$  directly. To determine the value of  $k_Q$  from intensity or quantum yield measurements, we need to make an independent measurement of  $\tau_0$ .

**Self-test 21.12** The quenching of tryptophan fluorescence by dissolved  $\text{O}_2$  gas was monitored by measuring emission lifetimes at 348 nm in aqueous solutions. Determine the quenching rate constant for this process from the following data:

|                                                                     |     |     |      |      |      |
|---------------------------------------------------------------------|-----|-----|------|------|------|
| $[\text{O}_2]/(10^{-2} \text{ mol dm}^{-3})$                        | 0   | 2.3 | 5.5  | 8    | 10.8 |
| $\tau/(10^{-9} \text{ s})$                                          | 2.6 | 1.5 | 0.92 | 0.71 | 0.57 |
| $[1.3 \times 10^{10} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}]$ |     |     |      |      |      |

Three common mechanisms for bimolecular quenching of an excited singlet (or triplet) state are:

The quenching rate constant itself does not give much insight into the mechanism of quenching. For the system of Example 21.9, it is known that the quenching of the excited state of  $\text{Ru}(\text{bpy})_3^{2+}$  is a result of electron transfer to  $\text{Fe}^{3+}$ , but the quenching data do not allow us to prove the mechanism.

There are, however, some criteria that govern the relative efficiencies of collisional quenching, energy transfer, and electron transfer. Collisional quenching is particularly efficient when Q is a heavy species, such as iodide ion, which receives energy from  $\text{S}^*$  and then decays primarily by internal conversion to the ground state. As we show in detail in Section 22.9, according to the **Marcus theory** of electron transfer, which was proposed by R.A. Marcus in 1965, the rates of electron transfer (from ground or excited states) depend on:

- The distance between the donor and acceptor, with electron transfer becoming more efficient as the distance between donor and acceptor decreases.
- The reaction Gibbs energy,  $\Delta_r G$ , with electron transfer becoming more efficient as the reaction becomes more exergonic. For example, efficient photooxidation of S requires that the reduction potential of  $\text{S}^*$  be lower than the reduction potential of Q.
- The reorganization energy, the energy cost incurred by molecular rearrangements of donor, acceptor, and medium during electron transfer. The electron transfer rate is predicted to increase as this reorganization energy is matched closely by the reaction Gibbs energy.

Electron transfer can also be studied by time-resolved spectroscopy (Section 21.1). The oxidized and reduced products often have electronic absorption spectra distinct

from those of their neutral parent compounds. Therefore, the rapid appearance of such known features in the absorption spectrum after excitation by a laser pulse may be taken as indication of quenching by electron transfer. In the following section we explore energy transfer in detail.

#### (d) Resonance energy transfer

We visualize the process  $S^* + Q \rightarrow S + Q^*$  as follows. The oscillating electric field of the incoming electromagnetic radiation induces an oscillating electric dipole moment in S. Energy is absorbed by S if the frequency of the incident radiation,  $\nu$ , is such that  $\nu = \Delta E_S/h$ , where  $\Delta E_S$  is the energy separation between the ground and excited electronic states of S and  $h$  is Planck's constant. This is the 'resonance condition' for absorption of radiation. The oscillating dipole on S now can affect electrons bound to a nearby Q molecule by inducing an oscillating dipole moment in the latter. If the frequency of oscillation of the electric dipole moment in S is such that  $\nu = \Delta E_Q/h$  then Q will absorb energy from S.

The efficiency,  $\eta_T$ , of resonance energy transfer is defined as

$$\eta_T = 1 - \frac{\phi_f}{\phi_{f,0}} \quad \text{Definition of the efficiency of resonance energy transfer} \quad [21.85]$$

According to the **Förster theory** of resonance energy transfer, energy transfer is efficient when:

- The energy donor and acceptor are separated by a short distance (of the order of nanometres).
- Photons emitted by the excited state of the donor can be absorbed directly by the acceptor.

For donor–acceptor systems that are held rigidly either by covalent bonds or by a protein 'scaffold',  $\eta_T$  increases with decreasing distance,  $R$ , according to

$$\eta_T = \frac{R_0^6}{R_0^6 + R^6} \quad \text{Efficiency of energy transfer in terms of the donor–acceptor distance} \quad (21.86)$$

where  $R_0$  is a parameter (with units of distance) that is characteristic of each donor–acceptor pair.<sup>1</sup> Equation 21.86 has been verified experimentally and values of  $R_0$  are available for a number of donor–acceptor pairs (Table 21.7).

The emission and absorption spectra of molecules span a range of wavelengths, so the second requirement of the Förster theory is met when the emission spectrum of the donor molecule overlaps significantly with the absorption spectrum of the acceptor. In the overlap region, photons emitted by the donor have the proper energy to be absorbed by the acceptor (Fig. 21.26).

In many cases, it is possible to prove that energy transfer is the predominant mechanism of quenching if the excited state of the acceptor fluoresces or phosphoresces at a characteristic wavelength. In a pulsed laser experiment, the rise in fluorescence intensity from  $Q^*$  with a characteristic time that is the same as that for the decay of the fluorescence of  $S^*$  is often taken as indication of energy transfer from S to Q.

Equation 21.86 forms the basis of **fluorescence resonance energy transfer** (FRET), in which the dependence of the energy transfer efficiency,  $\eta_T$ , on the distance,  $R$ ,

**Table 21.7** Values of  $R_0$  for some donor–acceptor pairs\*

| Donor <sup>†</sup> | Acceptor    | $R_0/\text{nm}$ |
|--------------------|-------------|-----------------|
| Naphthalene        | Dansyl      | 2.2             |
| Dansyl             | ODR         | 4.3             |
| Pyrene             | Coumarin    | 3.9             |
| IEDANS             | FITC        | 4.9             |
| Tryptophan         | IEDANS      | 2.2             |
| Tryptophan         | Haem (heme) | 2.9             |

\* Additional values may be found in J.R. Lacowicz, *Principles of fluorescence spectroscopy*, Kluwer Academic/Plenum, New York (1999).

<sup>†</sup> Abbreviations:

Dansyl: 5-dimethylamino-1-naphthalenesulfonic acid;

IEDANS: 5-(((2-iodoacetyl)amino)ethyl)amino)naphthalene-1-sulfonic acid;

ODR: octadecyl-rhodamine.

**Fig. 21.26** According to the Förster theory, the rate of energy transfer from a molecule  $S^*$  in an excited state to a quencher molecule Q is optimized at radiation frequencies in which the emission spectrum of  $S^*$  overlaps with the absorption spectrum of Q, as shown in the shaded region.

<sup>1</sup> See our *Quanta, matter, and change* (2009) for a justification of eqn 21.86.

3 1.5-I AEDANS

4 11-*cis*-Retinal

between energy donor and acceptor can be used to measure distances in biological systems. In a typical FRET experiment, a site on a biopolymer or membrane is labelled covalently with an energy donor and another site is labelled covalently with an energy acceptor. In certain cases, the donor or acceptor may be natural constituents of the system, such as amino acid groups, co-factors, or enzyme substrates. The distance between the labels is then calculated from the known value of  $R_0$  and eqn 21.86. Several tests have shown that the FRET technique is useful for measuring distances ranging from 1 to 9 nm.

#### • A brief illustration

As an illustration of the FRET technique, consider a study of the protein rhodopsin (*Impact I13.1*). When an amino acid on the surface of rhodopsin was labelled covalently with the energy donor 1.5-I AEDANS (3), the fluorescence quantum yield of the label decreased from 0.75 to 0.68 due to quenching by the visual pigment 11-*cis*-retinal (4). From eqn 21.85, we calculate  $\eta_T = 1 - (0.68/0.75) = 0.093$  and from eqn 21.86 and the known value of  $R_0 = 5.4$  nm for the 1.5-I AEDANS/11-*cis*-retinal pair we calculate  $R = 7.9$  nm. Therefore, we take 7.9 nm to be the distance between the surface of the protein and 11-*cis*-retinal. •

If donor and acceptor molecules diffuse in solution or in the gas phase, Förster theory predicts that the efficiency of quenching by energy transfer increases as the average distance travelled between collisions of donor and acceptor decreases. That is, the quenching efficiency increases with concentration of quencher, as predicted by the Stern–Volmer equation.

### IMPACT ON BIOCHEMISTRY

#### I21.1 Harvesting of light during plant photosynthesis

A large proportion of solar radiation with wavelengths below 400 nm and above 1000 nm is absorbed by atmospheric gases such as ozone and  $O_2$ , which absorb ultraviolet radiation, and  $CO_2$  and  $H_2O$ , which absorb infrared radiation (*Impact I12.2*). As a result, plants, algae, and some species of bacteria evolved photosynthetic apparatus that captures visible and near-infrared radiation. Plants use radiation in the wavelength range of 400–700 nm to drive the endergonic reduction of  $CO_2$  to glucose, with concomitant oxidation of water to  $O_2$  ( $\Delta_r G^\ominus = +2880$  kJ mol<sup>-1</sup>), in essence the reverse of glycolysis and the citric acid cycle (*Impact I6.1*):

Electrons flow from reductant to oxidant via a series of electrochemical reactions that are coupled to the synthesis of ATP. The process takes place in the *chloroplast*, a special organelle of the plant cell, where chlorophylls *a* and *b* (5) and carotenoids (of which  $\beta$ -carotene, 6, is an example) bind to integral proteins called *light-harvesting complexes*, which absorb solar energy and transfer it to protein complexes known as *reaction centres*, where light-induced electron transfer reactions occur. The combination of a light-harvesting complex and a reaction centre complex is called a *photosystem*. Plants have two photosystems that drive the reduction of  $NADP^+$  (7) by water:

It is clear that energy from light is required to drive this reaction because, in the dark,  $E^\ominus = -1.135$  V and  $\Delta_r G^\ominus = +438.0$  kJ mol<sup>-1</sup>.

5 Chlorophyll *a* and *b*6  $\beta$ -Carotene7 NADP<sup>+</sup>

Light-harvesting complexes bind large numbers of pigments in order to provide a sufficiently large area for capture of radiation. In photosystems I and II, absorption of a photon *raises* a chlorophyll or carotenoid molecule to an excited singlet state and within 0.1–5 ps the energy hops to a nearby pigment via the Förster mechanism. About 100–200 ps later, which corresponds to thousands of hops within the light-harvesting complex, more than 90 per cent of the absorbed energy reaches the reaction centre. There, a chlorophyll *a* dimer becomes electronically excited and initiates ultrafast electron transfer reactions. For example, the transfer of an electron from the excited singlet state of P680, the chlorophyll dimer of the photosystem II reaction

**8** Plastoquinone

centre, to its immediate electron acceptor, a phaeophytin *a* molecule (a chlorophyll *a* molecule where the central  $\text{Mg}^{2+}$  ion is replaced by two protons, which are bound to two of the pyrrole nitrogens in the ring), occurs within 3 ps. Once the excited state of P680 has been quenched efficiently by this first reaction, subsequent steps that lead to the oxidation of water occur more slowly, with reaction times varying from 200 ps to 1 ms. The electrochemical reactions within the photosystem I reaction centre also occur in this time interval. We see that the initial energy and electron transfer events of photosynthesis are under tight kinetic control. Photosynthesis captures solar energy efficiently because the excited singlet state of chlorophyll is quenched rapidly by processes that occur with relaxation times that are much shorter than the fluorescence lifetime, which is typically about 1 ns in organic solvents at room temperature.

Working together, photosystem I and the enzyme ferredoxin:NADP<sup>+</sup> oxidoreductase catalyse the light-induced oxidation of NADP<sup>+</sup> to NADPH. The electrons required for this process come initially from P700 in its excited state. The resulting P700<sup>+</sup> is then reduced by the mobile carrier plastocyanin (Pc), a protein in which the bound copper ion can exist in oxidation states +2 and +1. The net reaction is

Oxidized plastocyanin accepts electrons from reduced plastoquinone (PQ, **8**). The process is catalysed by the cytochrome *b<sub>6</sub>f* complex, a membrane protein complex:

This reaction is sufficiently exergonic to drive the synthesis of ATP in the process known as *photophosphorylation*.

Plastoquinone is reduced by water in a process catalysed by light and photosystem II. The electrons required for the reduction of plastoquinone come initially from P680 in its excited state. The resulting P680<sup>+</sup> is then reduced ultimately by water. The net reaction is

In this way, plant photosynthesis uses an abundant source of electrons (water) and of energy (the Sun) to drive the endergonic reduction of NADP<sup>+</sup>, with concomitant synthesis of ATP (Fig. 21.27). Experiments show that, for each molecule of NADPH formed in the chloroplast of green plants, one molecule of ATP is synthesized.

**Fig. 21.27** In plant photosynthesis, light-induced electron transfer processes lead to the oxidation of water to O<sub>2</sub> and the reduction of NADP<sup>+</sup> to NADPH, with concomitant production of ATP. The energy stored in ATP and NADPH is used to reduce CO<sub>2</sub> to carbohydrate in a separate set of reactions. The scheme summarizes the general patterns of electron flow and does not show all the intermediate electron carriers in photosystems I and II, the cytochrome *b<sub>6</sub>f* complex, and ferredoxin:NADP<sup>+</sup> oxidoreductase.

The ATP and NADPH molecules formed by the light-induced electron transfer reactions of plant photosynthesis participate directly in the reduction of CO<sub>2</sub> to glucose in the chloroplast:

In summary, plant photosynthesis uses solar energy to transfer electrons from a poor reductant (water) to carbon dioxide. In the process, high energy molecules (carbohydrates, such as glucose) are synthesized in the cell. Animals feed on the carbohydrates derived from photosynthesis. During aerobic metabolism, the O<sub>2</sub> released by photosynthesis as a waste product is used to oxidize carbohydrates to CO<sub>2</sub>, driving biological processes, such as biosynthesis, muscle contraction, cell division, and nerve conduction. Hence, the sustenance of life on Earth depends on a tightly regulated carbon–oxygen cycle that is driven by solar energy.

## Checklist of key equations

| Property or process                                                                                   | Equation                                                                                                  | Comment                       |
|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|-------------------------------|
| Rate of a reaction                                                                                    | $v = (1/V)(d\xi/dt)$ , $\xi = (n_j - n_{j,0})/v_j$                                                        | Definition                    |
| (a) Integrated rate law, (b) half-life, and (c) time constant of a first-order reaction of type A → P | (a) $\ln([A]/[A]_0) = -k_r t$ or $[A] = [A]_0 e^{-k_r t}$<br>(b) $t_{1/2} = \ln 2/k_r$ (c) $\tau = 1/k_r$ |                               |
| (a) Integrated rate law and (b) half-life of a second-order reaction of type A → P                    | (a) $1/[A] - 1/[A]_0 = k_r t$ or $[A] = [A]_0/(1 + k_r t[A]_0)$<br>(b) $t_{1/2} = 1/k_r[A]_0$             |                               |
| Integrated rate law of a second-order reaction of type A + B → P                                      | $\ln\{([B]/[B]_0)/([A]/[A]_0)\} = ([B]_0 - [A]_0)k_r t$                                                   |                               |
| Half-life of an $n$ th order reaction                                                                 | $t_{1/2} = (2^{n-1} - 1)/(n - 1)k_r[A]_0^{n-1}$                                                           |                               |
| Equilibrium constant in terms of rate constants                                                       | $K = (k_a/k'_a) \times (k_b/k'_b) \times \dots$                                                           |                               |
| Relaxation of an equilibrium A ⇌ B after a temperature jump                                           | $x = x_0 e^{-t/\tau}$ $1/\tau = k_r + k'_r$                                                               | First-order in each direction |
| Arrhenius equation                                                                                    | $\ln k_r = \ln A - E_a/RT$                                                                                |                               |
| Activation energy                                                                                     | $E_a = RT^2(d \ln k_r/dT)$                                                                                | Definition                    |
| Degree of polymerization                                                                              | $\langle N \rangle = 1/(1 - p)$ or $\langle N \rangle = 1 + k_r t[A]_0$                                   | Stepwise polymerization       |
| Kinetic chain length                                                                                  | $\nu = k_t[M][I]^{-1/2}$ $k_r = \frac{1}{2}k_p(fk_i k_t)^{-1/2}$                                          | Chain polymerization          |
| Primary quantum yield                                                                                 | $\phi = \nu/I_{\text{abs}}$                                                                               |                               |
| Quantum yield of fluorescence                                                                         | $\phi_f = k_f/(k_f + k_{\text{ISC}} + k_{\text{IC}})$                                                     |                               |
| Observed excited state lifetime                                                                       | $\tau_0 = \phi_f/k_f$                                                                                     | Absence of quencher           |
| Stern–Volmer equation                                                                                 | $\phi_{f,0}/\phi_f = 1 + \tau_0 k_Q[Q]$                                                                   |                               |
| Efficiency of resonance energy transfer                                                               | $\eta_T = 1 - (\phi_f/\phi_{f,0})$ or $\eta_T = R_0^6/(R_0^6 + R^6)$                                      |                               |

## Discussion questions

**21.1** Consult literature sources and list the observed ranges of timescales during which the following processes occur: radiative decay of excited electronic states, molecular rotational motion, molecular vibrational motion, proton transfer reactions, energy transfer between fluorescent molecules used in FRET analysis, electron transfer events between complex ions in solution, and collisions in liquids.

**21.2** Describe the main features, including advantages and disadvantages, of the following experimental methods for determining the rate law of a reaction: the isolation method, the method of initial rates, and fitting data to integrated rate law expressions.

**21.3** Why may reaction orders change under different circumstances?

**21.4** When might deviations from the Arrhenius law be observed?

**21.5** Is it possible for the activation energy of a reaction to be negative? Explain your conclusion and provide a molecular interpretation.

**21.6** Assess the validity of the following statement: the rate-determining step is the slowest step in a reaction mechanism.

**21.7** Distinguish between kinetic and thermodynamic control of a reaction. Suggest criteria for expecting one rather than the other.

**21.8** Bearing in mind distinctions between the mechanisms of stepwise and chain polymerization, describe ways in which it is possible to control the

molar mass of a polymer by manipulating the kinetic parameters of polymerization.

**21.9** Distinguish between the primary quantum yield and overall quantum yield of a chemical reaction. Describe an experimental procedure for the determination of the quantum yield.

**21.10** Summarize the factors that govern the rates of photo-induced electron transfer according to Marcus theory and that govern the rates of resonance energy transfer according to Förster theory. Can you find similarities between the two theories?

## Exercises

**21.1(a)** Predict how the total pressure varies during the gas-phase reaction  $2 \text{ICl(g)} + \text{H}_2(\text{g}) \rightarrow \text{I}_2(\text{g}) + 2 \text{HCl(g)}$  in a constant-volume container.

**21.1(b)** Predict how the total pressure varies during the gas-phase reaction  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightarrow 2 \text{NH}_3(\text{g})$  in a constant-volume container.

**21.2(a)** The rate of the reaction  $\text{A} + 2 \text{B} \rightarrow 3 \text{C} + \text{D}$  was reported as  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ . State the rates of formation and consumption of the participants.

**21.2(b)** The rate of the reaction  $\text{A} + 3 \text{B} \rightarrow \text{C} + 2 \text{D}$  was reported as  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ . State the rates of formation and consumption of the participants.

**21.3(a)** The rate of formation of C in the reaction  $2 \text{A} + \text{B} \rightarrow 2 \text{C} + 3 \text{D}$  is  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ . State the reaction rate, and the rates of formation or consumption of A, C, and D.

**21.3(b)** The rate of consumption of B in the reaction  $\text{A} + 3 \text{B} \rightarrow \text{C} + 2 \text{D}$  is  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ . State the reaction rate, and the rates of formation or consumption of A, B, and D.

**21.4(a)** The rate law for the reaction in Exercise 21.2a was found to be  $v = k_r[\text{A}][\text{B}]$ . What are the units of  $k_r$ ? Express the rate law in terms of the rates of formation and consumption of (a) A, (b) C.

**21.4(b)** The rate law for the reaction in Exercise 21.2b was found to be  $v = k_r[\text{A}][\text{B}]^2$ . What are the units of  $k_r$ ? Express the rate law in terms of the rates of formation and consumption of (a) A, (b) C.

**21.5(a)** The rate law for the reaction in Exercise 21.3a was reported as  $d[\text{C}]/dt = k_r[\text{A}][\text{B}][\text{C}]$ . Express the rate law in terms of the reaction rate; what are the units for  $k_r$  in each case?

**21.5(b)** The rate law for the reaction in Exercise 21.3b was reported as  $d[\text{C}]/dt = k_r[\text{A}][\text{B}][\text{C}]^{-1}$ . Express the rate law in terms of the reaction rate; what are the units for  $k_r$  in each case?

**21.6(a)** If the rate laws are expressed with (a) concentrations in moles per decimetre cubed, (b) pressures in kilopascals, what are the units of the second-order and third-order rate constants?

**21.6(b)** If the rate laws are expressed with (a) concentrations in molecules per metre cubed, (b) pressures in pascals, what are the units of the second-order and third-order rate constants?

**21.7(a)** At  $518^\circ\text{C}$ , the rate of decomposition of a sample of gaseous acetaldehyde, initially at a pressure of 363 Torr, was  $1.07 \text{ Torr s}^{-1}$  when 5.0 per cent had reacted and  $0.76 \text{ Torr s}^{-1}$  when 20.0 per cent had reacted. Determine the order of the reaction.

**21.7(b)** At 400 K, the rate of decomposition of a gaseous compound initially at a pressure of 12.6 kPa, was  $9.71 \text{ Pa s}^{-1}$  when 10.0 per cent had reacted and  $7.67 \text{ Pa s}^{-1}$  when 20.0 per cent had reacted. Determine the order of the reaction.

**21.8(a)** At  $518^\circ\text{C}$ , the half-life for the decomposition of a sample of gaseous acetaldehyde (ethanal) initially at 363 Torr was 410 s. When the pressure was 169 Torr, the half-life was 880 s. Determine the order of the reaction.

**21.8(b)** At 400 K, the half-life for the decomposition of a sample of a gaseous compound initially at 55.5 kPa was 340 s. When the pressure was 28.9 kPa, the half-life was 178 s. Determine the order of the reaction.

**21.9(a)** The rate constant for the first-order decomposition of  $\text{N}_2\text{O}_5$  in the reaction  $2 \text{N}_2\text{O}_5(\text{g}) \rightarrow 4 \text{NO}_2(\text{g}) + \text{O}_2(\text{g})$  is  $k_r = 3.38 \times 10^{-5} \text{ s}^{-1}$  at  $25^\circ\text{C}$ . What is the half-life of  $\text{N}_2\text{O}_5$ ? What will be the pressure, initially 500 Torr, at (a) 50 s, (b) 20 min after initiation of the reaction?

**21.9(b)** The rate constant for the first-order decomposition of a compound A in the reaction  $2 \text{A} \rightarrow \text{P}$  is  $k_r = 3.56 \times 10^{-7} \text{ s}^{-1}$  at  $25^\circ\text{C}$ . What is the half-life of A? What will be the pressure, initially 33.0 kPa at (a) 50 s, (b) 20 min after initiation of the reaction?

**21.10(a)** A second-order reaction of the type  $\text{A} + \text{B} \rightarrow \text{P}$  was carried out in a solution that was initially  $0.075 \text{ mol dm}^{-3}$  in A and  $0.050 \text{ mol dm}^{-3}$  in B. After 1.0 h the concentration of A had fallen to  $0.020 \text{ mol dm}^{-3}$ . (a) Calculate the rate constant. (b) What is the half-life of the reactants?

**21.10(b)** A second-order reaction of the type  $\text{A} + 2 \text{B} \rightarrow \text{P}$  was carried out in a solution that was initially  $0.050 \text{ mol dm}^{-3}$  in A and  $0.030 \text{ mol dm}^{-3}$  in B. After 1.0 h the concentration of A had fallen to  $0.010 \text{ mol dm}^{-3}$ . (a) Calculate the rate constant. (b) What is the half-life of the reactants?

**21.11(a)** The second-order rate constant for the reaction

is  $0.11 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . What is the concentration of ester ( $\text{CH}_3\text{COOC}_2\text{H}_5$ ) after (a) 20 s, (b) 15 min when ethyl acetate is added to sodium hydroxide so that the initial concentrations are  $[\text{NaOH}] = 0.060 \text{ mol dm}^{-3}$  and  $[\text{CH}_3\text{COOC}_2\text{H}_5] = 0.110 \text{ mol dm}^{-3}$ ?

**21.11(b)** The second-order rate constant for the reaction  $\text{A} + 2 \text{B} \rightarrow \text{C} + \text{D}$  is  $0.34 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . What is the concentration of C after (a) 20 s, (b) 15 min when the reactants are mixed with initial concentrations of  $[\text{A}] = 0.027 \text{ mol dm}^{-3}$  and  $[\text{B}] = 0.130 \text{ mol dm}^{-3}$ ?

**21.12(a)** A reaction  $2 \text{A} \rightarrow \text{P}$  has a second-order rate law with  $k_r = 4.30 \times 10^{-4} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . Calculate the time required for the concentration of A to change from  $0.210 \text{ mol dm}^{-3}$  to  $0.010 \text{ mol dm}^{-3}$ .

**21.12(b)** A reaction  $2A \rightarrow P$  has a third-order rate law with  $k_t = 6.50 \times 10^{-4} \text{ dm}^6 \text{ mol}^{-2} \text{ s}^{-1}$ . Calculate the time required for the concentration of A to change from  $0.067 \text{ mol dm}^{-3}$  to  $0.015 \text{ mol dm}^{-3}$ .

**21.13(a)** The equilibrium  $\text{NH}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq})$  at  $25^\circ\text{C}$  is subjected to a temperature jump that slightly increases the concentration of  $\text{NH}_4^+(\text{aq})$  and  $\text{OH}^-(\text{aq})$ . The measured relaxation time is  $7.61 \text{ ns}$ . The equilibrium constant for the system is  $1.78 \times 10^{-5}$  at  $25^\circ\text{C}$ , and the equilibrium concentration of  $\text{NH}_3(\text{aq})$  is  $0.15 \text{ mol dm}^{-3}$ . Calculate the rate constants for the forward and reversed steps.

**21.13(b)** The equilibrium  $A \rightleftharpoons B + C$  at  $25^\circ\text{C}$  is subjected to a temperature jump that slightly increases the concentrations of B and C. The measured relaxation time is  $3.0 \mu\text{s}$ . The equilibrium constant for the system is  $2.0 \times 10^{-16}$  at  $25^\circ\text{C}$ , and the equilibrium concentrations of B and C at  $25^\circ\text{C}$  are both  $2.0 \times 10^{-4} \text{ mol dm}^{-3}$ . Calculate the rate constants for the forward and reverse steps.

**21.14(a)** The rate constant for the decomposition of a certain substance is  $2.80 \times 10^{-3} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at  $30^\circ\text{C}$  and  $1.38 \times 10^{-2} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at  $50^\circ\text{C}$ . Evaluate the Arrhenius parameters of the reaction.

**21.14(b)** The rate constant for the decomposition of a certain substance is  $1.70 \times 10^{-2} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at  $24^\circ\text{C}$  and  $2.01 \times 10^{-2} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at  $37^\circ\text{C}$ . Evaluate the Arrhenius parameters of the reaction.

**21.15(a)** The rate of a chemical reaction is found to triple when the temperature is raised from  $24^\circ\text{C}$  to  $49^\circ\text{C}$ . Determine the activation energy.

**21.15(b)** The rate of a chemical reaction is found to double when the temperature is raised from  $25^\circ\text{C}$  to  $35^\circ\text{C}$ . Determine the activation energy.

**21.16(a)** The reaction mechanism for the decomposition of  $\text{A}_2$

involves an intermediate A. Deduce the rate law for the reaction in two ways by (a) assuming a pre-equilibrium and (b) making a steady-state approximation.

**21.16(b)** The reaction mechanism for renaturation of a double helix from its strands A and B:

involves an intermediate. Deduce the rate law for the reaction in two ways by (a) assuming a pre-equilibrium and (b) making a steady-state approximation.

**21.17(a)** The effective rate constant for a gaseous reaction that has a Lindemann–Hinshelwood mechanism is  $2.50 \times 10^{-4} \text{ s}^{-1}$  at  $1.30 \text{ kPa}$  and  $2.10 \times 10^{-5} \text{ s}^{-1}$  at  $12 \text{ Pa}$ . Calculate the rate constant for the activation step in the mechanism.

**21.17(b)** The effective rate constant for a gaseous reaction that has a Lindemann–Hinshelwood mechanism is  $1.7 \times 10^{-3} \text{ s}^{-1}$  at  $1.09 \text{ kPa}$  and  $2.2 \times 10^{-4} \text{ s}^{-1}$  at  $25 \text{ Pa}$ . Calculate the rate constant for the activation step in the mechanism.

**21.18(a)** The mechanism of a composite reaction consists of a fast pre-equilibrium step with forward and reverse activation energies of  $25 \text{ kJ mol}^{-1}$  and  $38 \text{ kJ mol}^{-1}$ , respectively, followed by an elementary step of activation energy  $10 \text{ kJ mol}^{-1}$ . What is the activation energy of the composite reaction?

**21.18(b)** The mechanism of a composite reaction consists of a fast pre-equilibrium step with forward and reverse activation energies of  $27 \text{ kJ mol}^{-1}$  and  $35 \text{ kJ mol}^{-1}$ , respectively, followed by an elementary step of activation energy  $15 \text{ kJ mol}^{-1}$ . What is the activation energy of the composite reaction?

**21.19(a)** Calculate the fraction condensed and the degree of polymerization at  $t = 5.00 \text{ h}$  of a polymer formed by a stepwise process with  $k_t = 1.39 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  and an initial monomer concentration of  $1.00 \times 10^{-2} \text{ mol dm}^{-3}$ .

**21.19(b)** Calculate the fraction condensed and the degree of polymerization at  $t = 10.00 \text{ hr}$  of a polymer formed by a stepwise process with  $k_t = 2.80 \times 10^{-2} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  and an initial monomer concentration of  $5.00 \times 10^{-2} \text{ mol dm}^{-3}$ .

**21.20(a)** Consider a polymer formed by a chain process. By how much does the kinetic chain length change if the concentration of initiator increases by a factor of 3.6 and the concentration of monomer decreases by a factor of 4.2?

**21.20(b)** Consider a polymer formed by a chain process. By how much does the kinetic chain length change if the concentration of initiator decreases by a factor of 10.0 and the concentration of monomer increases by a factor of 5.0?

**21.21(a)** In a photochemical reaction  $A \rightarrow 2B + C$ , the quantum yield with  $500 \text{ nm}$  light is  $2.1 \times 10^2 \text{ mol einstein}^{-1}$  (1 einstein = 1 mol photons). After exposure of  $300 \text{ mmol}$  of A to the light,  $2.28 \text{ mmol}$  of B is formed. How many photons were absorbed by A?

**21.21(b)** In a photochemical reaction  $A \rightarrow B + C$ , the quantum yield with  $500 \text{ nm}$  light is  $1.2 \times 10^2 \text{ mol einstein}^{-1}$ . After exposure of  $200 \text{ mmol}$  A to the light,  $1.77 \text{ mmol}$  B is formed. How many photons were absorbed by A?

**21.22(a)** In an experiment to measure the quantum yield of a photochemical reaction, the absorbing substance was exposed to  $490 \text{ nm}$  light from a  $100 \text{ W}$  source for  $45 \text{ min}$ . The intensity of the transmitted light was 40 per cent of the intensity of the incident light. As a result of irradiation,  $0.344 \text{ mol}$  of the absorbing substance decomposed. Determine the quantum yield.

**21.22(b)** In an experiment to measure the quantum yield of a photochemical reaction, the absorbing substance was exposed to  $320 \text{ nm}$  radiation from a  $87.5 \text{ W}$  source for  $28.0 \text{ min}$ . The intensity of the transmitted light was 0.257 that of the incident light. As a result of irradiation,  $0.324 \text{ mol}$  of the absorbing substance decomposed. Determine the quantum yield.

**21.23(a)** Consider the quenching of an organic fluorescent species with  $\tau_0 = 6.0 \text{ ns}$  by a d-metal ion with  $k_Q = 3.0 \times 10^8 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . Predict the concentration of quencher required to decrease the fluorescence intensity of the organic species to 50 per cent of the unquenched value.

**21.23(b)** Consider the quenching of an organic fluorescent species with  $\tau_0 = 3.5 \text{ ns}$  by a d-metal ion with  $k_Q = 2.5 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . Predict the concentration of quencher required to decrease the fluorescence intensity of the organic species to 75 per cent of the unquenched value.

**21.24(a)** An aminoacid on the surface of a protein was labelled covalently with 1.5-I AEDANS and another was labelled covalently with FITC. The fluorescence quantum yield of 1.5-IAEDANS decreased by 10 per cent due to quenching by FITC. What is the distance between the aminoacids? *Hint*. See Table 21.6.

**21.24(b)** An aminoacid on the surface of an enzyme was labelled covalently with 1.5-I AEDANS and it is known that the active site contains a tryptophan residue. The fluorescence quantum yield of tryptophan decreased by 15 per cent due to quenching by 1.5-IAEDANS. What is the distance between the active site and the surface of the enzyme?

## Problems\*

## Numerical problems

**21.1** The data below apply to the formation of urea from ammonium cyanate,  $\text{NH}_4\text{CNO} \rightarrow \text{NH}_2\text{CONH}_2$ . Initially 22.9 g of ammonium cyanate was dissolved in enough water to prepare 1.00 dm<sup>3</sup> of solution. Determine the order of the reaction, the rate constant, and the mass of ammonium cyanate left after 300 min.

|                           |   |      |      |      |      |

**21.5** The gas-phase decomposition of acetic acid at 1189 K proceeds by way of two parallel reactions:

What is the maximum percentage yield of the ketene  $\text{CH}_2\text{CO}$  obtainable at this temperature?

**21.6** Sucrose is readily hydrolysed to glucose and fructose in acidic solution. The hydrolysis is often monitored by measuring the angle of rotation of plane-polarized light passing through the solution. From the angle of rotation the concentration of sucrose can be determined. An experiment on the hydrolysis of sucrose in 0.50 M  $\text{HCl}(\text{aq})$  produced the following data:

|                                         |       |       |       |       |       |       |       |       |       |
|-----------------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|

| $[\text{sucrose}]/(\text{mol dm}^{-3})$ | 0.316 | 0.300 | 0.274 | 0.256 | 0.238 | 0.211 | 0.190 | 0.170 | 0.146 |

Determine the rate constant of the reaction and the half-life of a sucrose molecule.

**21.7** The composition of a liquid-phase reaction  $2 \text{A} \rightarrow \text{B}$  was followed by a spectrophotometric method with the following results:

|                                   |   |       |       |       |       |          |
|-----------------------------------|---|-------|-------|-------|-------|----------|
| $t/\text{min}$                    | 0 | 10    | 20    | 30    | 40    | $\infty$ |
| $[\text{B}]/(\text{mol dm}^{-3})$ | 0 | 0.089 | 0.153 | 0.200 | 0.230 | 0.312    |

Determine the order of the reaction and its rate constant.

**21.8** The ClO radical decays rapidly by way of the reaction,  $2 \text{ClO} \rightarrow \text{Cl}_2 + \text{O}_2$ . The following data have been obtained:

|                                              |      |      |      |      |      |      |      |
|----------------------------------------------|------|------|------|------|------|------|------|
| $t/(10^{-3} \text{ s})$                      | 0.12 | 0.62 | 0.96 | 1.60 | 3.20 | 4.00 | 5.75 |
| $[\text{ClO}]/(10^{-6} \text{ mol dm}^{-3})$ | 8.49 | 8.09 | 7.10 | 5.79 | 5.20 | 4.77 | 3.95 |

Determine the rate constant of the reaction and the half-life of a ClO radical.

**21.9** Cyclopropane isomerizes into propene when heated to 500°C in the gas phase. The extent of conversion for various initial pressures has been followed by gas chromatography by allowing the reaction to proceed for a time with various initial pressures:

|                   |     |     |     |     |     |     |
|-------------------|-----|-----|-----|-----|-----|-----|
| $p_0/\text{Torr}$ | 200 | 200 | 400 | 400 | 600 | 600 |
| $t/\text{s}$      | 100 | 200 | 100 | 200 | 100 | 200 |
| $p/\text{Torr}$   | 186 | 173 | 373 | 347 | 559 | 520 |

where  $p_0$  is the initial pressure and  $p$  is the final pressure of cyclopropane. What is the order and rate constant for the reaction under these conditions?

**21.10** The addition of hydrogen halides to alkenes has played a fundamental role in the investigation of organic reaction mechanisms. In one study (M.J. Haugh and D.R. Dalton, *J. Amer. Chem. Soc.* **97**, 5674 (1975)), high pressures of hydrogen chloride (up to 25 atm) and propene (up to 5 atm) were examined over a range of temperatures and the amount of 2-chloropropane formed was determined by NMR. Show that, if the reaction  $\text{A} + \text{B} \rightarrow \text{P}$  proceeds for a short time  $\delta t$ , the concentration of product follows  $[\text{P}]/[\text{A}] = k_r[\text{A}]^{m-1}[\text{B}]^n\delta t$  if the reaction is  $m$ th-order in A and  $n$ th-order in B. In a series of runs the ratio of [chloropropane] to [propene] was independent of [propene] but the ratio of [chloropropane] to [HCl] for constant amounts of propene depended on [HCl]. For  $\delta t \approx 100 \text{ h}$  (which is short on the timescale of the reaction) the latter ratio rose from zero to 0.05, 0.03, 0.01 for  $p(\text{HCl}) = 10 \text{ atm}$ , 7.5 atm, 5.0 atm, respectively. What are the orders of the reaction with respect to each reactant?

**21.11** Show that the following mechanism can account for the rate law of the reaction in Problem 21.10:

What further tests could you apply to verify this mechanism?

**21.12** A first-order decomposition reaction is observed to have the following rate constants at the indicated temperatures. Estimate the activation energy.

|                                |      |      |      |
|--------------------------------|------|------|------|
| $k_r/(10^{-3} \text{ s}^{-1})$ | 2.46 | 45.1 | 576  |
| $\theta/^\circ\text{C}$        | 0    | 20.0 | 40.0 |

**21.13** The second-order rate constants for the reaction of oxygen atoms with aromatic hydrocarbons have been measured (R. Atkinson and J.N. Pitts, *J. Phys. Chem.* **79**, 295 (1975)). In the reaction with benzene the rate constants are  $1.44 \times 10^7 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at 300.3 K,  $3.03 \times 10^7 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at 341.2 K, and  $6.9 \times 10^7 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at 392.2 K. Find the pre-exponential factor and activation energy of the reaction.

**21.14** In the experiments described in Problems 21.10 and 21.11 an inverse temperature dependence of the reaction rate was observed, the overall rate of reaction at 70°C being approximately one-third that at 19°C. Estimate the apparent activation energy and the activation energy of the rate-determining

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp, Carmen Giunta, and Marshall Cady.

step given that the enthalpies of the two equilibria are both of the order of  $-14 \text{ kJ mol}^{-1}$ .

**21.15** Use mathematical software or an electronic spreadsheet to examine the time dependence of  $[I]$  in the reaction mechanism  $A \rightarrow I \rightarrow P$  ( $k_a, k_b$ ). In all of the following calculations, use  $[A]_0 = 1 \text{ mol dm}^{-3}$  and a time range of 0 to 5 s. (a) Plot  $[I]$  against  $t$  for  $k_a = 10 \text{ s}^{-1}$  and  $k_b = 1 \text{ s}^{-1}$ . (b) Increase the ratio  $k_b/k_a$  steadily by decreasing the value of  $k_a$  and examine the plot of  $[I]$  against  $t$  at each turn. What approximation about  $d[I]/dt$  becomes increasingly valid?

**21.16** Consider the dimerization  $2A \rightleftharpoons A_2$ , with forward rate constant  $k_a$  and reverse rate constant  $k'_a$ . (a) Derive the following expression for the relaxation time in terms of the total concentration of protein,  $[A]_{\text{tot}} = [A] + 2[A_2]$ :

$$\frac{1}{\tau^2} = k_a'^2 + 8k_a k'_a [A]_{\text{tot}}$$

(b) Describe the computational procedures that lead to the determination of the rate constants  $k_a$  and  $k'_a$  from measurements of  $\tau$  for different values of  $[A]_{\text{tot}}$ . (c) Use the data provided below and the procedure you outlined in part (b) to calculate the rate constants  $k_a$  and  $k'_a$ , and the equilibrium constant  $K$  for formation of hydrogen-bonded dimers of 2-pyridone:

|                            |       |       |       |       |       |
|----------------------------|-------|-------|-------|-------|-------|
| $[P]/(\text{mol dm}^{-3})$ | 0.500 | 0.352 | 0.251 | 0.151 | 0.101 |
| $\tau/\text{ns}$           | 2.3   | 2.7   | 3.3   | 4.0   | 5.3   |

**21.17** In Problem 21.9 the isomerization of cyclopropane over a limited pressure range was examined. If the Lindemann mechanism of first-order reactions is to be tested we also need data at low pressures. These have been obtained (H.O. Pritchard *et al.*, *Proc. R. Soc. A* **217**, 563 (1953)):

|                          |      |      |      |       |       |       |
|--------------------------|------|------|------|-------|-------|-------|
| $p/\text{Torr}$          | 84.1 | 11.0 | 2.89 | 0.569 | 0.120 | 0.067 |
| $10^4 k_t/\text{s}^{-1}$ | 2.98 | 2.23 | 1.54 | 0.857 | 0.392 | 0.303 |

Test the Lindemann theory with these data.

**21.18** Dansyl chloride, which absorbs maximally at 330 nm and fluoresces maximally at 510 nm, can be used to label aminoacids in fluorescence microscopy and FRET studies. Tabulated below is the variation of the fluorescence intensity of an aqueous solution of dansyl chloride with time after excitation by a short laser pulse (with  $I_0$  the initial fluorescence intensity). The ratio of intensities is equal to the ratio of the rates of photon emission.

|               |      |      |      |      |
|---------------|------|------|------|------|
| $t/\text{ns}$ | 5.0  | 10.0 | 15.0 | 20.0 |
| $I_t/I_0$     | 0.45 | 0.21 | 0.11 | 0.05 |

(a) Calculate the observed fluorescence lifetime of dansyl chloride in water. (b) The fluorescence quantum yield of dansyl chloride in water is 0.70. What is the fluorescence rate constant?

**21.19** When benzophenone is illuminated with ultraviolet radiation it is excited into a singlet state. This singlet changes rapidly into a triplet, which phosphoresces. Triethylamine acts as a quencher for the triplet. In an experiment in methanol as solvent, the phosphorescence intensity varied with amine concentration as shown below. A time-resolved laser spectroscopy experiment had also shown that the half-life of the fluorescence in the absence of quencher is 29  $\mu\text{s}$ . What is the value of  $k_Q$ ?

|                                |        |        |        |
|--------------------------------|--------|--------|--------|
| $[Q]/(\text{mol dm}^{-3})$     | 0.0010 | 0.0050 | 0.0100 |
| $I_t/(\text{arbitrary units})$ | 0.41   | 0.25   | 0.16   |

**21.20** An electronically excited state of Hg can be quenched by  $\text{N}_2$  according to

in which energy transfer from  $\text{Hg}^*$  excites  $\text{N}_2$  vibrationally. Fluorescence lifetime measurements of samples of Hg with and without  $\text{N}_2$  present are summarized below ( $T = 300 \text{ K}$ ):

$$p_{\text{N}_2} = 0.0 \text{ atm}$$

|                                 |       |       |       |      |       |
|---------------------------------|-------|-------|-------|------|-------|
| Relative fluorescence intensity | 1.000 | 0.606 | 0.360 | 0.22 | 0.135 |
| $t/\mu\text{s}$                 | 0.0   | 5.0   | 10.0  | 15.0 | 20.0  |

$$p_{\text{N}_2} = 9.74 \times 10^{-4} \text{ atm}$$

|                                 |       |       |       |       |       |
|---------------------------------|-------|-------|-------|-------|-------|
| Relative fluorescence intensity | 1.000 | 0.585 | 0.342 | 0.200 | 0.117 |
| $t/\mu\text{s}$                 | 0.0   | 3.0   | 6.0   | 9.0   | 12.0  |

You may assume that all gases are perfect. Determine the rate constant for the energy transfer process.

**21.21** The Förster theory of resonance energy transfer and the basis for the FRET technique can be tested by performing fluorescence measurements on a series of compounds in which an energy donor and an energy acceptor are covalently linked by a rigid molecular linker of variable and known length. L. Stryer and R.P. Haugland, *Proc. Natl. Acad. Sci. USA* **58**, 719 (1967) collected the following data on a family of compounds with the general composition dansyl-(L-prolyl) $_n$ -naphthyl, in which the distance  $R$  between the naphthyl donor and the dansyl acceptor was varied from 1.2 nm to 4.6 nm by increasing the number of prolyl units in the linker:

|               |      |      |      |      |      |      |      |      |      |      |
|---------------|------|------|------|------|------|------|------|------|------|------|
| $R/\text{nm}$ | 1.2  | 1.5  | 1.8  | 2.8  | 3.1  | 3.4  | 3.7  | 4.0  | 4.3  | 4.6  |
| $\eta_T$      | 0.99 | 0.94 | 0.97 | 0.82 | 0.74 | 0.65 | 0.40 | 0.28 | 0.24 | 0.16 |

Are the data described adequately by eqn 21.86? If so, what is the value of  $R_0$  for the naphthyl–dansyl pair?

## Theoretical problems

**21.22** Show that  $t_{1/2}$  is given by eqn 21.17 for a reaction that is  $n$ th-order in A. Then deduce an expression for the time it takes for the concentration of a substance to fall to one-third the initial value in an  $n$ th-order reaction.

**21.23** The equilibrium  $A \rightleftharpoons B$  is first-order in both directions. Derive an expression for the concentration of A as a function of time when the initial molar concentrations of A and B are  $[A]_0$  and  $[B]_0$ . What is the final composition of the system?

**21.24** Derive an integrated expression for a second-order rate law  $v = k[A][B]$  for a reaction of stoichiometry  $2A + 3B \rightarrow P$ .

**21.25** Derive the integrated form of a third-order rate law  $v = k[A]^2[B]$  in which the stoichiometry is  $2A + B \rightarrow P$  and the reactants are initially present in (a) their stoichiometric proportions, (b) with B present initially in twice the amount.

**21.26** Show that the definition of  $E_a$  given in eqn 21.30 reduces to eqn 21.29 for a temperature-independent activation energy.

**21.27** Set up the rate equations for the reaction mechanism:

Show that the mechanism is equivalent to

under specified circumstances.

**21.28** Show that the ratio  $t_{1/2}/t_{3/4}$ , where  $t_{1/2}$  is the half-life and  $t_{3/4}$  is the time for the concentration of A to decrease to  $\frac{3}{4}$  of its initial value (implying that  $t_{3/4} < t_{1/2}$ ), can be written as a function of  $n$  alone, and can therefore be used as a rapid assessment of the order of a reaction.

**21.29** Derive an equation for the steady state rate of the sequence of reactions  $A \rightleftharpoons B \rightleftharpoons C \rightleftharpoons D$ , with  $[A]$  maintained at a fixed value and the product D removed as soon as it is formed.

**21.30** Consider the dimerization  $2A \rightleftharpoons A_2$  with forward rate constant  $k_t$  and backward rate constant  $k'_t$ . Show that the relaxation time is:

$$\tau = \frac{1}{k'_t + 4k_t[A]_{\text{eq}}}$$

**21.31** Express the root mean square deviation  $\{\langle M^2 \rangle - \langle M \rangle^2\}^{1/2}$  of the molar mass of a condensation polymer in terms of the fraction  $p$ , and deduce its time dependence.

**21.32** Calculate the ratio of the mean cube molar mass to the mean square molar mass in terms of (a) the fraction  $p$ , (b) the chain length.

**21.33** Calculate the average polymer length in a polymer produced by a chain mechanism in which termination occurs by a disproportionation reaction of the form  $M\cdot + M\cdot \rightarrow M + :M$ .

**21.34** Derive an expression for the time dependence of the degree of polymerization for a stepwise polymerization in which the reaction is acid-catalysed by the  $-\text{COOH}$  acid functional group. The rate law is  $d[A]/dt = -k_r[A]^2[\text{OH}]$ .

**21.35** Conventional equilibrium considerations do not apply when a reaction is being driven by light absorption. Thus the steady-state concentration of products and reactants might differ significantly from equilibrium values. For instance, suppose the reaction  $A \rightarrow B$  is driven by light absorption, and that its rate is  $I_a$ , but that the reverse reaction  $B \rightarrow A$  is bimolecular and second-order with a rate  $k_r[B]^2$ . What is the stationary state concentration of B? Why does this 'photostationary state' differ from the equilibrium state?

**21.36** The photochemical chlorination of chloroform in the gas phase has been found to follow the rate law  $d[\text{CCl}_4]/dt = k_r[\text{Cl}_2]^{1/2}I_a^{1/2}$ . Devise a mechanism that leads to this rate law when the chlorine pressure is high.

### Applications to: biochemistry and environmental science

**21.37** Pharmacokinetics is the study of the rates of absorption and elimination of drugs by organisms. In most cases, elimination is slower than absorption and is a more important determinant of availability of a drug for binding to its target. A drug can be eliminated by many mechanisms, such as metabolism in the liver, intestine, or kidney followed by excretion of breakdown products through urine or faeces. As an example of pharmacokinetic analysis, consider the elimination of beta adrenergic blocking agents (beta blockers), drugs used in the treatment of hypertension. After intravenous administration of a beta blocker, the blood plasma of a patient was analysed for remaining drug and the data are shown below, where  $c$  is the drug concentration measured at a time  $t$  after the injection.

|                         |     |     |     |     |     |     |     |
|-------------------------|-----|-----|-----|-----|-----|-----|-----|
| $t/\text{min}$          | 30  | 60  | 120 | 150 | 240 | 360 | 480 |
| $c/(\text{ng cm}^{-3})$ | 699 | 622 | 413 | 292 | 152 | 60  | 24  |

(a) Is removal of the drug a first- or second-order process? (b) Calculate the rate constant and half-life of the process. *Comment.* An essential aspect of drug development is the optimization of the half-life of elimination, which needs to be long enough to allow the drug to find and act on its target organ but not so long that harmful side-effects become important.

**21.38** Consider a mechanism for the helix-coil transition in polypeptides that begins in the middle of the chain:

The first conversion from  $h$  to  $c$ , also called a nucleation step, is relatively slow, so neither step may be rate-determining. (a) Set up the rate equations for this mechanism. (b) Apply the steady-state approximation and show that, under these circumstances, the mechanism is equivalent to  $hhhh \dots \rightleftharpoons cccc \dots$ .

**21.39†** The oxidation of  $\text{HSO}_3^-$  by  $\text{O}_2$  in aqueous solution is a reaction of importance to the processes of acid rain formation and flue gas desulfurization. R.E. Connick *et al.* (*Inorg. Chem.* **34**, 4543 (1995)) report that the reaction  $2\text{HSO}_3^- + \text{O}_2 \rightarrow 2\text{SO}_4^{2-} + 2\text{H}^+$  follows the rate law  $v = k_r[\text{HSO}_3^-]^2[\text{H}^+]^2$ . Given  $\text{pH} = 5.6$  and an oxygen molar concentration of  $2.4 \times 10^{-4} \text{ mol dm}^{-3}$  (both presumed constant), an initial  $\text{HSO}_3^-$  molar concentration of  $5 \times 10^{-5} \text{ mol dm}^{-3}$ , and a rate constant of  $3.6 \times 10^6 \text{ dm}^9 \text{ mol}^{-3} \text{ s}^{-1}$ , what is the initial rate of reaction? How long would it take for  $\text{HSO}_3^-$  to reach half its initial concentration?

**21.40** In light-harvesting complexes, the fluorescence of a chlorophyll molecule is quenched by nearby chlorophyll molecules. Given that for a pair of chlorophyll  $a$  molecules  $R_0 = 5.6 \text{ nm}$ , by what distance should two chlorophyll  $a$  molecules be separated to shorten the fluorescence lifetime from 1 ns (a typical value for monomeric chlorophyll  $a$  in organic solvents) to 10 ps?

**21.41†** Ultraviolet radiation photolyses  $\text{O}_3$  to  $\text{O}_2$  and  $\text{O}$ . Determine the rate at which ozone is consumed by 305 nm radiation in a layer of the stratosphere of thickness 1 km. The quantum yield is 0.94 at 220 K, the concentration about  $8 \times 10^{-9} \text{ mol dm}^{-3}$ , the molar absorption coefficient  $260 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$ , and the flux of 305 nm radiation about  $1 \times 10^{14} \text{ photons cm}^{-2} \text{ s}^{-1}$ . # Reaction dynamics

# 22

The simplest quantitative account of reaction rates is in terms of collision theory, which can be used only for the discussion of reactions between simple species in the gas phase. Reactions in solution are classified into two types: diffusion-controlled and activation-controlled. The former can be expressed quantitatively in terms of the diffusion equation. In transition state theory, it is assumed that the reactant molecules form a complex that can be discussed in terms of the population of its energy levels. Transition state theory inspires a thermodynamic approach to reaction rates, in which the rate constant is expressed in terms of thermodynamic parameters. This approach is useful for parametrizing the rates of reactions in solution. The highest level of sophistication is in terms of potential energy surfaces and the motion of molecules through these surfaces. As we shall see, such an approach gives an intimate picture of the events that occur when reactions occur and is open to experimental study. We also use transition state theory to examine the transfer of electrons in homogeneous systems and at electrodes.

Now we are at the heart of chemistry. Here we examine the details of what happens to molecules at the climax of reactions. Extensive changes of structure are taking place and energies the size of dissociation energies are being redistributed among bonds: old bonds are being ripped apart and new bonds are being formed.

As may be imagined, the calculation of the rates of such processes from first principles is very difficult. Nevertheless, like so many intricate problems, the broad features can be established quite simply. Only when we enquire more deeply do the complications emerge. In this chapter we look at several approaches to the calculation of a rate constant for elementary bimolecular processes, ranging from electron transfer to chemical reactions involving bond breakage and formation. Although a great deal of information can be obtained from gas-phase reactions, many reactions of interest take place in condensed phases, and we shall also see to what extent their rates can be predicted.

## Reactive encounters

In this section we consider two elementary approaches to the calculation of reaction rates, one relating to gas-phase reactions and the other to reactions in solution. Both approaches are based on the view that reactant molecules must meet, and that reaction takes place only if the molecules have a certain minimum energy. In the collision theory of bimolecular gas-phase reactions, which we mentioned briefly in Section 21.5b, products are formed only if the collision is sufficiently energetic; otherwise the colliding reactant molecules separate again. In solution, the reactant molecules may simply

diffuse together and then acquire energy from their immediate surroundings while they are in contact.

## 22.1 Collision theory

**Key points** In collision theory, it is supposed that the rate is proportional to (a) the collision frequency, (b) the fraction of collisions that occur with at least the kinetic energy  $E_a$  along their lines of centres, and (c) a steric factor. (d) The RRK model predicts the steric factor and rate constant of unimolecular reactions.

We shall consider the bimolecular elementary reaction

where P denotes products, and aim to calculate the second-order rate constant  $k_r$ .

We can anticipate the general form of the expression for  $k_r$  by considering the physical requirements for reaction. We expect the rate  $v$  to be proportional to the rate of collisions, and therefore to the mean speed of the molecules,  $\bar{c} \propto (T/M)^{1/2}$ , where  $M$  is the molar mass of the molecules, their collision cross-section,  $\sigma$ , and the number densities  $\mathcal{N}_A$  and  $\mathcal{N}_B$  of A and B (and therefore to their molar concentrations):

$$v \propto \sigma(T/M)^{1/2} \mathcal{N}_A \mathcal{N}_B \propto \sigma(T/M)^{1/2} [A][B]$$

However, a collision will be successful only if the kinetic energy exceeds a minimum value, the activation energy,  $E_a$ , of the reaction. This requirement suggests that the rate constant should also be proportional to a Boltzmann factor of the form  $e^{-E_a/RT}$ . So we can anticipate, by writing the reaction rate in the form given in eqn 22.1, that

$$k_r \propto \sigma(T/M)^{1/2} e^{-E_a/RT}$$

Not every collision will lead to reaction even if the energy requirement is satisfied, because the reactants may need to collide in a certain relative orientation. This ‘steric requirement’ suggests that a further factor,  $P$ , should be introduced, and that

$$k_r \propto P\sigma(T/M)^{1/2} e^{-E_a/RT} \quad (22.2)$$

As we shall see in detail below, this expression (which resembles the Arrhenius expression for the rate constant) has the form predicted by collision theory. It reflects three aspects of a successful collision:

$$k_r \propto \text{steric requirement} \times \text{encounter rate} \times \text{minimum energy requirement}$$

**Fig. 22.1** The collision cross-section for two molecules can be regarded to be the area within which the projectile molecule (A) must enter around the target molecule (B) in order for a collision to occur. If the diameters of the two molecules are  $d_A$  and  $d_B$ , the radius of the target area is  $d = \frac{1}{2}(d_A + d_B)$  and the cross-section is  $\pi d^2$ .

### (a) Collision rates in gases

We have anticipated that the reaction rate, and hence  $k_r$ , depends on the frequency with which molecules collide. The **collision density**,  $Z_{AB}$ , is the number of collisions between molecules A and B in a region of the sample in an interval of time divided by the volume of the region and the duration of the interval. The frequency of collisions of a single molecule in a gas was calculated in Section 20.1. As shown in the following *Justification*, that result can be adapted to deduce that

$$Z_{AB} = \sigma \left( \frac{8kT}{\pi\mu} \right)^{1/2} N_A^2 [A][B] \quad \text{Collision density for two different molecules in a perfect gas} \quad (22.3a)$$

where  $N_A$  is Avogadro's constant,  $\sigma$  is the collision cross-section (Fig. 22.1):

$$\sigma = \pi d^2 \quad d = \frac{1}{2}(d_A + d_B) \quad \text{Collision cross-section} \quad (22.3b)$$

and  $\mu$  is the reduced mass:

$$\mu = \frac{m_A m_B}{m_A + m_B} \quad \text{Reduced mass of a two-particle system} \quad (22.3c)$$

Similarly, the collision density for like molecules at a molar concentration  $[A]$  is

$$Z_{AA} = \sigma \left( \frac{4kT}{\pi m_A} \right)^{1/2} N_A^2 [A]^2 \quad \text{Collision density for two like molecules in a perfect gas} \quad (22.4)$$

Collision densities may be very large. For example, in nitrogen at room temperature and pressure, with  $d = 280$  pm,  $Z = 5 \times 10^{34} \text{ m}^{-3} \text{ s}^{-1}$ .

#### Justification 22.1 The collision density

It follows from eqn 20.11 that the collision frequency,  $z$ , for a single A molecule of mass  $m_A$  in a gas of other A molecules is

$$z = \sigma \bar{c}_{\text{rel}} \mathcal{N}_A \quad (22.5)$$

where  $\mathcal{N}_A$  is the number density of A molecules,  $\bar{c}_{\text{rel}}$  is their relative mean speed,

$$\bar{c}_{\text{rel}} = \left( \frac{8kT}{\pi \mu} \right)^{1/2} \quad (22.6)$$

and  $\mu$  is the reduced mass (eqn 22.3c), which in this case is simply  $\frac{1}{2} m_A$ .

The total collision density is the collision frequency multiplied by the number density of A molecules:

$$Z_{AA} = \frac{1}{2} z \mathcal{N}_A = \frac{1}{2} \sigma \bar{c}_{\text{rel}} \mathcal{N}_A^2 \quad (22.7a)$$

The factor of  $\frac{1}{2}$  has been introduced to avoid double counting of the collisions (so one A molecule colliding with another A molecule is counted as one collision regardless of their actual identities). For collisions of A and B molecules present at number densities  $\mathcal{N}_A$  and  $\mathcal{N}_B$ , the collision density is

$$Z_{AB} = \sigma \bar{c}_{\text{rel}} \mathcal{N}_A \mathcal{N}_B \quad (22.7b)$$

Note that we have discarded the factor  $\frac{1}{2}$  because now we are considering an A molecule colliding with any of the B molecules as a collision.

The number density of a species J is  $\mathcal{N}_J = N_A [J]$ , where  $[J]$  is the molar concentration and  $N_A$  is Avogadro's constant. Equations 22.3a and 22.4 then follow.

#### (b) The energy requirement

According to collision theory, the rate of change in the molar concentration of A molecules is the product of the collision density and the probability that a collision occurs with sufficient energy. The latter condition can be incorporated by writing the collision cross-section as a function of the kinetic energy of approach of the two colliding species, and setting the cross-section,  $\sigma(\epsilon)$ , equal to zero if the kinetic energy of approach is below a certain threshold value,  $\epsilon_a$ . Later, we shall identify  $N_A \epsilon_a$  as  $E_a$ , the (molar) activation energy of the reaction. Then, for a collision with a specific relative speed of approach  $v_{\text{rel}}$  (not, at this stage, a mean value),

$$\frac{d\mathcal{N}_A}{dt} = -\sigma(\epsilon) v_{\text{rel}} \mathcal{N}_A \mathcal{N}_B \quad (22.8a)$$

Or, in terms of molar concentrations,

$$\frac{d[A]}{dt} = -\sigma(\epsilon) v_{\text{rel}} N_A [A] [B] \quad (22.8b)$$

The kinetic energy associated with the relative motion of the two particles is  $\epsilon = \frac{1}{2} \mu v_{\text{rel}}^2$ ; therefore the relative speed is  $v_{\text{rel}} = (2\epsilon/\mu)^{1/2}$ . At this point we recognize that a wide range of approach energies  $\epsilon$  is present in a sample, so we should average the expression just derived over a Boltzmann distribution of energies  $f(\epsilon)$  (Section 15.1b), and write

$$\frac{d[A]}{dt} = - \left\{ \int_0^\infty \sigma(\epsilon) v_{\text{rel}} f(\epsilon) d\epsilon \right\} N_A [A] [B] \quad (22.9)$$

and hence recognize the rate constant as

$$k_r = N_A \int_0^\infty \sigma(\epsilon) v_{\text{rel}} f(\epsilon) d\epsilon \quad (22.10)$$

Now suppose that the reactive collision cross-section is zero below  $\epsilon_a$ . We show in the following *Justification* that, above  $\epsilon_a$ , a plausible expression for  $\sigma(\epsilon)$  is

$$\sigma(\epsilon) = \left( 1 - \frac{\epsilon_a}{\epsilon} \right) \sigma \quad \text{The collision cross-section} \quad (22.11)$$

Note that, when  $\epsilon = \epsilon_a$ ,  $\sigma(\epsilon) = 0$ , so the cross-section rises smoothly from its value 0 below  $\epsilon_a$ , and that, when  $\epsilon \gg \epsilon_a$ , it attains the constant value  $\sigma(\epsilon) = \sigma$ .

**Fig. 22.2** The parameters used in the calculation of the dependence of the collision cross-section on the relative kinetic energy of two molecules A and B.

#### Justification 22.2 The collision cross-section

Consider two colliding molecules A and B with relative speed  $v_{\text{rel}}$  and relative kinetic energy  $\epsilon = \frac{1}{2} \mu v_{\text{rel}}^2$  (Fig. 22.2). Intuitively we expect that a head-on collision between A and B will be most effective in bringing about a chemical reaction. Therefore,  $v_{\text{rel}, A-B}$ , the magnitude of the relative velocity component parallel to an axis that contains the vector connecting the centres of A and B, must be large. From trigonometry and the definitions of the distances  $a$  and  $d$ , and the angle  $\theta$  given in Fig. 22.2, it follows that

$$v_{\text{rel}, A-B} = v_{\text{rel}} \cos \theta = v_{\text{rel}} \left( \frac{d^2 - a^2}{d^2} \right)^{1/2}$$

We assume that only the kinetic energy associated with the head-on component of the collision,  $\epsilon_{A-B}$ , can lead to a chemical reaction. After squaring both sides of the equation above and multiplying by  $\frac{1}{2} \mu$ , it follows that

$$\epsilon_{A-B} = \epsilon \frac{d^2 - a^2}{d^2}$$

The existence of an energy threshold,  $\epsilon_a$ , for the formation of products implies that there is a maximum value of  $a$ ,  $a_{\text{max}}$ , above which reactions do not occur. Setting  $a = a_{\text{max}}$  and  $\epsilon_{A-B} = \epsilon_a$  in this expression gives

$$a_{\text{max}}^2 = \left( 1 - \frac{\epsilon_a}{\epsilon} \right) d^2$$

Substitution of  $\sigma(\epsilon)$  for  $\pi a_{\text{max}}^2$  and  $\sigma$  for  $\pi d^2$  in the equation above gives eqn 22.11. Note that the equation can be used only when  $\epsilon > \epsilon_a$ .

With the energy dependence of the collision cross-section established, we can evaluate the integral in eqn 22.10. In the following *Justification* we show that

$$k_r = N_A \sigma \bar{v}_{\text{rel}} e^{-E_a/RT} \quad (22.12)$$

The rate constant for a gas-phase bimolecular elementary reaction (excluding steric requirements)

### Justification 22.3 The rate constant

The Maxwell distribution of molecular speeds given in Section 20.1 may be expressed in terms of the kinetic energy,  $\epsilon$ , by writing  $\epsilon = \frac{1}{2}\mu v^2$ , then  $dv = d\epsilon/(2\mu\epsilon)^{1/2}$  and eqn 20.4 becomes

$$\begin{aligned} f(v)dv &= 4\pi \left( \frac{\mu}{2\pi kT} \right)^{3/2} \left( \frac{2\epsilon}{\mu} \right) e^{-\epsilon/kT} \frac{d\epsilon}{(2\mu\epsilon)^{1/2}} \\ &= 2\pi \left( \frac{1}{\pi kT} \right)^{3/2} \epsilon^{1/2} e^{-\epsilon/kT} d\epsilon = f(\epsilon)d\epsilon \end{aligned}$$

The integral we need to evaluate is therefore

$$\begin{aligned} \int_0^\infty \sigma(\epsilon) v_{\text{rel}} f(\epsilon) d\epsilon &= 2\pi \left( \frac{1}{\pi kT} \right)^{3/2} \int_0^\infty \sigma(\epsilon) \left( \frac{2\epsilon}{\mu} \right)^{1/2} \epsilon^{1/2} e^{-\epsilon/kT} d\epsilon \\ &= \left( \frac{8}{\pi \mu kT} \right)^{1/2} \left( \frac{1}{kT} \right) \int_0^\infty \epsilon \sigma(\epsilon) e^{-\epsilon/kT} d\epsilon \end{aligned}$$

To proceed, we introduce the expression for  $\sigma(\epsilon)$  in eqn 22.11, and evaluate

$$\int_0^\infty \epsilon \sigma(\epsilon) e^{-\epsilon/kT} d\epsilon = \sigma \int_{\epsilon_a}^\infty \epsilon \left( 1 - \frac{\epsilon_a}{\epsilon} \right) e^{-\epsilon/kT} d\epsilon = (kT)^2 \sigma e^{-\epsilon_a/kT}$$

We have made use of the fact that  $\sigma = 0$  for  $\epsilon < \epsilon_a$  and have used the two integrals

$$\int e^{-ax} dx = -\frac{e^{-ax}}{a} + \text{constant} \quad \text{and} \quad \int x e^{-ax} dx = \frac{e^{-ax}}{a^2} + \frac{x e^{-ax}}{a} + \text{constant}$$

It follows that

$$\int_0^\infty \sigma(\epsilon) v_{\text{rel}} f(\epsilon) d\epsilon = \sigma \left( \frac{8kT}{\pi \mu} \right)^{1/2} e^{-\epsilon_a/kT}$$

as in eqn 22.12 (with  $\epsilon_a/kT = E_a/RT$ ).

Equation 22.12 has the Arrhenius form  $k_r = A e^{-E_a/RT}$  provided the exponential temperature dependence dominates the weak square-root temperature dependence of the pre-exponential factor. It follows that we can identify the activation energy,  $E_a$ , with the minimum kinetic energy along the line of approach that is needed for reaction, and that the pre-exponential factor is a measure of the rate at which collisions occur in the gas.

### (c) The steric requirement

The simplest procedure for calculating  $k_r$  is to use for  $\sigma$  the values obtained for non-reactive collisions (for example, typically those obtained from viscosity measurements) or from tables of molecular radii. Table 22.1 compares some values of the pre-exponential factor calculated in this way with values obtained from Arrhenius

**Fig. 22.3** The collision cross-section is the target area that results in simple deflection of the projectile molecule; the reactive cross-section is the corresponding area for chemical change to occur on collision.

\* More values are given in the Data section.

plots (Section 21.5). One of the reactions shows fair agreement between theory and experiment, but for others there are major discrepancies. In some cases the experimental values are orders of magnitude smaller than those calculated, which suggests that the collision energy is not the only criterion for reaction and that some other feature, such as the relative orientation of the colliding species, is important. Moreover, one reaction in the table has a pre-exponential factor larger than theory, which seems to indicate that the reaction occurs more quickly than the particles collide!

We can accommodate the disagreement between experiment and theory by introducing a **steric factor**,  $P$ , and expressing the **reactive cross-section**,  $\sigma^*$ , as a multiple of the collision cross-section,  $\sigma^* = P\sigma$  (Fig. 22.3). Then the rate constant becomes

$$k_r = P\sigma \left( \frac{8kT}{\pi\mu} \right)^{1/2} N_A e^{-E_a/RT} \quad (22.13)$$

The rate constant for a gas-phase bimolecular elementary reaction (including steric requirements)

This expression has the form we anticipated in eqn 22.2. The steric factor is normally found to be several orders of magnitude smaller than 1.

#### Example 22.1 Estimating a steric factor (1)

Estimate the steric factor for the reaction  $\text{H}_2 + \text{C}_2\text{H}_4 \rightarrow \text{C}_2\text{H}_6$  at 628 K given that the pre-exponential factor is  $1.24 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ .

**Method** To calculate  $P$ , we need to calculate the pre-exponential factor,  $A$ , by using eqn 22.12 and then compare the answer with experiment: the ratio is  $P$ . Table 20.1 lists collision cross-sections for non-reactive encounters. The best way to estimate the collision cross-section for dissimilar spherical species is to calculate the collision diameter for each one (from  $\sigma = \pi d^2$ ), to calculate the mean of the two diameters, and then to calculate the cross-section for that mean diameter. However, as neither species is spherical, a simpler but more approximate procedure is just to take the average of the two collision cross-sections.

**Answer** The reduced mass of the colliding pair is

$$\mu = \frac{m_1 m_2}{m_1 + m_2} = 3.12 \times 10^{-27} \text{ kg}$$

because  $m_1 = 2.016m_u$  for  $\text{H}_2$  and  $m_2 = 28.05m_u$  for  $\text{C}_2\text{H}_4$  (the atomic mass constant,  $m_u$ , is defined inside the front cover). Hence at 628 K

$$\left( \frac{8kT}{\pi\mu} \right)^{1/2} = 2.66 \times 10^3 \text{ m s}^{-1}$$

From Table 20.1,  $\sigma(\text{H}_2) = 0.27 \text{ nm}^2$  and  $\sigma(\text{C}_2\text{H}_4) = 0.64 \text{ nm}^2$ , giving a mean collision cross-section of  $\sigma = 0.46 \text{ nm}^2$ . Therefore,

$$A = \sigma \left( \frac{8kT}{\pi\mu} \right)^{1/2} N_A = 7.37 \times 10^{11} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

Experimentally  $A = 1.24 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ , so it follows that  $P = 1.7 \times 10^{-6}$ . The very small value of  $P$  is one reason why catalysts are needed to bring this reaction about at a reasonable rate. As a general guide, the more complex the molecules, the smaller the value of  $P$ .

**Self-test 22.1** It is found for the reaction  $\text{NO} + \text{Cl}_2 \rightarrow \text{NOCl} + \text{Cl}$  that  $A = 4.0 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at 298 K. Use  $\sigma(\text{NO}) = 0.42 \text{ nm}^2$  and  $\sigma(\text{Cl}_2) = 0.93 \text{ nm}^2$  to estimate the  $P$  factor for the reaction. [0.018]

An example of a reaction for which it is possible to estimate the steric factor is  $\text{K} + \text{Br}_2 \rightarrow \text{KBr} + \text{Br}$ , for which  $P = 4.8$ . In this reaction, the distance of approach at which reaction occurs appears to be considerably larger than the distance needed for deflection of the path of the approaching molecules in a non-reactive collision. It has been proposed that the reaction proceeds by a **harpoon mechanism**. This brilliant name is based on a model of the reaction that pictures the K atom as approaching a  $\text{Br}_2$  molecule, and when the two are close enough an electron (the harpoon) flips across from K to  $\text{Br}_2$ . In place of two neutral particles there are now two ions, so there is a Coulombic attraction between them: this attraction is the line on the harpoon. Under its influence the ions move together (the line is wound in), the reaction takes place, and  $\text{KBr} + \text{Br}$  emerge. The harpoon extends the cross-section for the reactive encounter, and the reaction rate is greatly underestimated by taking for the collision cross-section the value for simple mechanical contact between  $\text{K} + \text{Br}_2$ .

**Example 22.2** Estimating a steric factor (2)

Estimate the value of  $P$  for the harpoon mechanism by calculating the distance at which it becomes energetically favourable for the electron to leap from K to  $\text{Br}_2$ .

**Method** We should begin by identifying all the contributions to the energy of interaction between the colliding species. There are three contributions to the energy of the process  $\text{K} + \text{Br}_2 \rightarrow \text{K}^+ + \text{Br}_2^-$ . The first is the ionization energy,  $I$ , of K. The second is the electron affinity,  $E_{\text{ea}}$ , of  $\text{Br}_2$ . The third is the Coulombic interaction energy between the ions when they have been formed: when their separation is  $R$ , this energy is  $-e^2/4\pi\epsilon_0 R$ . The electron flips across when the sum of these three contributions changes from positive to negative (that is, when the sum is zero).

**Answer** The net change in energy when the transfer occurs at a separation  $R$  is

$$E = I - E_{\text{ea}} - \frac{e^2}{4\pi\epsilon_0 R}$$

The ionization energy  $I$  is larger than  $E_{\text{ea}}$ , so  $E$  becomes negative only when  $R$  has decreased to less than some critical value  $R^*$  given by

$$\frac{e^2}{4\pi\epsilon_0 R^*} = I - E_{\text{ea}}$$

When the particles are at this separation, the harpoon shoots across from K to  $\text{Br}_2$ , so we can identify the reactive cross-section as  $\sigma^* = \pi R^{*2}$ . This value of  $\sigma^*$  implies that the steric factor is

$$P = \frac{\sigma^*}{\sigma} = \frac{R^{*2}}{d^2} = \left\{ \frac{e^2}{4\pi\epsilon_0 d(I - E_{\text{ea}})} \right\}^2$$

where  $d = R(\text{K}) + R(\text{Br}_2)$ . With  $I = 420 \text{ kJ mol}^{-1}$  (corresponding to 0.70 aJ),  $E_{\text{ea}} \approx 250 \text{ kJ mol}^{-1}$  (corresponding to 0.42 aJ), and  $d = 400 \text{ pm}$ , we find  $P = 4.2$ , in good agreement with the experimental value (4.8).

**Self-test 22.2** Estimate the value of  $P$  for the harpoon reaction between Na and  $\text{Cl}_2$  for which  $d \approx 350 \text{ pm}$ ; take  $E_{\text{ea}} \approx 230 \text{ kJ mol}^{-1}$ . [2.2]

**Fig. 22.4** The pressure dependence of the unimolecular isomerization of *trans*-CHD=CHD showing a pronounced departure from the straight line predicted by the Lindemann–Hinshelwood mechanism.

#### (d) The RRK model

Another instance where the steric factor  $P$  can be estimated is for unimolecular gas-phase reactions and its introduction brings the Lindemann–Hinshelwood mechanism into closer agreement with experiment. According to that theory (Section 21.8a), a plot of  $1/k_r$  against  $1/[A]$  should be linear. However, as Fig. 22.4 shows, a typical plot has a pronounced curvature, corresponding to a larger value of  $k_r$  (a smaller value of  $1/k_r$ ) at high pressures (low  $1/[A]$ ) than would be expected by extrapolation of the reasonably linear low pressure (high  $1/[A]$ ) data.

The improved model was proposed in 1926 by O.K. Rice and H.C. Ramsperger and almost simultaneously by L.S. Kassel, and is now known as the **Rice–Ramsperger–Kassel model** (RRK model). The model has been elaborated, largely by R.A. Marcus, into the RRKM model. Here we outline Kassel’s original approach to the RRK model. The essential feature of the model is that, although a molecule might have enough energy to react, that energy is distributed over all the modes of motion of the molecule, and reaction will occur only when enough of that energy has migrated into a particular location (such as a bond) in the molecule. This distribution leads to a  $P$  factor of the form<sup>1</sup>

$$P = \left( 1 - \frac{E^*}{E} \right)^{s-1} \quad \text{The steric factor from the RRK model} \quad (22.14a)$$

where  $s$  is the number of modes of motion over which the energy may be dissipated,  $E^*$  is the energy required for the bond of interest to break, and  $E$  is the energy available in the collision. We can then write the **Kassel form** of the unimolecular rate constant for the decay of  $A^*$  to products as

$$k_b(E) = \left( 1 - \frac{E^*}{E} \right)^{s-1} k_b \quad \text{for } E \geq E^* \quad \text{Kassel form of the unimolecular rate constant} \quad (22.14b)$$

where  $k_b$  is the rate constant used in the original Lindemann theory.

#### • A brief illustration

Suppose that an energy of  $250 \text{ kJ mol}^{-1}$  is available in a collision but  $200 \text{ kJ mol}^{-1}$  is needed to break a particular bond in a molecule with  $s = 10$ . Then

$$P = \left( 1 - \frac{200 \text{ kJ mol}^{-1}}{250 \text{ kJ mol}^{-1}} \right)^9 = 5 \times 10^{-7}$$

If  $500 \text{ kJ mol}^{-1}$  is available,

$$P = \left( 1 - \frac{200 \text{ kJ mol}^{-1}}{500 \text{ kJ mol}^{-1}} \right)^9 = 1 \times 10^{-2}$$

and the collision is much more efficient. •

<sup>1</sup> The derivation is given in our *Quanta, matter, and change* (2009).

The energy dependence of the rate constant given by eqn 21.14b is shown in Fig. 22.5 for various values of  $s$ . We see that the rate constant is smaller at a given excitation energy if  $s$  is large, as it takes longer for the excitation energy to migrate through all the oscillators of a large molecule and accumulate in the critical mode. As  $E$  becomes very large, however, the term in parentheses approaches 1, and  $k_b(E)$  becomes independent of the energy and the number of oscillators in the molecule, as there is now enough energy to accumulate immediately in the critical mode regardless of the size of the molecule.

Example 22.2 and the calculations summarized in this section illustrate two points about steric factors. First, the concept is not wholly useless because in some cases its numerical value can be estimated. Second (and more pessimistically) most reactions are much more complex than  $K + Br_2$  and unimolecular gas-phase reactions and we cannot expect to obtain  $P$  so easily. It is clear that we need a more powerful theory that lets us calculate rate constants for a wider variety of reactions. We go part of the way toward describing such a theory in Section 22.4 after we have established some of the features of reactions in solution.

**Fig. 22.5** The energy dependence of the rate constant given by eqn 22.14b for three values of  $s$ .

## 22.2 Diffusion-controlled reactions

**Key points** (a) The rate of a diffusion-controlled reaction is controlled by the rate at which reactant molecules encounter each other in solution. The rate of an activation-controlled reaction is controlled by the rate of accumulating sufficient energy. (b) An indication that a reaction is diffusion-controlled is that its rate constant is of the order of  $10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  or greater.

Encounters between reactants in solution occur in a very different manner from encounters in gases. Reactant molecules have to jostle their way through the solvent, so their encounter frequency is considerably less than in a gas. However, because a molecule also migrates only slowly away from a location, two reactant molecules that encounter each other stay near each other for much longer than in a gas. This lingering of one molecule near another on account of the hindering presence of solvent molecules is called the **cage effect**. Such an encounter pair may accumulate enough energy to react even though it does not have enough energy to do so when it first forms. The activation energy of a reaction is a much more complicated quantity in solution than in a gas because the encounter pair is surrounded by solvent and we need to consider the energy of the entire local assembly of reactant and solvent molecules. Some experimental data on Arrhenius parameters in solution are given in Table 22.2.

### (a) Classes of reaction

The complicated overall process can be divided into simpler parts by setting up a simple kinetic scheme. We suppose that the rate of formation of an encounter pair AB is first-order in each of the reactants A and B:

**Table 22.2\*** Arrhenius parameters for reactions in solution

|                                                 | Solvent    | $A/(\text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1})$ | $E_a/(\text{kJ mol}^{-1})$ |
|-------------------------------------------------|------------|---------------------------------------------------|----------------------------|
| $(\text{CH}_3)_3\text{CCl}$ solvolysis          | Water      | $7.1 \times 10^{16}$                              | 100                        |
|                                                 | Ethanol    | $3.0 \times 10^{13}$                              | 112                        |
|                                                 | Chloroform | $1.4 \times 10^4$                                 | 45                         |
| $\text{CH}_3\text{CH}_2\text{Br} + \text{OH}^-$ | Ethanol    | $4.3 \times 10^{11}$                              | 90                         |

\* More values are given in the Data section.

As we shall see,  $k_d$  (where the d signifies diffusion) is determined by the diffusional characteristics of A and B. The encounter pair can break up without reaction with a rate constant  $k'_d$  or it can go on to form products P with a rate constant  $k_a$  (where the a signifies an activated process). If we suppose that both processes are pseudofirst-order reactions (with the solvent perhaps playing a role), then we can write

and

The concentration of AB can now be found from the equation for the net rate of change of concentration of AB and using the steady-state approximation:

$$\frac{d[AB]}{dt} = k_d[A][B] - k'_d[AB] - k_a[AB] \approx 0$$

This expression solves to

$$[AB] = \frac{k_d[A][B]}{k_a + k'_d}$$

The rate of formation of products is therefore

$$\frac{d[P]}{dt} \approx k_a[AB] = k_r[A][B] \quad k_r = \frac{k_a k_d}{k_a + k'_d} \quad (22.15)$$

Two limits can now be distinguished. If the rate of separation of the unreacted encounter pair is much slower than the rate at which it forms products, then  $k'_d \ll k_a$  and the effective rate constant is

$$k_r \approx \frac{k_a k_d}{k_a} = k_d \quad \text{Rate constant for a diffusion-controlled reaction} \quad (22.16)$$

In this **diffusion-controlled limit**, the rate of reaction is governed by the rate at which the reactant molecules diffuse through the solvent. Because the combination of radicals involves very little activation energy, radical and atom recombination reactions are often diffusion-controlled.

An **activation-controlled reaction** arises when a substantial activation energy is involved in the reaction  $AB \rightarrow P$ . Then  $k_a \ll k'_d$  and

$$k_r \approx \frac{k_a k_d}{k'_d} = k_a K \quad \text{Rate constant for an activation-controlled reaction} \quad (22.17)$$

where  $K$  is the equilibrium constant for  $A + B \rightleftharpoons AB$ . In this limit, the reaction proceeds at the rate at which energy accumulates in the encounter pair from the surrounding solvent.

### (b) Diffusion and reaction

The rate of a diffusion-controlled reaction is calculated by considering the rate at which the reactants diffuse together. As shown in the following *Justification*, the rate constant for a reaction in which the two reactant molecules react if they come within a distance  $R^*$  of one another is

$$k_d = 4\pi R^* D N_A \quad \text{The rate constant of a diffusion-controlled reaction in terms of the diffusion coefficients} \quad (22.18)$$

where  $D$  is the sum of the diffusion coefficients of the two reactant species in the solution. It follows from this expression that an indication that a reaction is diffusion-controlled is that its rate constant is of the order of  $10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  or greater, as may be confirmed by taking values of  $R^*$  and  $D$  to be  $100 \text{ nm}$  and  $10^{-9} \text{ m}^2 \text{ s}^{-1}$ , respectively.

**Justification 22.4** *Solution of the radial diffusion equation*

From the form of the diffusion equation (Section 20.9) corresponding to motion in three dimensions,  $D_B \nabla^2[B] = \partial[B]/\partial t$ , the concentration of B when the system has reached a steady state ( $\partial[B]/\partial t = 0$ ) satisfies  $\nabla^2[B]_r = 0$ , where the subscript  $r$  signifies a quantity that varies with the distance  $r$ . For a spherically symmetrical system,  $\nabla^2$  can be replaced by radial derivatives alone (see Table 7.1), so the equation satisfied by  $[B]_r$  is

$$\frac{d^2[B]_r}{dr^2} + \frac{2}{r} \frac{d[B]_r}{dr} = 0$$

The general solution of this equation is

$$[B]_r = a + \frac{b}{r}$$

as may be verified by substitution. We need two boundary conditions to pin down the values of the two constants. One condition is that  $[B]_r$  has its bulk value  $[B]$  as  $r \rightarrow \infty$ . The second condition is that the concentration of B is zero at  $r = R^*$ , the distance at which reaction occurs. It follows that  $a = [B]$  and  $b = -R^*[B]$ , and hence that (for  $r \geq R^*$ )

$$[B]_r = \left(1 - \frac{R^*}{r}\right)[B] \quad (22.19)$$

Figure 22.6 illustrates the variation of concentration expressed by this equation.

The rate of reaction is the (molar) flux,  $J$ , of the reactant B towards A multiplied by the area of the spherical surface of radius  $R^*$ :

$$\text{Rate of reaction} = 4\pi R^{*2} J$$

From Fick's first law (eqn 20.19), the flux towards A is proportional to the concentration gradient, so at a radius  $R^*$ :

$$J = D_B \left( \frac{d[B]_r}{dr} \right)_{r=R^*} = \frac{D_B[B]}{R^*}$$

(A sign change has been introduced because we are interested in the flux towards decreasing values of  $r$ .) When this condition is substituted into the previous equation we obtain

$$\text{Rate of reaction} = 4\pi R^* D_B [B]$$

The rate of the diffusion-controlled reaction is equal to the average flow of B molecules to all the A molecules in the sample. If the bulk concentration of A is  $[A]$ , the number of A molecules in the sample of volume  $V$  is  $N_A[A]V$ ; the global flow of all B to all A is therefore  $4\pi R^* D_B N_A[A][B]V$ . Because it is unrealistic to suppose that all A are stationary; we replace  $D_B$  by the sum of the diffusion coefficients of the two species and write  $D = D_A + D_B$ . Then the rate of formation of the encounter pair AB is

$$\frac{d[AB]}{dt} = 4\pi R^* D N_A [A][B]$$

Hence, the diffusion-controlled rate constant is as given in eqn 22.18.

**Fig. 22.6** The concentration profile for reaction in solution when a molecule B diffuses towards another reactant molecule and reacts if it reaches  $R^*$ .

We can take eqn 22.18 further by incorporating the Stokes–Einstein equation (eqn 20.51) relating the diffusion constant and the hydrodynamic radius  $R_A$  and  $R_B$  of each molecule in a medium of viscosity  $\eta$ :

$$D_A = \frac{kT}{6\pi\eta R_A} \quad D_B = \frac{kT}{6\pi\eta R_B} \quad (22.20)$$

As these relations are approximate, little extra error is introduced if we write  $R_A = R_B = \frac{1}{2}R^*$ , which leads to

$$k_d = \frac{8RT}{3\eta} \quad (22.21)$$

The rate constant of a diffusion-controlled reaction in terms of the viscosity coefficient

(The  $R$  in this equation is the gas constant.) The radii have cancelled because, although the diffusion constants are smaller when the radii are large, the reactive collision radius is larger and the particles need to travel a shorter distance to meet. In this approximation, the rate constant is independent of the identities of the reactants, and depends only on the temperature and the viscosity of the solvent.

#### • A brief illustration

The rate constant for the recombination of I atoms in hexane at 298 K, when the viscosity of the solvent is 0.326 cP (with 1 P =  $10^{-1}$  kg m<sup>-1</sup> s<sup>-1</sup>) is

$$k_d = \frac{8 \times (8.3145 \text{ J K}^{-1} \text{ mol}^{-1}) \times (298 \text{ K})}{3 \times (3.26 \times 10^{-4} \text{ kg m}^{-1} \text{ s}^{-1})} = 2.0 \times 10^7 \text{ m}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

where we have used 1 J = 1 kg m<sup>2</sup> s<sup>-2</sup>. Because 1 m<sup>3</sup> = 10<sup>3</sup> dm<sup>3</sup>, this result corresponds to  $2.0 \times 10^{10} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . The experimental value is  $1.3 \times 10^{10} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ , so the agreement is very good considering the approximations involved. •

### 22.3 The material balance equation

**Key point** The material balance equation combines the effects of diffusion, convection, and reaction.

The diffusion of reactants plays an important role in many chemical processes, such as the diffusion of O<sub>2</sub> molecules into red blood corpuscles and the diffusion of a gas towards a catalyst. We can have a glimpse of the kinds of calculations involved by considering the diffusion equation (Section 20.9) generalized to take into account the possibility that the diffusing, convecting molecules are also reacting.

Consider a small volume element in a chemical reactor (or a biological cell) modelled as a one-dimensional system. The net rate at which J molecules enter the region by diffusion and convection is given by eqn 20.56:

$$\frac{\partial[J]}{\partial t} = D \frac{\partial^2[J]}{\partial x^2} - v \frac{\partial[J]}{\partial x} \quad (22.22)$$

The net rate of change of molar concentration due to chemical reaction is

$$\frac{\partial[J]}{\partial t} = -k_r[J] \quad (22.23)$$

if we suppose that J disappears by a pseudofirst-order reaction. Therefore, the overall rate of change of the concentration of J is

$$\frac{\partial[J]}{\partial t} = \underbrace{D \frac{\partial^2[J]}{\partial x^2}}_{\text{Spread due to non-uniform concentration}} - \underbrace{v \frac{\partial[J]}{\partial x}}_{\text{Change due to convection}} - \underbrace{k_r[J]}_{\text{Loss due to reaction}} \quad \text{Material balance equation} \quad (22.24)$$

Equation 22.24 is called the **material balance equation**. If the rate constant is large, then [J] will decline rapidly. However, if the diffusion constant is large, then the decline can be replenished as J diffuses rapidly into the region. The convection term, which may represent the effects of stirring, can sweep material either into or out of the region according to the signs of  $v$  and the concentration gradient  $\partial[J]/\partial x$ .

The material balance equation, even for a one-dimensional system, is a second-order partial differential equation and is far from easy to solve in general. Some idea of how it is solved can be obtained by considering the special case in which there is no convective motion (as in an unstirred reaction vessel):

$$\frac{\partial[J]}{\partial t} = D \frac{\partial^2[J]}{\partial x^2} - k_r[J] \quad (22.25)$$

As may be verified by substitution, if the solution of this equation in the absence of reaction (that is, for  $k_r = 0$ ) is [J], then the solution [J]\* in the presence of reaction ( $k_r > 0$ ) is

$$[J]^* = [J]e^{-k_r t} \quad (22.26)$$

We have already met one solution of the diffusion equation in the absence of reaction: eqn 20.57 is the solution for a system in which initially a layer of  $n_0 N_A$  molecules is spread over a plane of area  $A$ :

$$[J] = \frac{n_0 e^{-x^2/4Dt}}{A(\pi Dt)^{1/2}} \quad \text{Solution of the material balance equation} \quad (22.27)$$

When this expression is substituted into eqn 22.26, we obtain the concentration of J as it diffuses away from its initial surface layer and undergoes reaction in the solution above (Fig. 22.7).

Only in some special cases can the full material balance equation be solved analytically. Most modern work on reactor design and cell kinetics uses numerical methods to solve the equation, and detailed solutions for realistic environments, such as vessels of different shapes (which influence the boundary conditions on the solutions) and with a variety of inhomogeneously distributed reactants, can be obtained reasonably easily.

## Transition state theory

We saw in Section 21.5 that an activated complex forms between reactants as they collide and begin to assume the nuclear and electronic configurations characteristic of products. We also saw that the change in potential energy associated with formation of the activated complex accounts for the activation energy of the reaction. We now consider a more detailed calculation of rate constants which uses the concepts of statistical thermodynamics developed in Chapter 16. The approach we describe, which is called **transition state theory** (also widely referred to as *activated complex theory*), has the advantage that a quantity corresponding to the steric factor appears

**Fig. 22.7** The concentration profiles for a diffusing, reacting system (for example, a column of solution) in which one reactant is initially in a layer at  $x = 0$ . In the absence of reaction (grey lines) the concentration profiles are the same as in Fig. 20.20.

**interActivity** Use the interactive applet found in the *Living graphs* section of the text's web site to explore the effect of varying the value of the rate constant  $k$  on the spatial variation of [J] for a constant value of the diffusion constant  $D$ .

**Fig. 22.8** A reaction profile (for an exothermic reaction). The horizontal axis is the reaction coordinate, and the vertical axis is potential energy. The activated complex is the region near the potential maximum, and the transition state corresponds to the maximum itself.

automatically and  $P$  does not need to be grafted on to an equation as an afterthought. Transition state theory is an attempt to identify the principal features governing the size of a rate constant in terms of a model of the events that take place during the reaction. There are several approaches to the calculation, all of which lead to the same final expression; here we present the simplest approach.

## 22.4 The Eyring equation

**Key points** (a) In transition state theory, it is supposed that an activated complex is in equilibrium with the reactants, and that the rate at which that complex forms products depends on the rate at which it passes through a transition state. (b) The concentration of the activated complex can be calculated from the partition functions of the participating species. (c) The Eyring equation is an expression for the rate constant in transition state theory. (d) Results of collision and transition state theory agree when considering collisions of structureless particles. (e) Ultrafast laser spectroscopy can be used to observe and manipulate clusters that resemble activated complexes.

Transition state theory pictures a reaction between A and B as proceeding through the formation of an activated complex,  $C^\ddagger$ , in a rapid pre-equilibrium (Fig. 22.8):

When we express the partial pressures,  $p_j$ , in terms of the molar concentrations,  $[J]$ , by using  $p_j = RT[J]$ , the concentration of activated complex is related to the (dimensionless) equilibrium constant by

$$[C^\ddagger] = \frac{RT}{p^\ominus} K^\ddagger [A][B] \quad (22.29)$$

The activated complex falls apart by unimolecular decay into products, P, with a rate constant  $k^\ddagger$ :

It follows that

$$v = k_r [A][B] \quad k_r = \frac{RT}{p^\ominus} k^\ddagger K^\ddagger \quad (22.31)$$

Our task is to calculate the unimolecular rate constant  $k^\ddagger$  and the equilibrium constant  $K^\ddagger$ .

### (a) The rate of decay of the activated complex

An activated complex can form products if it passes through the **transition state**, the arrangement the atoms must achieve in order to convert to products (Section 21.5b). If its vibration-like motion along the reaction coordinate occurs with a frequency  $\nu^\ddagger$ , then the frequency with which the cluster of atoms forming the complex approaches the transition state is also  $\nu^\ddagger$ . However, it is possible that not every oscillation along the reaction coordinate takes the complex through the transition state. For instance, the centrifugal effect of rotations might also be an important contribution to the breakup of the complex, and in some cases the complex might be rotating too slowly, or rotating rapidly but about the wrong axis. Therefore, we suppose that the rate of passage of the complex through the transition state is only proportional to rather than equal to the vibrational frequency along the reaction coordinate, and write

**A note on good practice** We consider it appropriate to distinguish the transition state from the activated complex, but not everyone does so. The *activated complex* is a cluster of atoms formed from the reactants; the *transition state* is the specific configuration of those atoms that is the gateway to the formation of products.

$$k^\ddagger = \kappa v^\ddagger$$

Rate constant for passage through  
the transition state in terms of  
the transmission coefficient

(22.32)

where  $\kappa$  is the **transmission coefficient**. In the absence of information to the contrary,  $\kappa$  is assumed to be about 1, signifying that almost every visit to the transition state leads on to products.

### (b) The concentration of the activated complex

We saw in Section 16.8 how to calculate equilibrium constants from structural data. Equation 16.52a of that section can be used directly, which in this case gives

$$K^\ddagger = \frac{N_A q_{C^\ddagger}^\ominus}{q_A^\ominus q_B^\ominus} e^{-\Delta_r E_0/RT} \quad (22.33)$$

where  $p^\ominus = 1$  bar and

$$\Delta_r E_0 = E_0(C^\ddagger) - E_0(A) - E_0(B) \quad (22.34)$$

The  $q_j^\ominus$  are the standard molar partition functions, as defined in Section 16.2. Note that the units of  $N_A$  and the  $q_j^\ominus$  are  $\text{mol}^{-1}$ , so  $K^\ddagger$  is dimensionless (as is appropriate for an equilibrium constant).

In the final step of this part of the calculation, we focus attention on the partition function of the activated complex. We have already assumed that a vibration of the activated complex  $C^\ddagger$  tips it through the transition state. The partition function for this vibration is

$$q = \frac{1}{1 - e^{-h\nu^\ddagger/kT}}$$

where  $\nu^\ddagger$  is its frequency (the same frequency that determines  $k^\ddagger$ ). This frequency is much lower than for an ordinary molecular vibration because the oscillation corresponds to the complex falling apart (Fig. 22.9), so the force constant is very low. Therefore, provided that  $h\nu^\ddagger/kT \ll 1$  the exponential may be expanded and the partition function reduces to

$$q = \frac{1}{1 - \left(1 - \frac{h\nu^\ddagger}{kT} + \dots\right)} \approx \frac{kT}{h\nu^\ddagger}$$

We can therefore write

$$q_{C^\ddagger} \approx \frac{kT}{h\nu^\ddagger} \bar{q}_{C^\ddagger} \quad (22.35)$$

where  $\bar{q}$  denotes the partition function for all the other modes of the complex. The constant  $K^\ddagger$  is therefore

$$K^\ddagger = \frac{kT}{h\nu^\ddagger} \bar{K}^\ddagger \quad \bar{K}^\ddagger = \frac{N_A \bar{q}_{C^\ddagger}^\ominus}{q_A^\ominus q_B^\ominus} e^{-\Delta_r E_0/RT} \quad (22.36)$$

with  $\bar{K}^\ddagger$  a kind of equilibrium constant, but with one vibrational mode of  $C^\ddagger$  discarded.

### (c) The rate constant

We can now combine all the parts of the calculation into

$$k_r = k^\ddagger \frac{RT}{p^\ominus} K^\ddagger = \kappa v^\ddagger \frac{kT}{h\nu^\ddagger} \frac{RT}{p^\ominus} \bar{K}^\ddagger \quad (22.37a)$$

**Fig. 22.9** In an elementary depiction of the activated complex close to the transition state, there is a broad, shallow dip in the potential energy surface along the reaction coordinate. The complex vibrates harmonically and almost classically in this well. However, this depiction is an oversimplification, for in many cases there is no dip at the top of the barrier, and the curvature of the potential energy, and therefore the force constant, is negative. Formally, the vibrational frequency is then imaginary. We ignore this problem here.

At this stage the unknown frequencies  $\nu^\ddagger$  cancel and, after writing  $\bar{K}_C^\ddagger = (RT/p^\ominus)\bar{K}^\ddagger$ , we obtain the Eyring equation:

$$k_r = \kappa \frac{kT}{h} \bar{K}_C^\ddagger \quad \text{Eyring equation} \quad (22.37b)$$

The factor  $\bar{K}_C^\ddagger$  is given by eqn 22.36 and the definition  $\bar{K}_C^\ddagger = (RT/p^\ominus)\bar{K}^\ddagger$  in terms of the partition functions of A, B, and  $C^\ddagger$ , so in principle we now have an explicit expression for calculating the second-order rate constant for a bimolecular reaction in terms of the molecular parameters for the reactants and the activated complex and the quantity  $\kappa$ .

The partition functions for the reactants can normally be calculated quite readily, using either spectroscopic information about their energy levels or the approximate expressions set out in the Checklist at the end of Chapter 16. The difficulty with the Eyring equation, however, lies in the calculation of the partition function of the activated complex:  $C^\ddagger$  is difficult to investigate spectroscopically (but see Section 22.4e), and in general we need to make assumptions about its size, shape, and structure. We shall illustrate what is involved in one simple but significant case.

#### (d) The collision of structureless particles

Consider the case of two structureless particles A and B colliding to give an activated complex that resembles a diatomic molecule. Because the reactants  $J = A, B$  are structureless ‘atoms’, the only contributions to their partition functions are the translational terms:

$$q_J^\ominus = \frac{V_m^\ominus}{\Lambda_J^3} \quad \Lambda_J = \frac{h}{(2\pi m_J kT)^{1/2}} \quad V_m^\ominus = \frac{RT}{p^\ominus} \quad (22.38a)$$

The activated complex is a diatomic cluster of mass  $m_{C^\ddagger} = m_A + m_B$  and moment of inertia  $I$ . It has one vibrational mode, but that mode corresponds to motion along the reaction coordinate and therefore does not appear in  $\bar{q}_{C^\ddagger}$ . It follows that the standard molar partition function of the activated complex is

$$\bar{q}_{C^\ddagger}^\ominus = \left( \frac{2IkT}{\hbar^2} \right) \frac{V_m^\ominus}{\Lambda_{C^\ddagger}^3} \quad (22.38b)$$

The moment of inertia of a diatomic molecule of bond length  $r$  is  $\mu r^2$ , where  $\mu = m_A m_B / (m_A + m_B)$  is the effective mass, so the expression for the rate constant is

$$\begin{aligned} k_r &= \kappa \frac{kT}{h} \frac{RT}{p^\ominus} \left( \frac{N_A \Lambda_A^3 \Lambda_B^3}{\Lambda_{C^\ddagger}^3 V_m^\ominus} \right) \left( \frac{2IkT}{\hbar^2} \right) e^{-\Delta_r E_0/RT} \\ &= \kappa \frac{kT}{h} N_A \left( \frac{\Lambda_A \Lambda_B}{\Lambda_{C^\ddagger}} \right)^3 \left( \frac{2IkT}{\hbar^2} \right) e^{-\Delta_r E_0/RT} \\ &= \kappa N_A \left( \frac{8kT}{\pi\mu} \right)^{1/2} \pi r^2 e^{-\Delta_r E_0/RT} \end{aligned} \quad \text{The rate constant for a reaction between structureless particles} \quad (22.39)$$

Finally, by identifying  $\kappa\pi r^2$  as the reactive cross-section  $\sigma^*$ , we arrive at precisely the same expression as that obtained from simple collision theory (eqn 22.13 with  $\Delta_r E_0 = E_a$ ).

#### (e) Observation and manipulation of the activated complex

The development of femtosecond pulsed lasers has made it possible to make observations on species that have such short lifetimes that in a number of respects they resemble an activated complex. In a typical experiment designed to detect an activated

complex, a femtosecond laser pulse is used to excite a molecule to a dissociative state, and then a second femtosecond pulse is fired at an interval after the dissociating pulse. The frequency of the second pulse is set at an absorption of one of the free fragmentation products, so its absorption is a measure of the abundance of the dissociation product. For example, when ICN is dissociated by the first pulse, the emergence of CN from the photoactivated state can be monitored by watching the growth of the free CN absorption (or, more commonly, its laser-induced fluorescence). In this way it has been found that the CN signal remains zero until the fragments have separated by about 600 pm, which takes about 205 fs.

Some sense of the progress that has been made in the study of the intimate mechanism of chemical reactions can be obtained by considering the decay of the ion pair  $\text{Na}^+\text{I}^-$ . As shown in Fig. 22.10, excitation of the ionic species with a femtosecond laser pulse forms an excited state that corresponds to a covalently bonded NaI molecule. The system can be described with two potential energy surfaces, one largely 'ionic' and another 'covalent', which cross at an internuclear separation of 693 pm. A short laser pulse is composed of a wide range of frequencies, which excite many vibrational states of NaI simultaneously. Consequently, the electronically excited complex exists as a superposition of states, or a localized wavepacket (Section 7.6), which oscillates between the 'covalent' and 'ionic' potential energy surfaces, as shown in Fig. 22.10. The complex can also dissociate, shown as movement of the wavepacket toward very long internuclear separation along the dissociative surface. However, not every outward-going swing leads to dissociation because there is a chance that the I atom can be harpooned again, in which case it fails to make good its escape. The dynamics of the system is probed by a second laser pulse with a frequency that corresponds to the absorption frequency of the free Na product or to the frequency at which Na absorbs when it is a part of the complex. The latter frequency depends on the  $\text{Na}\cdots\text{I}$  distance, so an absorption (in practice, a laser-induced fluorescence) is obtained each time the wavepacket returns to that separation.

A typical set of results is shown in Fig. 22.11. The bound Na absorption intensity shows up as a series of pulses that recur in about 1 ps, showing that the wavepacket oscillates with about that period. The decline in intensity shows the rate at which the complex can dissociate as the two atoms swing away from each other. The free Na absorption also grows in an oscillating manner, showing the periodicity of wavepacket oscillation, each swing of which gives it a chance to dissociate. The precise period of the oscillation in NaI is 1.25 ps, corresponding to a vibrational wavenumber of  $27\text{ cm}^{-1}$  (recall that the activated complex theory assumes that such a vibration has a very low frequency). The complex survives for about ten oscillations. In contrast, although the oscillation frequency of NaBr is similar, it barely survives one oscillation.

Femtosecond spectroscopy has also been used to examine analogues of the activated complex involved in bimolecular reactions. Thus, a molecular beam can be used to produce a van der Waals molecule (Section 17.7), such as  $\text{IH}\cdots\text{OCO}$ . The HI bond can be dissociated by a femtosecond pulse, and the H atom is ejected towards the O atom of the neighbouring  $\text{CO}_2$  molecule to form HOCO. Hence, the van der Waals molecule is a source of a species that resembles the activated complex of the reaction

The probe pulse is tuned to the OH radical, which enables the evolution of  $[\text{HOCO}]^\ddagger$  to be studied in real time. Femtosecond transition state spectroscopy has also been used to study more complex reactions, such as the Diels–Alder reaction, nucleophilic substitution reactions, and pericyclic addition and cleavage reactions. Biological processes that are open to study by femtosecond spectroscopy include the energy-converting processes of photosynthesis and the photostimulated processes of

**Fig. 22.10** Excitation of the ion pair  $\text{Na}^+\text{I}^-$  forms an excited state with covalent character. Also shown is movement between a 'covalent' surface and an 'ionic' surface of the wavepacket formed by laser excitation.

**Fig. 22.11** Femtosecond spectroscopic results for the reaction in which sodium iodide separates into Na and I. The lower curve is the absorption of the electronically excited complex and the upper curve is the absorption of free Na atoms. (Adapted from A.H. Zewail, *Science* 242, 1645 (1988).)

vision. In other experiments, the photoejection of carbon monoxide from myoglobin and the attachment of O<sub>2</sub> to the exposed site have been studied to obtain rate constants for the two processes.

## 22.5 Thermodynamic aspects

**Key points** (a) The rate constant may be parametrized in terms of the Gibbs energy, entropy, and enthalpy of activation. (b) The kinetic salt effect is the effect of an added inert salt on the rate of a reaction between ions.

The statistical thermodynamic version of transition state theory rapidly runs into difficulties because only in some cases is anything known about the structure of the activated complex. However, the concepts that it introduces, principally that of an equilibrium between the reactants and the activated complex, have motivated a more general, empirical approach in which the activation process is expressed in terms of thermodynamic functions.

### (a) Activation parameters

If we accept that  $\bar{K}^\ddagger$  is an equilibrium constant (despite one mode of C<sup>‡</sup> having been discarded), we can express it in terms of a **Gibbs energy of activation**,  $\Delta^\ddagger G$ , through the definition

$$\Delta^\ddagger G = -RT \ln \bar{K}^\ddagger$$

Definition of the Gibbs energy of activation in terms of  $\bar{K}^\ddagger$

[22.40]

(All the  $\Delta^\ddagger X$  in this section are *standard* thermodynamic quantities,  $\Delta^\ddagger X^\ominus$ , but we shall omit the standard state sign to avoid overburdening the notation.) Then the rate constant becomes

$$k_r = \kappa \frac{kT}{h} \frac{RT}{p^\ominus} e^{-\Delta^\ddagger G/RT}$$

The Eyring equation in terms of the Gibbs energy of activation

(22.41)

Because  $G = H - TS$ , the Gibbs energy of activation can be divided into an **entropy of activation**,  $\Delta^\ddagger S$ , and an **enthalpy of activation**,  $\Delta^\ddagger H$ , by writing

$$\Delta^\ddagger G = \Delta^\ddagger H - T\Delta^\ddagger S$$

Relation of the Gibbs energy of activation to  $\Delta^\ddagger S$  and  $\Delta^\ddagger H$

(22.42)

When eqn 22.42 is used in eqn 22.41 and  $\kappa$  is absorbed into the entropy term, we obtain

$$k_r = B e^{\Delta^\ddagger S/R} e^{-\Delta^\ddagger H/RT} \quad B = \frac{kT}{h} \frac{RT}{p^\ominus}$$

The Eyring equation in terms of the entropy and enthalpy of activation

(22.43)

The formal definition of activation energy,  $E_a = RT^2(\partial \ln k_r / \partial T)$ , then gives  $E_a = \Delta^\ddagger H + 2RT$ , so

$$k_r = e^2 B e^{\Delta^\ddagger S/R} e^{-E_a/RT}$$

The Eyring equation in terms of the entropy of activation and the activation energy

(22.44)

#### A brief comment

For reactions of the type  $A + B \rightarrow P$  in the gas phase,  $E_a = \Delta^\ddagger H + 2RT$ . For these reactions in solution,  $E_a = \Delta^\ddagger H + RT$ .

from which it follows that the Arrhenius factor  $A$  can be identified as

$$A = e^2 B e^{\Delta^\ddagger S/R} \quad \text{The pre-exponential factor in terms of the entropy of activation} \quad (22.45)$$

The entropy of activation is negative because two reactant species come together to form one species. However, if there is a reduction in entropy below what would be expected for the simple encounter of A and B, then  $A$  will be smaller than that expected on the basis of simple collision theory. Indeed, we can identify that additional reduction in entropy,  $\Delta^\ddagger S_{\text{steric}}$ , as the origin of the steric factor of collision theory, and write

$$P = e^{\Delta^\ddagger S_{\text{steric}}/R} \quad \text{The steric factor in terms of the entropy of activation} \quad (22.46)$$

Thus, the more complex the steric requirements of the encounter, the more negative the value of  $\Delta^\ddagger S_{\text{steric}}$ , and the smaller the value of  $P$ .

Gibbs energies, enthalpies, entropies, volumes, and heat capacities of activation are widely used to report experimental reaction rates, especially for organic reactions in solution. They are encountered when relationships between equilibrium constants and rates of reaction are explored using **correlation analysis**, in which  $\ln K$  (which is equal to  $-\Delta_r G^\circ/RT$ ) is plotted against  $\ln k_r$  (which is proportional to  $-\Delta^\ddagger G/RT$ ). In many cases the correlation is linear, signifying that, as the reaction becomes thermodynamically more favourable, its rate constant increases (Fig. 22.12). This linear correlation is the origin of the alternative name **linear free energy relation**.

### (b) Reactions between ions

The thermodynamic version of transition state theory simplifies the discussion of reactions in solution. The statistical thermodynamic theory is very complicated to apply because the solvent plays a role in the activated complex. In the thermodynamic approach we combine the rate law

$$\frac{d[P]}{dt} = k^\ddagger [C^\ddagger]$$

with the thermodynamic equilibrium constant

$$K = \frac{a_{C^\ddagger}}{a_A a_B} = K_\gamma \frac{[C^\ddagger] c^\ominus}{[A][B]} \quad K_\gamma = \frac{\gamma_{C^\ddagger}}{\gamma_A \gamma_B}$$

Then

$$\frac{d[P]}{dt} = k_r [A][B] \quad k_r = \frac{k^\ddagger K}{K_\gamma} \quad (22.47a)$$

If  $k_r^\ominus$  is the rate constant when the activity coefficients are 1 (that is,  $k_r^\ominus = k^\ddagger K$ ), we can write

$$k_r = \frac{k_r^\ominus}{K_\gamma} \quad (22.47b)$$

At low concentrations the activity coefficients can be expressed in terms of the ionic strength,  $I$ , of the solution by using the Debye–Hückel limiting law (Section 5.13, particularly eqn 5.75.) Although eqn 5.75 is for the mean activity coefficient, eqn 5.95a shows that it is the outcome of two contributions for each type of ion present and that we may write

$$\log \gamma_A = -Az_A^2 I^{1/2} \quad \log \gamma_B = -Az_B^2 I^{1/2} \quad (22.48a)$$

**Fig. 22.12** For a related series of reactions, as the magnitude of the standard reaction Gibbs energy increases, so the activation barrier decreases. The approximate linear correlation between  $\Delta^\ddagger G$  and  $\Delta_r G^\circ$  is the origin of linear free energy relations.

**Fig. 22.13** Experimental tests of the kinetic salt effect for reactions in water at 298 K. The ion types are shown as spheres, and the slopes of the lines are those given by the Debye–Hückel limiting law and eqn 22.49.

**Fig. 22.14** The experimental ionic strength dependence of the rate constant of a hydrolysis reaction: the slope gives information about the charge types involved in the activated complex of the rate-determining step. See Example 22.3.

with  $A = 0.509$  in aqueous solution at 298 K and  $z_A$  and  $z_B$  the charge numbers of A and B, respectively. Since the activated complex forms from reaction of one of the ions of A with one of the ions of B, the charge number of the activated complex is  $z_A + z_B$ . Therefore

$$\log \gamma_{C^\ddagger} = -A(z_A + z_B)^2 I^{1/2} \quad (22.48b)$$

Inserting these relations into eqn 22.47b results in

$$\begin{aligned} \log k_r &= \log k_r^0 - A\{z_A^2 + z_B^2 - (z_A + z_B)^2\} I^{1/2} \\ &= \log k_r^0 + 2Az_A z_B I^{1/2} \end{aligned} \quad \text{Kinetic salt effect} \quad (22.49)$$

Equation 22.49 expresses the **kinetic salt effect**, the variation of the rate constant of a reaction between ions with the ionic strength of the solution (Fig. 22.13). If the reactant ions have the same sign (as in a reaction between cations or between anions), then increasing the ionic strength by the addition of inert ions increases the rate constant. The formation of a single, highly charged ionic complex from two less highly charged ions is favoured by a high ionic strength because the new ion has a denser ionic atmosphere and interacts with that atmosphere more strongly. Conversely, ions of opposite charge react more slowly in solutions of high ionic strength. Now the charges cancel and the complex has a less favourable interaction with its atmosphere than the separated ions.

### Example 22.3 Analysing the kinetic salt effect

The rate constant for the base ( $\text{OH}^-$ ) hydrolysis of  $[\text{CoBr}(\text{NH}_3)_5]^{2+}$  varies with ionic strength as tabulated below. What can be deduced about the charge of the activated complex in the rate-determining stage?

|             |        |        |        |        |        |        |
|-------------|--------|--------|--------|--------|--------|--------|
| $I$         | 0.0050 | 0.0100 | 0.0150 | 0.0200 | 0.0250 | 0.0300 |
| $k_t/k_t^0$ | 0.718  | 0.631  | 0.562  | 0.515  | 0.475  | 0.447  |

**Method** According to eqn 22.49, plot  $\log(k_t/k_t^0)$  against  $I^{1/2}$ , when the slope will give  $1.02z_A z_B$ , from which we can infer the charges of the ions involved in the formation of the activated complex.

**Answer** Form the following table:

|                   |        |        |        |        |        |        |
|-------------------|--------|--------|--------|--------|--------|--------|
| $I$               | 0.0050 | 0.0100 | 0.0150 | 0.0200 | 0.0250 | 0.0300 |
| $I^{1/2}$         | 0.071  | 0.100  | 0.122  | 0.141  | 0.158  | 0.173  |
| $\log(k_t/k_t^0)$ | -0.14  | -0.20  | -0.25  | -0.29  | -0.32  | -0.35  |

These points are plotted in Fig. 22.14. The slope of the (least squares) straight line is  $-2.04$ , indicating that  $z_A z_B = -2$ . Because  $z_A = -1$  for the  $\text{OH}^-$  ion, if that ion is involved in the formation of the activated complex, then the charge number of the second ion is  $+2$ . This analysis suggests that the pentaamminebromocobalt(III) cation participates in the formation of the activated complex. The rate constant is also influenced by the relative permittivity of the medium.

**Self-test 22.3** An ion of charge number  $+1$  is known to be involved in the activated complex of a reaction. Deduce the charge number of the other ion from the following data:

|             |        |        |        |        |        |        |
|-------------|--------|--------|--------|--------|--------|--------|
| $I$         | 0.0015 | 0.0025 | 0.0035 | 0.0045 | 0.0055 | 0.0065 |
| $k_t/k_t^0$ | 0.930  | 0.902  | 0.884  | 0.867  | 0.853  | 0.841  |

[−1]

## The dynamics of molecular collisions

We now come to the third and most detailed level of our examination of the factors that govern the rates of reactions.

### 22.6 Reactive collisions

**Key points** (a) Techniques for the study of reactive collisions include infrared chemiluminescence, laser-induced fluorescence, multiphoton ionization, reaction product imaging, and resonant multiphoton ionization. (b) The rate constant of a reaction is the sum of state-to-state rate constants over all final states and over a Boltzmann-weighted sum of initial states.

Molecular beams allow us to study collisions between molecules in preselected energy states, and can be used to determine the states of the products of a reactive collision. Information of this kind is essential if a full picture of the reaction is to be built, because the rate constant is an average over events in which reactants in different initial states evolve into products in their final states.

#### (a) Experimental probes of reactive collisions

Detailed experimental information about the intimate processes that occur during reactive encounters comes from molecular beams, especially crossed molecular beams (Fig. 22.15). The detector for the products of the collision of two beams can be moved to different angles, so the angular distribution of the products can be determined. Because the molecules in the incoming beams can be prepared with different energies (for example, with different translational energies by using rotating sectors and supersonic nozzles, with different vibrational energies by using selective excitation with lasers, as shown in Section 22.9b, and with different orientations by using electric fields), it is possible to study the dependence of the success of collisions on these variables and to study how they affect the properties of the outgoing product molecules.

One method for examining the energy distribution in the products is **infrared chemiluminescence**, in which vibrationally excited molecules emit infrared radiation as they return to their ground states. By studying the intensities of the infrared emission spectrum, the populations of the vibrational states may be determined (Fig. 22.16). Another method makes use of **laser-induced fluorescence**. In this technique, a laser is used to excite a product molecule from a specific vibration–rotation level; the intensity of the fluorescence from the upper state is monitored and interpreted in terms of the population of the initial vibration–rotation state. **Multiphoton ionization** (MPI) techniques are also good alternatives for the study of weakly fluorescing molecules. In MPI, the absorption of several photons by a molecule results in ionization if the total photon energy is greater than the ionization energy of the molecule. One or more pulsed lasers are used to generate the molecular ions, which are commonly detected by time-of-flight mass spectrometry (TOF-MS, Section 18.9). An important variant of MPI is **resonant multiphoton ionization** (REMPI), in which one or more photons promote a molecule to an electronically excited state and then additional photons are used to generate ions from the excited state. The power of REMPI lies in the fact that the experimenter can choose which reactant or product to study by tuning the laser frequency to the electronic absorption band of a specific molecule.

#### (b) State-to-state dynamics

The concept of collision cross-section was introduced in connection with collision theory in Section 22.1, where we saw that the second-order rate constant,  $k_r$ , can be

**Fig. 22.15** In a crossed-beam experiment, state-selected molecules are generated in two separate sources, and are directed perpendicular to one another. The detector responds to molecules (which may be product molecules if chemical reaction occurs) scattered into a chosen direction.

**Fig. 22.16** Infrared chemiluminescence from CO produced in the reaction  $\text{O} + \text{CS} \rightarrow \text{CO} + \text{S}$  arises from the non-equilibrium populations of the vibrational states of CO and the radiative relaxation to equilibrium.

expressed as a Boltzmann-weighted average of the reactive collision cross-section and the relative speed of approach. We shall write eqn 22.10 as

$$k_r = \langle \sigma v_{\text{rel}} \rangle N_A \quad (22.50)$$

where the angle brackets denote a Boltzmann average. Molecular beam studies provide a more sophisticated version of this quantity, for they provide the **state-to-state cross-section**,  $\sigma_{nn'}$ , and hence the **state-to-state rate constant**,  $k_{nn'}$ :

$$k_{nn'} = \langle \sigma_{nn'} v_{\text{rel}} \rangle N_A \quad (22.51)$$

The state-to-state  
rate constant

The rate constant  $k_r$  is the sum of the state-to-state rate constants over all final states (because a reaction is successful whatever the final state of the products) and over a Boltzmann-weighted sum of initial states (because the reactants are initially present with a characteristic distribution of populations at a temperature  $T$ ):

$$k_r = \sum_{n,n'} k_{nn'}(T) f_n(T) \quad (22.52)$$

The reaction rate constant  
in terms of the state-to-  
state rate constant

where  $f_n(T)$  is the Boltzmann factor at a temperature  $T$ . It follows that, if we can determine or calculate the state-to-state cross-sections for a wide range of approach speeds and initial and final states, then we have a route to the calculation of the rate constant for the reaction.

**Fig. 22.17** The potential energy surface for the  $\text{H} + \text{H}_2 \rightarrow \text{H}_2 + \text{H}$  reaction when the atoms are constrained to be collinear.

**Fig. 22.18** The contour diagram (with contours of equal potential energy) corresponding to the surface in Fig. 22.17.  $R_e$  marks the equilibrium bond length of an  $\text{H}_2$  molecule (strictly, it relates to the arrangement when the third atom is at infinity).

## 22.7 Potential energy surfaces

**Key point** A potential energy surface maps the potential energy as a function of the relative positions of all the atoms taking part in a reaction.

One of the most important concepts for discussing beam results and calculating the state-to-state collision cross-section is the **potential energy surface** of a reaction, the potential energy as a function of the relative positions of all the atoms taking part in the reaction. Potential energy surfaces may be constructed from experimental data, with the techniques described in Section 22.6, and from results of quantum chemical calculations. Density functional theory (DFT, Section 10.7c) provides a relatively cheap way of incorporating electron correlation and is increasingly being applied to reactive systems.

To illustrate the features of a potential energy surface we consider the collision between an H atom and an  $\text{H}_2$  molecule. Detailed calculations show that the approach of an atom along the H–H axis requires less energy for reaction than any other approach, so initially we confine our attention to a collinear approach. Two parameters are required to define the nuclear separations: one is the  $\text{H}_\text{A} - \text{H}_\text{B}$  separation  $R_{\text{AB}}$ , and the other is the  $\text{H}_\text{B} - \text{H}_\text{C}$  separation  $R_{\text{BC}}$ .

At the start of the encounter  $R_{\text{AB}}$  is infinite and  $R_{\text{BC}}$  is the  $\text{H}_2$  equilibrium bond length. At the end of a successful reactive encounter  $R_{\text{AB}}$  is equal to the equilibrium bond length and  $R_{\text{BC}}$  is infinite. The total energy of the three-atom system depends on their relative separations, and can be found by doing a molecular orbital calculation. The plot of the total energy of the system against  $R_{\text{AB}}$  and  $R_{\text{BC}}$  gives the potential energy surface of this collinear reaction (Fig. 22.17). This surface is normally depicted as a contour diagram (Fig. 22.18).

When  $R_{\text{AB}}$  is very large, the variations in potential energy represented by the surface as  $R_{\text{BC}}$  changes are those of an isolated  $\text{H}_2$  molecule as its bond length is altered. A section through the surface at  $R_{\text{AB}} = \infty$ , for example, is the same as the  $\text{H}_2$  bonding

potential energy curve like that shown in Fig. 10.17. At the edge of the diagram where  $R_{BC}$  is very large, a section through the surface is the molecular potential energy curve of an isolated  $H_AH_B$  molecule.

The actual path of the atoms in the course of the encounter depends on their total energy, the sum of their kinetic and potential energies. However, we can obtain an initial idea of the paths available to the system for paths that correspond to least potential energy. For example, consider the changes in potential energy as  $H_A$  approaches  $H_BH_C$ . If the  $H_B-H_C$  bond length is constant during the initial approach of  $H_A$ , the potential energy of the  $H_3$  cluster rises along the path marked A in Fig. 22.19. We see that the potential energy reaches a high value as  $H_A$  is pushed into the molecule and then decreases sharply as  $H_C$  breaks off and separates to a great distance. An alternative reaction path can be imagined (B) in which the  $H_B-H_C$  bond length increases while  $H_A$  is still far away. Both paths, although feasible if the molecules have sufficient initial kinetic energy, take the three atoms to regions of high potential energy in the course of the encounter.

The path of least potential energy is the one marked C, corresponding to  $R_{BC}$  lengthening as  $H_A$  approaches and begins to form a bond with  $H_B$ . The  $H_B-H_C$  bond relaxes at the demand of the incoming atom, and the potential energy climbs only as far as the saddle-shaped region of the surface, to the saddle point marked  $C^\ddagger$ . The encounter of least potential energy is one in which the atoms take route C up the floor of the valley, through the saddle point, and down the floor of the other valley as  $H_C$  recedes and the new  $H_A-H_B$  bond achieves its equilibrium length. This path is the reaction coordinate we met in Section 22.4.

We can now make contact with the transition state theory of reaction rates. In terms of trajectories on potential surfaces, the transition state can be identified with a critical geometry such that every trajectory that goes through this geometry goes on to react (Fig. 22.20).

## 22.8 Some results from experiments and calculations

**Key points** (a) The direction of approach between reactants affects the distribution of reaction products. (b) In an attractive surface, the saddle point (the highest point) occurs early on the reaction coordinate. In a repulsive surface, the saddle point occurs late on the reaction coordinate. (c) Classical mechanics may be used to map the trajectories of atoms during a reaction. (d) Quantum mechanical scattering theory focuses on the evolution of a wavefunction representing initially the reactants and finally the products.

To travel successfully from reactants to products the incoming molecules must possess enough kinetic energy to be able to climb to the saddle point of the potential surface. Therefore, the shape of the surface can be explored experimentally by changing the relative speed of approach (by selecting the beam velocity) and the degree of vibrational excitation and observing whether reaction occurs and whether the products emerge in a vibrationally excited state (Fig. 22.21). For example, one question that can be answered is whether it is better to smash the reactants together with a lot of translational kinetic energy or to ensure instead that they approach in highly excited vibrational states. Thus, is trajectory  $C_2^\ddagger$ , where the  $H_BH_C$  molecule is initially vibrationally excited, more efficient at leading to reaction than the trajectory  $C_1^\ddagger$ , in which the total energy is the same but has a high translational kinetic energy?

### (a) The direction of attack and separation

Figure 22.22 shows the results of a calculation of the potential energy as an H atom approaches an  $H_2$  molecule from different angles, the  $H_2$  bond being allowed to relax to the optimum length in each case. The potential barrier is least for collinear attack, as

**Fig. 22.19** Various trajectories through the potential energy surface shown in Fig. 22.18. Path A corresponds to a route in which  $R_{BC}$  is held constant as  $H_A$  approaches; path B corresponds to a route in which  $R_{BC}$  lengthens at an early stage during the approach of  $H_A$ ; path C is the route along the floor of the potential valley.

**Fig. 22.20** The transition state is a set of configurations (here, marked by the line across the saddle point) through which successful reactive trajectories must pass.

**Fig. 22.21** Some successful (\*) and unsuccessful encounters. (a)  $C_1^*$  corresponds to the path along the foot of the valley; (b)  $C_2^*$  corresponds to an approach of A to a vibrating BC molecule, and the formation of a vibrating AB molecule as C departs. (c)  $C_3$  corresponds to A approaching a non-vibrating BC molecule, but with insufficient translational kinetic energy; (d)  $C_4$  corresponds to A approaching a vibrating BC molecule, but still the energy, and the phase of the vibration, is insufficient for reaction.

**Fig. 22.22** An indication of the anisotropy of the potential energy changes as H approaches  $H_2$  with different angles of attack. The collinear attack has the lowest potential barrier to reaction. The contours indicate the potential energy along the reaction coordinate for each configuration.

we assumed earlier. (But we must be aware that other lines of attack are feasible and contribute to the overall rate.) In contrast, Fig. 22.23 shows the potential energy changes that occur as a Cl atom approaches an HI molecule. The lowest barrier occurs for approaches within a cone of half-angle  $30^\circ$  surrounding the H atom. The relevance of this result to the calculation of the steric factor of collision theory should be noted: not every collision is successful, because not every one lies within the reactive cone.

If the collision is sticky, so that when the reactants collide they orbit around each other, the products can be expected to emerge in random directions because all memory of the approach direction has been lost. A rotation takes about 1 ps, so if the collision is over in less than that time the complex will not have had time to rotate and the products will be thrown off in a specific direction. In the collision of K and  $I_2$ , for example, most of the products are thrown off in the forward direction. This product distribution is consistent with the harpoon mechanism (Section 22.1c) because the transition takes place at long range. In contrast, the collision of K with  $CH_3I$  leads to reaction only if the molecules approach each other very closely. In this mechanism, K effectively bumps into a brick wall, and the KI product bounces out in the backward direction. The detection of this anisotropy in the angular distribution of products gives an indication of the distance and orientation of approach needed for reaction, as well as showing that the event is complete in less than 1 ps.

### (b) Attractive and repulsive surfaces

Some reactions are very sensitive to whether the energy has been predigested into a vibrational mode or left as the relative translational kinetic energy of the colliding molecules. For example, if two HI molecules are hurled together with more than twice the activation energy of the reaction, then no reaction occurs if all the energy is translational. For  $F + HCl \rightarrow Cl + HF$ , for example, the reaction is about five times as efficient when the HCl is in its first vibrational excited state than when, although HCl has the same total energy, it is in its vibrational ground state.

The origin of these requirements can be found by examining the potential energy surface. Figure 22.24 shows an **attractive surface** in which the saddle point occurs early in the reaction coordinate. Figure 22.25 shows a **repulsive surface** in which the saddle point occurs late. A surface that is attractive in one direction is repulsive in the reverse direction.

Consider first the attractive surface. If the original molecule is vibrationally excited, then a collision with an incoming molecule takes the system along C. This path is

**Fig. 22.23** The potential energy barrier for the approach of Cl to HI. In this case, successful encounters occur only when Cl approaches within a cone surrounding the H atom.

**Fig. 22.24** An attractive potential energy surface. A successful encounter ( $C^*$ ) involves high translational kinetic energy and results in a vibrationally excited product.

**Fig. 22.25** A repulsive potential energy surface. A successful encounter ( $C^*$ ) involves initial vibrational excitation and the products have high translational kinetic energy. A reaction that is attractive in one direction is repulsive in the reverse direction.

bottled up in the region of the reactants, and does not take the system to the saddle point. If, however, the same amount of energy is present solely as translational kinetic energy, then the system moves along  $C^*$  and travels smoothly over the saddle point into products. We can therefore conclude that reactions with attractive potential energy surfaces proceed more efficiently if the energy is in relative translational motion. Moreover, the potential surface shows that once past the saddle point the trajectory runs up the steep wall of the product valley, and then rolls from side to side as it falls to the foot of the valley as the products separate. In other words, the products emerge in a vibrationally excited state.

Now consider the repulsive surface (Fig. 22.25). On trajectory  $C$  the collisional energy is largely in translation. As the reactants approach, the potential energy rises. Their path takes them up the opposing face of the valley, and they are reflected back into the reactant region. This path corresponds to an unsuccessful encounter, even though the energy is sufficient for reaction. On  $C^*$  some of the energy is in the vibration of the reactant molecule and the motion causes the trajectory to weave from side to side up the valley as it approaches the saddle point. This motion may be sufficient to tip the system round the corner to the saddle point and then on to products. In this case, the product molecule is expected to be in an unexcited vibrational state. Reactions with repulsive potential surfaces can therefore be expected to proceed more efficiently if the excess energy is present as vibrations. This is the case with the  $\text{H} + \text{Cl}_2 \rightarrow \text{HCl} + \text{Cl}$  reaction, for instance.

### (c) Classical trajectories

A clear picture of the reaction event can be obtained by using classical mechanics to calculate the trajectories of the atoms taking place in a reaction from a set of initial conditions, such as velocities, relative orientations, and internal energies of the reacting particles. The initial values used for the internal energy reflect the quantization of electronic, vibrational, and rotational energies in molecules but the features of quantum mechanics are not used explicitly in the calculation of the trajectory.

Figure 22.26 shows the result of such a calculation of the positions of the three atoms in the reaction  $\text{H} + \text{H}_2 \rightarrow \text{H}_2 + \text{H}$ , the horizontal coordinate now being time and the vertical coordinate the separations. This illustration shows clearly the vibration of the original molecule and the approach of the attacking atom. The reaction itself, the

**Fig. 22.26** The calculated trajectories for a reactive encounter between A and a vibrating BC molecule leading to the formation of a vibrating AB molecule. This direct-mode reaction is between H and  $\text{H}_2$ . (M. Karplus, R.N. Porter, and R.D. Sharma, *J. Chem. Phys.* 43, 3258 (1965).)

**Fig. 22.27** An example of the trajectories calculated for a complex-mode reaction,  $\text{KCl} + \text{NaBr} \rightarrow \text{KBr} + \text{NaCl}$ , in which the collision cluster has a long lifetime. (P. Brumer and M. Karplus, *Faraday Disc. Chem. Soc.*, 55, 80 (1973).)

switch of partners, takes place very rapidly and is an example of a **direct mode process**. The newly formed molecule shakes, but quickly settles down to steady, harmonic vibration as the expelled atom departs. In contrast, Fig. 22.27 shows an example of a **complex mode process**, in which the activated complex survives for an extended period. The reaction in the illustration is the exchange reaction  $\text{KCl} + \text{NaBr} \rightarrow \text{KBr} + \text{NaCl}$ . The tetratomic activated complex survives for about 5 ps, during which time the atoms make about 15 oscillations before dissociating into products.

#### (d) Quantum mechanical scattering theory

Classical trajectory calculations do not recognize the fact that the motion of atoms, electrons, and nuclei is governed by quantum mechanics. The concept of trajectory then fades and is replaced by the unfolding in time of a wavefunction that represents initially the reactants and finally products.

Complete quantum mechanical calculations of time-dependent wavefunctions and rate constants are very onerous because it is necessary to take into account all the allowed electronic, vibrational, and rotational states populated by each atom and molecule in the system at a given temperature. It is common to define a ‘channel’ as a group of molecules in well-defined quantum mechanically allowed states. Then, at a given temperature, there are many channels that represent the reactants and many channels that represent possible products, with some transitions between channels being allowed but others not allowed. Furthermore, not every transition leads to a chemical reaction. For example, the process  $\text{H}_2^* + \text{OH} \rightarrow \text{H}_2 + (\text{OH})^*$ , where the asterisk denotes an excited state, amounts to energy transfer between  $\text{H}_2$  and  $\text{OH}$ , whereas the process  $\text{H}_2^* + \text{OH} \rightarrow \text{H}_2\text{O} + \text{H}$  represents a chemical reaction. What complicates a quantum mechanical calculation of wavefunctions and rate constants even in this simple four-atom system is that many reacting channels present at a given temperature can lead to the desired products  $\text{H}_2\text{O} + \text{H}$ , which themselves may be formed as many distinct channels. The **cumulative reaction probability**,  $\mathcal{P}(E)$ , at a fixed total energy  $E$  is then written as

$$\mathcal{P}(E) = \sum_{i,j} P_{ij}(E) \quad \text{Cumulative reaction probability} \quad (22.53)$$

where  $P_{ij}(E)$  is the probability for a transition between a reacting channel  $i$  and a product channel  $j$  and the summation is over all possible transitions that lead to product. It is then possible to show that the rate constant is given by

$$k_{\text{r}}(T) = \frac{\int_0^\infty \mathcal{P}(E) e^{-E/kT} dE}{hQ_{\text{R}}(T)} \quad \text{The rate constant in terms of the cumulative reaction probability} \quad (22.54)$$

where  $Q_{\text{R}}(T)$  is the partition function density (the partition function divided by the volume) of the reactants at the temperature  $T$ . The significance of eqn 22.54 is that it provides a direct connection between an experimental quantity, the rate constant, and a theoretical quantity,  $\mathcal{P}(E)$ .

## The dynamics of electron transfer

We end the chapter by applying the concepts of transition state theory and quantum theory to the study of a deceptively simple process, electron transfer. We begin by examining the features of a theory that describes the factors governing the rates of

electron transfer in homogeneous systems. Then, we discuss electron transfer processes occurring on the surfaces of electrodes.

## 22.9 Electron transfer in homogeneous systems

**Key points** (a) Electrons are transferred by tunnelling through a potential energy barrier. (b) The rate constant of electron transfer in a donor–acceptor complex depends on the distance between electron donor and acceptor, the standard reaction Gibbs energy, and the reorganization energy. (c) The key features of the theory of electron transfer in homogeneous systems have been verified experimentally.

Consider electron transfer from a donor species D to an acceptor species A in solution. The net reaction is

In the first step of the mechanism, D and A must diffuse through the solution and collide to form a complex DA, in which the donor and acceptor are separated by a distance comparable to  $r$ , the distance between the edges of each species. The first (reversible) step is the formation of an encounter complex:

Next, (reversible) electron transfer occurs within the DA complex to yield  $D^+A^-$ :

The  $D^+A^-$  complex can also break apart and the ions diffuse through the solution:

We show in the following *Justification* that

$$\frac{1}{k_r} = \frac{1}{k_a} + \frac{k'_a}{k_a k_{et}} \left( 1 + \frac{k'_{et}}{k_d} \right) \quad (22.57)$$

The rate constant for the overall electron transfer process

**Justification 22.5** *The rate constant for electron transfer in solution*

We begin by identifying the rate of the overall reaction (eqn 22.55) to the rate of formation of separated ions, the reaction products:

$$v = k_r[D][A] = k_d[D^+A^-]$$

There are two reaction intermediates, DA and  $D^+A^-$ , and we apply the steady-state approximation to both. From

$$\frac{d[D^+A^-]}{dt} = k_{et}[DA] - k'_{et}[D^+A^-] - k_d[D^+A^-] = 0$$

it follows that

$$[DA] = \frac{k'_{et} + k_d}{k_{et}} [D^+A^-]$$

and from

$$\begin{aligned} \frac{d[DA]}{dt} &= k_a[D][A] - k'_a[DA] - k_{et}[DA] + k'_{et}[D^+A^-] \\ &= k_a[D][A] - \left\{ \frac{(k'_a + k_{et})(k'_{et} + k_d)}{k_{et}} - k'_{et} \right\} [D^+A^-] = 0 \end{aligned}$$

it follows that

$$[D^+A^-] = \frac{k_a k_{et}}{k'_a k'_{et} + k'_a k_d + k_d k_{et}} [D][A]$$

When we multiply this expression by  $k_d$ , we see that the resulting equation has the form of the rate of electron transfer,  $v = k_r [D][A]$ , with  $k_r$  given by

$$k_r = \frac{k_d k_a k_{et}}{k'_a k'_{et} + k'_a k_d + k_d k_{et}}$$

To obtain eqn 22.57, we divide the numerator and denominator on the right-hand side of this expression by  $k_d k_{et}$  and then form the reciprocal of both sides.

To gain insight into eqn 22.57 and the factors that determine the rate of electron transfer reactions in solution, we assume that the main decay route for  $D^+A^-$  is dissociation of the complex into separated ions, or  $k_d \gg k'_{et}$ . It follows that

$$\frac{1}{k_r} \approx \frac{1}{k_a} \left( 1 + \frac{k'_a}{k_{et}} \right)$$

When  $k_{et} \gg k'_a$ , we see that  $k_r \approx k_a$  and the rate of product formation is controlled by diffusion of D and A in solution, which results in the formation of the DA complex. When  $k_{et} \ll k'_a$ , we see that  $k_r = (k_a/k'_a)k_{et}$  or, after using eqn 22.56a,

$$k_r \approx K_{DA} k_{et} \text{ with } K_{DA} = k_a/k'_a \quad (22.58)$$

The overall rate constant in the limit  $k_{et} \ll k'_a$

and the process is controlled by the activation energy of electron transfer in the DA complex. Using transition state theory (Section 22.5), we write

$$k_{et} = \kappa \nu^\ddagger e^{-\Delta^\ddagger G/RT} \quad (22.59)$$

where  $\kappa$  is the transmission coefficient,  $\nu^\ddagger$  is the vibrational frequency with which the activated complex approaches the transition state, and  $\Delta^\ddagger G$  is the Gibbs energy of activation.

Our first task is to write theoretical expressions for  $\kappa \nu^\ddagger$  and  $\Delta^\ddagger G$ . The discussion concentrates on the following two key aspects of the theory, which was developed independently by R.A. Marcus, N.S. Hush, V.G. Levich, and R.R. Dogonadze:

- Electrons are transferred by tunnelling through a potential energy barrier, the height of which is partly determined by the ionization energies of the DA and  $D^+A^-$  complexes. Electron tunnelling influences the magnitude of  $\kappa \nu^\ddagger$ .
- The complex DA and the solvent molecules surrounding it undergo structural rearrangements prior to electron transfer. The energy associated with these rearrangements and the standard reaction Gibbs energy determine  $\Delta^\ddagger G$ .

### (a) The role of electron tunnelling

We saw in Section 13.2c that, according to the Franck–Condon principle, electronic transitions are so fast that they can be regarded as taking place in a stationary nuclear framework. This principle also applies to an electron transfer process in which an electron migrates from one energy surface, representing the dependence of the energy of DA on its geometry, to another representing the energy of  $D^+A^-$ . We can represent the potential energy (and the Gibbs energy) surfaces of the two complexes (the reactant complex, DA, and the product complex,  $D^+A^-$ ) by the parabolas characteristic of

harmonic oscillators, with the displacement coordinate  $q$  corresponding to the changing geometries (Fig. 22.28). This coordinate represents a collective mode of the donor, acceptor, and solvent.

According to the Franck–Condon principle, the nuclei do not have time to move when the system passes from the reactant to the product surface as a result of the transfer of an electron. Therefore, electron transfer can occur only after thermal fluctuations bring the geometry of DA to  $q^*$  in Fig. 22.28, the value of the nuclear coordinate at which the two parabolas intersect.

The factor  $\kappa\nu^\ddagger$  is a measure of the probability that the system will convert from reactants (DA) to products ( $D^+A^-$ ) at  $q^*$  by electron transfer within the thermally excited DA complex. To understand the process, we must turn our attention to the effect that the rearrangement of nuclear coordinates has on electronic energy levels of DA and  $D^+A^-$  for a given distance  $r$  between D and A (Fig. 22.29). Initially, the electron to be transferred occupies the HOMO of D, and the overall energy of DA is lower than that of  $D^+A^-$  (Fig. 22.29a). As the nuclei rearrange to a configuration represented by  $q^*$  in Fig. 22.29b, the highest occupied electronic level of DA and the lowest unoccupied electronic level of  $D^+A^-$  converge in energy and electron transfer becomes energetically feasible. Over reasonably short distances  $r$ , the main mechanism of electron transfer is tunnelling through the potential energy barrier depicted in Fig. 22.29b. The height of the barrier increases with the ionization energies of the DA and  $D^+A^-$  complexes. After an electron moves from the HOMO of D to the LUMO of A, the system relaxes to the configuration represented by  $q_0^P$  in Fig. 22.29c. As shown in the illustration, now the energy of  $D^+A^-$  is lower than that of DA, reflecting the thermodynamic tendency for A to remain reduced and for D to remain oxidized.

The tunnelling event responsible for electron transfer is similar to that described in Section 8.3 where we saw that the transmission probability decreases exponentially with the thickness of the barrier. So the theory supposes similarly that the probability of electron transfer from D to A decreases exponentially with increasing distance between D and A in the DA complex and that for fixed values of the temperature and the Gibbs energy of activation, the rate constant  $k_{et}$  varies with the edge-to-edge distance  $r$  as<sup>2</sup>

$$k_{et} \propto e^{-\beta r} \quad (22.60)$$

The value of  $\beta$  depends on the medium through which the electron must travel from donor to acceptor. In a vacuum,  $28 \text{ nm}^{-1} < \beta < 35 \text{ nm}^{-1}$ , whereas  $\beta \approx 9 \text{ nm}^{-1}$  when the intervening medium is a molecular link.

### (b) The expression for the rate of electron transfer

Marcus noted that the DA complex and the medium surrounding it must rearrange spatially as charge is redistributed to form the ions  $D^+$  and  $A^-$ . These molecular rearrangements, which contribute to the Gibbs energy of activation,  $\Delta^\ddagger G$ , include the relative reorientation of the D and A molecules in DA and the relative reorientation of the solvent molecules surrounding DA. We show in *Further information 22.1* that

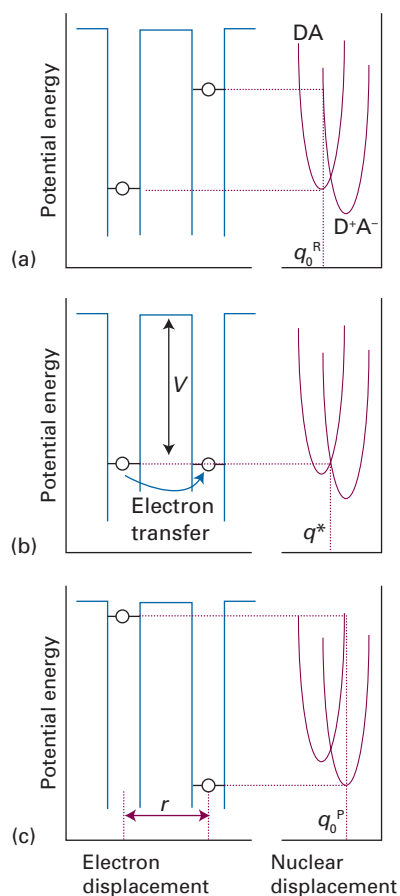

$$\Delta^\ddagger G = \frac{(\Delta_r G^\ominus + \lambda)^2}{4\lambda} \quad (22.61)$$

where  $\Delta_r G^\ominus$  is the standard reaction Gibbs energy for the electron transfer process  $DA \rightarrow D^+A^-$ , and  $\lambda$  is the **reorganization energy**, the energy needed for the molecular

**Fig. 22.28** The Gibbs energy surfaces of the complexes DA and  $D^+A^-$  involved in an electron transfer process are represented by parabolas characteristic of harmonic oscillators, with the displacement coordinate  $q$  corresponding to the changing geometries of the system. In the plot,  $q_0^R$  and  $q_0^P$  are the values of  $q$  at which the minima of the reactant and product parabolas occur, respectively. The plots also portray the Gibbs energy of activation,  $\Delta^\ddagger G$ , the standard reaction Gibbs energy,  $\Delta_r G^\ominus$ , and the reorganization energy,  $\lambda$  (discussed in Section 22.9b).

<sup>2</sup> For a full mathematical treatment of Marcus theory, see our *Quanta, matter, and change* (2009).

**Fig. 22.29** Correspondence between the electronic energy levels (shown on the left) and the nuclear energy levels (shown on the right) for the DA and  $D^+A^-$  complexes involved in an electron transfer process. (a) At the nuclear configuration denoted by  $q_0^R$ , the electron to be transferred in DA is in an occupied electronic energy level and the lowest unoccupied energy level of  $D^+A^-$  is of too high an energy to be a good electron acceptor. (b) As the nuclei rearrange to a configuration represented by  $q^*$ , DA and  $D^+A^-$  become degenerate and electron transfer occurs by tunnelling through the barrier of height  $V$  and width  $r$ , the edge-to-edge distance between donor and acceptor. (c) The system relaxes to the equilibrium nuclear configuration of  $D^+A^-$  denoted by  $q_0^P$ , in which the lowest unoccupied electronic level of DA is higher in energy than the highest occupied electronic level of  $D^+A^-$ . (Adapted from R.A. Marcus and N. Sutin, *Biochim. Biophys. Acta* **811**, 265 (1985).)

rearrangement that must take place for DA to attain the equilibrium geometry of  $D^+A^-$ . Equation 22.61 shows that  $\Delta^\ddagger G = 0$  when  $\Delta_r G^\circ = -\lambda$ , with the implication that the reaction is not slowed down by an activation barrier when the reorganization energy is equal to the standard reaction Gibbs energy.

Equations 22.59 and 22.60 suggest that the expression for  $k_{et}$  has the form

$$k_{et} \propto e^{-\beta r} e^{-\Delta^\ddagger G/RT} \quad \text{The rate constant of electron transfer} \quad (22.62)$$

However, this expression has some limitations which are revealed by the detailed derivation. First, it describes only systems in which the electroactive species are so far apart that the wavefunctions for D and A do not overlap extensively. An example of such a 'weakly coupled system' is the cytochrome *c*/cytochrome *b*<sub>5</sub> complex, in which the electroactive haem-bound Fe atoms shuttle between oxidation states +2 and +3 during electron transfer and are about 1.7 nm apart. Examples of 'strongly coupled systems', in which wavefunctions for D and A do overlap extensively, are mixed-valence, binuclear d-metal complexes with the general structure  $L_m M^{n+} - B - M^{p+} L_m$  with the electroactive metal ions separated by a bridging ligand B. In these systems,  $r < 1.0$  nm. The weak coupling limit applies to a large number of electron transfer reactions, including those between proteins during metabolism.

A second limitation of eqn 22.62 is that it applies only at high temperatures. At low temperatures, thermal fluctuations alone cannot bring the reactants to the transition state and transition state theory, which is at the heart of the theory, fails to account for any observed electron transfer. Electron transfer can still occur, but by *nuclear* tunnelling from the reactant to the product surfaces. We saw in Section 8.5 that the wavefunctions for the lower levels of the quantum mechanical harmonic oscillator extend significantly beyond classically allowed regions, so an oscillator can tunnel into a region of space in which another oscillator may be found.

### (c) Experimental results

It is difficult to measure the distance dependence of  $k_{et}$  when the reactants are ions or molecules that are free to move in solution. In such cases, electron transfer occurs after a donor-acceptor complex forms and it is not possible to exert control over  $r$ , the edge-to-edge distance. The most meaningful experimental tests of the dependence of  $k_{et}$  on  $r$  are those in which the same donor and acceptor are positioned at a variety of distances, perhaps by covalent attachment to molecular linkers (1, for example). Under these conditions, the term  $e^{-\Delta^\ddagger G/RT}$  is a constant and, after taking the natural logarithm of eqn 22.60, we obtain

$$\ln k_{\text{et}} = -\beta r + \text{constant}$$

Distance dependence  
of the rate constant  
of electron transfer

(22.63)

This expression implies that a plot of  $\ln k_{\text{et}}$  against  $r$  should be a straight line with slope  $-\beta$ .

The dependence of  $k_{\text{et}}$  on the standard reaction Gibbs energy has been investigated in systems where the edge-to-edge distance, the reorganization energy, and  $\kappa\nu^\ddagger$  are constant for a series of reactions. Then eqn 22.62 may be written after taking logarithms of both sides and using eqn 22.61 as

$$\ln k_{\text{et}} = -\frac{RT}{4\lambda} \left( \frac{\Delta_r G^\ominus}{RT} \right)^2 - \frac{1}{2} \left( \frac{\Delta_r G^\ominus}{RT} \right) + \text{constant}$$

Dependence of the rate  
constant of electron  
transfer on the reaction  
Gibbs energy

(22.64)

This expression implies that a plot of  $\ln k_{\text{et}}$  (or  $\log k_{\text{et}}$ ) against  $\Delta_r G^\ominus$  (or  $-\Delta_r G^\ominus$ ) should be shaped like a downward parabola. It also indicates that the rate constant increases as  $\Delta_r G^\ominus$  decreases but only up to the stage when  $-\Delta_r G^\ominus = \lambda$ . Beyond that, the reaction enters the **inverted region**, in which the rate constant decreases as the reaction becomes more exergonic ( $\Delta_r G^\ominus$  becomes more negative). The inverted region has been observed in a series of special compounds in which the electron donor and acceptor are linked covalently to a molecular spacer of known and fixed size (Fig. 22.30).

## 22.10 Electron transfer processes at electrodes

**Key points** (a) An electrical double layer consists of sheets of opposite charge at the surface of the electrode and next to it in the solution. Models of the double layer include the Helmholtz layer model and the Gouy–Chapman model. The Galvani potential difference is the potential difference between the bulk of the metal electrode and the bulk of the solution. (b) The current density at an electrode is expressed by the Butler–Volmer equation. (c) To induce current to flow through an electrolytic cell and bring about a nonspontaneous cell reaction, the applied potential difference must exceed the cell potential by at least the cell overpotential. (d) In working galvanic cells the overpotential leads to a smaller potential than under zero-current conditions and the cell potential decreases as current is generated.

As for homogeneous systems (Section 22.9), electron transfer at the surface of an electrode involves electron tunnelling. However, the electrode possesses a nearly infinite number of closely spaced electronic energy levels rather than the small number of discrete levels of a typical complex. Furthermore, specific interactions with the electrode surface give the solute and solvent special properties that can be very different from those observed in the bulk of the solution. For this reason, we begin with a description of the electrode–solution interface. Then, we describe the kinetics of electrode processes by using a largely phenomenological (rather than strictly theoretical) approach that draws on the thermodynamic language inspired by transition state theory.

### (a) The electrode–solution interface

The most primitive model of the boundary between the solid and liquid phases is as an **electrical double layer**, which consists of a sheet of positive charge at the surface of the electrode and a sheet of negative charge next to it in the solution (or vice versa). We shall see that this arrangement creates an electrical potential difference, called the **Galvani potential difference**, between the bulk of the metal electrode and the bulk of the solution.

**Fig. 22.30** Variation of  $\log k_{\text{et}}$  with  $-\Delta_r G^\ominus$  for a series of compounds with the structures given in (1). Kinetic measurements were conducted in 2-methyltetrahydrofuran and at 296 K. The distance between donor (the reduced biphenyl group) and the acceptor is constant for all compounds in the series because the molecular linker remains the same. Each acceptor has a characteristic standard reduction potential, so it follows that the standard Gibbs energy for the electron transfer process is different for each compound in the series. The line is a fit to a version of eqn 22.64 and the maximum of the parabola occurs at  $-\Delta_r G^\ominus = \lambda = 1.2 \text{ eV} = 1.2 \times 10^2 \text{ kJ mol}^{-1}$ . (Reproduced with permission from J.R. Miller *et al.*, *J. Am. Chem. Soc.* **106**, 3047 (1984).)

**Fig. 22.31** A simple model of the electrode–solution interface treats it as two rigid planes of charge. One plane, the outer Helmholtz plane (OHP), is due to the ions with their solvating molecules and the other plane is that of the electrode itself. The plot shows the dependence of the electric potential with distance from the electrode surface according to this model. Between the electrode surface and the OHP, the potential varies linearly from  $\phi_M$ , the value in the metal, to  $\phi_S$ , the value in the bulk of the solution.

More sophisticated models for the electrode–solution interface attempt to describe the gradual changes in the structure of the solution between two extremes, one the charged electrode surface and the other the bulk solution. In the **Helmholtz layer model** of the interface the solvated ions arrange themselves along the surface of the electrode but are held away from it by their hydration spheres (Fig. 22.31). The location of the sheet of ionic charge, which is called the **outer Helmholtz plane** (OHP), is identified as the plane running through the solvated ions. In this simple model, the electrical potential changes linearly within the layer bounded by the electrode surface on one side and the OHP on the other. In a refinement of this model, ions that have discarded their solvating molecules and have become attached to the electrode surface by chemical bonds are regarded as forming the **inner Helmholtz plane** (IHP). The Helmholtz layer model ignores the disrupting effect of thermal motion, which tends to break up and disperse the rigid outer plane of charge. In the **Gouy–Chapman model** of the **diffuse double layer**, the disordering effect of thermal motion is taken into account in much the same way as the Debye–Hückel model describes the ionic atmosphere of an ion (Section 5.13) with the latter’s single central ion replaced by an infinite, plane electrode.

Figure 22.32 shows how the local concentrations of cations and anions differ in the Gouy–Chapman model from their bulk concentrations. Ions of opposite charge cluster close to the electrode and ions of the same charge are repelled from it. The modification of the local concentrations near an electrode implies that it might be misleading to use activity coefficients characteristic of the bulk to discuss the thermodynamic properties of ions near the interface. This is one of the reasons why measurements of the dynamics of electrode processes are almost always done using a large excess of supporting electrolyte (for example, a 1 M solution of a salt, an acid, or a base). Under such conditions, the activity coefficients are almost constant because the inert ions dominate the effects of local changes caused by any reactions taking place.

Neither the Helmholtz nor the Gouy–Chapman model is a very good representation of the structure of the double layer. The former overemphasizes the rigidity of the local solution; the latter underemphasizes its structure. The two are combined in the **Stern model**, in which the ions closest to the electrode are constrained into a rigid Helmholtz plane while outside that plane the ions are dispersed as in the Gouy–Chapman model (Fig. 22.33). Yet another level of sophistication is found in the **Grahame model**, which adds an inner Helmholtz plane to the Stern model.

The potential difference between points in the bulk metal and the bulk solution is the **Galvani potential difference**,  $\Delta\phi$ . Apart from a constant, this Galvani potential difference is the electrode potential that was discussed in Chapter 6. We shall ignore the constant, which cannot be measured anyway, and identify changes in  $\Delta\phi$  with changes in electrode potential.

### (b) The Butler–Volmer equation

We shall consider a reaction at the electrode in which an ion is reduced by the transfer of a single electron in the rate-determining step. The quantity we focus on is the **current density**,  $j$ , the electric current flowing through a region of an electrode divided by the area of the region. We show in *Further information 22.2* that an analysis of the effect of the Galvani potential difference at the electrode on the current density leads to the **Butler–Volmer equation**:

$$j = j_0 \{ e^{(1-\alpha)f\eta} - e^{-\alpha f\eta} \} \quad \text{Butler–Volmer equation} \quad (22.65)$$

**Fig. 22.32** The Gouy–Chapman model of the electrical double layer treats the outer region as an atmosphere of counter-charge, similar to the Debye–Hückel theory of ion atmospheres. The plot of electrical potential against distance from the electrode surface shows the meaning of the diffuse double layer (see text for details).

**Fig. 22.33** A representation of the Stern model of the electrode–solution interface. The model incorporates the idea of an outer Helmholtz plane near the electrode surface and of a diffuse double layer further away from the surface.

where we have written  $f = F/RT$ , with  $F$  as Faraday's constant. The quantity  $\eta$  (eta) is the **overpotential**:

$$\eta = E' - E$$

Definition of the overpotential

[22.66]

where  $E$  is the electrode potential at equilibrium (when there is no net flow of current), and  $E'$  is the electrode potential when a current is being drawn from the cell. The quantity  $\alpha$  is the **transfer coefficient**, and is an indication of whether the transition state between the reduced and oxidized forms of the electroactive species in solution is reactant-like ( $\alpha = 0$ ) or product-like ( $\alpha = 1$ ). The quantity  $j_0$  is the **exchange-current density**, the magnitude of the equal but opposite current densities when the electrode is at equilibrium. Figure 22.34 shows how eqn 22.65 predicts the current density to depend on the overpotential for different values of the transfer coefficient.

When the overpotential is so small that  $f\eta \ll 1$  (in practice,  $\eta$  less than about 0.01 V) the exponentials in eqn 22.65 can be expanded by using  $e^x = 1 + x + \dots$  to give

$$j = j_0 \{1 + (1 - \alpha)f\eta + \dots - (1 - \alpha f\eta + \dots)\} \approx j_0 f\eta \quad (22.67)$$

This equation shows that the current density is proportional to the overpotential, so at low overpotentials the interface behaves like a conductor that obeys Ohm's law. When there is a small positive overpotential the current is anodic ( $j > 0$  when  $\eta > 0$ ), and when the overpotential is small and negative the current is cathodic ( $j < 0$  when

**Fig. 22.34** The dependence of the current density on the overpotential for different values of the transfer coefficient.

$\eta < 0$ ). The relation can also be reversed to calculate the potential difference that must exist if a current density  $j$  has been established by some external circuit:

$$\eta = \frac{RTj}{Fj_0} \quad (22.68)$$

The importance of this interpretation will become clear below.

#### • A brief illustration

The exchange current density of a  $\text{Pt(s)}|\text{H}_2(\text{g})|\text{H}^+(\text{aq})$  electrode at 298 K is  $0.79 \text{ mA cm}^{-2}$ . Therefore, the current density when the overpotential is +5.0 mV is obtained by using eqn 22.67 and  $f = F/RT = 1/(25.69 \text{ mV})$ :

$$j = j_0 f \eta = \frac{(0.79 \text{ mA cm}^{-2}) \times (5.0 \text{ mV})}{25.69 \text{ mV}} = 0.15 \text{ mA cm}^{-2}$$

The current through an electrode of total area  $5.0 \text{ cm}^2$  is therefore 0.75 mA. •

**Self-test 22.4** What would be the current at  $\text{pH} = 2.0$ , the other conditions being the same? [−18 mA (cathodic)]

When the overpotential is large and positive (in practice,  $\eta \geq 0.12 \text{ V}$ ), corresponding to the electrode being the anode in electrolysis, the second exponential in eqn 22.65 is much smaller than the first, and may be neglected. Then

$$j = j_0 e^{(1-\alpha)f\eta} \quad (22.69)$$

so

$$\ln j = \ln j_0 + (1 - \alpha)f\eta \quad (22.70)$$

When the overpotential is large but negative (in practice,  $\eta < -0.12 \text{ V}$ ), corresponding to the cathode in electrolysis, the first exponential in eqn 22.65 may be neglected. Then

$$j = -j_0 e^{-\alpha f\eta} \quad (22.71)$$

so

$$\ln(-j) = \ln j_0 - \alpha f\eta \quad (22.72)$$

Some experimental values for the Butler–Volmer parameters are given in Table 22.3. From them we can see that exchange current densities vary over a very wide range. Exchange currents are generally large when the redox process involves no bond breaking (as in the  $[\text{Fe}(\text{CN})_6]^{3-}$ ,  $[\text{Fe}(\text{CN})_6]^{4-}$  couple) or if only weak bonds are broken

**Table 22.3\*** Exchange current densities and transfer coefficients at 298 K

| Reaction                                                 | Electrode | $j_0/(\text{A cm}^{-2})$ | $\alpha$ |
|----------------------------------------------------------|-----------|--------------------------|----------|
| $2 \text{ H}^+ + 2 \text{ e}^- \rightarrow \text{H}_2$   | Pt        | $7.9 \times 10^{-4}$     | 0.58     |
|                                                          | Ni        | $6.3 \times 10^{-6}$     |          |
|                                                          | Pb        | $5.0 \times 10^{-12}$    |          |
| $\text{Fe}^{3+} + \text{e}^- \rightarrow \text{Fe}^{2+}$ | Pt        | $2.5 \times 10^{-3}$     | 0.58     |

\* More values are given in the Data section.

(as in  $\text{Cl}_2$ ,  $\text{Cl}^-$ ). They are generally small when more than one electron needs to be transferred, or when multiple or strong bonds are broken, as in the  $\text{N}_2$ ,  $\text{N}_3^-$  couple and in redox reactions of organic compounds.

### (c) Electrolysis

To induce current to flow through an electrolytic cell and bring about a nonspontaneous cell reaction, the applied potential difference must exceed the zero-current potential by at least the **cell overpotential**, the sum of the overpotentials at the two electrodes and the ohmic drop ( $IR_s$ , where  $R_s$  is the internal resistance of the cell) due to the current through the electrolyte. The additional potential needed to achieve a detectable rate of reaction may need to be large when the exchange current density at the electrodes is small. For similar reasons, a working galvanic cell generates a smaller potential than under zero-current conditions. In this section we see how to cope with both aspects of the overpotential.

The relative rates of gas evolution or metal deposition during electrolysis can be estimated from the Butler–Volmer equation and tables of exchange current densities. From eqn 22.71 and assuming equal transfer coefficients, we write the ratio of the cathodic currents as

$$\frac{j'}{j} = \frac{j'_0}{j_0} e^{(\eta - \eta')\alpha f} \quad (22.73)$$

where  $j'$  is the current density for electrodeposition and  $j$  is that for gas evolution, and  $j'_0$  and  $j_0$  are the corresponding exchange current densities. This equation shows that metal deposition is favoured by a large exchange current density and relatively high gas evolution overpotential (so  $\eta - \eta'$  is positive and large). Note that  $\eta < 0$  for a cathodic process, so  $-\eta' > 0$ . The exchange current density depends strongly on the nature of the electrode surface, and changes in the course of the electrodeposition of one metal on another. A very crude criterion is that significant evolution or deposition occurs only if the overpotential exceeds about 0.6 V.

A glance at Table 22.3 shows the wide range of exchange current densities for a metal/hydrogen electrode. The most sluggish exchange currents occur for lead and mercury, and the value of  $1 \text{ pA cm}^{-2}$  corresponds to a monolayer of atoms being replaced in about 5 years. For such systems, a high overpotential is needed to induce significant hydrogen evolution. In contrast, the value for platinum ( $1 \text{ mA cm}^{-2}$ ) corresponds to a monolayer being replaced in 0.1 s, so gas evolution occurs for a much lower overpotential.

The exchange current density also depends on the crystal face exposed. For the deposition of copper on copper, the (100) face has  $j_0 = 1 \text{ mA cm}^{-2}$ , so for the same overpotential the (100) face grows at 2.5 times the rate of the (111) face, for which  $j_0 = 0.4 \text{ mA cm}^{-2}$ .

### (d) Working galvanic cells

In working galvanic cells (those not balanced against an external potential), the overpotential results in a smaller generated potential than under zero-current conditions. Furthermore, we expect the cell potential to decrease as current is generated because it is then no longer working reversibly and can therefore do less than maximum work.

We shall consider the cell  $\text{M}|\text{M}^+(\text{aq})||\text{M}'^+(\text{aq})|\text{M}'$  and ignore all the complications arising from liquid junctions. The potential of the cell is  $E' = \Delta\phi_R - \Delta\phi_L$ . Because the cell potential differences differ from their zero-current values by overpotentials, we can write  $\Delta\phi_X = E_X + \eta_X$  where X is L or R for the left or right electrode, respectively. The cell potential is therefore

$$E' = E + \eta_R - \eta_L \quad (22.74a)$$

To avoid confusion about signs ( $\eta_R$  is negative;  $\eta_L$  is positive) and to emphasize that a working cell has a lower potential than a zero-current cell, we shall write this expression as

$$E' = E - |\eta_R| - |\eta_L| \quad (22.74b)$$

with  $E$  the cell potential. We should also subtract the ohmic potential difference  $IR_s$ , where  $R_s$  is the cell's internal resistance:

$$E' = E - |\eta_R| - |\eta_L| - IR_s \quad (22.74c)$$

The ohmic term is a contribution to the cell's irreversibility—it is a thermal dissipation term—so the sign of  $IR_s$  is always such as to reduce the potential in the direction of zero.

The overpotentials in eqn 22.74 can be calculated from the Butler–Volmer equation for a given current,  $I$ , being drawn. We shall simplify the equations by supposing that the areas,  $A$ , of the electrodes are the same, that only one electron is transferred in the rate-determining steps at the electrodes, that the transfer coefficients are both  $\frac{1}{2}$ , and that the high-overpotential limit of the Butler–Volmer equation may be used. Then from eqns 22.71 and 22.74c we find

$$E' = E - IR_s - \frac{4RT}{F} \ln \left( \frac{I}{A\bar{j}} \right) \quad \bar{j} = (j_{0L}j_{0R})^{1/2} \quad (22.75)$$

where  $j_{0L}$  and  $j_{0R}$  are the exchange current densities for the two electrodes.

#### • A brief illustration

Suppose that a cell consists of two electrodes each of area  $10 \text{ cm}^2$  with exchange current densities  $5 \mu\text{A cm}^{-2}$  and has internal resistance  $10 \Omega$ . At  $298 \text{ K}$   $RT/F = 25.7 \text{ mV}$ . The zero-current cell potential is  $1.5 \text{ V}$ . If the cell is producing a current of  $10 \text{ mA}$ , its working potential will be

$$E' = 1.5 \text{ V} - \overbrace{(10 \text{ mA}) \times (10 \Omega)}^{0.10 \text{ V}} - \overbrace{4(25.7 \text{ mV}) \ln \left( \frac{10 \text{ mA}}{(10 \text{ cm}^2) \times (5 \mu\text{A cm}^{-2})} \right)}^{0.54 \text{ V}} = 0.9 \text{ V}$$

We have used  $1 \text{ A } \Omega = 1 \text{ V}$ . Note that we have ignored various other factors that reduce the cell potential, such as the inability of reactants to diffuse rapidly enough to the electrodes. •

Electric storage cells operate as galvanic cells while they are producing electricity but as electrolytic cells while they are being charged by an external supply. The lead–acid battery is an old device, but one well suited to the job of starting cars (and the only one available). During charging the cathode reaction is the reduction of  $\text{Pb}^{2+}$  and its deposition as lead on the lead electrode. Deposition occurs instead of the reduction of the acid to hydrogen because the latter has a low exchange current density on lead. The anode reaction during charging is the oxidation of  $\text{Pb(II)}$  to  $\text{Pb(IV)}$ , which is deposited as the oxide  $\text{PbO}_2$ . On discharge, the two reactions run in reverse. Because they have such high exchange current densities the discharge can occur rapidly, which is why the lead battery can produce large currents on demand.

## IMPACT ON TECHNOLOGY

## I22.1 Fuel cells

A fuel cell operates like a conventional galvanic cell with the exception that the reactants are supplied from outside rather than forming an integral part of its construction. A fundamental and important example of a fuel cell is the hydrogen/oxygen cell, such as the ones used in space missions (Fig. 22.35). One of the electrolytes used is concentrated aqueous potassium hydroxide maintained at 200°C and 20–40 atm; the electrodes may be porous nickel in the form of sheets of compressed powder. The cathode reaction is the reduction

and the anode reaction is the oxidation

For the corresponding reduction,  $E^\ominus = -0.83 \text{ V}$ . Because the overall reaction

is exothermic as well as spontaneous, it is less favourable thermodynamically at 200°C than at 25°C, so the cell potential is lower at the higher temperature. However, the increased pressure compensates for the increased temperature, and  $E \approx +1.2 \text{ V}$  at 200°C and 40 atm.

One advantage of the hydrogen/oxygen system is the large exchange current density of the hydrogen reaction. Unfortunately, the oxygen reaction has an exchange current density of only about  $0.1 \text{ nA cm}^{-2}$ , which limits the current available from the cell. One way round the difficulty is to use a catalytic surface (to increase  $j_0$ ) with a large surface area. One type of highly developed fuel cell has phosphoric acid as the electrolyte and operates with hydrogen and air at about 200°C; the hydrogen is obtained from a reforming reaction on natural gas:

This fuel cell has shown promise for *combined heat and power systems* (CHP systems). In such systems, the waste heat is used to heat buildings or to do work. Efficiency in a CHP plant can reach 80 per cent. The power output of batteries of such cells has reached the order of 10 MW. Although hydrogen gas is an attractive fuel, it has disadvantages for mobile applications: it is difficult to store and dangerous to handle. One possibility for portable fuel cells is to store the hydrogen in carbon nanotubes. It has been shown that carbon nanofibres in herringbone patterns can store huge amounts of hydrogen and result in an energy density (the magnitude of the released energy divided by the volume of the material) twice that of gasoline.

Cells with molten carbonate electrolytes at about 600°C can make use of natural gas directly. Solid-state electrolytes are also used. They include one version in which the electrolyte is a solid polymeric ionic conductor at about 100°C, but in current versions it requires very pure hydrogen to operate successfully. Solid ionic conducting oxide cells operate at about 1000°C and can use hydrocarbons directly as fuel. Until these materials have been developed, one attractive fuel is methanol, which is easy to handle and is rich in hydrogen atoms:

Fig. 22.35 A single cell of a hydrogen/oxygen fuel cell. In practice, a stack of many cells is used.

One disadvantage of methanol, however, is the phenomenon of ‘electro-osmotic drag’ in which protons moving through the polymer electrolyte membrane separating the anode and cathode carry water and methanol with them into the cathode compartment where the potential is sufficient to oxidize  $\text{CH}_3\text{OH}$  to  $\text{CO}_2$ , so reducing the efficiency of the cell.

## Checklist of key equations

| Property                                                     | Equation                                                                                                                          | Comment          |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|------------------|
| Rate constant of a gas-phase bimolecular elementary reaction | $k_r = P\sigma(8kT/\pi\mu)^{1/2}N_A e^{-E_d/RT}$                                                                                  | Collision theory |
| Steric factor for a unimolecular reaction                    | $P = (1 - (E^*/E))^s$                                                                                                             | RRK model        |
| Rate constant of a diffusion-controlled reaction             | $k_d = 4\pi R^*DN_A = 8RT/3\eta$                                                                                                  |                  |
| Material balance equation                                    | $\partial[J]/\partial t = D\partial^2[J]/\partial x^2 - v\partial[J]/\partial x - k_r[J]$                                         |                  |
| Eyring equation                                              | $k_r = \kappa(kT/h)\tilde{K}_C^\ddagger$<br>$k_r = e^2 B e^{\Delta^\ddagger S/R} e^{-E_d/RT}$                                     |                  |
| Kinetic salt effect                                          | $\log k_r = \log k_r^\circ + 2A z_A z_B I^{1/2}$                                                                                  |                  |
| State-to-state rate constant                                 | $k_{mm'} = \langle \sigma_{mm'} v_{\text{rel}} \rangle N_A$                                                                       |                  |
| Rate constant in terms of the cumulative                     | $k_r(T) = \left( \int_0^\infty \mathcal{P}(E) e^{-E/kT} dE \right) / h Q_R(T)$                                                    |                  |
| reaction probability                                         | $\mathcal{P}(E) = \sum_{i,j} P_{ij}(E)$                                                                                           |                  |
| Rate constant of electron transfer in homogeneous systems    | $k_{\text{et}} \propto e^{-\beta r} e^{-\Delta^\ddagger G/RT}$<br>$\Delta^\ddagger G = (\Delta_r G^\circ + \lambda)^2 / 4\lambda$ | Marcus theory    |

## Further information

### Further information 22.1 The Gibbs energy of activation of electron transfer

The simplest way to derive an expression for the Gibbs energy of activation of electron transfer processes is to construct a model in which the surfaces for DA (the ‘reactant complex’, denoted R) and for  $\text{D}^+\text{A}^-$  (the ‘product complex’, denoted P) are described by classical harmonic oscillators with identical effective masses  $\mu$  and angular frequencies  $\omega$ , but displaced minima, as shown in Fig. 22.28. The molar Gibbs energies  $G_{\text{m,R}}(q)$  and  $G_{\text{m,P}}(q)$  of the reactant and product complexes, respectively, may be written as

$$G_{\text{m,R}}(q) = \frac{1}{2} N_A \mu \omega^2 (q - q_0^{\text{R}})^2 + G_{\text{m,R}}(q_0^{\text{R}}) \quad (22.76a)$$

$$G_{\text{m,P}}(q) = \frac{1}{2} N_A \mu \omega^2 (q - q_0^{\text{P}})^2 + G_{\text{m,P}}(q_0^{\text{P}}) \quad (22.76b)$$

where  $q_0^{\text{R}}$  and  $q_0^{\text{P}}$  are the values of  $q$  at which the minima of the reactant and product parabolas occur, respectively. The standard reaction Gibbs energy for the electron transfer process  $\text{DA} \rightarrow \text{D}^+\text{A}^-$  is  $\Delta_r G^\circ = G_{\text{m,P}}(q_0^{\text{P}}) - G_{\text{m,R}}(q_0^{\text{R}})$ , the difference in standard molar Gibbs energy between the minima of the parabolas. In Fig. 22.28,  $\Delta_r G^\circ < 0$ .

We also note that  $q^*$ , the value of  $q$  corresponding to the transition state of the complex, may be written in terms of the parameter  $\alpha$ , the fractional change in  $q$ :

$$q^* = q_0^{\text{R}} + \alpha(q_0^{\text{P}} - q_0^{\text{R}}) \quad (22.77)$$

We see from Fig. 22.28 that  $\Delta^\ddagger G = G_{\text{m,R}}(q^*) - G_{\text{m,R}}(q_0^{\text{R}})$ . It then follows from eqns 22.76a, 22.76b, and 22.77 that

$$\Delta^\ddagger G = \frac{1}{2} N_A \mu \omega^2 (q^* - q_0^{\text{R}})^2 = \frac{1}{2} N_A \mu \omega^2 \{ \alpha(q_0^{\text{P}} - q_0^{\text{R}}) \}^2 \quad (22.78)$$

We now define the reorganization energy,  $\lambda$ , as

$$\lambda = \frac{1}{2} N_A \mu \omega^2 (q_0^P - q_0^R)^2 \quad (22.79)$$

which can be interpreted as  $G_{m,R}(q_0^P) - G_{m,R}(q_0^R)$  and, consequently, as the (Gibbs) energy required to deform the equilibrium configuration of DA to the equilibrium configuration of  $D^+A^-$  (as shown in Fig. 22.28). It follows from eqns 22.78 and 22.79 that

$$\Delta^\ddagger G = \alpha^2 \lambda \quad (22.80)$$

Because  $G_{m,R}(q^*) = G_{m,P}(q^*)$ , it follows from eqns 22.76b, 22.77, 22.79, and 22.80 that

$$\begin{aligned} \alpha^2 \lambda &= \frac{1}{2} N_A \mu \omega^2 \{(\alpha - 1)(q_0^P - q_0^R)\}^2 + \Delta_r G^\circ \\ &= (\alpha - 1)^2 \lambda + \Delta_r G^\circ \end{aligned} \quad (22.81)$$

which implies that

$$\alpha = \frac{1}{2} \left( \frac{\Delta_r G^\circ}{\lambda} + 1 \right) \quad (22.82)$$

By combining eqns 22.80 and 22.82, we obtain eqn 22.61. We can obtain an identical relation if we allow the harmonic oscillators to have different angular frequencies and hence different curvatures.

### Further information 22.2 The Butler–Volmer equation

Because an electrode reaction is heterogeneous, we express the rate of charge transfer as the flux of products, the amount of material produced over a region of the electrode surface in an interval of time divided by the area of the region and the duration of the interval.

A first-order heterogeneous rate law has the form

$$\text{Product flux} = k_r [\text{species}] \quad (22.83)$$

where [species] is the molar concentration of the relevant species in solution close to the electrode, just outside the double layer. The rate constant has dimensions of length/time (with units, for example, of centimetres per second,  $\text{cm s}^{-1}$ ). If the molar concentrations of the oxidized and reduced materials outside the double layer are [Ox] and [Red], respectively, then the rate of reduction of Ox,  $v_{\text{Ox}}$ , is

$$v_{\text{Ox}} = k_c [\text{Ox}] \quad (22.84a)$$

and the rate of oxidation of Red,  $v_{\text{Red}}$ , is

$$v_{\text{Red}} = k_a [\text{Red}] \quad (22.84b)$$

(The notation  $k_c$  and  $k_a$  is justified below.)

Consider a reaction at the electrode in which an ion is reduced by the transfer of a single electron in the rate-determining step. The net current density at the electrode is the difference between the current densities arising from the reduction of Ox and the oxidation of Red. Because the redox processes at the electrode involve the transfer of one electron per reaction event, the current densities,  $j$ , arising from the redox processes are the rates (as expressed above) multiplied by the charge transferred per mole of reaction, which is given by Faraday's constant. Therefore, there is a **cathodic current density** of magnitude

$$j_c = Fk_c [\text{Ox}] \quad \text{for} \quad \text{Ox} + e^- \rightarrow \text{Red} \quad \text{Cathodic current density} \quad (22.85a)$$

arising from the reduction (because, as we saw in Chapter 6, the cathode is the site of reduction). There is also an opposing **anodic current density** of magnitude

$$j_a = Fk_a [\text{Red}] \quad \text{for} \quad \text{Red} \rightarrow \text{Ox} + e^- \quad \text{Anodic current density} \quad (22.85b)$$

arising from the oxidation (because the anode is the site of oxidation). The net current density at the electrode is the difference

$$j = j_a - j_c = Fk_a [\text{Red}] - Fk_c [\text{Ox}] \quad \text{Net current density} \quad (22.85c)$$

Note that, when  $j_a > j_c$ , so that  $j > 0$ , the current is anodic (Fig. 22.36a); when  $j_c > j_a$ , so that  $j < 0$ , the current is cathodic (Fig. 22.36b).

**Fig. 22.36** The net current density is defined as the difference between the cathodic and anodic contributions. (a) When  $j_a > j_c$ , the net current is anodic, and there is a net oxidation of the species in solution. (b) When  $j_c > j_a$ , the net current is cathodic, and the net process is reduction.

If a species is to participate in reduction or oxidation at an electrode, it must discard any solvating molecules, migrate through the electrode–solution interface, and adjust its hydration sphere as it receives or discards electrons. Likewise, a species already at the inner plane must be detached and migrate into the bulk. Because both processes are activated, we can expect to write their rate constants in the form suggested by transition state theory (Section 22.5) as

$$k_r = B e^{-\Delta^\ddagger G/RT} \quad (22.86)$$

where  $\Delta^\ddagger G$  is the activation Gibbs energy and  $B$  is a constant with the same dimensions as  $k_r$ .

When eqn 22.86 is inserted into eqn 22.85c we obtain

$$j = Fk_a [\text{Red}] e^{-\Delta^\ddagger G_a/RT} - Fk_c [\text{Ox}] e^{-\Delta^\ddagger G_c/RT} \quad (22.87)$$

This expression allows the activation Gibbs energies to be different for the cathodic and anodic processes. That they are different is the central feature of the remaining discussion.

Next, we relate  $j$  to the Galvani potential difference, which varies across the electrode–solution interface as shown schematically in Fig. 22.37. Consider the reduction reaction,  $\text{Ox} + e^- \rightarrow \text{Red}$ , and the corresponding reaction profile. If the transition state of the activated

**Fig. 22.37** The potential,  $\phi$ , varies linearly between two plane parallel sheets of charge, and its effect on the Gibbs energy of the transition state depends on the extent to which the latter resembles the species at the inner or outer planes.

**Fig. 22.38** When the transition state resembles a species that has undergone reduction, the activation Gibbs energy for the anodic current is almost unchanged, but the full effect applies to the cathodic current. (a) Zero potential difference; (b) nonzero potential difference.

complex is product-like (as represented by the peak of the reaction profile being close to the electrode in Fig. 22.38), the activation Gibbs energy is changed from  $\Delta^\ddagger G_c(0)$ , the value it has in the absence of a potential difference across the double layer, to

$$\Delta^\ddagger G_c = \Delta^\ddagger G_c(0) + F\Delta\phi \quad (22.88a)$$

**Fig. 22.39** When the transition state resembles a species that has undergone oxidation, the activation Gibbs energy for the cathodic current is almost unchanged but the activation Gibbs energy for the anodic current is strongly affected. (a) Zero potential difference; (b) nonzero potential difference.

Thus, if the electrode is more positive than the solution,  $\Delta\phi > 0$ , then more work has to be done to form an activated complex from Ox; in this case the activation Gibbs energy is increased. If the transition state is reactant-like (represented by the peak of the reaction profile being close to the outer plane of the double-layer in Fig. 22.39), then  $\Delta^\ddagger G_c$  is independent of  $\Delta\phi$ . In a real system, the transition state has an intermediate resemblance to these extremes (Fig. 22.40) and the activation Gibbs energy for reduction may be written as

$$\Delta^\ddagger G_c = \Delta^\ddagger G_c(0) + \alpha F\Delta\phi \quad (22.88b)$$

The parameter  $\alpha$  lies in the range 0 to 1. Experimentally,  $\alpha$  is often found to be about 0.5.

Now consider the oxidation reaction,  $\text{Red} + e^- \rightarrow \text{Ox}$  and its reaction profile. Similar remarks apply. In this case, Red discards an electron to the electrode, so the extra work is zero if the transition state is reactant-like (represented by a peak close to the electrode). The extra work is the full  $-F\Delta\phi$  if it resembles the product (the peak close to the outer plane). In general, the activation Gibbs energy for this anodic process is

$$\Delta^\ddagger G_a = \Delta^\ddagger G_a(0) - (1 - \alpha)F\Delta\phi \quad (22.89)$$

The two activation Gibbs energies can now be inserted in place of the values used in eqn 22.87 with the result that

$$j = F B_a [\text{Red}] e^{-\Delta^\ddagger G_a(0)/RT} e^{(1-\alpha)F\Delta\phi/RT} - F B_c [\text{Ox}] e^{-\Delta^\ddagger G_c(0)/RT} e^{-\alpha F\Delta\phi/RT} \quad (22.90)$$

**Fig. 22.40** When the transition state is intermediate in its resemblance to reduced and oxidized species, as represented here by a peak located at an intermediate position as measured by  $\alpha$  (with  $0 < \alpha < 1$ ), both activation Gibbs energies are affected; here,  $\alpha \approx 0.5$ . (a) Zero potential difference; (b) nonzero potential difference.

This is an explicit, if complicated, expression for the net current density in terms of the potential difference.

The appearance of eqn 22.90 can be simplified. First, in a purely cosmetic step we write  $f = F/RT$ . Next, we identify the individual cathodic and anodic current densities:

$$\left. \begin{aligned} j_a &= FB_a[\text{Red}]e^{-\Delta^\ddagger G_a(0)/RT}e^{(1-\alpha)f\Delta\phi} \\ j_c &= FB_c[\text{Ox}]e^{-\Delta^\ddagger G_c(0)/RT}e^{-\alpha f\Delta\phi} \end{aligned} \right\} j = j_a - j_c \quad (22.91)$$

If the cell is balanced against an external source, the Galvani potential difference,  $\Delta\phi$ , can be identified as the (zero-current) electrode potential,  $E$ , and we can write

$$\left. \begin{aligned} j_a &= FB_a[\text{Red}]e^{-\Delta^\ddagger G_a(0)/RT}e^{(1-\alpha)fE} \\ j_c &= FB_c[\text{Ox}]e^{-\Delta^\ddagger G_c(0)/RT}e^{-\alpha fE} \end{aligned} \right\} \quad (22.92)$$

When these equations apply, there is no net current at the electrode (as the cell is balanced), so the two current densities must be equal.

From now on we denote them both as  $j_0$ .

When the cell is producing current (that is, when a load is connected between the electrode being studied and a second counter electrode) the electrode potential changes from its zero-current value,  $E$ , to a new value,  $E'$ , and the difference is the electrode's overpotential,  $\eta = E' - E$ . Hence,  $\Delta\phi$  changes to  $\Delta\phi = E + \eta$  and the two current densities become

$$j_a = j_0 e^{(1-\alpha)f\eta} \quad j_c = j_0 e^{-\alpha f\eta} \quad (22.93)$$

Then from eqn 22.90 we obtain the Butler–Volmer equation, eqn 22.65.

## Discussion questions

**22.1** Describe the essential features of the harpoon mechanism.

**22.2** In what senses are diffusion-controlled reactions and activation-controlled reactions activated processes?

**22.3** Discuss critically the formulation of the Eyring equation.

**22.4** What quantum mechanical effects play a role in molecular collisions?

**22.5** Discuss the physical origin of the kinetic salt effect.

**22.6** Describe how the shape of a potential energy surface governs the efficiencies of reactive collisions and the role of molecular vibration.

**22.7** Describe how the distance between electron donor and acceptor, and the reorganization energy of redox active species and the surrounding medium determine the rate of electron transfer in homogeneous systems.

**22.8** In what sense is electron transfer at an electrode an activated process?

## Exercises

**22.1(a)** Calculate the collision frequency,  $z$ , and the collision density,  $Z$ , in ammonia,  $R = 190$  pm, at  $25^\circ\text{C}$  and  $100$  kPa. What is the percentage increase when the temperature is raised by  $10$  K at constant volume?

**22.1(b)** Calculate the collision frequency,  $z$ , and the collision density,  $Z$ , in carbon monoxide,  $R = 180$  pm at  $25^\circ\text{C}$  and  $100$  kPa. What is the percentage increase when the temperature is raised by  $10$  K at constant volume?

**22.2(a)** Collision theory demands knowing the fraction of molecular collisions having at least the kinetic energy  $E_a$  along the line of flight. What is

this fraction when (a)  $E_a = 10$  kJ mol $^{-1}$ , (b)  $E_a = 100$  kJ mol $^{-1}$  at (i)  $300$  K and (ii)  $1000$  K?

**22.2(b)** Collision theory demands knowing the fraction of molecular collisions having at least the kinetic energy  $E_a$  along the line of flight. What is this fraction when (a)  $E_a = 15$  kJ mol $^{-1}$ , (b)  $E_a = 150$  kJ mol $^{-1}$  at (i)  $300$  K and (ii)  $800$  K?

**22.3(a)** Calculate the percentage increase in the fractions in Exercise 22.2a when the temperature is raised by  $10$  K.

**22.3(b)** Calculate the percentage increase in the fractions in Exercise 22.2b when the temperature is raised by 10 K.

**22.4(a)** Use the collision theory of gas-phase reactions to calculate the theoretical value of the second-order rate constant for the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightarrow 2 \text{HI}(\text{g})$  at 650 K, assuming that it is elementary bimolecular. The collision cross-section is  $0.36 \text{ nm}^2$ , the reduced mass is  $3.32 \times 10^{-27} \text{ kg}$ , and the activation energy is  $171 \text{ kJ mol}^{-1}$ .

**22.4(b)** Use the collision theory of gas-phase reactions to calculate the theoretical value of the second-order rate constant for the reaction  $\text{D}_2(\text{g}) + \text{Br}_2(\text{g}) \rightarrow 2 \text{DBr}(\text{g})$  at 450 K, assuming that it is elementary bimolecular. Take the collision cross-section as  $0.30 \text{ nm}^2$ , the reduced mass as  $3.930 m_{\text{u}}$ , and the activation energy as  $200 \text{ kJ mol}^{-1}$ .

**22.5(a)** In a certain collision, an energy equivalent to  $400 \text{ kJ mol}^{-1}$  is delivered; the energy needed to break a bond is  $350 \text{ kJ mol}^{-1}$ ; there are 5 relevant molecular modes. What is the value of the  $P$ -factor for the reactive encounter?

**22.5(b)** In a certain collision, an energy equivalent to  $300 \text{ kJ mol}^{-1}$  is delivered; the energy needed to break a bond is  $250 \text{ kJ mol}^{-1}$ ; there are 6 relevant molecular modes. What is the value of the  $P$ -factor for the reactive encounter?

**22.6(a)** A typical diffusion coefficient for small molecules in aqueous solution at  $25^\circ\text{C}$  is  $5 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ . If the critical reaction distance is  $0.4 \text{ nm}$ , what value is expected for the second-order rate constant for a diffusion-controlled reaction?

**22.6(b)** Suppose that the typical diffusion coefficient for a reactant in aqueous solution at  $25^\circ\text{C}$  is  $4.2 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ . If the critical reaction distance is  $0.50 \text{ nm}$ , what value is expected for the second-order rate constant for the diffusion-controlled reaction?

**22.7(a)** Calculate the magnitude of the diffusion-controlled rate constant at  $298 \text{ K}$  for a species in (a) water, (b) pentane. The viscosities are  $1.00 \times 10^{-3} \text{ kg m}^{-1} \text{ s}^{-1}$ , and  $2.2 \times 10^{-4} \text{ kg m}^{-1} \text{ s}^{-1}$ , respectively.

**22.7(b)** Calculate the magnitude of the diffusion-controlled rate constant at  $298 \text{ K}$  for a species in (a) decylbenzene, (b) concentrated sulfuric acid. The viscosities are  $3.36 \text{ cP}$  and  $27 \text{ cP}$ , respectively.

**22.8(a)** Calculate the magnitude of the diffusion-controlled rate constant at  $298 \text{ K}$  for the recombination of two atoms in water, for which  $\eta = 0.89 \text{ cP}$ . Assuming the concentration of the reacting species is  $1.0 \text{ mmol dm}^{-3}$  initially, how long does it take for the concentration of the atoms to fall to half that value? Assume the reaction is elementary.

**22.8(b)** Calculate the magnitude of the diffusion-controlled rate constant at  $298 \text{ K}$  for the recombination of two atoms in benzene, for which  $\eta = 0.601 \text{ cP}$ . Assuming the concentration of the reacting species is  $1.8 \text{ mmol dm}^{-3}$  initially, how long does it take for the concentration of the atoms to fall to half that value? Assume the reaction is elementary.

**22.9(a)** For the gaseous reaction  $\text{A} + \text{B} \rightarrow \text{P}$ , the reactive cross-section obtained from the experimental value of the pre-exponential factor is  $9.2 \times 10^{-22} \text{ m}^2$ . The collision cross-sections of A and B estimated from the transport properties are  $0.95$  and  $0.65 \text{ nm}^2$ , respectively. Calculate the  $P$ -factor for the reaction.

**22.9(b)** For the gaseous reaction  $\text{A} + \text{B} \rightarrow \text{P}$ , the reactive cross-section obtained from the experimental value of the pre-exponential factor is  $8.7 \times 10^{-22} \text{ m}^2$ . The collision cross-sections of A and B estimated from the transport properties are  $0.88$  and  $0.40 \text{ nm}^2$ , respectively. Calculate the  $P$ -factor for the reaction.

**22.10(a)** Two neutral species, A and B, with diameters  $588 \text{ pm}$  and  $1650 \text{ pm}$ , respectively, undergo the diffusion-controlled reaction  $\text{A} + \text{B} \rightarrow \text{P}$  in a solvent of viscosity  $2.37 \times 10^{-3} \text{ kg m}^{-1} \text{ s}^{-1}$  at  $40^\circ\text{C}$ . Calculate the initial rate  $d[\text{P}]/dt$  if the initial concentrations of A and B are  $0.150 \text{ mol dm}^{-3}$  and  $0.330 \text{ mol dm}^{-3}$ , respectively.

**22.10(b)** Two neutral species, A and B, with diameters  $442 \text{ pm}$  and  $885 \text{ pm}$ , respectively, undergo the diffusion-controlled reaction  $\text{A} + \text{B} \rightarrow \text{P}$  in a solvent of viscosity  $1.27 \text{ cP}$  at  $20^\circ\text{C}$ . Calculate the initial rate  $d[\text{P}]/dt$  if the initial concentrations of A and B are  $0.200 \text{ mol dm}^{-3}$  and  $0.150 \text{ mol dm}^{-3}$ , respectively.

**22.11(a)** The reaction of propylxanthate ion in acetic acid buffer solutions has the mechanism  $\text{A}^- + \text{H}^+ \rightarrow \text{P}$ . Near  $30^\circ\text{C}$  the rate constant is given by the empirical expression  $k_2 = (2.05 \times 10^{13})e^{-(8681 \text{ K})/T} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . Evaluate the energy and entropy of activation at  $30^\circ\text{C}$ .

**22.11(b)** The reaction  $\text{A}^- + \text{H}^+ \rightarrow \text{P}$  has a rate constant given by the empirical expression  $k_2 = (8.72 \times 10^{12})e^{(6134 \text{ K})/T} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . Evaluate the energy and entropy of activation at  $25^\circ\text{C}$ .

**22.12(a)** When the reaction in Exercise 22.11a occurs in a dioxane/water mixture that is 30 per cent dioxane by mass, the rate constant fits  $k_2 = (7.78 \times 10^{14})e^{-(9134 \text{ K})/T} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  near  $30^\circ\text{C}$ . Calculate  $\Delta^\ddagger G$  for the reaction at  $30^\circ\text{C}$ .

**22.12(b)** A rate constant is found to fit the expression  $k_2 = (6.45 \times 10^{13})e^{-(5375 \text{ K})/T} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  near  $25^\circ\text{C}$ . Calculate  $\Delta^\ddagger G$  for the reaction at  $25^\circ\text{C}$ .

**22.13(a)** The gas-phase association reaction between  $\text{F}_2$  and  $\text{IF}_5$  is first-order in each of the reactants. The energy of activation for the reaction is  $58.6 \text{ kJ mol}^{-1}$ . At  $65^\circ\text{C}$  the rate constant is  $7.84 \times 10^{-3} \text{ kPa}^{-1} \text{ s}^{-1}$ . Calculate the entropy of activation at  $65^\circ\text{C}$ .

**22.13(b)** A gas-phase recombination reaction is first-order in each of the reactants. The energy of activation for the reaction is  $49.6 \text{ kJ mol}^{-1}$ . At  $55^\circ\text{C}$  the rate constant is  $0.23 \text{ m}^3 \text{ s}^{-1}$ . Calculate the entropy of activation at  $55^\circ\text{C}$ .

**22.14(a)** Calculate the entropy of activation for a collision between two structureless particles at  $300 \text{ K}$ , taking  $M = 50 \text{ g mol}^{-1}$  and  $\sigma = 0.40 \text{ nm}^2$ .

**22.14(b)** Calculate the entropy of activation for a collision between two structureless particles at  $500 \text{ K}$ , taking  $M = 78 \text{ g mol}^{-1}$  and  $\sigma = 0.62 \text{ nm}^2$ .

**22.15(a)** The pre-exponential factor for the gas-phase decomposition of ozone at low pressures is  $4.6 \times 10^{12} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  and its activation energy is  $10.0 \text{ kJ mol}^{-1}$ . What are (a) the entropy of activation, (b) the enthalpy of activation, (c) the Gibbs energy of activation at  $298 \text{ K}$ ?

**22.15(b)** The pre-exponential factor for a gas-phase decomposition of ozone at low pressures is  $2.3 \times 10^{13} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  and its activation energy is  $30.0 \text{ kJ mol}^{-1}$ . What are (a) the entropy of activation, (b) the enthalpy of activation, (c) the Gibbs energy of activation at  $298 \text{ K}$ ?

**22.16(a)** The rate constant of the reaction  $\text{H}_2\text{O}_2(\text{aq}) + \text{I}^-(\text{aq}) + \text{H}^+(\text{aq}) \rightarrow \text{H}_2\text{O}(\text{l}) + \text{HIO}(\text{aq})$  is sensitive to the ionic strength of the aqueous solution in which the reaction occurs. At  $25^\circ\text{C}$ ,  $k = 12.2 \text{ dm}^6 \text{ mol}^{-2} \text{ min}^{-1}$  at an ionic strength of  $0.0525$ . Use the Debye–Hückel limiting law to estimate the rate constant at zero ionic strength.

**22.16(b)** At  $25^\circ\text{C}$ ,  $k_r = 1.55 \text{ dm}^6 \text{ mol}^{-2} \text{ min}^{-1}$  at an ionic strength of  $0.0241$  for a reaction in which the rate-determining step involves the encounter of two singly charged cations. Use the Debye–Hückel limiting law to estimate the rate constant at zero ionic strength.

**22.17(a)** For an electron donor–acceptor pair,  $H_{\text{AB}} = 0.03 \text{ cm}^{-1}$ ,  $\Delta_r G^\circ = -0.182 \text{ eV}$ , and  $k_{\text{et}} = 30.5 \text{ s}^{-1}$  at  $298 \text{ K}$ . Estimate the value of the reorganization energy.

**22.17(b)** For an electron donor–acceptor pair,  $k_{\text{et}} = 2.02 \times 10^5 \text{ s}^{-1}$  for  $\Delta_r G^\circ = -0.665 \text{ eV}$ . The standard reaction Gibbs energy changes to  $\Delta_r G^\circ = -0.975 \text{ eV}$  when a substituent is added to the electron acceptor and the rate constant for electron transfer changes to  $k_{\text{et}} = 3.33 \times 10^6 \text{ s}^{-1}$ . The experiments were conducted at  $298 \text{ K}$ . Assume that the distance between donor and acceptor is the same in both experiments and estimate the values of  $H_{\text{AB}}$  and  $\lambda$ .

**22.18(a)** For an electron donor–acceptor pair,  $k_{\text{et}} = 2.02 \times 10^5 \text{ s}^{-1}$  when  $r = 1.11 \text{ nm}$  and  $k_{\text{et}} = 4.51 \times 10^5 \text{ s}^{-1}$  when  $r = 1.23 \text{ nm}$ . Assuming that  $\Delta_r G^\circ$  and  $\lambda$  are the same in both experiments, estimate the value of  $\beta$ .

**22.18(b)** Refer to Exercise 22.18a. Estimate the value of  $k_{\text{et}}$  when  $r = 1.48 \text{ nm}$ .

**22.19(a)** The transfer coefficient of a certain electrode in contact with  $\text{M}^{3+}$  and  $\text{M}^{4+}$  in aqueous solution at  $25^\circ\text{C}$  is 0.39. The current density is found to be  $55.0 \text{ mA cm}^{-2}$  when the overpotential is 125 mV. What is the overpotential required for a current density of  $75 \text{ mA cm}^{-2}$ ?

**22.19(b)** The transfer coefficient of a certain electrode in contact with  $\text{M}^{2+}$  and  $\text{M}^{3+}$  in aqueous solution at  $25^\circ\text{C}$  is 0.42. The current density is found to be  $17.0 \text{ mA cm}^{-2}$  when the overpotential is 105 mV. What is the overpotential required for a current density of  $72 \text{ mA cm}^{-2}$ ?

**22.20(a)** Determine the exchange current density from the information given in Exercise 22.19a.

**22.20(b)** Determine the exchange current density from the information given in Exercise 22.19b.

**22.21(a)** To a first approximation, significant evolution or deposition occurs in electrolysis only if the overpotential exceeds about 0.6 V. To illustrate this criterion determine the effect that increasing the overpotential from 0.40 V to 0.60 V has on the current density in the electrolysis of a certain electrolyte solution, which is  $1.0 \text{ mA cm}^{-2}$  at 0.4 V and  $25^\circ\text{C}$ . Take  $\alpha = 0.5$ .

**22.21(b)** Determine the effect that increasing the overpotential from 0.50 V to 0.60 V has on the current density in the electrolysis of a certain electrolyte solution, which is  $1.22 \text{ mA cm}^{-2}$  at 0.50 V and  $25^\circ\text{C}$ . Take  $\alpha = 0.50$ .

**22.22(a)** Use the data in Table 22.3 for the exchange current density and transfer coefficient for the reaction  $2 \text{H}^+ + 2 \text{e}^- \rightarrow \text{H}_2$  on nickel at  $25^\circ\text{C}$  to determine what current density would be needed to obtain an overpotential of 0.20 V as calculated from (a) the Butler–Volmer equation, and (b) the Tafel equation (eqn 22.69). Is the validity of the Tafel approximation affected at higher overpotentials (of 0.4 V and more)?

**22.22(b)** Use the data in Table 22.3 for the exchange current density and transfer coefficient for the reaction  $\text{Fe}^{3+} + \text{e}^- \rightarrow \text{Fe}^{2+}$  on platinum at  $25^\circ\text{C}$  to determine what current density would be needed to obtain an overpotential of

0.30 V as calculated from (a) the Butler–Volmer equation, and (b) the Tafel equation (eqn 22.69). Is the validity of the Tafel approximation affected at higher overpotentials (of 0.4 V and more)?

**22.23(a)** A typical exchange current density, that for  $\text{H}^+$  discharge at platinum, is  $0.79 \text{ mA cm}^{-2}$  at  $25^\circ\text{C}$ . What is the current density at an electrode when its overpotential is (a) 10 mV, (b) 100 mV, (c)  $-5.0 \text{ V}$ ? Take  $\alpha = 0.5$ .

**22.23(b)** The exchange current density for a  $\text{Pt}|\text{Fe}^{3+}, \text{Fe}^{2+}$  electrode is  $2.5 \text{ mA cm}^{-2}$ . The standard potential of the electrode is  $+0.77 \text{ V}$ . Calculate the current flowing through an electrode of surface area  $1.0 \text{ cm}^2$  as a function of the potential of the electrode. Take unit activity for both ions.

**22.24(a)** How many electrons or protons are transported through the double layer in each second when the  $\text{Pt}, \text{H}_2|\text{H}^+$ ,  $\text{Pt}|\text{Fe}^{3+}, \text{Fe}^{2+}$ , and  $\text{Pb}, \text{H}_2|\text{H}^+$  electrodes are at equilibrium at  $25^\circ\text{C}$ ? Take the area as  $1.0 \text{ cm}^2$  in each case. Estimate the number of times each second a single atom on the surface takes part in an electron transfer event, assuming an electrode atom occupies about  $(280 \text{ pm})^2$  of the surface.

**22.24(b)** How many electrons or protons are transported through the double layer in each second when the  $\text{Cu}, \text{H}_2|\text{H}^+$  and  $\text{Pt}|\text{Ce}^{4+}, \text{Ce}^{3+}$  electrodes are at equilibrium at  $25^\circ\text{C}$ ? Take the area as  $1.0 \text{ cm}^2$  in each case. Estimate the number of times each second a single atom on the surface takes part in an electron transfer event, assuming an electrode atom occupies about  $(260 \text{ pm})^2$  of the surface.

**22.25(a)** What is the effective resistance at  $25^\circ\text{C}$  of an electrode interface when the overpotential is small? Evaluate it for  $1.0 \text{ cm}^2$  (a)  $\text{Pt}, \text{H}_2|\text{H}^+$ , (b)  $\text{Hg}, \text{H}_2|\text{H}^+$  electrodes.

**22.25(b)** Evaluate the effective resistance at  $25^\circ\text{C}$  of an electrode interface for  $1.0 \text{ cm}^2$  (a)  $\text{Pb}, \text{H}_2|\text{H}^+$ , (b)  $\text{Pt}|\text{Fe}^{2+}, \text{Fe}^{3+}$  electrodes.

**22.26(a)** The exchange current density for  $\text{H}^+$  discharge at zinc is about  $50 \text{ pA cm}^{-2}$ . Can zinc be deposited from a unit activity aqueous solution of a zinc salt?

**22.26(b)** The standard potential of the  $\text{Zn}^{2+}|\text{Zn}$  electrode is  $-0.76 \text{ V}$  at  $25^\circ\text{C}$ . The exchange current density for  $\text{H}^+$  discharge at platinum is  $0.79 \text{ mA cm}^{-2}$ . Can zinc be plated on to platinum at that temperature? (Take unit activities.)

## Problems\*

### Numerical problems

**22.1** In the dimerization of methyl radicals at  $25^\circ\text{C}$ , the experimental pre-exponential factor is  $2.4 \times 10^{10} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ . What are (a) the reactive cross-section, (b) the  $P$  factor for the reaction if the C–H bond length is  $154 \text{ pm}$ ?

**22.2** Nitrogen dioxide reacts bimolecularly in the gas phase to give  $2 \text{NO} + \text{O}_2$ . The temperature dependence of the second-order rate constant for the rate law  $d[\text{P}]/dt = k[\text{NO}_2]^2$  is given below. What are the  $P$  factor and the reactive cross-section for the reaction?

|                                                     |                   |                   |                   |                   |
|-----------------------------------------------------|-------------------|-------------------|-------------------|-------------------|
| $T/\text{K}$                                        | 600               | 700               | 800               | 1000              |
| $k_r/(\text{cm}^3 \text{ mol}^{-1} \text{ s}^{-1})$ | $4.6 \times 10^2$ | $9.7 \times 10^3$ | $1.3 \times 10^5$ | $3.1 \times 10^6$ |

Take  $\sigma = 0.60 \text{ nm}^2$ .

**22.3** The diameter of the methyl radical is about  $308 \text{ pm}$ . What is the maximum rate constant in the expression  $d[\text{C}_2\text{H}_6]/dt = k_r[\text{CH}_3]^2$  for

second-order recombination of radicals at room temperature? 10 per cent of a  $1.0\text{-dm}^3$  sample of ethane at  $298 \text{ K}$  and  $100 \text{ kPa}$  is dissociated into methyl radicals. What is the minimum time for 90 per cent recombination?

**22.4** The rates of thermolysis of a variety of *cis*- and *trans*-azoalkanes have been measured over a range of temperatures in order to settle a controversy concerning the mechanism of the reaction. In ethanol an unstable *cis*-azoalkane decomposed at a rate that was followed by observing the  $\text{N}_2$  evolution, and this led to the rate constants listed below (P.S. Engel and D.J. Bishop, *J. Amer. Chem. Soc.* **97**, 6754 (1975)). Calculate the enthalpy, entropy, energy, and Gibbs energy of activation at  $-20^\circ\text{C}$ .

|                                 |        |        |        |        |       |
|---------------------------------|--------|--------|--------|--------|-------|

| $10^4 \times k_r/\text{s}^{-1}$ | 1.22   | 2.31   | 4.39   | 8.50   | 14.3  |

**22.5** In an experimental study of a bimolecular reaction in aqueous solution, the second-order rate constant was measured at  $25^\circ\text{C}$  and at a variety of ionic

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp, Carmen Giunta, and Marshall Cady.

strengths and the results are tabulated below. It is known that a singly charged ion is involved in the rate-determining step. What is the charge on the other ion involved?

|                                                     |        |        |        |        |        |
|-----------------------------------------------------|--------|--------|--------|--------|--------|
| $I$                                                 | 0.0025 | 0.0037 | 0.0045 | 0.0065 | 0.0085 |
| $k_r/(\text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1})$ | 1.05   | 1.12   | 1.16   | 1.18   | 1.26   |

**22.6** The rate constant of the reaction  $\text{I}^-(\text{aq}) + \text{H}_2\text{O}_2(\text{aq}) \rightarrow \text{H}_2\text{O}(\text{l}) + \text{IO}^-(\text{aq})$  varies slowly with ionic strength, even though the Debye–Hückel limiting law predicts no effect. Use the following data from 25°C to find the dependence of  $\log k_r$  on the ionic strength:

|                                                       |        |        |        |        |
|-------------------------------------------------------|--------|--------|--------|--------|
| $I$                                                   | 0.0207 | 0.0525 | 0.0925 | 0.1575 |
| $k_r/(\text{dm}^3 \text{ mol}^{-1} \text{ min}^{-1})$ | 0.663  | 0.670  | 0.679  | 0.694  |

Evaluate the limiting value of  $k_r$  at zero ionic strength. What does the result suggest for the dependence of  $\log \gamma$  on ionic strength for a neutral molecule in an electrolyte solution?

**22.7** The total cross-sections for reactions between alkali metal atoms and halogen molecules are given in the table below (R.D. Levine and R.B. Bernstein, *Molecular reaction dynamics*, Clarendon Press, Oxford, 72 (1974)). Assess the data in terms of the harpoon mechanism.

|                        |               |               |              |
|------------------------|---------------|---------------|--------------|
| $\sigma^*/\text{nm}^2$ | $\text{Cl}_2$ | $\text{Br}_2$ | $\text{I}_2$ |
| Na                     | 1.24          | 1.16          | 0.97         |
| K                      | 1.54          | 1.51          | 1.27         |
| Rb                     | 1.90          | 1.97          | 1.67         |
| Cs                     | 1.96          | 2.04          | 1.95         |

Electron affinities are approximately 1.3 eV ( $\text{Cl}_2$ ), 1.2 eV ( $\text{Br}_2$ ), and 1.7 eV ( $\text{I}_2$ ), and ionization energies are 5.1 eV (Na), 4.3 eV (K), 4.2 eV (Rb), and 3.9 eV (Cs).

**22.8†** One of the most historically significant studies of chemical reaction rates was that by M. Bodenstein (*Z. physik. Chem.* 29, 295 (1899)) of the gas-phase reaction  $2 \text{HI}(\text{g}) \rightarrow \text{H}_2(\text{g}) + \text{I}_2(\text{g})$  and its reverse, with rate constants  $k_r$  and  $k'_r$ , respectively. The measured rate constants as a function of temperature are

|                                                              |        |        |        |       |       |       |
|--------------------------------------------------------------|--------|--------|--------|-------|-------|-------|
| $T/\text{K}$                                                 | 647    | 666    | 683    | 700   | 716   | 781   |
| $k_r/(22.4 \text{ dm}^3 \text{ mol}^{-1} \text{ min}^{-1})$  | 0.230  | 0.588  | 1.37   | 3.10  | 6.70  | 105.9 |
| $k'_r/(22.4 \text{ dm}^3 \text{ mol}^{-1} \text{ min}^{-1})$ | 0.0140 | 0.0379 | 0.0659 | 0.172 | 0.375 | 3.58  |

Demonstrate that these data are consistent with the collision theory of bimolecular gas-phase reactions.

**22.9** In an experiment on the  $\text{Pt}|\text{H}_2|\text{H}^+$  electrode in dilute  $\text{H}_2\text{SO}_4$  the following current densities were observed at 25°C. Evaluate  $\alpha$  and  $j_0$  for the electrode.

|                         |      |      |      |     |     |
|-------------------------|------|------|------|-----|-----|
| $\eta/\text{mV}$        | 50   | 100  | 150  | 200 | 250 |
| $j/(\text{mA cm}^{-2})$ | 2.66 | 8.91 | 29.9 | 100 | 335 |

How would the current density at this electrode depend on the overpotential of the same set of magnitudes but of opposite sign?

**22.10** The standard potentials of lead and tin are  $-126 \text{ mV}$  and  $-136 \text{ mV}$ , respectively, at 25°C, and the overpotentials for their deposition are close to zero. What should their relative activities be in order to ensure simultaneous deposition from a mixture?

**22.11†** The rate of deposition of iron,  $v$ , on the surface of an iron electrode from an aqueous solution of  $\text{Fe}^{2+}$  has been studied as a function of potential,  $E$ , relative to the standard hydrogen electrode, by J. Kanya (*J. Electroanal. Chem.* 84, 83 (1977)). The values in the table below are based on the data obtained with an electrode of surface area  $9.1 \text{ cm}^2$  in contact with a solution of concentration  $1.70 \mu\text{mol dm}^{-3}$  in  $\text{Fe}^{2+}$ . (a) Assuming unit activity coefficients, calculate the zero current potential of the  $\text{Fe}^{2+}/\text{Fe}$  cathode and the overpotential at each value of the working potential. (b) Calculate the cathodic current density,  $j_c$ , from the rate of deposition of  $\text{Fe}^{2+}$  for each value

of  $E$ . (c) Examine the extent to which the data fit eqn 22.69 and calculate the exchange current density.

|                          |      |      |      |      |
|--------------------------|------|------|------|------|
| $v/(\text{pmol s}^{-1})$ | 1.47 | 2.18 | 3.11 | 7.26 |
| $-E/\text{mV}$           | 702  | 727  | 752  | 812  |

**22.12†** The thickness of the diffuse double layer according to the Gouy–Chapman model is given by eqn 18.16. Use this equation to calculate and plot the thickness as a function of concentration and electrolyte type at 25°C. For examples, choose aqueous solutions of  $\text{NaCl}$  and  $\text{Na}_2\text{SO}_4$  ranging in concentration from 0.1 to 100  $\text{mmol dm}^{-3}$ .

**22.13†** V.V. Losev and A.P. Pchel'nikov (*Soviet Electrochem.* 6, 34 (1970)) obtained the following current–voltage data for an indium anode relative to a standard hydrogen electrode at 293 K:

|                       |       |       |       |       |
|-----------------------|-------|-------|-------|-------|
| $-E/\text{V}$         | 0.388 | 0.365 | 0.350 | 0.335 |
| $j/(\text{A m}^{-2})$ | 0     | 0.590 | 1.438 | 3.507 |

Use these data to calculate the transfer coefficient and the exchange current density. What is the cathodic current density when the potential is 0.365 V?

**22.14†** An early study of the hydrogen overpotential is that of H. Bowden and T. Rideal (*Proc. Roy. Soc. A* 120, 59 (1928)), who measured the overpotential for  $\text{H}_2$  evolution with a mercury electrode in dilute aqueous solutions of  $\text{H}_2\text{SO}_4$  at 25°C. Determine the exchange current density and transfer coefficient,  $\alpha$ , from their data:

|                        |      |      |      |      |      |      |      |      |
|------------------------|------|------|------|------|------|------|------|------|
| $j/(\text{mA m}^{-2})$ | 2.9  | 6.3  | 28   | 100  | 250  | 630  | 1650 | 3300 |
| $\eta/\text{V}$        | 0.60 | 0.65 | 0.73 | 0.79 | 0.84 | 0.89 | 0.93 | 0.96 |

Explain any deviations from the result expected from eqn 22.69.

## Theoretical problems

**22.15** Confirm that eqn 22.26 is a solution of eqn 22.25, where  $[J]$  is a solution of the same equation but with  $k_r = 0$  and for the same initial conditions.

**22.16** Confirm that, if the initial condition is  $[J] = 0$  at  $t = 0$  everywhere, and the boundary condition is  $[J] = [J]_0$  at  $t > 0$  at all points on a surface, then the solutions  $[J]^*$  in the presence of a first-order reaction that removed  $J$  are related to those in the absence of reaction,  $[J]$ , by

$$[J]^* = k_r \int_0^t [J] e^{-k_r t} dt + [J] e^{-k_r t}$$

Base your answer on eqn 22.25.

**22.17** Estimate the orders of magnitude of the partition functions involved in a rate expression. State the order of magnitude of  $q_m^T/N_A$ ,  $q^R$ ,  $q^V$ ,  $q^E$  for typical molecules. Check that in the collision of two structureless molecules the order of magnitude of the pre-exponential factor is of the same order as that predicted by collision theory. Go on to estimate the  $P$  factor for a reaction in which  $\text{A} + \text{B} \rightarrow \text{P}$ , and  $\text{A}$  and  $\text{B}$  are nonlinear triatomic molecules.

**22.18** Use the Debye–Hückel limiting law to show that changes in ionic strength can affect the rate of reaction catalysed by  $\text{H}^+$  from the deprotonation of a weak acid. Consider the mechanism:  $\text{H}^+(\text{aq}) + \text{B}(\text{aq}) \rightarrow \text{P}$ , where  $\text{H}^+$  comes from the deprotonation of the weak acid,  $\text{HA}$ . The weak acid has a fixed concentration. First show that  $\log [\text{H}^+]$ , derived from the ionization of  $\text{HA}$ , depends on the activity coefficients of ions and thus depends on the ionic strength. Then find the relationship between  $\log(\text{rate})$  and  $\log [\text{H}^+]$  to show that the rate also depends on the ionic strength.

**22.19** The Eyring equation can also be applied to physical processes. As an example, consider the rate of diffusion of an atom stuck to the surface of a solid. Suppose that in order to move from one site to another it has to reach the top of the barrier where it can vibrate classically in the vertical direction

and in one horizontal direction, but vibration along the other horizontal direction takes it into the neighbouring site. Find an expression for the rate of diffusion, and evaluate it for W atoms on a tungsten surface ( $E_a = 60 \text{ kJ mol}^{-1}$ ). Suppose that the vibration frequencies at the transition state are (a) the same as, (b) one-half the value for the adsorbed atom. What is the value of the diffusion coefficient  $D$  at 500 K? (Take the site separation as 316 pm and  $\nu = 1 \times 10^{11} \text{ Hz}$ .)

**22.20‡** Show that bimolecular reactions between nonlinear molecules are much slower than between atoms even when the activation energies of both reactions are equal. Use transition state theory and make the following assumptions. (1) All vibrational partition functions are close to 1; (2) all rotational partition functions are approximately  $1 \times 10^{1.5}$ , which is a reasonable order of magnitude number; (3) the translational partition function for each species is  $1 \times 10^{26}$ .

**22.21** This exercise gives some familiarity with the difficulties involved in predicting the structure of activated complexes. It also demonstrates the importance of femtosecond spectroscopy to our understanding of chemical dynamics because direct experimental observation of the activated complex removes much of the ambiguity of theoretical predictions. Consider the attack of H on  $D_2$ , which is one step in the  $H_2 + D_2$  reaction. (a) Suppose that the H approaches  $D_2$  from the side and forms a complex in the form of an isosceles triangle. Take the H–D distance as 30 per cent greater than in  $H_2$  (74 pm) and the D–D distance as 20 per cent greater than in  $H_2$ . Let the critical coordinate be the antisymmetric stretching vibration in which one H–D bond stretches as the other shortens. Let all the vibrations be at about  $1000 \text{ cm}^{-1}$ . Estimate  $k_2$  for this reaction at 400 K using the experimental activation energy of about  $35 \text{ kJ mol}^{-1}$ . (b) Now change the model of the activated complex in part (a) and make it linear. Use the same estimated molecular bond lengths and vibrational frequencies to calculate  $k_2$  for this choice of model. (c) Clearly, there is much scope for modifying the parameters of the models of the activated complex. Use mathematical software or write and run a program that allows you to vary the structure of the complex and the parameters in a plausible way, and look for a model (or more than one model) that gives a value of  $k$  close to the experimental value,  $4 \times 10^5 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ .

**22.22** If  $\alpha = \frac{1}{2}$ , an electrode interface is unable to rectify alternating current because the current density curve is symmetrical about  $\eta = 0$ . When  $\alpha \neq \frac{1}{2}$ , the magnitude of the current density depends on the sign of the overpotential, and so some degree of ‘faradaic rectification’ may be obtained. Suppose that the overpotential varies as  $\eta = \eta_0 \cos \omega t$ . Derive an expression for the mean flow of current (averaged over a cycle) for general  $\alpha$ , and confirm that the mean current is zero when  $\alpha = \frac{1}{2}$ . In each case work in the limit of small  $\eta_0$  but to second order in  $\eta_0 F/RT$ . Calculate the mean direct current at  $25^\circ\text{C}$  for a  $1.0 \text{ cm}^2$  hydrogen–platinum electrode with  $\alpha = 0.38$  when the overpotential varies between  $\pm 10 \text{ mV}$  at 50 Hz.

**22.23** Now suppose that the overpotential is in the high overpotential region at all times even though it is oscillating. What waveform will the current across the interface show if it varies linearly and periodically (as a sawtooth waveform) between  $\eta_-$  and  $\eta_+$  around  $\eta_0$ ? Take  $\alpha = \frac{1}{2}$ .

### Applications: to biochemistry and environmental science

**22.24‡** R. Atkinson (*J. Phys. Chem. Ref. Data* 26, 215 (1997)) has reviewed a large set of rate constants relevant to the atmospheric chemistry of volatile organic compounds. The recommended rate constant for the bimolecular association of  $O_2$  with an alkyl radical R at 298 K is  $4.7 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$

for  $R = C_2H_5$  and  $8.4 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  for  $R = \text{cyclohexyl}$ . Assuming no energy barrier, compute the steric factor,  $P$ , for each reaction. (*Hint*. Obtain collision diameters from collision cross-sections of similar molecules in the *Data section*.)

**22.25‡** The compound  $\alpha$ -tocopherol, a form of vitamin E, is a powerful antioxidant that may help to maintain the integrity of biological membranes. R.H. Bisby and A.W. Parker (*J. Amer. Chem. Soc.* 117, 5664 (1995)) studied the reaction of photochemically excited duroquinone with the antioxidant in ethanol. Once the duroquinone was photochemically excited, a bimolecular reaction took place at a rate described as diffusion-limited. (a) Estimate the rate constant for a diffusion-limited reaction in ethanol. (b) The reported rate constant was  $2.77 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ; estimate the critical reaction distance if the sum of diffusion constants is  $1 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ .

**22.26** The study of conditions that optimize the association of proteins in solution guides the design of protocols for formation of large crystals that are amenable to analysis by the X-ray diffraction techniques discussed in Chapter 19. It is important to characterize protein dimerization because the process is considered to be the rate-determining step in the growth of crystals of many proteins. Consider the variation with ionic strength of the rate constant of dimerization in aqueous solution of a cationic protein P:

|             |        |        |        |        |        |        |
|-------------|--------|--------|--------|--------|--------|--------|
| $I$         | 0.0100 | 0.0150 | 0.0200 | 0.0250 | 0.0300 | 0.0350 |
| $k/k^\circ$ | 8.10   | 13.30  | 20.50  | 27.80  | 38.10  | 52.00  |

What can be deduced about the charge of P?

**22.27** A useful strategy for the study of electron transfer in proteins consists of attaching an electroactive species to the protein's surface and then measuring  $k_{et}$  between the attached species and an electroactive protein cofactor. J.W. Winkler and H.B. Gray (*Chem. Rev.* 92, 369 (1992)) summarize data for cytochrome *c* (*Impact 16.1*) modified by replacement of the haem iron by a zinc ion, resulting in a zinc-porphyrin (ZnP) moiety in the interior of the protein, and by attachment of a ruthenium ion complex to a surface histidine aminoacid. The edge-to-edge distance between the electroactive species was thus fixed at 1.23 nm. A variety of ruthenium ion complexes with different standard reduction potentials were used. For each ruthenium-modified protein, either the  $Ru^{2+} \rightarrow ZnP^+$  or the  $ZnP^+ \rightarrow Ru^{3+}$ , in which the electron donor is an electronic excited state of the zinc-porphyrin formed by laser excitation, was monitored. This arrangement leads to different standard reaction Gibbs energies because the redox couples  $ZnP^+/ZnP$  and  $ZnP^+/ZnP^+$  have different standard potentials, with the electronically excited porphyrin being a more powerful reductant. Use the following data to estimate the reorganization energy for this system:

|                                |       |       |       |       |       |       |
|--------------------------------|-------|-------|-------|-------|-------|-------|
| $-\Delta_r G^\circ/\text{eV}$  | 0.665 | 0.705 | 0.745 | 0.975 | 1.015 | 1.055 |
| $k_{et}/(10^6 \text{ s}^{-1})$ | 0.657 | 1.52  | 1.12  | 8.99  | 5.76  | 10.1  |

**22.28** The rate constant for electron transfer between a cytochrome *c* and the bacteriochlorophyll dimer of the reaction centre of the purple bacterium *Rhodospirillum rubrum* decreases with decreasing temperature in the range 300 K to 130 K. Below 130 K, the rate constant becomes independent of temperature. Account for these results.

**22.29** Calculate the thermodynamic limit to the zero-current potential of fuel cells operating on (a) hydrogen and oxygen, (b) methane and air, and (c) propane and air. Use the Gibbs energy information in the *Data section*, and take the species to be in their standard states at  $25^\circ\text{C}$ .

Problems

This chapter extends the material introduced in Chapters 21 and 22 by showing how to deal with catalysis. We begin with a description of homogeneous catalysis and apply the associated concepts to enzyme-catalysed reactions. We go on to consider heterogeneous catalysis by exploring the extent to which a solid surface is covered and the variation of the extent of coverage with pressure and temperature. Then we use this material to discuss how surfaces affect the rate and course of chemical change by acting as the site of catalysis.

A **catalyst** is a substance that accelerates a reaction but undergoes no net chemical change. The catalyst lowers the activation energy of the reaction by providing an alternative path that avoids the slow, rate-determining step of the uncatalysed reaction (Fig. 23.1).

A **homogeneous catalyst** is a catalyst in the same phase as the reaction mixture. For example, the decomposition of hydrogen peroxide in aqueous solution is catalysed by iodide ion. **Enzymes**, which are biological catalysts, are very specific and can have a dramatic effect on the reactions they control. We shall examine enzyme catalysis in Section 23.2. A **heterogeneous catalyst** is a catalyst in a different phase from the reaction mixture. For example, the hydrogenation of ethene to ethane, a gas-phase reaction, is accelerated in the presence of a solid catalyst such as palladium, platinum, or nickel. The metal provides a surface upon which the reactants bind; this binding facilitates encounters between reactants and increases the rate of the reaction. Most of this chapter is an exploration of catalytic activity on surfaces.

## Homogeneous catalysis

Homogeneous catalysts can be very effective. For instance, the activation energy for the decomposition of hydrogen peroxide in solution is  $76 \text{ kJ mol}^{-1}$ , and the reaction is slow at room temperature. When a little iodide ion is added, the activation energy falls to  $57 \text{ kJ mol}^{-1}$  and the rate constant increases by a factor of 2000. The enzyme catalase reduces the activation energy even further, to  $8 \text{ kJ mol}^{-1}$ , corresponding to an acceleration of the reaction by a factor of  $10^{15}$  at 298 K.

### 23.1 Features of homogeneous catalysis

---

**Key points** Catalysts are substances that accelerate reactions but undergo no net chemical change. A homogeneous catalyst is a catalyst in the same phase as the reaction mixture. Examples of homogeneous catalysis include acid and base catalysis.

---

We can obtain some idea of the mode of action of homogeneous catalysts by examining the kinetics of the iodide-catalysed decomposition of hydrogen peroxide:

The reaction is believed to proceed through the following pre-equilibrium:

where we have set the activity of  $\text{H}_2\text{O}$  in the equilibrium constant equal to 1 and assumed that the thermodynamic properties of the other substances are ideal. The second step is rate-determining. Therefore, we can obtain the rate law of the overall reaction by setting the overall rate equal to the rate of the second step and using the equilibrium constant to express the concentration of  $\text{H}_3\text{O}_2^+$  in terms of the reactants. The result is

$$\frac{d[\text{O}_2]}{dt} = k_r[\text{H}_2\text{O}_2][\text{H}_3\text{O}^+][\text{I}^-]$$

with  $k_r = k_a K$ , in agreement with the observed dependence of the rate on the  $\text{I}^-$  concentration and the pH of the solution. The observed activation energy is that of the effective rate constant  $k_a K$ .

In acid catalysis the crucial step is the transfer of a proton to the substrate:

Acid catalysis is the primary process in the solvolysis of esters and keto–enol tautomerism:

In base catalysis, a proton is transferred from the substrate to a base:

Base catalysis is the primary step in the isomerization and halogenation of organic compounds, and of the Claisen and aldol condensation reactions. The base-catalysed version of keto–enol tautomerism, for instance, is

**Fig. 23.1** A catalyst provides a different path with a lower activation energy. The result is an increase in the rate of formation of products.

## 23.2 Enzymes

**Key points** Enzymes are homogeneous, biological catalysts. (a) The Michaelis–Menten mechanism of enzyme kinetics accounts for the dependence of rate on the concentration of the substrate. A Lineweaver–Burk plot is used to determine the parameters that occur in the mechanism. (b) The turnover frequency is the number of catalytic cycles performed by the active site of an enzyme in a given interval divided by the duration of the interval. The catalytic efficiency is the effective rate constant of the enzymatic reaction. (c) In competitive inhibition of an enzyme, the inhibitor binds only to the active site of the enzyme. In uncompetitive inhibition the inhibitor binds to a site of the enzyme that is removed from the active site, but only if the substrate is already present. In non-competitive inhibition, the inhibitor binds to a site other than the active site.

**Fig. 23.2** Two models that explain the binding of a substrate to the active site of an enzyme. In the lock-and-key model, the active site and substrate have complementary three-dimensional structures and dock perfectly without the need for major atomic rearrangements. In the induced fit model, binding of the substrate induces a conformational change in the active site. The substrate fits well in the active site after the conformational change has taken place.

Enzymes are homogeneous biological catalysts. These ubiquitous compounds are special proteins or nucleic acids that contain an **active site**, which is responsible for binding the **substrates**, the reactants, and processing them into products. As is true of any catalyst, the active site returns to its original state after the products are released. Many enzymes consist primarily of proteins, some featuring organic or inorganic co-factors in their active sites. However, certain RNA molecules can also be biological catalysts, forming *ribozymes*. A very important example of a ribozyme is the *ribosome*, a large assembly of proteins and catalytically active RNA molecules responsible for the synthesis of proteins in the cell.

The structure of the active site is specific to the reaction that it catalyses, with groups in the substrate interacting with groups in the active site by intermolecular interactions, such as hydrogen bonding, electrostatic, or van der Waals interactions. Figure 23.2 shows two models that explain the binding of a substrate to the active site of an enzyme. In the **lock-and-key model**, the active site and substrate have complementary three-dimensional structures and dock perfectly without the need for major atomic rearrangements. Experimental evidence favours the **induced fit model**, in which binding of the substrate induces a conformational change in the active site. Only after the change does the substrate fit snugly in the active site.

Enzyme-catalysed reactions are prone to inhibition by molecules that interfere with the formation of product. Many drugs for the treatment of disease function by inhibiting enzymes. For example, an important strategy in the treatment of acquired immune deficiency syndrome (AIDS) involves the steady administration of a specially designed protease inhibitor. The drug inhibits an enzyme that is key to the formation of the protein envelope surrounding the genetic material of the human immunodeficiency virus (HIV). Without a properly formed envelope, HIV cannot replicate in the host organism.

### (a) The Michaelis–Menten mechanism of enzyme catalysis

Experimental studies of enzyme kinetics are typically conducted by monitoring the initial rate of product formation in a solution in which the enzyme is present at very low concentration. Indeed, enzymes are such efficient catalysts that significant accelerations may be observed even when their concentration is more than three orders of magnitude smaller than that of the substrate.

The principal features of many enzyme-catalysed reactions are as follows:

- For a given initial concentration of substrate,  $[S]_0$ , the initial rate of product formation is proportional to the total concentration of enzyme,  $[E]_0$ .
- For a given  $[E]_0$  and low values of  $[S]_0$ , the rate of product formation is proportional to  $[S]_0$ .

• For a given  $[E]_0$  and high values of  $[S]_0$ , the rate of product formation becomes independent of  $[S]_0$ , reaching a maximum value known as the **maximum velocity**,  $v_{\max}$ .

The **Michaelis–Menten mechanism** accounts for these features. According to this mechanism, an enzyme–substrate complex is formed in the first step and either the substrate is released unchanged or after modification to form products:

We show in the following *Justification* that this mechanism leads to the **Michaelis–Menten equation** for the rate of product formation

$$v = \frac{k_b[E]_0}{1 + K_M/[S]_0} \quad \begin{array}{c} \text{Michaelis–Menten} \\ \text{equation} \end{array} \quad (23.1)$$

where  $K_M = (k'_a + k_b)/k_a$  is the **Michaelis constant**, characteristic of a given enzyme acting on a given substrate and having the dimensions of a molar concentration.

#### Justification 23.1 The Michaelis–Menten equation

The rate of product formation according to the Michaelis–Menten mechanism is

$$v = k_b[ES]$$

We can obtain the concentration of the enzyme–substrate complex by invoking the steady-state approximation and writing

$$\frac{d[ES]}{dt} = k_a[E][S] - k'_a[ES] - k_b[ES] = 0$$

It follows that

$$[ES] = \left( \frac{k_a}{k'_a + k_b} \right) [E][S]$$

where  $[E]$  and  $[S]$  are the concentrations of *free* enzyme and substrate, respectively. Now we define the Michaelis constant as

$$K_M = \frac{k'_a + k_b}{k_a} = \frac{[E][S]}{[ES]}$$

To express the rate law in terms of the concentrations of enzyme and substrate added, we note that  $[E]_0 = [E] + [ES]$ . Moreover, because the substrate is typically in large excess relative to the enzyme, the free substrate concentration is approximately equal to the initial substrate concentration and we can write  $[S] \approx [S]_0$ . It then follows that:

$$[ES] = \frac{[E]_0}{1 + K_M/[S]_0}$$

Equation 23.1 is obtained when this expression for  $[ES]$  is substituted into that for the rate of product formation ( $v = k_b[ES]$ ).

Equation 23.1 shows that, in accord with experimental observations (Fig. 23.3):

- When  $[S]_0 \ll K_M$  the rate is proportional to  $[S]_0$ :

$$v = \frac{k_b}{K_M} [S]_0 [E]_0 \quad (23.2a)$$

**Fig. 23.3** The variation of the rate of an enzyme-catalysed reaction with substrate concentration. The approach to a maximum rate,  $v_{\max}$ , for large  $[S]_0$  is explained by the Michaelis–Menten mechanism.

**interActivity** Use the Michaelis–Menten equation to generate two families of curves showing the dependence of  $v$  on  $[S]_0$ : one in which  $K_M$  varies but  $v_{\max}$  is constant, and another in which  $v_{\max}$  varies but  $K_M$  is constant.

**Fig. 23.4** A Lineweaver–Burk plot for the analysis of an enzyme-catalysed reaction that proceeds by a Michaelis–Menten mechanism and the significance of the intercepts and the slope.

- When  $[S]_0 \gg K_M$  the rate reaches its maximum value and is independent of  $[S]_0$ :

$$v = v_{\max} = k_b[E]_0 \quad (23.2b)$$

Substitution of the definition of  $v_{\max}$  into eqn 23.1 gives

$$v = \frac{v_{\max}}{1 + K_M/[S]_0} \quad (23.3a)$$

which can be rearranged into a form amenable to data analysis by linear regression by taking reciprocals of both sides:

$$\frac{1}{v} = \frac{1}{v_{\max}} + \left( \frac{K_M}{v_{\max}} \right) \frac{1}{[S]_0} \quad (23.3b)$$

Form of the Michaelis–Menten equation used in a Lineweaver–Burk plot

A **Lineweaver–Burk plot** is a plot of  $1/v$  against  $1/[S]_0$ , and according to eqn 23.3b it should yield a straight line with slope of  $K_M/v_{\max}$ , a  $y$ -intercept at  $1/v_{\max}$ , and an  $x$ -intercept at  $-1/K_M$  (Fig. 23.4). The value of  $k_b$  is then calculated from the  $y$ -intercept and eqn 23.2b. However, the plot cannot give the individual rate constants  $k_a$  and  $k'_a$  that appear in the expression for  $K_M$ . The stopped-flow technique described in Section 21.1b can give the additional data needed, because we can find the rate of formation of the enzyme–substrate complex by monitoring the concentration after mixing the enzyme and substrate. This procedure gives a value for  $k_a$ , and  $k'_a$  is then found by combining this result with the values of  $k_b$  and  $K_M$ .

### (b) The catalytic efficiency of enzymes

The **turnover frequency**, or **catalytic constant**, of an enzyme,  $k_{\text{cat}}$ , is the number of catalytic cycles (turnovers) performed by the active site in a given interval divided by the duration of the interval. This quantity has units of a first-order rate constant and, in terms of the Michaelis–Menten mechanism, is numerically equivalent to  $k_b$ , the rate constant for release of product from the enzyme–substrate complex. It follows from the identification of  $k_{\text{cat}}$  with  $k_b$  and from eqn 23.2b that

$$k_{\text{cat}} = k_b = \frac{v_{\max}}{[E]_0} \quad (23.4)$$

Turnover frequency

The **catalytic efficiency**,  $\eta$  (eta), of an enzyme is the ratio  $k_{\text{cat}}/K_M$ . The higher the value of  $\eta$ , the more efficient is the enzyme. We can think of the catalytic efficiency as the effective rate constant of the enzymatic reaction. From  $K_M = (k'_a + k_b)/k_a$  and eqn 23.4, it follows that

$$\eta = \frac{k_{\text{cat}}}{K_M} = \frac{k_a k_b}{k'_a + k_b} \quad (23.5)$$

Catalytic efficiency

The efficiency reaches its maximum value of  $k_a$  when  $k_b \gg k'_a$ . Because  $k_a$  is the rate constant for the formation of a complex from two species that are diffusing freely in solution, the maximum efficiency is related to the maximum rate of diffusion of E and S in solution. This limit (which is discussed further in Section 22.2) leads to rate constants of about  $10^8$ – $10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  for molecules as large as enzymes at room temperature. The enzyme catalase has  $\eta = 4.0 \times 10^8 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  and is said to have attained ‘catalytic perfection’, in the sense that the rate of the reaction it catalyses is controlled only by diffusion: it acts as soon as a substrate makes contact.

**Example 23.1** Determining the catalytic efficiency of an enzyme

The enzyme carbonic anhydrase catalyses the hydration of  $\text{CO}_2$  in red blood cells to give bicarbonate (hydrogencarbonate) ion:

The following data were obtained for the reaction at pH = 7.1, 273.5 K, and an enzyme concentration of  $2.3 \text{ nmol dm}^{-3}$ :

|                                              |                       |                       |                       |                       |
|----------------------------------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| $[\text{CO}_2]/(\text{mmol dm}^{-3})$        | 1.25                  | 2.5                   | 5                     | 20                    |
| rate/ $(\text{mmol dm}^{-3} \text{ s}^{-1})$ | $2.78 \times 10^{-2}$ | $5.00 \times 10^{-2}$ | $8.33 \times 10^{-2}$ | $1.67 \times 10^{-1}$ |

Determine the catalytic efficiency of carbonic anhydrase at 273.5 K.

**Method** Prepare a Lineweaver–Burk plot and determine the values of  $K_M$  and  $v_{\max}$  by linear regression analysis. From eqn 23.4 and the enzyme concentration, calculate  $k_{\text{cat}}$  and the catalytic efficiency from eqn 23.5.

**Answer** We draw up the following table:

|                                              |       |       |       |        |
|----------------------------------------------|-------|-------|-------|--------|
| $1/([\text{CO}_2]/(\text{mmol dm}^{-3}))$    | 0.800 | 0.400 | 0.200 | 0.0500 |
| $1/(v/(\text{mmol dm}^{-3} \text{ s}^{-1}))$ | 36.0  | 20.0  | 12.0  | 6.0    |

Figure 23.5 shows the Lineweaver–Burk plot for the data. The slope is 40.0 and the  $y$ -intercept is 4.00. Hence,

$$v_{\max}/(\text{mmol dm}^{-3} \text{ s}^{-1}) = \frac{1}{\text{intercept}} = \frac{1}{4.00} = 0.250$$

and

$$K_M/(\text{mmol dm}^{-3}) = \frac{\text{slope}}{\text{intercept}} = \frac{40.00}{4.00} = 10.0$$

It follows that

$$k_{\text{cat}} = \frac{v_{\max}}{[E]_0} = \frac{2.5 \times 10^{-4} \text{ mol dm}^{-3} \text{ s}^{-1}}{2.3 \times 10^{-9} \text{ mol dm}^{-3}} = 1.1 \times 10^5 \text{ s}^{-1}$$

and

$$\eta = \frac{k_{\text{cat}}}{K_M} = \frac{1.1 \times 10^5 \text{ s}^{-1}}{10.0 \times 10^{-3} \text{ mol dm}^{-3}} = 1.1 \times 10^7 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

**Self-test 23.1** The enzyme  $\alpha$ -chymotrypsin is secreted in the pancreas of mammals and cleaves peptide bonds made between certain amino acids. Several solutions containing the small peptide *N*-glutaryl-L-phenylalanine-*p*-nitroanilide at different concentrations were prepared and the same small amount of  $\alpha$ -chymotrypsin was added to each one. The following data were obtained on the initial rates of the formation of product:

|                                          |       |       |       |       |       |       |
|------------------------------------------|-------|-------|-------|-------|-------|-------|
| $[\text{S}]/(\text{mmol dm}^{-3})$       | 0.334 | 0.450 | 0.667 | 1.00  | 1.33  | 1.67  |
| $v/(\text{mmol dm}^{-3} \text{ s}^{-1})$ | 0.152 | 0.201 | 0.269 | 0.417 | 0.505 | 0.667 |

Determine the maximum velocity and the Michaelis constant for the reaction.

$$[v_{\max} = 2.76 \text{ mmol dm}^{-3} \text{ s}^{-1}, K_M = 5.77 \text{ mmol dm}^{-3}]$$

**Fig. 23.5** The Lineweaver–Burk plot of the data for Example 23.1.

**A note on good practice** The slope and the intercept are unitless: we have remarked previously, that all graphs should be plotted as pure numbers.

## (c) Mechanisms of enzyme inhibition

An inhibitor, I, decreases the rate of product formation from the substrate by binding to the enzyme, to the ES complex, or to the enzyme and ES complex simultaneously. The most general kinetic scheme for enzyme inhibition is then:

The lower the values of  $K_I$  and  $K'_I$  the more efficient are the inhibitors. The rate of product formation is always given by  $v = k_b[\text{ES}]$ , because only ES leads to product. As shown in the following *Justification*, the rate of reaction in the presence of an inhibitor is

$$v = \frac{v_{\max}}{\alpha' + \alpha K_M/[S]_0} \quad (23.7)$$

Effect of inhibition on the rate

where  $\alpha = 1 + [\text{I}]/K_I$  and  $\alpha' = 1 + [\text{I}]/K'_I$ . This equation is very similar to the Michaelis–Menten equation for the uninhibited enzyme (eqn 23.1) and is also amenable to analysis by a Lineweaver–Burk plot:

$$\frac{1}{v} = \frac{\alpha'}{v_{\max}} + \left( \frac{\alpha K_M}{v_{\max}} \right) \frac{1}{[S]_0} \quad (23.8)$$

**Fig. 23.6** Lineweaver–Burk plots characteristic of the three major modes of enzyme inhibition: (a) competitive inhibition, (b) uncompetitive inhibition, and (c) non-competitive inhibition, showing the special case  $\alpha = \alpha' > 1$ .

**interActivity** Use eqn 23.8 to explore the effect of competitive, uncompetitive, and non-competitive inhibition on the shapes of the plots of  $v$  against  $[S]$  for constant  $K_M$  and  $v_{\max}$ .

**Justification 23.2** Enzyme inhibition

By mass balance, the total concentration of enzyme is:

$$[\text{E}]_0 = [\text{E}] + [\text{EI}] + [\text{ES}] + [\text{ESI}]$$

By using eqns 23.6a and 23.6b and the definitions

$$\alpha = 1 + \frac{[\text{I}]}{K_I} \quad \text{and} \quad \alpha' = 1 + \frac{[\text{I}]}{K'_I}$$

it follows that

$$[\text{E}]_0 = [\text{E}]\alpha + [\text{ES}]\alpha'$$

By using  $K_M = [\text{E}][\text{S}]/[\text{ES}]$  and replacing  $[\text{S}]$  with  $[\text{S}]_0$  we can write

$$[\text{E}]_0 = \frac{K_M[\text{ES}]}{[\text{S}]_0} \alpha + [\text{ES}]\alpha' = [\text{ES}] \left( \frac{\alpha K_M}{[\text{S}]_0} + \alpha' \right)$$

The expression for the rate of product formation is then:

$$v = k_b[\text{ES}] = \frac{k_b[\text{E}]_0}{\alpha K_M/[S]_0 + \alpha'}$$

which, by using eqn 23.2b, gives eqn 23.7.

There are three major modes of inhibition that give rise to distinctly different kinetic behaviour (Fig. 23.6). In **competitive inhibition** the inhibitor binds only to the active site of the enzyme and thereby inhibits the attachment of the substrate.

This condition corresponds to  $\alpha > 1$  and  $\alpha' = 1$  (because ESI does not form). In this limit, eqn 23.8 becomes

$$\frac{1}{v} = \frac{1}{v_{\max}} + \left( \frac{\alpha K_M}{v_{\max}} \right) \frac{1}{[S]_0}$$

Competitive inhibition

The  $y$ -intercept is unchanged but the slope of the Lineweaver–Burk plot increases by a factor of  $\alpha$  relative to the slope for data on the uninhibited enzyme (Fig. 23.6a). In **uncompetitive inhibition** the inhibitor binds to a site of the enzyme that is removed from the active site, but only if the substrate is already present. The inhibition occurs because ESI reduces the concentration of ES, the active type of complex. In this case  $\alpha = 1$  (because EI does not form) and  $\alpha' > 1$  and eqn 23.8 becomes

$$\frac{1}{v} = \frac{\alpha'}{v_{\max}} + \left( \frac{K_M}{v_{\max}} \right) \frac{1}{[S]_0}$$

Uncompetitive inhibition

The  $y$ -intercept of the Lineweaver–Burk plot increases by a factor of  $\alpha'$  relative to the  $y$ -intercept for data on the uninhibited enzyme but the slope does not change (Fig. 23.6b). In **non-competitive inhibition** (also called **mixed inhibition**) the inhibitor binds to a site other than the active site, and its presence reduces the ability of the substrate to bind to the active site. Inhibition occurs at both the E and ES sites. This condition corresponds to  $\alpha > 1$  and  $\alpha' > 1$ . Both the slope and  $y$ -intercept of the Lineweaver–Burk plot increase upon addition of the inhibitor. Figure 23.6c shows the special case of  $K_I = K'_I$  and  $\alpha = \alpha'$ , which results in intersection of the lines at the  $x$ -axis.

In all cases, the efficiency of the inhibitor may be obtained by determining  $K_M$  and  $v_{\max}$  from a control experiment with uninhibited enzyme and then repeating the experiment with a known concentration of inhibitor. From the slope and  $y$ -intercept of the Lineweaver–Burk plot for the inhibited enzyme (eqn 23.8), the mode of inhibition, the values of  $\alpha$  or  $\alpha'$ , and the values of  $K_I$  and  $K'_I$  may be obtained.

### Example 23.2 Distinguishing between types of inhibition

Five solutions of a substrate, S, were prepared with the concentrations given in the first column below and each one was divided into five equal volumes. The same concentration of enzyme was present in each one. An inhibitor, I, was then added in four different concentrations to the samples, and the initial rate of formation of product was determined with the results given below. Does the inhibitor act competitively or non-competitively? Determine  $K_I$  and  $K_M$ .

| $[S]_0/(\text{mmol dm}^{-3})$ | $v/(\mu\text{mol dm}^{-3} \text{ s}^{-1})$ for $[I]/(\text{mmol dm}^{-3}) =$ |       |       |       |       |
|-------------------------------|------------------------------------------------------------------------------|-------|-------|-------|-------|
|                               | 0                                                                            | 0.20  | 0.40  | 0.60  | 0.80  |
| 0.050                         | 0.033                                                                        | 0.026 | 0.021 | 0.018 | 0.016 |
| 0.10                          | 0.055                                                                        | 0.045 | 0.038 | 0.033 | 0.029 |
| 0.20                          | 0.083                                                                        | 0.071 | 0.062 | 0.055 | 0.050 |
| 0.40                          | 0.111                                                                        | 0.100 | 0.091 | 0.084 | 0.077 |
| 0.60                          | 0.126                                                                        | 0.116 | 0.108 | 0.101 | 0.094 |

**Method** We draw a series of Lineweaver–Burk plots for different inhibitor concentrations. If the plots resemble those in Fig. 23.6a, then the inhibition is

**Fig. 23.7** Lineweaver–Burk plots for the data in Example 23.2. Each line corresponds to a different concentration of inhibitor.

**Fig. 23.8** Plot of the slopes of the plots in Fig. 23.7 against  $[I]$  based on the data in Example 23.2.

competitive. On the other hand, if the plots resemble those in Fig. 23.6c, then the inhibition is non-competitive. To find  $K_I$ , we need to determine the slope at each value of  $[I]$ , which is equal to  $\alpha K_M/v_{\max}$ , or  $K_M/v_{\max} + K_M[I]/K_I v_{\max}$ , then plot this slope against  $[I]$ : the intercept at  $[I] = 0$  is the value of  $K_M/v_{\max}$  and the slope is  $K_M/K_I v_{\max}$ .

**Answer** First we draw up a table of  $1/[S]_0$  and  $1/v$  for each value of  $[I]$ :

| $1/([S]_0/(\text{mmol dm}^{-3}))$ | $1/(v/(\mu\text{mol dm}^{-3} \text{ s}^{-1}))$ for $[I]/(\text{mmol dm}^{-3}) =$ |      |      |      |      |
|-----------------------------------|----------------------------------------------------------------------------------|------|------|------|------|
|                                   | 0                                                                                | 0.20 | 0.40 | 0.60 | 0.80 |
| 20                                | 30                                                                               | 38   | 48   | 56   | 62   |
| 10                                | 18                                                                               | 22   | 26   | 30   | 34   |
| 5.0                               | 12                                                                               | 14   | 16   | 18   | 20   |
| 2.5                               | 9.01                                                                             | 10.0 | 11.0 | 11.9 | 13.0 |
| 1.7                               | 7.94                                                                             | 8.62 | 9.26 | 9.90 | 10.6 |

The five plots (one for each  $[I]$ ) are given in Fig. 23.7. We see that they pass through the same intercept on the vertical axis, so the inhibition is competitive. The mean of the (least squares) intercepts is 5.83, so  $v_{\max} = 0.172 \mu\text{mol dm}^{-3} \text{ s}^{-1}$  (note how it picks up the units for  $v$  in the data). The (least squares) slopes of the lines are as follows:

| $[I]/(\text{mmol dm}^{-3})$ | 0     | 0.20  | 0.40  | 0.60  | 0.80  |
|-----------------------------|-------|-------|-------|-------|-------|
| Slope                       | 1.219 | 1.627 | 2.090 | 2.489 | 2.832 |

These values are plotted in Fig. 23.8. The intercept at  $[I] = 0$  is 1.234, so  $K_M = 0.212 \text{ mmol dm}^{-3}$ . The (least squares) slope of the line is 2.045, so

$$K_I/(\text{mmol dm}^{-3}) = \frac{K_M}{\text{slope} \times v_{\max}} = \frac{0.212}{2.045 \times 0.172} = 0.603$$

**Self-test 23.2** Repeat the question using the following data:

| $[S]_0/(\text{mmol dm}^{-3})$ | $v/(\mu\text{mol dm}^{-3} \text{ s}^{-1})$ for $[I]/(\text{mmol dm}^{-3}) =$ |       |       |        |        |
|-------------------------------|------------------------------------------------------------------------------|-------|-------|--------|--------|
|                               | 0                                                                            | 0.20  | 0.40  | 0.60   | 0.80   |
| 0.050                         | 0.020                                                                        | 0.015 | 0.012 | 0.0098 | 0.0084 |
| 0.10                          | 0.035                                                                        | 0.026 | 0.021 | 0.017  | 0.015  |
| 0.20                          | 0.056                                                                        | 0.042 | 0.033 | 0.028  | 0.024  |
| 0.40                          | 0.080                                                                        | 0.059 | 0.047 | 0.039  | 0.034  |
| 0.60                          | 0.093                                                                        | 0.069 | 0.055 | 0.046  | 0.039  |

[Non-competitive,  $K_M = 0.30 \text{ mmol dm}^{-3}$ ,  $K_I = 0.57 \text{ mmol dm}^{-3}$ ]

## Heterogeneous catalysis

The remainder of this chapter is devoted to developing and applying concepts of structure and reactivity in heterogeneous catalysis. For simplicity, we consider only gas/solid systems. To understand the catalytic role of a solid surface we begin by

describing its unique structural features. Then, because many reactions catalysed by surfaces involve reactants and products in the gas phase, we discuss **adsorption**, the attachment of particles to a solid surface, and **desorption**, the reverse process. Finally, we consider specific mechanisms of heterogeneous catalysis.

### 23.3 The growth and structure of solid surfaces

**Key points** Adsorption is the attachment of molecules to a surface; the substance that adsorbs is the adsorbate and the underlying material is the adsorbent or substrate. The reverse of adsorption is desorption. (a) Surface defects play an important role in surface growth and catalysis. (b) Techniques for studying surface composition and structure include scanning electron microscopy, scanning probe microscopy, photoemission spectroscopy, Auger electron spectroscopy, and low energy electron diffraction.

The substance that adsorbs is the **adsorbate** and the underlying material that we are concerned with in this section is the **adsorbent** or **substrate**.

#### (a) Surface growth

A simple picture of a perfect crystal surface is as a tray of oranges in a grocery store (Fig. 23.9). A gas molecule that collides with the surface can be imagined as a ping-pong ball bouncing erratically over the oranges. The molecule loses energy as it bounces, but it is likely to escape from the surface before it has lost enough kinetic energy to be trapped. The same is true, to some extent, of an ionic crystal in contact with a solution. There is little energy advantage for an ion in solution to discard some of its solvating molecules and stick at an exposed position on the surface.

The picture changes when the surface has defects, for then there are ridges of incomplete layers of atoms or ions. A common type of surface defect is a **step** between two otherwise flat layers of atoms called **terraces** (Fig. 23.10). A step defect might itself have defects, for it might have kinks. When an atom settles on a terrace it bounces across it under the influence of the intermolecular potential, and might come to a step or a corner formed by a kink. Instead of interacting with a single terrace atom, the molecule now interacts with several, and the interaction may be strong enough to trap it. Likewise, when ions deposit from solution, the loss of the solvation interaction is offset by a strong Coulombic interaction between the arriving ions and several ions at the surface defect.

The rapidity of growth depends on the crystal plane concerned, and the slowest growing faces dominate the appearance of the crystal. This feature is explained in Fig. 23.11, where we see that, although the horizontal face grows forward most rapidly, it grows itself out of existence, and the slower-growing faces survive.

#### (b) Surface composition and structure

Under normal conditions, a surface exposed to a gas is constantly bombarded with molecules and a freshly prepared surface is covered very quickly. Just how quickly can be estimated using the kinetic model of gases and the following expression for the collision flux (eqn 20.14):

$$Z_w = \frac{P}{(2\pi mkT)^{1/2}} \quad \text{Collision flux} \quad (23.9)$$

A practical form of this equation is

$$Z_w = \frac{Z_0(p/\text{Pa})}{\{(T/\text{K})(M/(\text{g mol}^{-1}))\}^{1/2}} \quad \text{with} \quad Z_0 = 2.63 \times 10^{24} \text{ m}^{-2} \text{ s}^{-1}$$

**Fig. 23.9** A schematic diagram of the flat surface of a solid. This primitive model is largely supported by scanning tunnelling microscope images (see *Impact I8.2*).

**Fig. 23.10** Some of the kinds of defects that may occur on otherwise perfect terraces. Defects play an important role in surface growth and catalysis.

**Fig. 23.11** The more slowly growing faces of a crystal dominate its final external appearance. Three successive stages of the growth are shown.

**Fig. 23.12** The X-ray photoemission spectrum of a sample of gold contaminated with a surface layer of mercury. (M.W. Roberts and C.S. McKee, *Chemistry of the metal–gas interface*, Oxford (1978).)

**Fig. 23.13** When an electron is expelled from a solid (a) an electron of higher energy may fall into the vacated orbital and emit an X-ray photon to produce X-ray fluorescence. Alternatively (b) the electron falling into the orbital may give up its energy to another electron, which is ejected in the Auger effect.

where  $M$  is the molar mass of the gas. For air ( $M \approx 29 \text{ g mol}^{-1}$ ) at 1 atm and  $25^\circ\text{C}$  the collision flux is  $3 \times 10^{27} \text{ m}^{-2} \text{ s}^{-1}$ . Because  $1 \text{ m}^2$  of metal surface consists of about  $10^{19}$  atoms, each atom is struck about  $10^8$  times each second. Even if only a few collisions leave a molecule adsorbed to the surface, the time for which a freshly prepared surface remains clean is very short.

The obvious way to retain cleanliness is to reduce the pressure. When it is reduced to  $10^{-4} \text{ Pa}$  (as in a simple vacuum system) the collision flux falls to about  $10^{18} \text{ m}^{-2} \text{ s}^{-1}$ , corresponding to one hit per surface atom in each 0.1 s. Even that is too brief in most experiments, and in **ultrahigh vacuum** (UHV) techniques pressures as low as  $0.1 \text{ }\mu\text{Pa}$  (when  $Z_W = 10^{15} \text{ m}^{-2} \text{ s}^{-1}$ ) are reached on a routine basis and as low as  $1 \text{ nPa}$  (when  $Z_W = 10^{13} \text{ m}^{-2} \text{ s}^{-1}$ ) are reached with special care. These collision fluxes correspond to each surface atom being hit once every  $10^5$  to  $10^6 \text{ s}$ , or about once a day.

The chemical composition of a surface can be determined by a variety of ionization techniques. The same techniques can be used to detect any remaining contamination after cleaning and to detect layers of material adsorbed later in the experiment. One technique is **photoemission spectroscopy**, a derivative of the photoelectric effect, in which X-rays (for XPS) or hard (short wavelength) ultraviolet (for UPS) ionizing radiation is used, giving rise to ejected electrons from adsorbed species. The kinetic energies of the electrons ejected from their orbitals are measured and the pattern of energies is a fingerprint of the material present (Fig. 23.12). UPS, which examines electrons ejected from valence shells, is also used to establish the bonding characteristics and the details of valence shell electronic structures of substances on the surface. Its usefulness is its ability to reveal which orbitals of the adsorbate are involved in the bond to the substrate. For instance, the principal difference between the photoemission results on free benzene and benzene adsorbed on palladium is in the energies of the  $\pi$  electrons. This difference is interpreted as meaning that the  $\text{C}_6\text{H}_6$  molecules lie parallel to the surface and are attached to it by their  $\pi$  orbitals. In contrast, pyridine ( $\text{C}_5\text{H}_5\text{N}$ ) stands almost perpendicular to the surface, and is attached by a  $\sigma$  bond formed by the nitrogen lone pair.

A very important technique, which is widely used in the microelectronics industry, is **Auger electron spectroscopy** (AES). The **Auger effect** (pronounced oh-zhey) is the emission of a second electron after high energy radiation has expelled another. The first electron to depart leaves a hole in a low-lying orbital, and an upper electron falls into it. The energy this releases may result either in the generation of radiation, which is called **X-ray fluorescence** (Fig. 23.13a) or in the ejection of another electron (Fig. 23.13b). The latter is the secondary electron of the Auger effect. The energies of the secondary electrons are characteristic of the material present, so the Auger effect effectively takes a fingerprint of the sample. In practice, the Auger spectrum is normally obtained by irradiating the sample with an electron beam of energy in the range 1–5 keV rather than electromagnetic radiation. In **scanning Auger electron microscopy** (SAM), the finely focused electron beam is scanned over the surface and a map of composition is compiled; the resolution can reach below about 50 nm.

One of the most informative techniques for determining the arrangement of the atoms close to the surface is **low energy electron diffraction** (LEED). This technique is like X-ray diffraction (Chapter 19) but uses the wave character of electrons, and the sample is now the surface of a solid. The use of low energy electrons (with energies in the range 10–200 eV, corresponding to wavelengths in the range 100–400 pm) ensures that the diffraction is caused only by atoms on and close to the surface. The experimental arrangement is shown in Fig. 23.14, and typical LEED patterns, obtained by photographing the fluorescent screen through the viewing port, are shown in Fig. 23.15.

**Example 23.3** Interpreting a LEED pattern

The LEED pattern from a clean unreconstructed (110) face of palladium is shown in (a) below. The reconstructed surface gives a LEED pattern shown as (b). What can be inferred about the structure of the reconstructed surface?

**Method** Recall from Bragg's law (Section 19.3),  $\lambda = 2d \sin \theta$ , that, for a given wavelength, the smaller the separation  $d$  of the layers, the greater the scattering angle (so that  $2d \sin \theta$  remains constant). In terms of the LEED pattern, the farther apart the atoms responsible for the pattern, the closer the spots appear in the pattern. Twice the separation between the atoms corresponds to half the separation between the spots, and vice versa. Therefore, inspect the two patterns and identify how the new pattern relates to the old.

**Answer** The horizontal separation between spots is unchanged, which indicates that the atoms remain in the same position in that dimension when reconstruction occurs. However, the vertical spacing is halved, which suggests that the atoms are twice as far apart in that direction as they are in the unreconstructed surface.

**Self-test 23.3** Sketch the LEED pattern for a surface that was reconstructed from that shown in (a) above by tripling the vertical separation. [ ::::: ]

Observations using LEED show that the surface of a crystal rarely has exactly the same form as a slice through the bulk. As a general rule, it is found that metal surfaces are simply truncations of the bulk lattice, but the distance between the top layer of atoms and the one below is contracted by around 5 per cent. Semiconductors generally have surfaces reconstructed to a depth of several layers. Reconstruction occurs in ionic solids. For example, in lithium fluoride the  $\text{Li}^+$  and  $\text{F}^-$  ions close to the surface apparently lie on slightly different planes. An actual example of the detail that can now be obtained from refined LEED techniques is shown in Fig. 23.16 for  $\text{CH}_3\text{C}-$  adsorbed on a (111) plane of rhodium.

The presence of terraces, steps, and kinks in a surface shows up in LEED patterns, and their surface density (the number of defects in a region divided by the area of the

**Fig. 23.15** LEED photographs of (a) a clean platinum surface and (b) after its exposure to propyne,  $\text{CH}_3\text{C}\equiv\text{CH}$ . (Photographs provided by Professor G.A. Somorjai.)

**Fig. 23.14** A schematic diagram of the apparatus used for a LEED experiment. The electrons diffracted by the surface layers are detected by the fluorescence they cause on the phosphor screen.

**Fig. 23.16** The structure of a surface close to the point of attachment of  $\text{CH}_3\text{C}-$  to the (111) surface of rhodium at 300 K and the changes in positions of the metal atoms that accompany chemisorption.

**Fig. 23.17** LEED patterns may be used to assess the defect density of a surface. The photographs correspond to a platinum surface with (a) low defect density, (b) regular steps separated by about six atoms, and (c) regular steps with kinks. (Photographs provided by Professor G.A. Samorjai.)

region) can be estimated. The importance of this type of measurement will emerge later. Three examples of how steps and kinks affect the pattern are shown in Fig. 23.17. The samples used were obtained by cleaving a crystal at different angles to a plane of atoms. Only terraces are produced when the cut is parallel to the plane, and the density of steps increases as the angle of the cut increases. The observation of additional structure in the LEED patterns, rather than blurring, shows that the steps are arrayed regularly.

### 23.4 The extent of adsorption

**Key points** The fractional coverage,  $\theta$ , is the ratio of the number of occupied sites to the number of available sites. Techniques for studying the rates of surface processes include flash desorption, second harmonic generation, gravimetry, and molecular beam reactive scattering. (a) Physisorption is adsorption by a van der Waals interaction; chemisorption is adsorption by formation of a chemical bond. (b) An adsorption isotherm is the variation of  $\theta$  with pressure at a chosen temperature. Examples include the Langmuir, BET, Temkin, and Freundlich isotherms.

The extent of surface coverage is normally expressed as the **fractional coverage**,  $\theta$ :

$$\theta = \frac{\text{number of adsorption sites occupied}}{\text{number of adsorption sites available}} \quad \text{Definition of the fractional coverage} \quad [23.10]$$

The fractional coverage is often expressed in terms of the volume of adsorbate adsorbed by  $\theta = V/V_\infty$ , where  $V_\infty$  is the volume of adsorbate corresponding to complete monolayer coverage. The **rate of adsorption**,  $d\theta/dt$ , is the rate of change of surface coverage, and can be determined by observing the change of fractional coverage with time.

Among the principal techniques for measuring  $d\theta/dt$  are flow methods, in which the sample itself acts as a pump because adsorption removes particles from the gas. One commonly used technique is therefore to monitor the rates of flow of gas into and out of the system: the difference is the rate of gas uptake by the sample. Integration of this rate then gives the fractional coverage at any stage. In **flash desorption** the sample is suddenly heated (electrically) and the resulting rise of pressure is interpreted in terms of the amount of adsorbate originally on the sample. The interpretation may be confused by the desorption of a compound (for example,  $\text{WO}_3$  from oxygen on tungsten). **Gravimetry**, in which the sample is weighed on a microbalance during the experiment, can also be used. A common instrument for gravimetric measurements is the **quartz crystal microbalance (QCM)**, in which the mass of a sample laid on the surface of a quartz crystal is related to changes in the latter's mechanical properties. The key principle behind the operation of a QCM is the ability of a quartz crystal to vibrate at a characteristic frequency when an oscillating electric field is applied. The vibrational frequency decreases when material is spread over the surface of the crystal and the change in frequency is proportional to the mass of material. Masses as small as a few nanograms can be measured reliably in this way.

#### (a) Physisorption and chemisorptions

Molecules and atoms can attach to surfaces in two ways. In **physisorption** (an abbreviation of 'physical adsorption'), there is a van der Waals interaction (for example, a dispersion or a dipolar interaction) between the adsorbate and the substrate. van der Waals interactions have a long range but are weak, and the energy released when a particle is physisorbed is of the same order of magnitude as the enthalpy of condensation. Such small energies can be absorbed as vibrations of the lattice and

dissipated as thermal motion, and a molecule bouncing across the surface will gradually lose its energy and finally adsorb to it in the process called **accommodation**. The enthalpy of physisorption can be measured by monitoring the rise in temperature of a sample of known heat capacity, and typical values are in the region of  $-20 \text{ kJ mol}^{-1}$  (Table 23.1). This small enthalpy change is insufficient to lead to bond breaking, so a physisorbed molecule retains its identity, although it might be distorted by the presence of the surface.

In **chemisorption** (an abbreviation of ‘chemical adsorption’), the molecules (or atoms) stick to the surface by forming a chemical (usually covalent) bond, and tend to find sites that maximize their coordination number with the substrate. The enthalpy of chemisorption is very much greater than that for physisorption, and typical values are in the region of  $-200 \text{ kJ mol}^{-1}$  (Table 23.2). The distance between the surface and the closest adsorbate atom is also typically shorter for chemisorption than for physisorption. A chemisorbed molecule may be torn apart at the demand of the unsatisfied valencies of the surface atoms, and the existence of molecular fragments on the surface as a result of chemisorption is one reason why solid surfaces catalyse reactions.

Except in special cases, chemisorption must be exothermic. A spontaneous process requires  $\Delta G < 0$  at constant pressure and temperature. Because the translational freedom of the adsorbate is reduced when it is adsorbed,  $\Delta S$  is negative. Therefore, in order for  $\Delta G = \Delta H - T\Delta S$  to be negative,  $\Delta H$  must be negative (that is, the process is exothermic). Exceptions may occur if the adsorbate dissociates and has high translational mobility on the surface. For example,  $\text{H}_2$  adsorbs endothermically on glass because there is a large increase of translational entropy accompanying the dissociation of the molecules into atoms that move quite freely over the surface. In this case, the entropy change in the process  $\text{H}_2(\text{g}) \rightarrow 2 \text{ H}(\text{glass})$  is sufficiently positive to overcome the small positive enthalpy change.

The enthalpy of adsorption depends on the extent of surface coverage, mainly because the adsorbate particles interact. If the particles repel each other (as for CO on palladium) the adsorption becomes less exothermic (the enthalpy of adsorption less negative) as coverage increases. Moreover, LEED studies show that such species settle on the surface in a disordered way until packing requirements demand order. If the adsorbate particles attract one another (as for  $\text{O}_2$  on tungsten), then they tend to cluster together in islands, and growth occurs at the borders. These adsorbates also show order–disorder transitions when they are heated enough for thermal motion to overcome the particle–particle interactions, but not so much that they are desorbed.

### (b) Adsorption isotherms

In chemisorption the free gas and the adsorbed gas are in dynamic equilibrium, and the fractional coverage of the surface depends on the pressure of the overlying gas. The variation of  $\theta$  with pressure at a chosen temperature is called the **adsorption isotherm**.

The simplest physically plausible isotherm is based on three assumptions:

- Adsorption cannot proceed beyond monolayer coverage.
- All sites are equivalent and the surface is uniform (that is, the surface is perfectly flat on a microscopic scale).
- The ability of a molecule to adsorb at a given site is independent of the occupation of neighbouring sites (that is, there are no interactions between adsorbed molecules).

The dynamic equilibrium is

**Table 23.1\*** Maximum observed enthalpies of physisorption

| Adsorbate            | $\Delta_{\text{ad}}H^\ominus/(\text{kJ mol}^{-1})$ |
|----------------------|----------------------------------------------------|
| $\text{CH}_4$        | –21                                                |
| $\text{H}_2$         | –84                                                |
| $\text{H}_2\text{O}$ | –59                                                |
| $\text{N}_2$         | –21                                                |

\* More values are given in the *Data section*.

**Table 23.2\*** Enthalpies of chemisorption,  $\Delta_{\text{ad}}H^\ominus/(\text{kJ mol}^{-1})$

| Adsorbate              | Adsorbent (substrate) |      |      |
|------------------------|-----------------------|------|------|
|                        | Cr                    | Fe   | Ni   |
| $\text{C}_2\text{H}_4$ | –427                  | –285 | –243 |
| CO                     |                       | –192 |      |
| $\text{H}_2$           | –188                  | –134 |      |
| $\text{NH}_3$          |                       | –188 | –155 |

\* More values are given in the *Data section*.

with rate constants  $k_a$  for adsorption and  $k_d$  for desorption. The rate of change of surface coverage due to adsorption is proportional to the partial pressure  $p$  of A and the number of vacant sites  $N(1 - \theta)$ , where  $N$  is the total number of sites:

$$\frac{d\theta}{dt} = k_a p N (1 - \theta) \quad \text{Rate of adsorption} \quad (23.11a)$$

The rate of change of  $\theta$  due to desorption is proportional to the number of adsorbed species,  $N\theta$ :

$$\frac{d\theta}{dt} = -k_d N \theta \quad \text{Rate of desorption} \quad (23.11b)$$

At equilibrium there is no net change (that is, the sum of these two rates is zero), and solving for  $\theta$  gives the **Langmuir isotherm**:

$$\theta = \frac{Kp}{1 + Kp} \quad K = \frac{k_a}{k_d} \quad \text{Langmuir isotherm} \quad (23.12)$$

#### Example 23.4 Using the Langmuir isotherm

The data given below are for the adsorption of CO on charcoal at 273 K. Confirm that they fit the Langmuir isotherm, and find the constant  $K$  and the volume corresponding to complete coverage. In each case  $V$  has been corrected to 1.00 atm (101.325 kPa).

|                 |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|
| $p/\text{kPa}$  | 13.3 | 26.7 | 40.0 | 53.3 | 66.7 | 80.0 | 93.3 |
| $V/\text{cm}^3$ | 10.2 | 18.6 | 25.5 | 31.5 | 36.9 | 41.6 | 46.1 |

**Method** From eqn 23.12,

$$Kp\theta + \theta = Kp$$

With  $\theta = V/V_\infty$ , where  $V_\infty$  is the volume corresponding to complete coverage, this expression can be rearranged into

$$\frac{p}{V} = \frac{p}{V_\infty} + \frac{1}{KV_\infty}$$

Hence, a plot of  $p/V$  against  $p$  should give a straight line of slope  $1/V_\infty$  and intercept  $1/KV_\infty$ .

**Answer** The data for the plot are as follows:

|                                  |      |      |      |      |      |      |      |
|----------------------------------|------|------|------|------|------|------|------|
| $p/\text{kPa}$                   | 13.3 | 26.7 | 40.0 | 53.3 | 66.7 | 80.0 | 93.3 |
| $(p/\text{kPa})/(V/\text{cm}^3)$ | 1.30 | 1.44 | 1.57 | 1.69 | 1.81 | 1.92 | 2.02 |

The points are plotted in Fig. 23.18. The (least squares) slope is 0.00900, so  $V_\infty = 111 \text{ cm}^3$ . The intercept at  $p = 0$  is 1.20, so

$$K = \frac{1}{(111 \text{ cm}^3) \times (1.20 \text{ kPa cm}^{-3})} = 7.51 \times 10^{-3} \text{ kPa}^{-1}$$

**Self-test 23.4** Repeat the calculation for the following data:

|                                                                 |      |      |      |      |      |      |      |
|-----------------------------------------------------------------|------|------|------|------|------|------|------|
| $p/\text{kPa}$                                                  | 13.3 | 26.7 | 40.0 | 53.3 | 66.7 | 80.0 | 93.3 |
| $V/\text{cm}^3$                                                 | 10.3 | 19.3 | 27.3 | 34.1 | 40.0 | 45.5 | 48.0 |
| [128 cm <sup>3</sup> , $6.69 \times 10^{-3} \text{ kPa}^{-1}$ ] |      |      |      |      |      |      |      |

**Fig. 23.18** The plot of the data in Example 23.4. As illustrated here, the Langmuir isotherm predicts that a straight line should be obtained when  $p/V$  is plotted against  $p$ .

For adsorption with dissociation, the rate of adsorption is proportional to the pressure and to the probability that both atoms will find sites, which is proportional to the square of the number of vacant sites,

$$\frac{d\theta}{dt} = k_a p \{N(1 - \theta)\}^2 \quad (23.13a)$$

The rate of desorption is proportional to the frequency of encounters of atoms on the surface, and is therefore second-order in the number of atoms present:

$$\frac{d\theta}{dt} = -k_d (N\theta)^2 \quad (23.13b)$$

The condition for no net change leads to the isotherm

$$\theta = \frac{(Kp)^{1/2}}{1 + (Kp)^{1/2}} \quad (23.14)$$

Langmuir isotherm  
for adsorption with  
dissociation

The surface coverage now depends more weakly on pressure than for non-dissociative adsorption.

The shapes of the Langmuir isotherms with and without dissociation are shown in Figs. 23.19 and 23.20. The fractional coverage increases with increasing pressure, and approaches 1 only at very high pressure, when the gas is forced on to every available site of the surface. Different curves (and therefore different values of  $K$ ) are obtained at different temperatures, and the temperature dependence of  $K$  can be used to determine the **isosteric enthalpy of adsorption**,  $\Delta_{\text{ad}}H^\circ$ , the standard enthalpy of adsorption at a fixed surface coverage. To determine this quantity we recognize that  $K$  is essentially an equilibrium constant, and then use the van't Hoff equation (eqn 6.21) to write:

$$\left( \frac{\partial \ln K}{\partial T} \right)_\theta = \frac{\Delta_{\text{ad}}H^\circ}{RT^2} \quad (23.15)$$

Isosteric enthalpy of  
adsorption from the  
equilibrium constant

#### Example 23.5 Measuring the isosteric enthalpy of adsorption

The data below show the pressures of CO needed for the volume of adsorption (corrected to 1.00 atm and 273 K) to be 10.0 cm<sup>3</sup> using the same sample as in Example 23.4. Calculate the adsorption enthalpy at this surface coverage.

|                |      |      |      |      |      |      |
|----------------|------|------|------|------|------|------|
| $T/\text{K}$   | 200  | 210  | 220  | 230  | 240  | 250  |
| $p/\text{kPa}$ | 4.00 | 4.95 | 6.03 | 7.20 | 8.47 | 9.85 |

**Method** The Langmuir isotherm can be rearranged to

$$Kp = \frac{\theta}{1 - \theta}$$

Therefore, when  $\theta$  is constant,

$$\ln K + \ln p = \text{constant}$$

It follows from eqn 23.15 that

$$\left( \frac{\partial \ln p}{\partial T} \right)_\theta = - \left( \frac{\partial \ln K}{\partial T} \right)_\theta = - \frac{\Delta_{\text{ad}}H^\circ}{RT^2}$$

**Fig. 23.19** The Langmuir isotherm for dissociative adsorption,  $X_2(g) \rightarrow 2 X(\text{surface})$ , for different values of  $K$ .

**interActivity** Using eqn 23.14, generate a family of curves showing the dependence of  $1/\theta$  on  $1/p$  for several values of  $K$ .

**Fig. 23.20** The Langmuir isotherm for non-dissociative adsorption for different values of  $K$ .

**interActivity** Using eqn 23.12, generate a family of curves showing the dependence of  $1/\theta$  on  $1/p$  for several values of  $K$ . Taking these results together with those of the previous *interActivity*, discuss how plots of  $1/\theta$  against  $1/p$  can be used to distinguish between adsorption with and without dissociation.

**Fig. 23.21** The isosteric enthalpy of adsorption can be obtained from the slope of the plot of  $\ln p$  against  $1/T$ , where  $p$  is the pressure needed to achieve the specified surface coverage. The data used are from Example 23.5.

**Fig. 23.22** Plots of the BET isotherm for different values of  $c$ . The value of  $V/V_{\text{mon}}$  rises indefinitely because the adsorbate may condense on the covered substrate surface.

**InterActivity** Using eqn 23.16, generate a family of curves showing the dependence of  $zV_{\text{mon}}/(1-z)V$  on  $z$  for different values of  $c$ .

With  $d(1/T)/dT = -1/T^2$ , this expression rearranges to

$$\left( \frac{\partial \ln p}{\partial (1/T)} \right)_\theta = \frac{\Delta_{\text{ad}} H^\ominus}{R}$$

Therefore, a plot of  $\ln p$  against  $1/T$  should be a straight line of slope  $\Delta_{\text{ad}} H^\ominus/R$ .

**Answer** We draw up the following table:

| $T/\text{K}$        | 200  | 210  | 220  | 230  | 240  | 250  |
|---------------------|------|------|------|------|------|------|
| $10^3/(T/\text{K})$ | 5.00 | 4.76 | 4.55 | 4.35 | 4.17 | 4.00 |
| $\ln(p/\text{kPa})$ | 1.39 | 1.60 | 1.80 | 1.97 | 2.14 | 2.29 |

The points are plotted in Fig. 23.21. The slope (of the least squares fitted line) is  $-0.904$ , so

$$\Delta_{\text{ad}} H^\ominus = -(0.904 \times 10^3 \text{ K}) \times R = -7.52 \text{ kJ mol}^{-1}$$

The value of  $K$  can be used to obtain a value of  $\Delta_{\text{ad}} G^\ominus$ , and then that value combined with  $\Delta_{\text{ad}} H^\ominus$  to obtain the standard entropy of adsorption. The expression for  $(\partial \ln p / \partial T)_\theta$  in this example is independent of the model for the isotherm.

**Self-test 23.5** Repeat the calculation using the following data:

| $T/\text{K}$   | 200  | 210  | 220  | 230  | 240   | 250   |
|----------------|------|------|------|------|-------|-------|
| $p/\text{kPa}$ | 4.32 | 5.59 | 7.07 | 8.80 | 10.67 | 12.80 |

$$[-9.0 \text{ kJ mol}^{-1}]$$

If the initial adsorbed layer can act as a substrate for further (for example, physical) adsorption, then, instead of the isotherm levelling off to some saturated value at high pressures, it can be expected to rise indefinitely. The most widely used isotherm dealing with multilayer adsorption was derived by Stephen Brunauer, Paul Emmett, and Edward Teller (see *Further information 23.1*), and is called the **BET isotherm**:

$$\frac{V}{V_{\text{mon}}} = \frac{cz}{(1-z)\{1-(1-c)z\}} \quad \text{with} \quad z = \frac{p}{p^*} \quad \text{BET isotherm} \quad (23.16)$$

In this expression,  $p^*$  is the vapour pressure above a layer of adsorbate that is more than one molecule thick and which resembles a pure bulk liquid,  $V_{\text{mon}}$  is the volume corresponding to monolayer coverage, and  $c$  is a constant that is large when the enthalpy of desorption from a monolayer is large compared with the enthalpy of vaporization of the liquid adsorbate:

$$c = e^{(\Delta_{\text{des}} H^\ominus - \Delta_{\text{vap}} H^\ominus)/RT} \quad (23.17)$$

Figure 23.22 illustrates the shapes of BET isotherms. They rise indefinitely as the pressure is increased because there is no limit to the amount of material that may condense when multilayer coverage may occur. A BET isotherm is not accurate at all pressures, but it is widely used in industry to determine the surface areas of solids.

**Example 23.6** Using the BET isotherm

The data below relate to the adsorption of  $\text{N}_2$  on rutile ( $\text{TiO}_2$ ) at 75 K. Confirm that they fit a BET isotherm in the range of pressures reported, and determine  $V_{\text{mon}}$  and  $c$ .

| $p/\text{kPa}$  | 0.160 | 1.87 | 6.11 | 11.67 | 17.02 | 21.92 | 27.29 |
|-----------------|-------|------|------|-------|-------|-------|-------|
| $V/\text{mm}^3$ | 601   | 720  | 822  | 935   | 1046  | 1146  | 1254  |

At 75 K,  $p^* = 76.0$  kPa. The volumes have been corrected to 1.00 atm and 273 K and refer to 1.00 g of substrate.

**Method** Equation 23.16 can be reorganized into

$$\frac{z}{(1-z)V} = \frac{1}{cV_{\text{mon}}} + \frac{(c-1)z}{cV_{\text{mon}}}$$

It follows that  $(c-1)/cV_{\text{mon}}$  can be obtained from the slope of a plot of the expression on the left against  $z$ , and  $cV_{\text{mon}}$  can be found from the intercept at  $z = 0$ . The results can then be combined to give  $c$  and  $V_{\text{mon}}$ .

**Answer** We draw up the following table:

|                               |       |       |      |       |       |       |       |
|-------------------------------|-------|-------|------|-------|-------|-------|-------|
| $p/\text{kPa}$                | 0.160 | 1.87  | 6.11 | 11.67 | 17.02 | 21.92 | 27.29 |
| $10^3 z$                      | 2.11  | 24.6  | 80.4 | 154   | 224   | 288   | 359   |
| $10^4 z/(1-z)(V/\text{mm}^3)$ | 0.035 | 0.350 | 1.06 | 1.95  | 2.76  | 3.53  | 4.47  |

These points are plotted in Fig. 23.23. The least squares best line has an intercept at 0.0398, so

$$\frac{1}{cV_{\text{mon}}} = 3.98 \times 10^{-6} \text{ mm}^{-3}$$

The slope of the line is  $1.23 \times 10^{-2}$ , so

$$\frac{c-1}{cV_{\text{mon}}} = (1.23 \times 10^{-2}) \times 10^3 \times 10^{-4} \text{ mm}^{-3} = 1.23 \times 10^{-3} \text{ mm}^{-3}$$

The solutions of these equations are  $c = 310$  and  $V_{\text{mon}} = 811 \text{ mm}^3$ . At 1.00 atm and 273 K,  $811 \text{ mm}^3$  corresponds to  $3.6 \times 10^{-5} \text{ mol}$ , or  $2.2 \times 10^{19}$  atoms. Because each atom occupies an area of about  $0.16 \text{ nm}^2$ , the surface area of the sample is about  $3.5 \text{ m}^2$ .

**Self-test 23.6** Repeat the calculation for the following data:

|                 |                           |      |      |       |       |       |       |
|-----------------|---------------------------|------|------|-------|-------|-------|-------|
| $p/\text{kPa}$  | 0.160                     | 1.87 | 6.11 | 11.67 | 17.02 | 21.92 | 27.29 |
| $V/\text{cm}^3$ | 235                       | 559  | 649  | 719   | 790   | 860   | 950   |
|                 | [370, 615 $\text{cm}^3$ ] |      |      |       |       |       |       |

When  $c \gg 1$ , the BET isotherm takes the simpler form

$$\frac{V}{V_{\text{mon}}} = \frac{1}{1-z} \quad \text{BET isotherm when } c \gg 1 \quad (23.18)$$

This expression is applicable to unreactive gases on polar surfaces, for which  $c \approx 10^2$  because  $\Delta_{\text{des}} H^\circ$  is then significantly greater than  $\Delta_{\text{vap}} H^\circ$  (eqn 23.17). The BET isotherm fits experimental observations moderately well over restricted pressure ranges, but it errs by underestimating the extent of adsorption at low pressures and by overestimating it at high pressures.

An assumption of the Langmuir isotherm is the independence and equivalence of the adsorption sites. Deviations from the isotherm can often be traced to the failure of these assumptions. For example, the enthalpy of adsorption often becomes less negative as  $\theta$  increases, which suggests that the energetically most favourable sites are occupied first. Various attempts have been made to take these variations into account. The **Temkin isotherm**,

**Fig. 23.23** The BET isotherm can be tested, and the parameters determined, by plotting  $z/(1-z)V$  against  $z = p/p^*$ . The data are from Example 23.6.

$$\theta = c_1 \ln(c_2 p) \quad \text{Temkin isotherm} \quad (23.19)$$

where  $c_1$  and  $c_2$  are constants, corresponds to supposing that the adsorption enthalpy changes linearly with pressure. The **Freundlich isotherm**

$$\theta = c_1 p^{1/c_2} \quad \text{Freundlich isotherm} \quad (23.20)$$

corresponds to a logarithmic change. This isotherm attempts to incorporate the role of substrate–substrate interactions on the surface.

Different isotherms agree with experiment more or less well over restricted ranges of pressure, but they remain largely empirical. Empirical, however, does not mean useless for, if the parameters of a reasonably reliable isotherm are known, reasonably reliable results can be obtained for the extent of surface coverage under various conditions. This kind of information is essential for any discussion of heterogeneous catalysis.

### 23.5 The rates of surface processes

**Key points** (a) The sticking probability is the proportion of collisions with the surface that lead to adsorption. (b) Desorption is an activated process; the desorption activation energy is measured by temperature-programmed desorption) or thermal desorption spectroscopy. (c) Diffusion characteristics of an adsorbate can be examined by using STM or field-ionization microscopy.

**Fig. 23.24** The potential energy profiles for the dissociative chemisorption of an  $A_2$  molecule. In each case,  $P$  is the enthalpy of (non-dissociative) physisorption and  $C$  that for chemisorption (at  $T = 0$ ). The relative locations of the curves determines whether the chemisorption is (a) not activated or (b) activated.

The rates of surface processes may be studied by techniques already described in this chapter. Another technique, **second harmonic generation** (SHG), is very important for the study of all types of surfaces, including thin films and liquid–gas interfaces. We saw in Section 19.10 that second harmonic generation is the conversion of an intense, pulsed laser beam to radiation with twice its initial frequency as it passes through a material. In addition to a number of crystals, surfaces are also suitable materials for SHG. For example, adsorption of gas molecules on to a surface alters the intensity of the SHG signal, allowing for characterization of processes by the various isotherms discussed above. Because pulsed lasers are the excitation sources, time-resolved measurements of the kinetics and dynamics of surface processes are possible over timescales as short as femtoseconds.

Figure 23.24 shows how the potential energy of a molecule varies with its distance from the substrate surface. As the molecule approaches the surface its energy falls as it becomes physisorbed into the **precursor state** for chemisorption. Dissociation into fragments often takes place as a molecule moves into its chemisorbed state, and after an initial increase of energy as the bonds stretch there is a sharp decrease as the adsorbate–substrate bonds reach their full strength. Even if the molecule does not fragment, there is likely to be an initial increase of potential energy as the molecule approaches the surface and the bonds adjust.

In most cases, therefore, we can expect there to be a potential energy barrier separating the precursor and chemisorbed states. This barrier, though, might be low, and might not rise above the energy of a distant, stationary particle (as in Fig. 23.24a). In this case, chemisorption is not an activated process and can be expected to be rapid. Many gas adsorptions on clean metals appear to be non-activated. In some cases the barrier rises above the zero axis (as in Fig. 23.24b); such chemisorptions are activated and slower than the non-activated kind. An example is  $H_2$  on copper, which has an activation energy in the region of  $20\text{--}40\text{ kJ mol}^{-1}$ .

One point that emerges from this discussion is that rates are not good criteria for distinguishing between physisorption and chemisorption. Chemisorption can be fast

if the activation energy is small or zero, but it may be slow if the activation energy is large. Physisorption is usually fast, but it can appear to be slow if adsorption is taking place on a porous medium.

### (a) The rate of adsorption

The rate at which a surface is covered by adsorbate depends on the ability of the substrate to dissipate the energy of the incoming particle as thermal motion as it crashes on to the surface. If the energy is not dissipated quickly, the particle migrates over the surface until a vibration expels it into the overlying gas or it reaches an edge. The proportion of collisions with the surface that successfully lead to adsorption is called the **sticking probability**,  $s$ :

$$s = \frac{\text{rate of adsorption of particles by the surface}}{\text{rate of collision of particles with the surface}} \quad \text{Definition of the sticking probability} \quad [23.21]$$

The denominator can be calculated from the kinetic model, and the numerator can be measured by observing the rate of change of pressure.

Values of  $s$  vary widely. For example, at room temperature CO has  $s$  in the range 0.1–1.0 for several d-metal surfaces, but for  $\text{N}_2$  on rhenium  $s < 10^{-2}$ , indicating that more than a hundred collisions are needed before one molecule sticks successfully. Beam studies on specific crystal planes show a pronounced specificity: for  $\text{N}_2$  on tungsten,  $s$  ranges from 0.74 on the (320) faces down to less than 0.01 on the (110) faces at room temperature. The sticking probability decreases as the surface coverage increases (Fig. 23.25). A simple assumption is that  $s$  is proportional to  $1 - \theta$ , the fraction uncovered, and it is common to write

$$s = (1 - \theta)s_0 \quad (23.22)$$

where  $s_0$  is the sticking probability on a perfectly clean surface. The results in the illustration do not fit this expression because they show that  $s$  remains close to  $s_0$  until the coverage has risen to about  $6 \times 10^{13}$  molecules  $\text{cm}^{-2}$ , and then falls steeply. The explanation is probably that the colliding molecule does not enter the chemisorbed state at once, but moves over the surface until it encounters an empty site.

### (b) The rate of desorption

Desorption is always activated because the particles have to be lifted from the foot of a potential well. A physisorbed particle vibrates in its shallow potential well, and might shake itself off the surface after a short time. The temperature dependence of the first-order rate of departure can be expected to be Arrhenius-like, with an activation energy for desorption,  $E_d$ , comparable to the enthalpy of physisorption:

$$k_d = A e^{-E_d/RT} \quad (23.23)$$

Therefore, the half-life for remaining on the surface has a temperature dependence

$$t_{1/2} = \frac{\ln 2}{k_d} = \tau_0 e^{E_d/RT} \quad \tau_0 = \frac{\ln 2}{A} \quad (23.24)$$

(Note the positive sign in the exponent.) If we suppose that  $1/\tau_0$  is approximately the same as the vibrational frequency of the weak particle–surface bond (about  $10^{12}$  Hz) and  $E_d \approx 25$  kJ  $\text{mol}^{-1}$ , then residence half-lives of around 10 ns are predicted at room temperature. Lifetimes close to 1 s are obtained only by lowering the temperature to about 100 K. For chemisorption, with  $E_d = 100$  kJ  $\text{mol}^{-1}$  and guessing that  $\tau_0 = 10^{-14}$  s (because the adsorbate–substrate bond is quite stiff), we expect a residence half-life

**Fig. 23.25** The sticking probability of  $\text{N}_2$  on various faces of a tungsten crystal and its dependence on surface coverage. Note the very low sticking probability for the (110) and (111) faces. (Data provided by Professor D.A. King.)

**Fig. 23.26** The flash desorption spectrum of  $\text{H}_2$  on the (100) face of tungsten. The three peaks indicate the presence of three sites with different adsorption enthalpies and therefore different desorption activation energies. (P.W. Tamm and L.D. Schmidt, *J. Chem. Phys.*, 51, 5352 (1969).)

**Fig. 23.27** The events leading to an FIM image of a surface. The He atom migrates across the surface until it is ionized at an exposed atom, when it is pulled off by the externally applied potential. (The bouncing motion is due to the intermolecular potential, not gravity!)

of about  $3 \times 10^3$  s (about an hour) at room temperature, decreasing to 1 s at about 350 K.

The desorption activation energy can be measured in several ways. However, we must be guarded in its interpretation because it often depends on the fractional coverage, and so may change as desorption proceeds. Moreover, the transfer of concepts such as ‘reaction order’ and ‘rate constant’ from bulk studies to surfaces is hazardous, and there are few examples of strictly first-order or second-order desorption kinetics (just as there are few integral-order reactions in the gas phase too).

If we disregard these complications, one way of measuring the desorption activation energy is to monitor the rate of increase in pressure when the sample is maintained at a series of temperatures, and to attempt to make an Arrhenius plot. A more sophisticated technique is **temperature programmed desorption (TPD)** or **thermal desorption spectroscopy (TDS)**. The basic observation is a surge in desorption rate (as monitored by a mass spectrometer) when the temperature is raised linearly to the temperature at which desorption occurs rapidly, but once the desorption has occurred there is no more adsorbate to escape from the surface, so the desorption flux falls again as the temperature continues to rise. The TPD spectrum, the plot of desorption flux against temperature, therefore shows a peak, the location of which depends on the desorption activation energy. There are three maxima in the example shown in Fig. 23.26, indicating the presence of three sites with different activation energies.

In many cases only a single activation energy (and a single peak in the TPD spectrum) is observed. When several peaks are observed they might correspond to adsorption on different crystal planes or to multilayer adsorption. For instance, Cd atoms on tungsten show two activation energies, one of  $18 \text{ kJ mol}^{-1}$  and the other of  $90 \text{ kJ mol}^{-1}$ . The explanation is that the more tightly bound Cd atoms are attached directly to the substrate, and the less strongly bound are in a layer (or layers) above the primary overlayer. Another example of a system showing two desorption activation energies is CO on tungsten, the values being  $120 \text{ kJ mol}^{-1}$  and  $300 \text{ kJ mol}^{-1}$ . The explanation is believed to be the existence of two types of metal–adsorbate binding site, one involving a simple M–CO bond, the other adsorption with dissociation into individually adsorbed C and O atoms.

### (c) Mobility on surfaces

A further aspect of the strength of the interactions between adsorbate and substrate is the mobility of the adsorbate. Mobility is often a vital feature of a catalyst’s activity, because a catalyst might be impotent if the reactant molecules adsorb so strongly that they cannot migrate. The activation energy for diffusion over a surface need not be the same as for desorption because the particles may be able to move through valleys between potential peaks without leaving the surface completely. In general, the activation energy for migration is about 10–20 per cent of the energy of the surface–adsorbate bond, but the actual value depends on the extent of coverage. The defect structure of the sample (which depends on the temperature) may also play a dominant role because the adsorbed molecules might find it easier to skip across a terrace than to roll along the foot of a step, and these molecules might become trapped in vacancies in an otherwise flat terrace. Diffusion may also be easier across one crystal face than another, and so the surface mobility depends on which lattice planes are exposed.

Diffusion characteristics of an adsorbate can be examined by using STM to follow the change in surface characteristics or by **field-ionization microscopy (FIM)**, which portrays the electrical characteristics of a surface by using the ionization of noble gas atoms to probe the surface (Fig. 23.27). An individual atom is imaged, the temperature is raised, and then lowered after a definite interval. A new image is then recorded, and the new position of the atom measured (Fig. 23.28). A sequence of images shows

**Fig. 23.28** FIM micrographs showing the migration of Re atoms on rhenium during 3 s intervals at 375 K. (Photographs provided by Professor G. Ehrlich.)

that the atom makes a random walk across the surface, and the diffusion coefficient,  $D$ , can be inferred from the mean distance,  $d$ , travelled in an interval  $\tau$  by using the two-dimensional random walk expression  $d = (D\tau)^{1/2}$ . The value of  $D$  for different crystal planes at different temperatures can be determined directly in this way, and the activation energy for migration over each plane obtained from the Arrhenius-like expression

$$D = D_0 e^{-E_D/RT} \quad (23.25)$$

where  $E_D$  is the activation energy for diffusion. Typical values for W atoms on tungsten have  $E_D$  in the range 57–87 kJ mol<sup>-1</sup> and  $D_0 \approx 3.8 \times 10^{-11}$  m<sup>2</sup> s<sup>-1</sup>. For CO on tungsten, the activation energy falls from 144 kJ mol<sup>-1</sup> at low surface coverage to 88 kJ mol<sup>-1</sup> when the coverage is high.

### 23.6 Mechanisms of heterogeneous catalysis

**Key points** In the Langmuir–Hinshelwood mechanism of surface-catalysed reactions, the reaction takes place by encounters between molecular fragments and atoms adsorbed on the surface. In the Eley–Rideal mechanism of a surface-catalysed reaction, a gas-phase molecule collides with another molecule already adsorbed on the surface.

Many catalysts depend on **co-adsorption**, the adsorption of two or more species. One consequence of the presence of a second species may be the modification of the electronic structure at the surface of a metal. For instance, partial coverage of d-metal surfaces by alkali metals has a pronounced effect on the electron distribution and reduces the work function of the metal. Such modifiers can act as promoters (to enhance the action of catalysts) or as poisons (to inhibit catalytic action).

Figure 23.29 shows the potential energy curve for a reaction influenced by the action of a heterogeneous catalyst. Differences between Fig. 23.29 and 23.1 arise from the fact that heterogeneous catalysis normally depends on at least one reactant being adsorbed (usually chemisorbed) and modified to a form in which it readily undergoes reaction, and desorption of products. Modification of the reactant often takes the form of a fragmentation of the reactant molecules. In practice, the active phase is dispersed as very small particles of linear dimension less than 2 nm on a porous oxide support. **Shape-selective catalysts**, such as the zeolites (*Impact I23.1*), which have a pore size that can distinguish shapes and sizes at a molecular scale, have high internal specific surface areas, in the range of 100–500 m<sup>2</sup> g<sup>-1</sup>.

The decomposition of phosphine (PH<sub>3</sub>) on tungsten is first-order at low pressures and zeroth-order at high pressures. To account for these observations, we write down a plausible rate law in terms of an adsorption isotherm and explore its form in the limits of high and low pressure. If the rate is supposed to be proportional to the surface coverage and we suppose that  $\theta$  is given by the Langmuir isotherm, we would write

**Fig. 23.29** The reaction profile for catalysed and uncatalysed reactions. The catalysed reaction path includes activation energies for adsorption and desorption as well as an overall lower activation energy for the process.

$$v = k_r \theta = \frac{k_r K p}{1 + K p} \quad (23.26)$$

where  $p$  is the pressure of phosphine. When the pressure is so low that  $Kp \ll 1$ , we can neglect  $Kp$  in the denominator and obtain

$$v = k_r K p \quad (23.27a)$$

and the decomposition is first-order. When  $Kp \gg 1$ , we can neglect the 1 in the denominator, whereupon the  $Kp$  terms cancel and we are left with

$$v = k_r \quad (23.27b)$$

and the decomposition is zeroth-order.

**Self-test 23.7** Suggest the form of the rate law for the deuteration of  $\text{NH}_3$  in which  $\text{D}_2$  adsorbs dissociatively but not extensively (that is,  $Kp \ll 1$ , with  $p$  the partial pressure of  $\text{D}_2$ ), and  $\text{NH}_3$  (with partial pressure  $p'$ ) adsorbs at different sites.

$$[v = k_r (Kp)^{1/2} K' p' / (1 + K' p')]$$

In the **Langmuir–Hinshelwood mechanism** (LH mechanism) of surface-catalysed reactions, the reaction takes place by encounters between molecular fragments and atoms adsorbed on the surface. We therefore expect the rate law to be second-order in the extent of surface coverage:

Insertion of the appropriate isotherms for A and B then gives the reaction rate in terms of the partial pressures of the reactants. For example, if A and B follow Langmuir isotherms, and adsorb without dissociation, so that

$$\theta_A = \frac{K_A p_A}{1 + K_A p_A + K_B p_B} \quad \theta_B = \frac{K_B p_B}{1 + K_A p_A + K_B p_B} \quad (23.29)$$

then it follows that the rate law is

$$v = \frac{k_r K_A K_B p_A p_B}{(1 + K_A p_A + K_B p_B)^2} \quad (23.30)$$

The rate law according to the Langmuir–Hinshelwood mechanism

The parameters  $K$  in the isotherms and the rate constant  $k_r$  are all temperature-dependent, so the overall temperature dependence of the rate may be strongly non-Arrhenius (in the sense that the reaction rate is unlikely to be proportional to  $e^{-E_a/RT}$ ). The Langmuir–Hinshelwood mechanism is dominant for the catalytic oxidation of CO to  $\text{CO}_2$ .

In the **Eley–Rideal mechanism** (ER mechanism) of a surface-catalysed reaction, a gas-phase molecule collides with another molecule already adsorbed on the surface. The rate of formation of product is expected to be proportional to the partial pressure,  $p_B$ , of the non-adsorbed gas B and the extent of surface coverage,  $\theta_A$ , of the adsorbed gas A. It follows that the rate law should be

The rate constant,  $k_r$ , might be much larger than for the uncatalysed gas-phase reaction because the reaction on the surface has a low activation energy and the adsorption itself is often not activated.

If we know the adsorption isotherm for A, we can express the rate law in terms of its partial pressure,  $p_A$ . For example, if the adsorption of A follows a Langmuir isotherm in the pressure range of interest, then the rate law would be

$$v = \frac{k_r K p_A p_B}{1 + K p_A} \quad \text{The rate law according to the Eley-Rideal mechanism} \quad (23.32)$$

If A were a diatomic molecule that adsorbed as atoms, we would substitute the isotherm given in eqn 23.14 instead.

According to eqn 23.32, when the partial pressure of A is high (in the sense  $K p_A \gg 1$ ) there is almost complete surface coverage, and the rate is equal to  $k_r p_B$ . Now the rate-determining step is the collision of B with the adsorbed fragments. When the pressure of A is low  $K p_A \ll 1$ , perhaps because of its reaction, the rate is equal to  $k_r K p_A p_B$ ; now the extent of surface coverage is important in the determination of the rate.

Almost all thermal surface-catalysed reactions are thought to take place by the LH mechanism, but a number of reactions with an ER mechanism have also been identified from molecular beam investigations. For example, the reaction between  $\text{H(g)}$  and  $\text{D(ad)}$  to form  $\text{HD(g)}$  is thought to be by an ER mechanism involving the direct collision and pick-up of the adsorbed D atom by the incident H atom. However, the two mechanisms should really be thought of as ideal limits, and all reactions lie somewhere between the two and show features of each one.

## 23.7 Catalytic activity at surfaces

**Key point** The activity of a catalyst depends on the strength of chemisorption.

It has become possible to investigate how the catalytic activity of a surface depends on its structure as well as its composition. For instance, the cleavage of C–H and H–H bonds appears to depend on the presence of steps and kinks, and a terrace often has only minimal catalytic activity. The reaction  $\text{H}_2 + \text{D}_2 \rightarrow 2 \text{HD}$  has been studied in detail. For this reaction, terrace sites are inactive but one molecule in ten reacts when it strikes a step. Although the step itself might be the important feature, it may be that the presence of the step merely exposes a more reactive crystal face (the step face itself). Likewise, the dehydrogenation of hexane to hexene depends strongly on the kink density, and it appears that kinks are needed to cleave C–C bonds. These observations suggest a reason why even small amounts of impurities may poison a catalyst: they are likely to attach to step and kink sites, and so impair the activity of the catalyst entirely. A constructive outcome is that the extent of dehydrogenation may be controlled relative to other types of reactions by seeking impurities that adsorb at kinks and act as specific poisons.

The activity of a catalyst depends on the strength of chemisorption as indicated by the ‘volcano’ curve in Fig. 23.30 (which is so-called on account of its general shape). To be active, the catalyst should be extensively covered by adsorbate, which is the case if chemisorption is strong. On the other hand, if the strength of the substrate–adsorbate bond becomes too great, the activity declines either because the other reactant molecules cannot react with the adsorbate or because the adsorbate molecules are immobilized on the surface. This pattern of behaviour suggests that the activity of a catalyst should initially increase with strength of adsorption (as measured, for instance, by the enthalpy of adsorption) and then decline, and that the most active catalysts should be those lying near the summit of the volcano. Most active metals are those that lie close to the middle of the d block.

**Fig. 23.30** A volcano curve of catalytic activity arises because, although the reactants must adsorb reasonably strongly, they must not adsorb so strongly that they are immobilized. The lower curve refers to the first series of d-block metals, the upper curve to the second and third series d-block metals. The group numbers relate to the periodic table inside the back cover.

| Ni, Co         | +              | +                             | +                             | +  | +              | +               | –              |
| Pd, Pt         | +              | +                             | +                             | +  | +              | –               | –              |
| Mn, Cu         | +              | +                             | +                             | +  | ±              | –               | –              |
| Al, Au         | +              | +                             | +                             | –  | –              | –               | –              |
| Li, Na, K      | +              | +                             | –                             | –  | –              | –               | –              |
| Mg, Ag, Zn, Pb | +              | –                             | –                             | –  | –              | –               | –              |

\* +, Strong chemisorption; ±, chemisorption; –, no chemisorption.

Many metals are suitable for adsorbing gases, and the general order of adsorption strengths decreases along the series O<sub>2</sub>, C<sub>2</sub>H<sub>2</sub>, C<sub>2</sub>H<sub>4</sub>, CO, H<sub>2</sub>, CO<sub>2</sub>, N<sub>2</sub>. Some of these molecules adsorb dissociatively (for example, H<sub>2</sub>). Elements from the d block, such as iron, vanadium, and chromium, show a strong activity towards all these gases, but manganese and copper are unable to adsorb N<sub>2</sub> and CO<sub>2</sub>. Metals towards the left of the periodic table (for example, magnesium and lithium) can adsorb (and, in fact, react with) only the most active gas (O<sub>2</sub>). These trends are summarized in Table 23.3.

**IMPACT ON TECHNOLOGY**

**I23.1 Catalysis in the chemical industry**

Almost the whole of modern chemical industry depends on the development, selection, and application of catalysts (Table 23.4). All we can hope to do in this section is to give a brief indication of some of the problems involved. Other than the ones we consider, these problems include the danger of the catalyst being poisoned by byproducts or impurities, and economic considerations relating to cost and lifetime.

An example of catalytic action is found in the hydrogenation of alkenes. The alkene (1) adsorbs by forming two bonds with the surface (2), and on the same surface there may be adsorbed H atoms. When an encounter occurs, one of the alkene–surface bonds is broken (forming 3 or 4) and later an encounter with a second H atom releases the fully hydrogenated hydrocarbon, which is the thermodynamically more stable species. The evidence for a two-stage reaction is the appearance of different

**Table 23.4** Properties of catalysts

| Catalyst                           | Function                                                  | Examples                                                                                                                      |

isomeric alkenes in the mixture. The formation of isomers comes about because, while the hydrocarbon chain is waving about over the surface of the metal, an atom in the chain might chemisorb again to form (5) and then desorb to (6), an isomer of the original molecule. The new alkene would not be formed if the two hydrogen atoms attached simultaneously.

A major industrial application of catalytic hydrogenation is to the formation of edible fats from vegetable and animal oils. Raw oils obtained from sources such as the soya bean have the structure  $\text{CH}_2(\text{OOCR})\text{CH}(\text{OOCR}')\text{CH}_2(\text{OOCR}'')$ , where R, R', and R'' are long-chain hydrocarbons with several double bonds. One disadvantage of the presence of many double bonds is that the oils are susceptible to atmospheric oxidation, and therefore are liable to become rancid. The geometrical configuration of the chains is responsible for the liquid nature of the oil, and in many applications a solid fat is at least much better and often necessary. Controlled partial hydrogenation of an oil with a catalyst carefully selected so that hydrogenation is incomplete and so that the chains do not isomerize (finely divided nickel, in fact) is used on a wide scale to produce edible fats. The process, and the industry, are not made any easier by the seasonal variation of the number of double bonds in the oils.

Catalytic oxidation is also widely used in industry and in pollution control. Although in some cases it is desirable to achieve complete oxidation (as in the production of nitric acid from ammonia), in others partial oxidation is the aim. For example, the complete oxidation of propene to carbon dioxide and water is wasteful, but its partial oxidation to propenal (acrolein,  $\text{CH}_2=\text{CHCHO}$ ) is the start of important industrial processes. Likewise, the controlled oxidations of ethene to ethanol, ethanal (acetaldehyde), and (in the presence of acetic acid or chlorine) to chloroethene (vinyl chloride, for the manufacture of PVC), are the initial stages of very important chemical industries.

Some of these oxidation reactions are catalysed by d-metal oxides of various kinds. The physical chemistry of oxide surfaces is very complex, as can be appreciated by considering what happens during the oxidation of propene to propenal on bismuth molybdate. The first stage is the adsorption of the propene molecule with loss of a hydrogen to form the propenyl (allyl) radical,  $\text{CH}_2=\text{CHCH}_2\cdot$ . An O atom in the surface can now transfer to this radical, leading to the formation of propenal and its desorption from the surface. The H atom also escapes with a surface O atom, and goes on to form  $\text{H}_2\text{O}$ , which leaves the surface. The surface is left with vacancies and metal ions in lower oxidation states. These vacancies are attacked by  $\text{O}_2$  molecules in the overlying gas, which then chemisorb as  $\text{O}_2^-$  ions, so reforming the catalyst. This sequence of events, which is called the **Mars van Krevelen mechanism**, involves great upheavals of the surface, and some materials break up under the stress.

Many of the small organic molecules used in the preparation of all kinds of chemical products come from oil. These small building blocks of polymers, perfumes, and petrochemicals in general, are usually cut from the long-chain hydrocarbons drawn from the Earth as petroleum. The catalytically induced fragmentation of the long-chain hydrocarbons is called **cracking**, and is often brought about on silica-alumina catalysts. These catalysts act by forming unstable carbocations, which dissociate and rearrange to more highly branched isomers. These branched isomers burn more smoothly and efficiently in internal combustion engines, and are used to produce higher octane fuels.

Catalytic **reforming** uses a dual-function catalyst, such as a dispersion of platinum and acidic alumina. The platinum provides the metal function, and brings about dehydrogenation and hydrogenation. The alumina provides the acidic function, being able to form carbocations from alkenes. The sequence of events in catalytic reforming shows up very clearly the complications that must be unravelled if a reaction as

**Fig. 23.31** A framework representation of the general layout of the Si, Al, and O atoms in a zeolite material. Each vertex corresponds to a Si or Al atom and each edge corresponds to the approximate location of a O atom. Note the large central pore, which can hold cations, water molecules, or other small molecules.

important as this is to be understood and improved. The first step is the attachment of the long-chain hydrocarbon by chemisorption to the platinum. In this process first one and then a second H atom is lost, and an alkene is formed. The alkene migrates to a Brønsted acid site, where it accepts a proton and attaches to the surface as a carbocation. This carbocation can undergo several different reactions. It can break into two, isomerize into a more highly branched form, or undergo varieties of ring-closure. Then the adsorbed molecule loses a proton, escapes from the surface, and migrates (possibly through the gas) as an alkene to a metal part of the catalyst where it is hydrogenated. We end up with a rich selection of smaller molecules which can be withdrawn, fractionated, and then used as raw materials for other products.

The concept of a solid surface has been extended with the availability of **microporous materials**, in which the surface effectively extends deep inside the solid. Zeolites are microporous aluminosilicates with the general formula  $\{[M^{n+}]_{x/n} \cdot [H_2O]_m\} \{[AlO_2]_x[SiO_2]_y\}^{x-}$ , where  $M^{n+}$  cations and  $H_2O$  molecules bind inside the cavities, or pores, of the Al–O–Si framework (Fig. 23.31). Small neutral molecules, such as  $CO_2$ ,  $NH_3$ , and hydrocarbons (including aromatic compounds), can also adsorb to the internal surfaces, accounting partially for the utility of zeolites as catalysts.

Some zeolites for which  $M = H^+$  are very strong acids and catalyse a variety of reactions that are of particular importance to the petrochemical industry. Examples include the dehydration of methanol to form hydrocarbons such as gasoline and other fuels:

and the isomerization of *m*-xylene (7) to *p*-xylene (8). The catalytically important form of these acidic zeolites may be either a Brønsted acid (9) or a Lewis acid (10). Like enzymes, a zeolite catalyst with a specific composition and structure is very selective toward certain reactants and products because only molecules of certain sizes can enter and exit the pores in which catalysis occurs. It is also possible that zeolites derive their selectivity from the ability to bind and to stabilize only transition states that fit properly in the pores. The analysis of the mechanism of zeolite catalysis is greatly facilitated by computer simulation of microporous systems, which shows how molecules fit in the pores, migrate through the connecting tunnels, and react at the appropriate active sites.

## Checklist of key equations

| Property                         | Equation                                                              | Comment                                       |
|----------------------------------|-----------------------------------------------------------------------|-----------------------------------------------|
| Michaelis–Menten equation        | $v = v_{\max}[S]_0/([S]_0 + K_M)$                                     |                                               |
| Lineweaver–Burk plot             | $1/v = 1/v_{\max} + (K_M/v_{\max})(1/[S]_0)$                          |                                               |
| Turnover frequency               | $k_{\text{cat}} = v_{\max}/[E]_0$                                     | Definition                                    |
| Catalytic efficiency             | $\eta = k_{\text{cat}}/K_M$                                           | Definition                                    |
| Effect of inhibition             | $v = v_{\max}[S]_0/(\alpha'[S]_0 + \alpha K_M)$                       | Assumes Michaelis–Menten mechanism            |
| Langmuir isotherm                | $\theta = Kp/(1 + Kp)$                                                | Assumes independent sites, monolayer coverage |
| Isosteric enthalpy of adsorption | $(\partial \ln K/\partial T)_\theta = \Delta_{\text{ad}}H^\circ/RT^2$ |                                               |
| BET isotherm                     | $V/V_{\text{mon}} = cz/(1 - z)\{1 - (1 - c)z\}$                       | Multilayer adsorption                         |
| Temkin isotherm                  | $\theta = c_1 \ln(c_2 p)$                                             |                                               |
| Freundlich isotherm              | $\theta = c_1 p^{1/c_2}$                                              |                                               |
| Sticking probability             | $s = (1 - \theta)s_0$                                                 | Approximate form                              |
| Langmuir–Hinshelwood mechanism   | $v = k_t K_A K_B p_A p_B / (1 + K_A p_A + K_B p_B)^2$                 |                                               |
| Eley–Rideal mechanism            | $v = k_t K p_A p_B / (1 + K p_A)$                                     |                                               |

## Further information

### Further information 23.1 The BET isotherm

We suppose that at equilibrium a fraction  $\theta_0$  of the surface sites are unoccupied, a fraction  $\theta_1$  is covered by a monolayer, a fraction  $\theta_2$  is covered by a bilayer, and so on. The number of adsorbed molecules is therefore

$$N = N_{\text{sites}}(\theta_1 + 2\theta_2 + 3\theta_3 + \dots)$$

where  $N_{\text{sites}}$  is the total number of sites. We now follow the derivation that led to the Langmuir isotherm (eqn 23.12) but allow for different rates of desorption from the substrate and the various layers:

|               |                                                     |
|---------------|-----------------------------------------------------|
| First layer:  | Rate of adsorption = $Nk_{a,0}p\theta_0$            |
|               | Rate of desorption = $Nk_{d,0}\theta_1$             |
|               | At equilibrium $k_{a,0}p\theta_0 = k_{d,0}\theta_1$ |
| Second layer: | Rate of adsorption = $Nk_{a,1}p\theta_1$            |
|               | Rate of desorption = $Nk_{d,1}\theta_2$             |
|               | At equilibrium $k_{a,1}p\theta_1 = k_{d,1}\theta_2$ |
| Third layer:  | Rate of adsorption = $Nk_{a,2}p\theta_2$            |
|               | Rate of desorption = $Nk_{d,2}\theta_3$             |
|               | At equilibrium $k_{a,2}p\theta_2 = k_{d,2}\theta_3$ |

and so on. We now suppose that once a monolayer has been formed, all the rate constants involving adsorption and desorption from the physisorbed layers are the same, and write these equations as

$$\begin{aligned} k_{a,0}p\theta_0 &= k_{d,0}\theta_1, \text{ so } \theta_1 = (k_{a,0}/k_{d,0})p\theta_0 = K_0p\theta_0 \\ k_{a,1}p\theta_1 &= k_{d,1}\theta_2, \text{ so } \theta_2 = (k_{a,1}/k_{d,1})p\theta_1 = (k_{a,0}/k_{d,0})(k_{a,1}/k_{d,1})p^2\theta_0 \\ &= K_0K_1p^2\theta_0 \\ k_{a,1}p\theta_2 &= k_{d,1}\theta_3, \text{ so } \theta_3 = (k_{a,1}/k_{d,1})p\theta_2 = (k_{a,0}/k_{d,0})(k_{a,1}/k_{d,1})^2p^3\theta_0 \\ &= K_0K_1^2p^3\theta_0 \end{aligned}$$

and so on, with  $K_0 = k_{a,0}/k_{d,0}$  and  $K_1 = k_{a,1}/k_{d,1}$  the equilibrium constants for adsorption to the substrate and an overlayer, respectively. Now, because  $\theta_0 + \theta_1 + \theta_2 + \dots = 1$ , it follows that with

$$\begin{aligned} \theta_0 + K_0p\theta_0 + K_0K_1p^2\theta_0 + K_0K_1^2p^3\theta_0 + \dots \\ = \theta_0 + K_0p\theta_0\{1 + K_1p + K_1^2p^2 + \dots\} \\ = \left\{1 + \frac{K_0p}{1 - K_1p}\right\}\theta_0 = \left\{\frac{1 - K_1p + K_0p}{1 - K_1p}\right\}\theta_0 \end{aligned}$$

then, because this expression is equal to 1,

$$\theta_0 = \frac{1 - K_1p}{1 - (K_1 - K_0)p}$$

In a similar way, we can write the number of adsorbed species as

$$\begin{aligned} N &= N_{\text{sites}}K_0p\theta_0 + 2N_{\text{sites}}K_0K_1p^2\theta_0 + \dots \\ &= N_{\text{sites}}K_0p\theta_0(1 + 2K_1p + 3K_1^2p^2 + \dots) \\ &= \frac{N_{\text{sites}}K_0p\theta_0}{(1 - K_1p)^2} \end{aligned}$$

By combining the last two expressions, we obtain

$$N = \frac{N_{\text{sites}} K_0 p}{(1 - K_1 p)^2} \times \frac{1 - K_1 p}{1 - (K_1 - K_0) p}$$

$$= \frac{N_{\text{sites}} K_0 p}{(1 - K_1 p) \{1 - (K_1 - K_0) p\}}$$

The ratio  $N/N_{\text{sites}}$  is equal to the ratio  $V/V_{\text{mon}}$ , where  $V$  is the total volume adsorbed and  $V_{\text{mon}}$  the volume adsorbed had there been complete monolayer coverage. The term  $K_1$  is the equilibrium constant for the ‘reaction’ in which the ‘reactant’ is a molecule physisorbed on

to adsorbed layers and the ‘product’ is the molecule in the vapour. This process is very much like the equilibrium  $M(g) \rightleftharpoons M(l)$ , for which  $K = 1/p^*$ , where  $p^*$  is the vapour pressure of the liquid. Therefore, with  $K_1 = 1/p^*$ ,  $z = p/p^*$ , and  $c = K_0/K_1$ , the last equation becomes

$$\frac{V}{V_{\text{mon}}} = \frac{K_0 p}{(1 - p/p^*) \{1 - (1 - K_0/K_1) p/p^*\}}$$

$$= \frac{cz}{(1 - z) \{1 - (1 - c)z\}}$$

as in eqn 23.16.

## Discussion questions

**23.1** Discuss the features, advantages, and limitations of the Michaelis–Menten mechanism of enzyme action.

**23.2** Prepare a report on the application of the experimental strategies described in Chapter 21 to the study of enzyme-catalysed reactions. Refer to the following topics: (a) the determination of reaction rates over a large timescale; (b) the determination of the rate constants and equilibrium constant of binding of substrate to an enzyme; and (c) the characterization of intermediates in a catalytic cycle. Your report should be similar in content and extent to one of the *Impact* sections found throughout this text.

**23.3** A plot of the rate of an enzyme-catalysed reaction against temperature has a maximum, in an apparent deviation from the behaviour predicted by the Arrhenius relation (eqn 21.29). Suggest a molecular interpretation for this effect.

**23.4** Distinguish between competitive, non-competitive, and uncompetitive inhibition of enzymes. Discuss how these modes of inhibition may be detected experimentally.

**23.5** Drawing from knowledge you have acquired through the text, describe the advantages and limitations of each of the microscopy, diffraction, and scattering techniques designated by the acronyms AFM, FIM, LEED, SAM, SEM, and STM.

**23.6** Distinguish between the following adsorption isotherms: Langmuir, BET, Temkin, and Freundlich and indicate when and why they are likely to be appropriate.

**23.7** Account for the dependence of catalytic activity of a surface on the strength of chemisorption, as shown in Fig. 23.24.

## Exercises

**23.1(a)** Consider the base-catalysed reaction

Deduce the rate law.

**23.1(b)** Consider the acid-catalysed reaction

Deduce the rate law.

**23.2(a)** The enzyme-catalysed conversion of a substrate at 25°C has a Michaelis constant of  $0.046 \text{ mol dm}^{-3}$ . The rate of the reaction is  $1.04 \times 10^{-3} \text{ mol dm}^{-3} \text{ s}^{-1}$  when the substrate concentration is  $0.105 \text{ mol dm}^{-3}$ . What is the maximum velocity of this reaction?

**23.2(b)** The enzyme-catalysed conversion of a substrate at 25°C has a Michaelis constant of  $0.032 \text{ mol dm}^{-3}$ . The rate of the reaction is  $2.05 \times 10^{-4} \text{ mol dm}^{-3} \text{ s}^{-1}$  when the substrate concentration is  $0.875 \text{ mol dm}^{-3}$ . What is the maximum velocity of this reaction?

**23.3(a)** The enzyme-catalysed conversion of a substrate at 25°C has a Michaelis constant of  $0.015 \text{ mol dm}^{-3}$ , and a maximum velocity of  $4.25 \times 10^{-4} \text{ mol dm}^{-3} \text{ s}^{-1}$  when the enzyme concentration is  $3.60 \times 10^{-9} \text{ mol dm}^{-3}$ . Calculate  $k_{\text{cat}}$  and  $\eta$ . Is the enzyme ‘catalytically perfect’?

**23.3(b)** The enzyme-catalysed conversion of a substrate at 25°C has a Michaelis constant of  $9.0 \times 10^5 \text{ mol dm}^{-3}$  and a maximum velocity of  $2.24 \times 10^{-5} \text{ mol dm}^{-3} \text{ s}^{-1}$  when the enzyme concentration is  $1.60 \times 10^{-9} \text{ mol dm}^{-3}$ . Calculate  $k_{\text{cat}}$  and  $\eta$ . Is the enzyme ‘catalytically perfect’?

**23.4(a)** Consider an enzyme-catalysed reaction that follows Michaelis–Menten kinetics with  $K_M = 3.0 \times 10^{-3} \text{ mol dm}^{-3}$ . What concentration of a competitive inhibitor characterized by  $K_I = 2.0 \times 10^{-5} \text{ mol dm}^{-3}$  will reduce the rate of formation of product by 50 per cent when the substrate concentration is held at  $1.0 \times 10^{-4} \text{ mol dm}^{-3}$ ?

**23.4(b)** Consider an enzyme-catalysed reaction that follows Michaelis–Menten kinetics with  $K_M = 7.5 \times 10^{-4} \text{ mol dm}^{-3}$ . What concentration of a competitive inhibitor characterized by  $K_I = 5.6 \times 10^{-4} \text{ mol dm}^{-3}$  will reduce the rate of formation of product by 75 per cent when the substrate concentration is held at  $1.0 \times 10^{-4} \text{ mol dm}^{-3}$ ?

**23.5(a)** Calculate the frequency of molecular collisions per square centimetre of surface in a vessel containing (a) hydrogen, (b) propane at 25°C when the pressure is (i) 100 Pa, (ii) 0.10  $\mu$ Torr.

**23.5(b)** Calculate the frequency of molecular collisions per square centimetre of surface in a vessel containing (a) nitrogen, (b) methane at 25°C when the pressure is (i) 10.0 Pa, (ii) 0.150  $\mu$ Torr.

**23.6(a)** What pressure of argon gas is required to produce a collision rate of  $4.5 \times 10^{20} \text{ s}^{-1}$  at 425 K on a circular surface of diameter 1.5 mm?

**23.6(b)** What pressure of nitrogen gas is required to produce a collision rate of  $5.00 \times 10^{19} \text{ s}^{-1}$  at 525 K on a circular surface of diameter 2.0 mm?

**23.7(a)** The LEED pattern from a clean unreconstructed (110) face of a metal is shown below. Sketch the LEED pattern for a surface that was reconstructed by doubling the vertical separation between the atoms.

...  
...  
...  
...  
...

**23.7(b)** The LEED pattern from a clean unreconstructed (110) face of a metal is shown below. Sketch the LEED pattern for a surface that was reconstructed by tripling the horizontal separation between the atoms.

...  
...  
...

**23.8(a)** A monolayer of  $\text{N}_2$  molecules is adsorbed on the surface of 1.00 g of an  $\text{Fe}/\text{Al}_2\text{O}_3$  catalyst at 77 K, the boiling point of liquid nitrogen. Upon warming, the nitrogen occupies  $3.86 \text{ cm}^3$  at 0°C and 760 Torr. What is the surface area of the catalyst?

**23.8(b)** A monolayer of CO molecules is adsorbed on the surface of 1.00 g of an  $\text{Fe}/\text{Al}_2\text{O}_3$  catalyst at 77 K, the boiling point of liquid nitrogen. Upon warming, the carbon monoxide occupies  $3.75 \text{ cm}^3$  at 0°C and 1.00 bar. What is the surface area of the catalyst?

**23.9(a)** The volume of oxygen gas at 0°C and 104 kPa adsorbed on the surface of 1.00 g of a sample of silica at 0°C was  $0.286 \text{ cm}^3$  at 145.4 Torr and  $1.443 \text{ cm}^3$  at 760 Torr. What is the value of  $V_{\text{mon}}$ ?

**23.9(b)** The volume of gas at 20°C and 1.00 bar adsorbed on the surface of 1.50 g of a sample of silica at 0°C was  $1.52 \text{ cm}^3$  at 56.4 kPa and  $2.77 \text{ cm}^3$  at 108 kPa. What is the value of  $V_{\text{mon}}$ ?

**23.10(a)** The enthalpy of adsorption of CO on a surface is found to be  $-120 \text{ kJ mol}^{-1}$ . Estimate the mean lifetime of a CO molecule on the surface at 400 K.

**23.10(b)** The enthalpy of adsorption of ammonia on a nickel surface is found to be  $-155 \text{ kJ mol}^{-1}$ . Estimate the mean lifetime of an  $\text{NH}_3$  molecule on the surface at 500 K.

**23.11(a)** A certain solid sample adsorbs 0.44 mg of CO when the pressure of the gas is 26.0 kPa and the temperature is 300 K. The mass of gas adsorbed when the pressure is 3.0 kPa and the temperature is 300 K is 0.19 mg. The Langmuir isotherm is known to describe the adsorption. Find the fractional coverage of the surface at the two pressures.

**23.11(b)** A certain solid sample adsorbs 0.63 mg of CO when the pressure of the gas is 36.0 kPa and the temperature is 300 K. The mass of gas adsorbed when the pressure is 4.0 kPa and the temperature is 300 K is 0.21 mg. The Langmuir isotherm is known to describe the adsorption. Find the fractional coverage of the surface at the two pressures.

**23.12(a)** The adsorption of a gas is described by the Langmuir isotherm with  $K = 0.75 \text{ kPa}^{-1}$  at 25°C. Calculate the pressure at which the fractional surface coverage is (a) 0.15, (b) 0.95.

**23.12(b)** The adsorption of a gas is described by the Langmuir isotherm with  $K = 0.548 \text{ kPa}^{-1}$  at 25°C. Calculate the pressure at which the fractional surface coverage is (a) 0.20, (b) 0.75.

**23.13(a)** A solid in contact with a gas at 12 kPa and 25°C adsorbs 2.5 mg of the gas and obeys the Langmuir isotherm. The enthalpy change when 1.00 mmol of the adsorbed gas is desorbed is  $+10.2 \text{ kJ}$ . What is the equilibrium pressure for the adsorption of 2.5 mg of gas at 40°C?

**23.13(b)** A solid in contact with a gas at 8.86 kPa and 25°C adsorbs 4.67 mg of the gas and obeys the Langmuir isotherm. The enthalpy change when 1.00 mmol of the adsorbed gas is desorbed is  $+12.2 \text{ kJ}$ . What is the equilibrium pressure for the adsorption of the same mass of gas at 45°C?

**23.14(a)** Nitrogen gas adsorbed on charcoal to the extent of  $0.921 \text{ cm}^3 \text{ g}^{-1}$  at 490 kPa and 190 K, but at 250 K the same amount of adsorption was achieved only when the pressure was increased to 3.2 MPa. What is the enthalpy of adsorption of nitrogen on charcoal?

**23.14(b)** Nitrogen gas adsorbed on a surface to the extent of  $1.242 \text{ cm}^3 \text{ g}^{-1}$  at 350 kPa and 180 K, but at 240 K the same amount of adsorption was achieved only when the pressure was increased to 1.02 MPa. What is the enthalpy of adsorption of nitrogen on the surface?

**23.15(a)** In an experiment on the adsorption of oxygen on tungsten it was found that the same volume of oxygen was desorbed in 27 min at 1856 K and 2.0 min at 1978 K. What is the activation energy of desorption? How long would it take for the same amount to desorb at (a) 298 K, (b) 3000 K?

**23.15(b)** In an experiment on the adsorption of ethene on iron it was found that the same volume of the gas was desorbed in 1856 s at 873 K and 8.44 s at 1012 K. What is the activation energy of desorption? How long would it take for the same amount of ethene to desorb at (a) 298 K, (b) 1500 K?

**23.16(a)** The average time for which an oxygen atom remains adsorbed to a tungsten surface is 0.36 s at 2548 K and 3.49 s at 2362 K. What is the activation energy for chemisorption?

**23.16(b)** The average time for which a hydrogen atom remains adsorbed on a manganese surface is 35 per cent shorter at 1000 K than at 600 K. What is the activation energy for chemisorption?

**23.17(a)** For how long on average would an H atom remain on a surface at 400 K if its desorption activation energy is (a)  $15 \text{ kJ mol}^{-1}$ , (b)  $150 \text{ kJ mol}^{-1}$ ? Take  $\tau_0 = 0.10 \text{ ps}$ . For how long on average would the same atoms remain at 1000 K?

**23.17(b)** For how long on average would an atom remain on a surface at 298 K if its desorption activation energy is (a)  $20 \text{ kJ mol}^{-1}$ , (b)  $200 \text{ kJ mol}^{-1}$ ? Take  $\tau_0 = 0.12 \text{ ps}$ . For how long on average would the same atoms remain at 800 K?

**23.18(a)** Hydrogen iodide is very strongly adsorbed on gold but only slightly adsorbed on platinum. Assume the adsorption follows the Langmuir isotherm and predict the order of the HI decomposition reaction on each of the two metal surfaces.

**23.18(b)** Suppose it is known that ozone adsorbs on a particular surface in accord with a Langmuir isotherm. How could you use the pressure dependence of the fractional coverage to distinguish between adsorption (a) without dissociation, (b) with dissociation into  $\text{O} + \text{O}_2$ , (c) with dissociation into  $\text{O} + \text{O} + \text{O}$ ?

## Problems\*

## Numerical problems

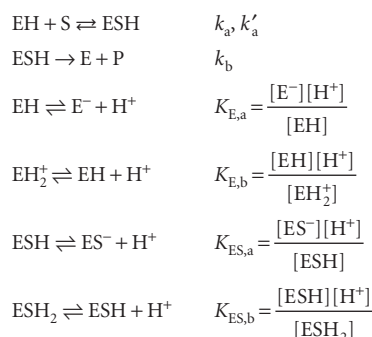

**23.1** The following results were obtained for the action of an ATPase on ATP at 20°C, when the concentration of the ATPase was 20 nmol dm<sup>-3</sup>:

|                                                    |      |      |      |      |      |
|----------------------------------------------------|------|------|------|------|------|
| [ATP]/(μmol dm <sup>-3</sup> )                     | 0.60 | 0.80 | 1.4  | 2.0  | 3.0  |
| <i>v</i> /(μmol dm <sup>-3</sup> s <sup>-1</sup> ) | 0.81 | 0.97 | 1.30 | 1.47 | 1.69 |

Determine the Michaelis constant, the maximum velocity of the reaction, the turnover number, and the catalytic efficiency of the enzyme.

**23.2** There are different ways to represent and analyse data for enzyme-catalysed reactions. For example, in the *Eadie–Hofstee plot*, *v*/[S]<sub>0</sub> is plotted against *v*. Alternatively, in the *Hanes plot* *v*/[S]<sub>0</sub> is plotted against [S]<sub>0</sub>. (a) Using the simple Michaelis–Menten mechanism, derive relations between *v*/[S]<sub>0</sub> and *v* and between *v*/[S]<sub>0</sub> and [S]<sub>0</sub>. (b) Discuss how the values of *K*<sub>M</sub> and *v*<sub>max</sub> are obtained from analysis of the Eadie–Hofstee and Hanes plots. (c) Determine the Michaelis constant and the maximum velocity of the reaction from Problem 23.1 by using Eadie–Hofstee and Hanes plots to analyse the data.

**23.3** In general, the catalytic efficiency of an enzyme depends on the pH of the medium in which it operates. One way to account for this behaviour is to propose that the enzyme and the enzyme–substrate complex are active only in specific protonation states. This proposition can be summarized by the following mechanism:

in which only the EH and ESH forms are active. (a) For the mechanism above, show that

$$v = \frac{v'_{\text{max}}}{1 + K'_M[\text{S}]_0}$$

with

$$\begin{aligned}
 v'_{\text{max}} &= \frac{v_{\text{max}}}{1 + \frac{[\text{H}^+]}{K_{\text{E},b}} + \frac{K_{\text{E},a}}{[\text{H}^+]}} \\
 K'_M &= K_M \frac{1 + \frac{[\text{H}^+]}{K_{\text{E},b}} + \frac{K_{\text{E},a}}{[\text{H}^+]}}{1 + \frac{[\text{H}^+]}{K_{\text{ES},b}} + \frac{K_{\text{ES},a}}{[\text{H}^+]}}
 \end{aligned}$$

where *v*<sub>max</sub> and *K*<sub>M</sub> correspond to the form EH of the enzyme. (b) For pH values ranging from 0 to 14, plot *v*'<sub>max</sub> against pH for a hypothetical reaction for which *v*<sub>max</sub> = 1.0 × 10<sup>-6</sup> mol dm<sup>-3</sup> s<sup>-1</sup>, *K*<sub>ES,b</sub> = 1.0 × 10<sup>-6</sup> mol dm<sup>-3</sup> and

*K*<sub>ES,a</sub> = 1.0 × 10<sup>-8</sup>. Is there a pH at which *v*<sub>max</sub> reaches a maximum value? If so, determine the pH. (c) Redraw the plot in part (b) by using the same value of *v*<sub>max</sub>, but *K*<sub>ES,b</sub> = 1.0 × 10<sup>-4</sup> mol dm<sup>-3</sup> and *K*<sub>ES,a</sub> = 1.0 × 10<sup>-10</sup> mol dm<sup>-3</sup>. Account for any differences between this plot and the plot from part (b).

**23.4** The enzyme carboxypeptidase catalyses the hydrolysis of polypeptides and here we consider its inhibition. The following results were obtained when the rate of the enzymolysis of carbobenzoxy-glycyl-D-phenylalanine (CBGP) was monitored without inhibitor:

|                                                               |       |       |       |       |
|---------------------------------------------------------------|-------|-------|-------|-------|
| [CBGP] <sub>0</sub> /(10 <sup>-2</sup> mol dm <sup>-3</sup> ) | 1.25  | 3.84  | 5.81  | 7.13  |
| Relative reaction rate                                        | 0.398 | 0.669 | 0.859 | 1.000 |

(All rates in this problem were measured with the same concentration of enzyme and are relative to the rate measured when [CBGP]<sub>0</sub> = 0.0713 mol dm<sup>-3</sup> in the absence of inhibitor.) When 2.0 × 10<sup>-3</sup> mol dm<sup>-3</sup> phenylbutyrate ion was added to a solution containing the enzyme and substrate, the following results were obtained:

|                                                               |       |       |       |       |
|---------------------------------------------------------------|-------|-------|-------|-------|
| [CBGP] <sub>0</sub> /(10 <sup>-2</sup> mol dm <sup>-3</sup> ) | 1.25  | 2.50  | 4.00  | 5.50  |
| Relative reaction rate                                        | 0.172 | 0.301 | 0.344 | 0.548 |

In a separate experiment, the effect of 5.0 × 10<sup>-2</sup> mol dm<sup>-3</sup> benzoate ion was monitored and the results were:

|                                                               |       |       |       |       |
|---------------------------------------------------------------|-------|-------|-------|-------|
| [CBGP] <sub>0</sub> /(10 <sup>-2</sup> mol dm <sup>-3</sup> ) | 1.75  | 2.50  | 5.00  | 10.00 |
| Relative reaction rate                                        | 0.183 | 0.201 | 0.231 | 0.246 |

Determine the mode of inhibition of carboxypeptidase by the phenylbutyrate ion and benzoate ion.

**23.5** The movement of atoms and ions on a surface depends on their ability to leave one position and stick to another, and therefore on the energy changes that occur. As an illustration, consider a two-dimensional square lattice of univalent positive and negative ions separated by 200 pm, and consider a cation on the upper terrace of this array. Calculate, by direct summation, its Coulombic interaction when it is in an empty lattice point directly above an anion. Now consider a high step in the same lattice, and let the cation move into the corner formed by the step and the terrace. Calculate the Coulombic energy for this position, and decide on the likely settling point for the cation.

**23.6** In a study of the catalytic properties of a titanium surface it was necessary to maintain the surface free from contamination. Calculate the collision frequency per square centimetre of surface made by O<sub>2</sub> molecules at (a) 100 kPa, (b) 1.00 Pa and 300 K. Estimate the number of collisions made with a single surface atom in each second. The conclusions underline the importance of working at very low pressures (much lower than 1 Pa, in fact) in order to study the properties of uncontaminated surfaces. Take the nearest-neighbour distance as 291 pm.

**23.7** Nickel is face-centred cubic with a unit cell of side 352 pm. What is the number of atoms per square centimetre exposed on a surface formed by (a) (100), (b) (110), (c) (111) planes? Calculate the frequency of molecular collisions per surface atom in a vessel containing (a) hydrogen, (b) propane at 25°C when the pressure is (i) 100 Pa, (ii) 0.10 μTorr.

**23.8** The data below are for the chemisorption of hydrogen on copper powder at 25°C. Confirm that they fit the Langmuir isotherm at low coverages. Then find the value of *K* for the adsorption equilibrium and the adsorption volume corresponding to complete coverage.

|                           |       |       |       |       |       |       |
|---------------------------|-------|-------|-------|-------|-------|-------|
| <i>p</i> /Pa              | 25    | 129   | 253   | 540   | 1000  | 1593  |
| <i>V</i> /cm <sup>3</sup> | 0.042 | 0.163 | 0.221 | 0.321 | 0.411 | 0.471 |

\* Problems denoted with the symbol ‡ were supplied by Charles Trapp, Carmen Giunta, and Marshall Cady.

**23.9** The data for the adsorption of ammonia on barium fluoride are reported below. Confirm that they fit a BET isotherm and find values of  $c$  and  $V_{\text{mon}}$ .

(a)  $\theta = 0^\circ\text{C}$ ,  $p^* = 429.6$  kPa:

|                 |      |      |      |      |      |       |       |
|-----------------|------|------|------|------|------|-------|-------|
| $p/\text{kPa}$  | 14.0 | 37.6 | 65.6 | 79.2 | 82.7 | 100.7 | 106.4 |
| $V/\text{cm}^3$ | 11.1 | 13.5 | 14.9 | 16.0 | 15.5 | 17.3  | 16.5  |

(b)  $\theta = 18.6^\circ\text{C}$ ,  $p^* = 819.7$  kPa:

|                 |     |     |      |      |      |      |      |       |
|-----------------|-----|-----|------|------|------|------|------|-------|
| $p/\text{kPa}$  | 5.3 | 8.4 | 14.4 | 29.2 | 62.1 | 74.0 | 80.1 | 102.0 |
| $V/\text{cm}^3$ | 9.2 | 9.8 | 10.3 | 11.3 | 12.9 | 13.1 | 13.4 | 14.1  |

**23.10** The following data have been obtained for the adsorption of  $\text{H}_2$  on the surface of 1.00 g of copper at  $0^\circ\text{C}$ . The volume of  $\text{H}_2$  below is the volume that the gas would occupy at STP ( $0^\circ\text{C}$  and 1 atm).

|                 |       |       |       |       |       |
|-----------------|-------|-------|-------|-------|-------|
| $p/\text{atm}$  | 0.050 | 0.100 | 0.150 | 0.200 | 0.250 |
| $V/\text{cm}^3$ | 23.8  | 13.3  | 8.70  | 6.80  | 5.71  |

Determine the volume of  $\text{H}_2$  necessary to form a monolayer and estimate the surface area of the copper sample. The density of liquid hydrogen is  $0.708$  g  $\text{cm}^{-3}$ .

**23.11** The adsorption of solutes on solids from liquids often follows a Freundlich isotherm. Check the applicability of this isotherm to the following data for the adsorption of acetic acid on charcoal at  $25^\circ\text{C}$  and find the values of the parameters  $c_1$  and  $c_2$ .

|                                |      |      |      |      |      |
|--------------------------------|------|------|------|------|------|
| [acid]/(mol $\text{dm}^{-3}$ ) | 0.05 | 0.10 | 0.50 | 1.0  | 1.5  |
| $w_a/\text{g}$                 | 0.04 | 0.06 | 0.12 | 0.16 | 0.19 |

$w_a$  is the mass adsorbed per gram of charcoal.

**23.12** In some catalytic reactions the products may adsorb more strongly than the reacting gas. This is the case, for instance, in the catalytic decomposition of ammonia on platinum at  $1000^\circ\text{C}$ . As a first step in examining the kinetics of this type of process, show that the rate of ammonia decomposition should follow

$$\frac{dp_{\text{NH}_3}}{dt} = -k_c \frac{p_{\text{NH}_3}}{p_{\text{H}_2}}$$

in the limit of very strong adsorption of hydrogen. Start by showing that, when a gas J adsorbs very strongly and its pressure is  $p_J$ , that the fraction of uncovered sites is approximately  $1/Kp_J$ . Solve the rate equation for the catalytic decomposition of  $\text{NH}_3$  on platinum and show that a plot of  $F(t) = (1/t) \ln(p/p_0)$  against  $G(t) = (p - p_0)/t$ , where  $p$  is the pressure of ammonia, should give a straight line from which  $k_c$  can be determined. Check the rate law on the basis of the data below, and find  $k_c$  for the reaction.

|                |      |      |      |      |      |     |     |
|----------------|------|------|------|------|------|-----|-----|
| $t/\text{s}$   | 0    | 30   | 60   | 100  | 160  | 200 | 250 |
| $p/\text{kPa}$ | 13.3 | 11.7 | 11.2 | 10.7 | 10.3 | 9.9 | 9.6 |

**23.13†** A. Akgerman and M. Zardkoobi (*J. Chem. Eng. Data* **41**, 185 (1996)) examined the adsorption of phenol from aqueous solution on to fly ash at  $20^\circ\text{C}$ . They fitted their observations to a Freundlich isotherm of the form  $c_{\text{ads}} = Kc_{\text{sol}}^{1/n}$ , where  $c_{\text{ads}}$  is the concentration of adsorbed phenol and  $c_{\text{sol}}$  is the concentration of aqueous phenol. Among the data reported are the following:

|                                     |      |       |       |       |       |
|-------------------------------------|------|-------|-------|-------|-------|
| $c_{\text{sol}}/(\text{mg g}^{-1})$ | 8.26 | 15.65 | 25.43 | 31.74 | 40.00 |
| $c_{\text{ads}}/(\text{mg g}^{-1})$ | 4.4  | 19.2  | 35.2  | 52.0  | 67.2  |

Determine the constants  $K$  and  $n$ . What further information would be necessary in order to express the data in terms of fractional coverage,  $\theta$ ?

**23.14†** C. Huang and W.P. Cheng (*J. Colloid Interface Sci.* **188**, 270 (1997)) examined the adsorption of the hexacyanoferrate(III) ion,  $[\text{Fe}(\text{CN})_6]^{3-}$ , on  $\gamma\text{-Al}_2\text{O}_3$  from aqueous solution. They modelled the adsorption with a modified Langmuir isotherm, obtaining the following values of  $K$  at pH = 6.5:

|              |       |       |       |       |
|--------------|-------|-------|-------|-------|
| $T/\text{K}$ | 283   | 298   | 308   | 318   |
| $10^{-11}K$  | 2.642 | 2.078 | 1.286 | 1.085 |

Determine the isosteric enthalpy of adsorption,  $\Delta_{\text{ads}} H^\circ$ , at this pH. The researchers also reported  $\Delta_{\text{ads}} S^\circ = +146$  J  $\text{mol}^{-1} \text{K}^{-1}$  under these conditions. Determine  $\Delta_{\text{ads}} G^\circ$ .

**23.15†** M.-G. Olivier and R. Jadot (*J. Chem. Eng. Data* **42**, 230 (1997)) studied the adsorption of butane on silica gel. They report the following amounts of absorption (in moles per kilogram of silica gel) at 303 K:

|                          |        |        |        |        |        |
|--------------------------|--------|--------|--------|--------|--------|
| $p/\text{kPa}$           | 31.00  | 38.22  | 53.03  | 76.38  | 101.97 |
| $n/(\text{mol kg}^{-1})$ | 1.00   | 1.17   | 1.54   | 2.04   | 2.49   |
| $p/\text{kPa}$           | 130.47 | 165.06 | 182.41 | 205.75 | 219.91 |
| $n/(\text{mol kg}^{-1})$ | 2.90   | 3.22   | 3.30   | 3.35   | 3.36   |

Fit these data to a Langmuir isotherm, and determine the value of  $n$  that corresponds to complete coverage and the constant  $K$ .

**23.16†** The following data were obtained for the extent of adsorption,  $s$ , of acetone on charcoal from an aqueous solution of molar concentration,  $c$ , at  $18^\circ\text{C}$ .

|                                      |      |      |      |      |      |      |      |
|--------------------------------------|------|------|------|------|------|------|------|
| $c/(\text{mmol dm}^{-3})$            | 15.0 | 23.0 | 42.0 | 84.0 | 165  | 390  | 800  |
| $s/(\text{mmol acetone/g charcoal})$ | 0.60 | 0.75 | 1.05 | 1.50 | 2.15 | 3.50 | 5.10 |

Which isotherm fits this data best: Langmuir, Freundlich, or Temkin?

## Theoretical problems

**23.17** Autocatalysis is the catalysis of a reaction by the products. For example, for a reaction  $\text{A} \rightarrow \text{P}$  it may be found that the rate law is  $v = k_r[\text{A}][\text{P}]$  and the reaction rate is proportional to the concentration of P. The reaction gets started because there are usually other reaction routes for the formation of some P initially, which then takes part in the autocatalytic reaction proper.

(a) Integrate the rate equation for an autocatalytic reaction of the form  $\text{A} \rightarrow \text{P}$ , with rate law  $v = k_r[\text{A}][\text{P}]$ , and show that

$$\frac{[\text{P}]}{[\text{P}]_0} = (b+1) \frac{e^{at}}{1+b e^{at}}$$

where  $a = ([\text{A}]_0 + [\text{P}]_0)k_r$  and  $b = [\text{P}]_0/[\text{A}]_0$ . *Hint.* Starting with the expression  $v = -d[\text{A}]/dt = k_r[\text{A}][\text{P}]$ , write  $[\text{A}] = [\text{A}]_0 - x$ ,  $[\text{P}] = [\text{P}]_0 + x$  and then write the expression for the rate of change of either species in terms of  $x$ . To integrate the resulting expression, use

$$\frac{1}{([\text{A}]_0 - x)([\text{P}]_0 + x)} = \frac{1}{[\text{A}]_0 + [\text{P}]_0} \left( \frac{1}{[\text{A}]_0 - x} + \frac{1}{[\text{P}]_0 + x} \right)$$

(b) Plot  $[\text{P}]/[\text{P}]_0$  against  $at$  for several values of  $b$ . Discuss the effect of autocatalysis on the shape of a plot of  $[\text{P}]/[\text{P}]_0$  against  $t$  by comparing your results with those for a first-order process, in which  $[\text{P}]/[\text{P}]_0 = 1 - e^{-k_r t}$ .

(c) Show that for the autocatalytic process discussed in parts (a) and (b), the reaction rate reaches a maximum at  $t_{\text{max}} = -(1/a) \ln b$ . (d) An autocatalytic reaction  $\text{A} \rightarrow \text{P}$  is observed to have the rate law  $d[\text{P}]/dt = k_r[\text{A}]^2[\text{P}]$ . Solve the rate law for initial concentrations  $[\text{A}]_0$  and  $[\text{P}]_0$ . Calculate the time at which the rate reaches a maximum. (e) Another reaction with the stoichiometry  $\text{A} \rightarrow \text{P}$  has the rate law  $d[\text{P}]/dt = k_r[\text{A}][\text{P}]^2$ ; integrate the rate law for initial concentrations  $[\text{A}]_0$  and  $[\text{P}]_0$ . Calculate the time at which the rate reaches a maximum.

**23.18** Many biological and biochemical processes involve autocatalytic steps (Problem 23.17). In the SIR model of the spread and decline of infectious diseases the population is divided into three classes; the susceptibles, S, who can catch the disease, the infectives, I, who have the disease and can transmit it, and the removed class, R, who have either had the disease and recovered, are dead, are immune or isolated. The model mechanism for this process implies the following rate laws:

$$\frac{dS}{dt} = -rSI \quad \frac{dI}{dt} = rSI - aI \quad \frac{dR}{dt} = aI$$

What are the autocatalytic steps of this mechanism? Find the conditions on the ratio  $a/r$  that decide whether the disease will spread (an epidemic) or die out. Show that a constant population is built into this system, namely that  $S + I + R = N$ , meaning that the timescales of births, deaths by other causes, and migration are assumed large compared to that of the spread of the disease.

**23.19** Michaelis and Menten derived their rate law by assuming a rapid pre-equilibrium of E, S, and ES. Derive the rate law in this manner, and identify the conditions under which it becomes the same as that based on the steady-state approximation (eqn 23.1).

**23.20** For many enzymes, the mechanism of action involves the formation of two intermediates:

Show that the rate of formation of product has the same form as that shown in eqn 23.1

$$v = \frac{v_{\max}}{1 + K_M/[S]_0}$$

but with  $v_{\max}$  and  $K_M$  given by

$$v_{\max} = \frac{k_b k_c [\text{E}]_0}{k_b + k_c} \quad \text{and} \quad K_M = \frac{k_c (k'_a + k_b)}{k_a (k_b + k_c)}$$

**23.21** Some enzymes are inhibited by high concentrations of their own substrates. (a) Show that when substrate inhibition is important the reaction rate  $v$  is given by

$$v = \frac{v_{\max}}{1 + K_M/[S]_0 + [S]_0/K_1}$$

where  $K_1$  is the equilibrium constant for dissociation of the inhibited enzyme–substrate complex. (b) What effect does substrate inhibition have on a plot of  $1/v$  against  $1/[S]_0$ ?

**23.22** Although the attractive van der Waals interaction between individual molecules varies as  $R^{-6}$ , the interaction of a molecule with a nearby solid (a homogeneous collection of molecules) varies as  $R^{-3}$ , where  $R$  is its vertical distance above the surface. Confirm this assertion. Calculate the interaction energy between an Ar atom and the surface of solid argon on the basis of a Lennard-Jones (6,12)-potential. Estimate the equilibrium distance of an atom above the surface.

### Applications to: chemical engineering and environmental science

**23.23** The designers of a new industrial plant wanted to use a catalyst code-named CR-1 in a step involving the fluorination of butadiene. As a first step in the investigation they determined the form of the adsorption isotherm. The volume of butadiene adsorbed per gram of CR-1 at 15°C varied with pressure as given below. Is the Langmuir isotherm suitable at this pressure?

|                 |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|
| $p/\text{kPa}$  | 13.3 | 26.7 | 40.0 | 53.3 | 66.7 | 80.0 |
| $V/\text{cm}^3$ | 17.9 | 33.0 | 47.0 | 60.8 | 75.3 | 91.3 |

Investigate whether the BET isotherm gives a better description of the adsorption of butadiene on CR-1. At 15°C,  $p^*$ (butadiene) = 200 kPa. Find  $V_{\text{mon}}$  and  $c$ .

**23.24†** In a study relevant to automobile catalytic converters, C.E. Wartnaby *et al.* (*J. Phys. Chem.* **100**, 12483 (1996)) measured the enthalpy of adsorption of CO, NO, and O<sub>2</sub> on initially clean platinum 110 surfaces. They report  $\Delta_{\text{ads}}H^\circ$  for NO to be  $-160 \text{ kJ mol}^{-1}$ . How much more strongly adsorbed is NO at 500°C than at 400°C?

**23.25†** The removal or recovery of volatile organic compounds (VOCs) from exhaust gas streams is an important process in environmental engineering. Activated carbon has long been used as an adsorbent in this process, but the presence of moisture in the stream reduces its effectiveness. M.-S. Chou and J.-H. Chiou (*J. Envir. Engrg.* ASCE, **123**, 437 (1997)) have studied the effect of moisture content on the adsorption capacities of granular activated carbon (GAC) for normal hexane and cyclohexane in air streams. From their data for

dry streams containing cyclohexane, shown in the table below, they conclude that GAC obeys a Langmuir-type model in which  $q_{\text{VOC,RH}=0} = abc_{\text{VOC}}/(1 + bc_{\text{VOC}})$ , where  $q = m_{\text{VOC}}/m_{\text{GAC}}$ , RH denotes relative humidity,  $a$  the maximum adsorption capacity,  $b$  is an affinity parameter, and  $p$  is the abundance in parts per million (ppm). The following table gives values of  $q_{\text{VOC,RH}=0}$  for cyclohexane:

|                |        |        |        |        |       |
|----------------|--------|--------|--------|--------|-------|
| $c/\text{ppm}$ | 33.6°C | 41.5°C | 57.4°C | 76.4°C | 99°C  |
| 200            | 0.080  | 0.069  | 0.052  | 0.042  | 0.027 |
| 500            | 0.093  | 0.083  | 0.072  | 0.056  | 0.042 |
| 1000           | 0.101  | 0.088  | 0.076  | 0.063  | 0.045 |
| 2000           | 0.105  | 0.092  | 0.083  | 0.068  | 0.052 |

(a) By linear regression of  $1/q_{\text{VOC,RH}=0}$  against  $1/c_{\text{VOC}}$ , test the goodness of fit and determine values of  $a$  and  $b$ . (b) The parameters  $a$  and  $b$  can be related to  $\Delta_{\text{ads}}H$ , the enthalpy of adsorption, and  $\Delta_b H$ , the difference in activation energy for adsorption and desorption of the VOC molecules, through Arrhenius-type equations of the form  $a = k_a \exp(-\Delta_{\text{ads}}H/RT)$  and  $b = k_b \exp(-\Delta_b H/RT)$ . Test the goodness of fit of the data to these equations and obtain values for  $k_a$ ,  $k_b$ ,  $\Delta_{\text{ads}}H$ , and  $\Delta_b H$ . (c) What interpretation might you give to  $k_a$  and  $k_b$ ?

**23.26†** M.-S. Chou and J.-H. Chiou (*J. Envir. Engrg.*, ASCE, **123**, 437 (1997)) have studied the effect of moisture content on the adsorption capacities of granular activated carbon (GAC, Norit PK 1-3) for the volatile organic compounds (VOCs) normal hexane and cyclohexane in air streams. The following table shows the adsorption capacities ( $q_{\text{water}} = m_{\text{water}}/m_{\text{GAC}}$ ) of GAC for pure water from moist air streams as a function of relative humidity (RH) in the absence of VOCs at 41.5°C.

|                    |      |       |       |       |       |       |
|--------------------|------|-------|-------|-------|-------|-------|
| RH                 | 0.00 | 0.26  | 0.49  | 0.57  | 0.80  | 1.00  |
| $q_{\text{water}}$ | 0.00 | 0.026 | 0.072 | 0.091 | 0.161 | 0.229 |

The authors conclude that the data at this and other temperatures obey a Freundlich-type isotherm,  $q_{\text{water}} = k(\text{RH})^{1/n}$ . (a) Test this hypothesis for their data at 41.5°C and determine the constants  $k$  and  $n$ . (b) Why might VOCs obey the Langmuir model, but water the Freundlich model? (c) When both water vapour and cyclohexane were present in the stream the values given in the table below were determined for the ratio  $r_{\text{VOC}} = q_{\text{VOC}}/q_{\text{VOC,RH}=0}$  at 41.5°C.

|                  |      |      |      |      |      |      |      |
|------------------|------|------|------|------|------|------|------|
| RH               | 0.00 | 0.10 | 0.25 | 0.40 | 0.53 | 0.76 | 0.81 |
| $r_{\text{VOC}}$ | 1.00 | 0.98 | 0.91 | 0.84 | 0.79 | 0.67 | 0.61 |

The authors propose that these data fit the equation  $r_{\text{VOC}} = 1 - q_{\text{water}}$ . Test their proposal and determine values for  $k$  and  $n$  and compare to those obtained in part (b) for pure water. Suggest reasons for any differences.

**23.27†** The release of petroleum products by leaky underground storage tanks is a serious threat to clean ground water. BTEX compounds (benzene, toluene, ethylbenzene, and xylenes) are of primary concern due to their ability to cause health problems at low concentrations. D.S. Kershaw *et al.* (*J. Geotech. & Geoenviron. Engrg.* **123**, 324 (1997)) have studied the ability of ground tyre rubber to sorb (adsorb and absorb) benzene and *o*-xylene. Though sorption involves more than surface interactions, sorption data are usually found to fit one of the adsorption isotherms. In this study, the authors have tested how well their data fit the linear ( $q = Kc_{\text{eq}}$ ), Freundlich ( $q = K_F c_{\text{eq}}^{1/n}$ ), and Langmuir ( $q = K_L M c_{\text{eq}}/(1 + K_L c_{\text{eq}})$ ) type isotherms, where  $q$  is the mass of solvent sorbed per gram of ground rubber (in milligrams per gram), the  $K$ s and  $M$  are empirical constants, and  $c_{\text{eq}}$  the equilibrium concentration of contaminant in solution (in milligrams per litre). (a) Determine the units of the empirical constants. (b) Determine which of the isotherms best fits the data in the table below for the sorption of benzene on ground rubber.

|                                     |       |       |       |      |      |      |
|-------------------------------------|-------|-------|-------|------|------|------|
| $c_{\text{eq}}/(\text{mg dm}^{-3})$ | 97.10 | 36.10 | 10.40 | 6.51 | 6.21 | 2.48 |
| $q/(\text{mg g}^{-1})$              | 7.13  | 4.60  | 1.80  | 1.10 | 0.55 | 0.31 |

(c) Compare the sorption efficiency of ground rubber to that of granulated activated charcoal, which for benzene has been shown to obey the Freundlich isotherm in the form  $q = 1.0c_{\text{eq}}^{1.6}$  with coefficient of determination  $R^2 = 0.94$ .

### Part 1 Road maps (911)

### Part 2 Data section (913)

The following is a directory of all tables in the text, those included in this *Data section* are marked with an asterisk. The remainder will be found on the pages indicated.

Physical properties of selected materials\*  
Masses and natural abundances of selected nuclides\*

- F.1** The SI base units (11)
- F.2** A selection of derived units (12)
- F.3** Common SI prefixes (12)
- F.4** Some common units (13)
  
- 1.1** Pressure units (20)
- 1.2** The gas constant (24)
- 1.3** The composition of dry air at sea level (28)
- 1.4** Second virial coefficients\*
- 1.5** Critical constants of gases\*
- 1.6** van der Waals coefficients\*
- 1.7** Selected equations of state (35)
  
- 2.1** Varieties of work (50)
- 2.2** Temperature variation of molar heat capacities\*
- 2.3** Standard enthalpies of fusion and vaporization at the transition temperature\*
- 2.4** Enthalpies of transition (66)
- 2.5** Lattice enthalpies at 298 K\*
- 2.6** Thermodynamic data for organic compounds at 298 K\*
- 2.7** Thermochemical properties of some fuels (70)
- 2.8** Thermodynamic data for elements and inorganic compounds at 298 K\*
- 2.9** Expansion coefficients and isothermal compressibilities\*
- 2.10** Inversion temperatures, normal freezing and boiling points, and Joule–Thomson coefficients at 1 atm and 298 K\*
  
- 3.1** Standard entropies (and temperatures) of phase transitions\*
- 3.2** Standard enthalpies and entropies of vaporization of liquids at their normal boiling points\*
- 3.3** Standard Third-Law entropies at 298 K [see Tables 2.6 and 2.8]\*
- 3.4** Standard Gibbs energies of formation (at 298 K) [see Tables 2.6 and 2.8]\*
- 3.5** The Maxwell relations (122)
- 3.6** The fugacity coefficient of nitrogen at 273 K\*
  
- 5.1** Henry's law constants for gases in water at 298 K\*
- 5.2** Freezing-point and boiling-point constants\*
- 5.3** Standard states (190)
- 5.4** Ionic strength and molality (197)
- 5.5** Mean activity coefficients in water at 298 K\*
  
- 6.1** Varieties of electrode (227)
- 6.2** Standard potentials at 298 K\*
- 6.3** The electrochemical series of the metals (236)
  
- 7.1** The Schrödinger equation (261)
- 7.2** Constraints of the uncertainty principle (278)
  
- 8.1** The Hermite polynomials (302)
- 8.2** The spherical harmonics (311)
- 8.3** Properties of the angular momentum of an electron (316)
  
- 9.1** Hydrogenic radial wavefunctions (328)
- 9.2** Effective nuclear charge\*
- 9.3** Ionization energies\*
- 9.4** Electron affinities\*
  
- 10.1** Some hybridization schemes (377)
- 10.2** Bond lengths\*
- 10.3** Bond dissociation enthalpies\*
- 10.4** Pauling and Mulliken electronegativities\*
- 10.5** *Ab initio* calculations and spectroscopic data (407)
  
- 11.1** The notation for point groups (420)
- 11.2** The  $C_{2v}$  character table (430)
- 11.3** The  $C_{3v}$  character table (430)
  
- 12.1** Moments of inertia (450)
- 12.2** Properties of diatomic molecules\*
- 12.3** Typical vibrational wavenumbers\*

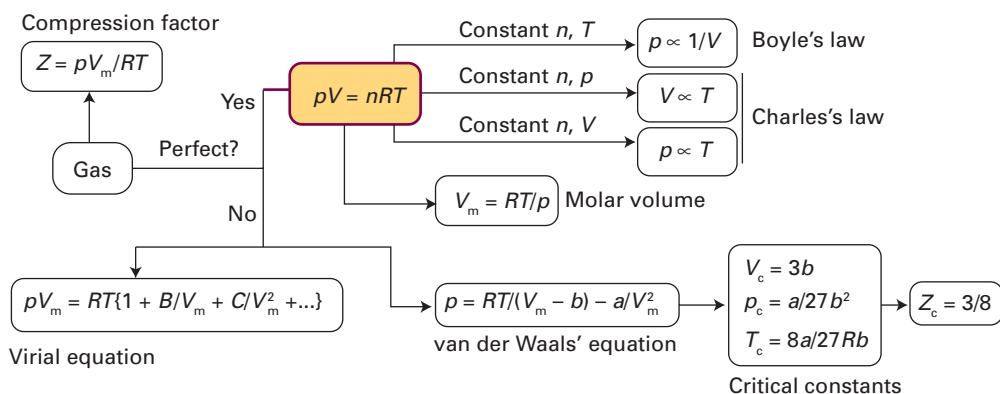

- 13.1** Colour, frequency, and energy of light\*
- 13.2** Absorption characteristics of some groups and molecules\*
- 13.3** Characteristics of laser radiation and their chemical applications (508)
- 14.1** Nuclear constitution and the nuclear spin quantum number (522)
- 14.2** Nuclear spin properties\*
- 14.3** Hyperfine coupling constants for atoms\*
- 16.1** Rotational and vibrational temperatures [see Table 12.2]\*
- 16.2** Symmetry numbers [see Table 12.2]\*
- 17.1** Dipole moments, polarizabilities, and polarizability volumes\*
- 17.2** Partial charges in polypeptides (625)
- 17.3** Multipole interaction potential energies (633)
- 17.4** Lennard-Jones (12,6) parameters\*
- 17.5** Surface tensions of liquids at 293 K\*
- 18.1** Variation of micelle shape with the surfactant parameter (675)
- 18.2** Radius of gyration of some macromolecules\*
- 18.3** Frictional coefficients and molecular geometry\*
- 18.4** Intrinsic viscosity\*
- 19.1** The seven crystal systems (697)
- 19.2** The crystal structures of some elements (710)
- 19.3** Ionic radii\*
- 19.4** Madelung constants (713)
- 19.5** Lattice enthalpies at 298 K [see Table 2.5]\*
- 19.6** Magnetic susceptibilities at 298 K\*
- 20.1** Collision cross-sections\*
- 20.2** Transport properties of gases at 1 atm\*
- 20.3** Transport properties of perfect gases (757)
- 20.4** Viscosities of liquids at 298 K\*
- 20.5** Ionic mobilities in water at 298 K\*
- 20.6** Debye–Hückel–Onsager coefficients for (1,1)-electrolytes at 298 K\*
- 20.7** Diffusion coefficients at 298 K\*
- 21.1** Kinetic data for first-order reactions\*
- 21.2** Kinetic data for second-order reactions\*
- 21.3** Integrated rate laws (795)
- 21.4** Arrhenius parameters\*
- 21.5** Examples of photochemical processes (816)
- 21.6** Common photophysical processes (816)
- 21.7** Values of  $R_0$  for some donor–acceptor pairs (821)
- 22.1** Arrhenius parameters for gas-phase reactions\*
- 22.2** Arrhenius parameters for reactions in solution [see Table 21.4]\*
- 22.3** Exchange current densities and transfer coefficients at 298 K\*
- 23.1** Maximum observed enthalpies of physisorption\*
- 23.2** Enthalpies of chemisorption\*
- 23.3** Chemisorption abilities (900)
- 23.4** Properties of catalysts (900)

| O <sub>2</sub>              | 120.75 |

## (b) Mean bond lengths from covalent radii\*

|    |       |    |       |    |        |    |     |
|----|-------|----|-------|----|--------|----|-----|
| H  | 37    |    |       |    |        |    |     |
| C  | 77(1) | N  | 74(1) | O  | 66(1)  | F  | 64  |
|    | 67(2) |    | 65(2) |    | 57(2)  |    |     |
|    | 60(3) |    |       |    |        |    |     |
| Si | 118   | P  | 110   | S  | 104(1) | Cl | 99  |
|    |       |    |       |    | 95(2)  |    |     |
| Ge | 122   | As | 121   | Se | 104    | Br | 114 |
|    |       | Sb | 141   | Te | 137    | I  | 133 |

\* Values are for single bonds except where indicated otherwise (values in parentheses). The length of an A—B covalent bond (of given order) is the sum of the corresponding covalent radii.

\* Radioactive.  
 $\mu$  is the magnetic moment of the spin state with the largest value of  $m_I$ ;  $\mu = g_I \mu_N I$  and  $\mu_N$  is the nuclear magneton (see inside front cover).  
Data: KL and HCP.

**Table 14.3** Hyperfine coupling constants for atoms,  $a/\text{mT}$

| Nuclide          | Spin          | Isotropic coupling | Anisotropic coupling |
|------------------|---------------|--------------------|----------------------|
| $^1\text{H}$     | $\frac{1}{2}$ | 50.8(1s)           |                      |
| $^2\text{H}$     | 1             | 7.8(1s)            |                      |
| $^{13}\text{C}$  | $\frac{1}{2}$ | 113.0(2s)          | 6.6(2p)              |
| $^{14}\text{N}$  | 1             | 55.2(2s)           | 4.8(2p)              |
| $^{19}\text{F}$  | $\frac{1}{2}$ | 1720(2s)           | 108.4(2p)            |
| $^{31}\text{P}$  | $\frac{1}{2}$ | 364(3s)            | 20.6(3p)             |
| $^{35}\text{Cl}$ | $\frac{3}{2}$ | 168(3s)            | 10.0(3p)             |
| $^{37}\text{Cl}$ | $\frac{3}{2}$ | 140(3s)            | 8.4(3p)              |

**Table 20.4** Viscosities of liquids at 298 K,  $\eta/(10^{-3} \text{ kg m}^{-1} \text{ s}^{-1})$

|                      |       |
|----------------------|-------|
| Benzene              | 0.601 |
| Carbon tetrachloride | 0.880 |
| Ethanol              | 1.06  |
| Mercury              | 1.55  |
| Methanol             | 0.553 |
| Pentane              | 0.224 |
| Sulfuric acid        | 27    |
| Water†               | 0.891 |

† The viscosity of water over its entire liquid range is represented with less than 1 per cent error by the expression

$$\log(\eta_{20}/\eta) = A/B,$$
$$A = 1.370\,23(t - 20) + 8.36 \times 10^{-4}(t - 20)^2$$
$$B = 109 + t \quad t = \theta/^\circ\text{C}$$

Convert  $\text{kg m}^{-1} \text{s}^{-1}$  to centipoise (cP) by multiplying by  $10^3$  (so  $\eta \approx 1 \text{ cP}$  for water).  
Data: AIP, KL.

**E10.17(a)** (a)  $14\alpha + 19.314\beta$  (b)  $14\alpha + 19.448\beta$

## Chapter 11

- E11.2(a)** (a)  $R_3$  (b)  $C_{2v}$  (c)  $D_{3h}$  (d)  $D_{\infty h}$   
**E11.3(a)** (a)  $C_{2v}$  (b)  $C_{\infty v}$  (c)  $C_{3v}$  (d)  $D_{2h}$   
**E11.4(a)** (a)  $C_{2v}$  (b)  $C_{2h}$   
**E11.7(a)**  $\sigma_h, i$   
**E11.12(a)**  $d_{xy}$   
**E11.14(a)**  $2A_1 + B_1 + E$   
**E11.15(a)** (a) either  $E_{1u}$  or  $A_{2u}$  (b)  $B_{3u}$  ( $x$ -polarized),  $B_{2u}$  ( $y$ -polarized),  $B_{1u}$  ( $z$ -polarized)

## Chapter 12

- E12.2(a)** (c)  $\text{CH}_4$  is inactive  
**E12.3(a)**  $7.173 \times 10^{-47} \text{ kg m}^2$ ,  $I_{\parallel}$  will not change  
**E12.4(a)**  $I_{\parallel} = 5.60 \times 10^{-47} \text{ kg m}^2$ ,  $I_{\perp} = 6.29 \times 10^{-46} \text{ kg m}^2$ ,  $\tilde{A} = 5.00 \text{ cm}^{-1}$ ,  
 $\tilde{B} = 0.445 \text{ cm}^{-1}$ ,  $A = 1.50 \times 10^{11} \text{ Hz}$ ,  $B = 1.33 \times 10^{10} \text{ Hz}$   
**E12.5(a)**  $4.09 \times 10^{11} \text{ Hz}$   
**E12.6(a)** (a)  $2.642 \times 10^{-47} \text{ kg m}^2$  (b) 127.4 pm  
**E12.7(a)**  $I = 4.442 \times 10^{-47} \text{ kg m}^2$ ,  $R = 165.9 \text{ pm}$   
**E12.8(a)** 232.1 pm

- E12.9(a)**  $R = 106.5 \text{ pm}$ ,  $R' = 115.6 \text{ pm}$   
**E12.10(a)**  $20\,475 \text{ cm}^{-1}$   
**E12.11(a)**  $198.9 \text{ pm}$   
**E12.12(a)**  $\tilde{D}_J = 2.111 \times 10^{-4} \text{ cm}^{-1}$ ,  $0.1253$   
**E12.13(a)** (a) 20 (b) 24  
**E12.14(a)**  $1.6 \times 10^2 \text{ N m}^{-1}$   
**E12.15(a)** 1.089 per cent  
**E12.16(a)**  $327.8 \text{ N m}^{-1}$   
**E12.17(a)** (a) 0.067 (b) 0.20

| <b>E12.18(a)</b>              | HF     | HCl    | HBr    | HI     |
|-------------------------------|--------|--------|--------|--------|
| $\tilde{\nu}/\text{cm}^{-1}$  | 4141.3 | 2988.9 | 2649.7 | 2309.5 |
| $m_{\text{eff}}/m_{\text{u}}$ | 0.9570 | 0.9697 | 0.9954 | 0.9999 |
| $k/(\text{N m}^{-1})$         | 967.0  | 515.6  | 411.8  | 314.2  |

- E12.19(a)**  $\tilde{\nu} = 1580.38 \text{ cm}^{-1}$ ,  $x_{\text{e}} = 7.644 \times 10^{-3}$   
**E12.20(a)**  $5.15 \text{ eV}$   
**E12.21(a)**  $x_{\text{e}} = 0.02101$ ,  $\frac{x_{\text{e}}(^2\text{H}^{19}\text{F})}{x_{\text{e}}(^1\text{H}^{19}\text{F})} = 0.5256$   
**E12.22(a)**  $2699.77 \text{ cm}^{-1}$   
**E12.26(a)** Raman active  
**E12.27(a)**  $4A_1 + A_2 + 2B_1 + 2B_2$

## Chapter 13

- E13.1(a)** 80 per cent  
**E13.2(a)**  $6.28 \times 10^3 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$   
**E13.3(a)**  $1.5 \text{ mmol dm}^{-3}$   
**E13.4(a)**  $5.4 \times 10^7 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-2}$   
**E13.5(a)**  $4.5 \times 10^2 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-2}$   
**E13.6(a)** 23 per cent  
**E13.7(a)** (a) 0.87 m (b) 2.9 m  
**E13.8(a)** (a)  $5 \times 10^7 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-2}$  (b)  $2.5 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-2}$   
**E13.9(a)**  $1\sigma_{\text{g}}^4 1\pi_{\text{u}}^1$   
**E13.10(a)** 3, u  
**E13.11(a)** (a) allowed (b) allowed (c) forbidden (d) forbidden (e) allowed  
**E13.12(a)**  $\frac{2\sqrt{2}}{3} e^{-2ax_0^2/3}$   
**E13.13(a)** R branch has a band head,  $J = 7$   
**E13.14(a)**  $30.4 \text{ cm}^{-1} < \tilde{B}' < 40.5 \text{ cm}^{-1}$   
**E13.17(a)**  $\Delta_{\text{O}} = P - \tilde{\nu}$ ,  $14 \times 10^3 \text{ cm}^{-1}$   
**E13.18(a)** (a)  $\tilde{\nu} \approx 1800 \text{ cm}^{-1}$   
**E13.19(a)**  $\lambda = 60 \text{ cm}$  ( $\nu = 500 \text{ MHz}$ )  
**E13.20(a)** 20 ps, 70 MHz

## Chapter 14

- E14.1(a)** 28 GHz  
**E14.2(a)**  $8.9 \times 10^{-12} \text{ s}$   
**E14.3(a)** 600 MHz  
**E14.4(a)** 154 MHz  
**E14.5(a)**  $\Delta E = 3.98 \times 10^{-25} \text{ J}$ ,  $\Delta E = 6.11 \times 10^{-26} \text{ J}$ , larger for the proton  
**E14.7(a)** (a)  $1 \times 10^{-6}$  (b)  $5.1 \times 10^{-6}$  (c)  $3.4 \times 10^{-5}$   
**E14.8(a)** (a) 1.86 T (b) 0  
**E14.9(a)** 13  
**E14.10(a)** (a) 11  $\mu\text{T}$  (b) 110  $\mu\text{T}$

- E14.13(a)**  $6.7 \times 10^2 \text{ s}^{-1}$   
**E14.17(a)** 0.21 s  
**E14.18(a)** 1.234  
**E14.19(a)**  $\mathcal{B}_1 = 5.9 \times 10^{-4} \text{ T}$ ,  $20 \mu\text{s}$   
**E14.20(a)** (a)  $2 \times 10^2 \text{ T}$  (b) 10 mT  
**E14.21(a)** 2.0022  
**E14.22(a)**  $a = 2.3 \text{ mT}$ ,  $g = 2.0025$   
**E14.23(a)** equal intensity, 330.2 mT, 332.2 mT, 332.8 mT, 334.8 mT  
**E14.25(a)** (a) 331.9 mT (b) 1.201 T  
**E14.26(a)**  $I = \frac{3}{2}$   
**E14.28(a)**  $1.9 \times 10^8 \text{ s}^{-1}$

## Chapter 15

- E15.1(a)** 21621600  
**E15.2(a)** 1  
**E15.3(a)** 524 K  
**E15.4(a)** 354 K  
**E15.5(a)** (a) (i) 8.23 pm (ii) 2.60 pm (b) (i)  $1.79 \times 10^{27}$  (ii)  $5.67 \times 10^{28}$   
**E15.6(a)** 2.83  
**E15.7(a)**  $2.4 \times 10^{25}$   
**E15.8(a)** 72.2  
**E15.9(a)** (a)  $7.97 \times 10^3$  (b)  $1.12 \times 10^4$   
**E15.10(a)** 18 K  
**E15.11(a)** 37 K  
**E15.12(a)** 4.5 K  
**E15.13(a)** (a) 1 (b) 2 (c) 2 (d) 12 (e) 3  
**E15.14(a)** 660.6  
**E15.14(a)** 4500 K  
**E15.16(a)** 2.571  
**E15.17(a)** 42.3  
**E15.18(a)** 3.1561  
**E15.19(a)** +2.46 kJ  
**E15.20(a)**  $1 + e^{-2\mu_{\text{B}}\beta B}$ ,  $\frac{2\mu_{\text{B}}\mathcal{B}e^{-2\mu_{\text{B}}\beta B}}{1 + e^{-2\mu_{\text{B}}\beta B}}$ ,  $-\mu_{\text{B}}\mathcal{B} + \frac{2\mu_{\text{B}}\mathcal{B}e^{-2\mu_{\text{B}}\beta B}}{1 + e^{-2\mu_{\text{B}}\beta B}}$  (a) 0.71 (b) 0.996  
**E15.21(a)** (a) (1)  $5 \times 10^{-5}$  (2) 0.4 (3) 0.905 (b) 1.4 (c) 22 J mol<sup>-1</sup>  
 (d) 1.6 J K<sup>-1</sup> mol<sup>-1</sup> (e) 4.8 J K<sup>-1</sup> mol<sup>-1</sup>  
**E15.22(a)** 4303 K  
**E15.23(a)** (a) 138 J K<sup>-1</sup> mol<sup>-1</sup> (b) 146 J K<sup>-1</sup> mol<sup>-1</sup>  
**E15.24(a)** 5.20 J K<sup>-1</sup> mol<sup>-1</sup>  
**E15.25(a)** (a) He gas (b) CO gas (d) H<sub>2</sub>O vapour

## Chapter 16

- E16.1(a)** 15.27 pm  
**E16.2(a)**  $2.8 \times 10^{26}$   
**E16.3(a)** (a)  $\frac{7}{2}R$  (b)  $3R$  (c)  $7R$   
**E16.4(a)** 15.24 K  
**E16.5(a)** (a) 19.6 (b) 34.3  
**E16.6(a)** (a) 1 (b) 2 (c) 2 (d) 12 (e) 3  
**E16.7(a)**  $q^{\text{R}} = 43.1$ ,  $\theta_{\text{R}} = 22.36 \text{ K}$   
**E16.8(a)** 43.76 J K<sup>-1</sup> mol<sup>-1</sup>  
**E16.9(a)** (a) 36.95, 80.08 (b) 36.7, 79.7  
**E16.10(a)** 72.5  
**E16.11(a)** closer, closer  
**E16.12(a)** (a) 14.93 J K<sup>-1</sup> mol<sup>-1</sup> (b) 25.65 J K<sup>-1</sup> mol<sup>-1</sup>  
**E16.13(a)** -13.8 kJ mol<sup>-1</sup>, -0.20 kJ mol<sup>-1</sup>

- E16.14(a)** (a) 4.158 (b) 4.489  
**E16.15(a)** (a) 0.236 (b) 0.193  
**E16.16(a)** (a)  $-6.42 \text{ kJ mol}^{-1}$  (b)  $-14.0 \text{ kJ mol}^{-1}$   
**E16.17(a)**  $11.5 \text{ J K}^{-1} \text{ mol}^{-1}$   
**E16.19(a)** (a)  $9.13 \text{ J K}^{-1} \text{ mol}^{-1}$  (b)  $13.4 \text{ J K}^{-1} \text{ mol}^{-1}$  (c)  $14.9 \text{ J K}^{-1} \text{ mol}^{-1}$   
**E16.20(a)**  $3.70 \times 10^{-3}$

## Chapter 17

- E17.1(a)**  $\text{ClF}_3$ ,  $\text{O}_3$ ,  $\text{H}_2\text{O}_2$   
**E17.2(a)** 1.4 D  
**E17.3(a)** 37D,  $11.7^\circ$   
**E17.4(a)**  $1.07 \times 10^3 \text{ kJ mol}^{-1}$   
**E17.5(a)**  $5.0 \mu\text{D}$   
**E17.6(a)** 1.66 D,  $1.01 \times 10^{-39} \text{ J}^{-1} \text{ C}^2 \text{ m}^2$ ,  $9.06 \times 10^{-30} \text{ m}^3$   
**E17.7(a)** 4.75  
**E17.8(a)**  $1.42 \times 10^{-39} \text{ J}^{-1} \text{ C}^2 \text{ m}^2$   
**E17.9(a)** 1.34  
**E17.10(a)** 17.7  
**E17.11(a)**  $0.071 \text{ J mol}^{-1}$   
**E17.12(a)**  $289 \text{ kJ mol}^{-1}$   
**E17.13(a)** 2.6 kPa  
**E17.14(a)**  $72.8 \text{ mN m}^{-1}$   
**E17.15(a)** 728 kPa

## Chapter 18

- E18.1(a)** 27 nm  
**E18.2(a)**  $R_c = 3.08 \mu\text{m}$ ,  $R_{\text{rms}} = 30.8 \text{ nm}$   
**E18.3(a)**  $1.4 \times 10^4$   
**E18.4(a)** 0.017  
**E18.5(a)**  $6.4 \times 10^{-3}$   
**E18.6(a)**  $-19 \text{ mJ mol}^{-1} \text{ K}^{-1}$   
**E18.7(a)**  $\left( \frac{R_{\text{g,constrained coil}} - R_{\text{g,random coil}}}{R_{\text{g,random coil}}} \right) \times 100\% = +41.42\%$ ,  
 $\left( \frac{V_{\text{constrained coil}} - V_{\text{random coil}}}{V_{\text{random coil}}} \right) \times 100\% = +182.8\%$   
**E18.8(a)**  $\left( \frac{R_g - R_{\text{g,random coil}}}{R_{\text{g,random coil}}} \right) \times 100\% = +895\%$  when  $N = 1000$ ,  
 $\left( \frac{V - V_{\text{g,random coil}}}{V_{\text{g,random coil}}} \right) \times 100\% = +9.84 \times 10^4 \%$  when  $N = 1000$   
**E18.9(a)**  $1.3 \times 10^4 \text{ pm}$   
**E18.10(a)**  $3.7 \times 10^{-14} \text{ N}$   
**E18.11(a)**  $\bar{M}_n = 70 \text{ kg mol}^{-1}$ ,  $\bar{M}_w = 69 \text{ kg mol}^{-1}$   
**E18.12(a)** (a)  $18 \text{ kg mol}^{-1}$  (b)  $20 \text{ kg mol}^{-1}$   
**E18.13(a)** 100  
**E18.14(a)**  $64 \text{ kg mol}^{-1}$   
**E18.15(a)**  $0.73 \text{ mm s}^{-1}$   
**E18.16(a)**  $31 \text{ kg mol}^{-1}$   
**E18.17(a)**  $3.4 \times 10^3 \text{ kg mol}^{-1}$

## Chapter 19

- E19.1(a)**  $(1, \frac{1}{2}, 0)$ ,  $(1, 0, \frac{1}{2})$ ,  $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$   
**E19.2(a)** (323) and (110)

- E19.3(a)**  $d_{111} = 249 \text{ pm}$ ,  $d_{211} = 176 \text{ pm}$ ,  $d_{100} = 432 \text{ pm}$   
**E19.4(a)** 70.7 pm  
**E19.5(a)**  $\sin \theta_{110} = 16^\circ$ ,  $\sin \theta_{200} = 23^\circ$ ,  $\sin \theta_{211} = 28^\circ$   
**E19.6(a)** 0.214 cm  
**E19.7(a)**  $f_{\text{Br}^-} = 36$   
**E19.8(a)**  $0.396 \text{ nm}^3$   
**E19.9(a)**  $N = 4$ ,  $\rho = 4.01 \text{ g cm}^{-3}$   
**E19.10(a)** 190 pm  
**E19.11(a)** 111, 200, 311, cubic F  
**E19.12(a)**  $\theta_{100} = 8.17^\circ$ ,  $\theta_{010} = 4.82^\circ$ ,  $\theta_{111} = 11.75^\circ$   
**E19.13(a)** face-centred cubic  
**E19.14(a)**  $f$   
**E19.18(a)**  $7.9 \text{ km s}^{-1}$   
**E19.19(a)** 252 pm  
**E19.20(a)** 0.9069  
**E19.21(a)** (a) 0.5236 (b) 0.6802 (c) 0.7405  
**E19.22(a)** 0.41421  
**E19.23(a)** (a) 58.0 pm (b) 102 pm  
**E19.24(a)** expansion  
**E19.25(a)**  $3500 \text{ kJ mol}^{-1}$   
**E19.26(a)** 0.010  
**E19.27(a)**  $9.3 \times 10^{-4} \text{ cm}^3$   
**E19.29(a)** 3.54 eV  
**E19.30(a)** 3 unpaired electrons  
**E19.31(a)**  $-6.4 \times 10^{-5} \text{ cm}^3 \text{ mol}^{-1}$   
**E19.32(a)** 5  
**E19.33(a)**  $+1.6 \times 10^{-8} \text{ m}^3 \text{ mol}^{-1}$   
**E19.34(a)** 6.0 K

## Chapter 20

- E20.1(a)** (a) 9.975  
**E20.2(a)** (a) 72 K (b)  $94\bar{6} \text{ m s}^{-1}$  (c) the temperature would not be different  
**E20.3(a)**  $9.06 \times 10^{-3}$   
**E20.4(a)**  $\left( 3 - \frac{8}{\pi} \right)^{1/2} \left( \frac{RT}{M} \right)^{1/2}$ ,  $\left( 1 - \frac{8}{\pi} \right)^{1/2} c$   
**E20.5(a)** 0.0652 Pa  
**E20.6(a)** 0.97  $\mu\text{m}$   
**E20.7(a)**  $397 \text{ m s}^{-1}$  (a)  $5.0 \times 10^{10} \text{ s}^{-1}$  (b)  $5.0 \times 10^9 \text{ s}^{-1}$  (c)  $5.0 \times 10^3 \text{ s}^{-1}$   
**E20.8(a)** (a) 6.7 nm (b) 67 nm (c) 6.7 cm  
**E20.9(a)**  $1.9 \times 10^{20}$   
**E20.10(a)** 104 mg  
**E20.11(a)** 415 Pa  
**E20.12(a)**  $42.4 \text{ g mol}^{-1}$   
**E20.13(a)** 1.3 days  
**E20.14(a)**  $-0.013 \text{ J m}^{-2} \text{ s}^{-1}$   
**E20.15(a)**  $0.0562 \text{ m}^2$   
**E20.16(a)** 17 W

- E20.31(a)**  $a = 0.42 \text{ nm}$
- E20.32(a)**  $27.3 \text{ ps}$
- E20.33(a)**  $\langle r^2 \rangle^{1/2} = 113 \text{ } \mu\text{m}$ ,  $\langle r^2 \rangle^{1/2} = 56 \text{ } \mu\text{m}$

## Chapter 21

- E21.1(a)** no change in pressure
- E21.2(a)**  $8.1 \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $5.4 \text{ mol dm}^{-3} \text{ s}^{-1}$
- E21.3(a)**  $v = 1.35 \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $4.05 \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $2.7 \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $1.35 \text{ mol dm}^{-3} \text{ s}^{-1}$
- E21.4(a)**  $\text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ,  
(a)  $k_t[\text{A}][\text{B}]$  (b)  $3k_t[\text{A}][\text{B}]$
- E21.5(a)**  $v = \frac{1}{2}k_t[\text{A}][\text{B}][\text{C}]$ ,  $[k_t] = \text{dm}^6 \text{ mol}^{-2} \text{ s}^{-1}$
- E21.6(a)** (a)  $[k_t] = \text{dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ,  $[k_r] = \text{dm}^6 \text{ mol}^{-2} \text{ s}^{-1}$   
(b)  $[k_t] = \text{kPa}^{-1} \text{ s}^{-1}$ ,  $[k_r] = \text{kPa}^{-2} \text{ s}^{-1}$
- E21.7(a)** second-order
- E21.8(a)**  $n = 2$
- E21.9(a)**  $1.03 \times 10^4 \text{ s}$ , (a) 498 Torr (b) 461 Torr
- E21.10(a)** (a)  $16.2 \text{ dm}^3 \text{ mol}^{-1} \text{ h}^{-1}$ ,  $4.5 \times 10^{-3} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$   
(b)  $5.1 \times 10^3 \text{ s}$ ,  $2.1 \times 10^3 \text{ s}$
- E21.11(a)** (a)  $0.098 \text{ mol dm}^{-3}$  (b)  $0.050 \text{ mol dm}^{-3}$
- E21.12(a)**  $1.11 \times 10^5 \text{ s} = 128 \text{ days}$
- E21.13(a)**  $1.28 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ,  $4.0 \times 10^{10} \text{ dm}^{-3} \text{ mol s}^{-1}$
- E21.14(a)**  $64.9 \text{ kJ mol}^{-1}$ ,  $4.32 \times 10^8 \text{ mol dm}^{-3} \text{ s}^{-1}$
- E21.15(a)**  $35 \text{ kJ mol}^{-1}$
- E21.16(a)** (i)  $k_3 K^{1/2} [\text{A}_2]^{1/2} [\text{B}]$  (ii)  $\frac{k_2^2 [\text{B}]^2}{4k_1'} \left( \sqrt{1 + \frac{16k_1' k_1 [\text{A}_2]}{k_2^2 [\text{B}]^2}} - 1 \right)$ ,  
 $k_2 K^{1/2} [\text{A}_2]^{1/2} [\text{B}]$ ,  $2k_1 [\text{A}_2]$
- E21.17(a)**  $1.9 \times 10^{-6} \text{ Pa}^{-1} \text{ s}^{-1}$ ,  $1.9 \text{ MPa}^{-1} \text{ s}^{-1}$
- E21.18(a)**  $-3 \text{ kJ mol}^{-1}$
- E21.19(a)** 251, 0.996
- E21.20(a)** 0.125
- E21.21(a)**  $3.3 \times 10^{18}$
- E21.22(a)** 0.52
- E21.23(a)**  $0.56 \text{ mol dm}^{-3}$
- E21.24(a)** 7.1 nm

## Chapter 22

- E22.1(a)**  $9.49 \times 10^9 \text{ s}^{-1}$ ,  $1.15 \times 10^{35} \text{ s}^{-1} \text{ m}^{-3}$ , 1.7 per cent
- E22.2(a)** (a) (i) 0.018, (ii) 0.30 (b) (i)  $3.9 \times 10^{-18}$  (ii)  $6.0 \times 10^{-6}$

- E22.3(a)** (a) (i) 14% (ii) 1% (b) (i) 280%, 260 % (ii) 13%
- E22.4(a)**  $1.03 \times 10^{-5} \text{ m}^3 \text{ mol}^{-1} \text{ s}^{-1} = 1.03 \times 10^{-2} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$
- E22.5(a)**  $2.4 \times 10^{-4}$
- E22.6(a)**  $3 \times 10^{10} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$
- E22.7(a)** (a)  $6.61 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  (b)  $3.0 \times 10^{10} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$
- E22.8(a)**  $7.4 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ,  $6.7 \times 10^{-8} \text{ s}$
- E22.9(a)**  $0.79 \text{ nm}^2$ ,  $1.16 \times 10^{-3}$
- E22.10(a)**  $1.87 \times 10^8 \text{ mol dm}^{-3} \text{ s}^{-1}$
- E22.11(a)**  $+69.66 \text{ kJ mol}^{-1}$ ,  $-25.3 \text{ J K}^{-1} \text{ mol}^{-1}$
- E22.12(a)**  $+73.4 \text{ kJ mol}^{-1}$ ,  $+71.9 \text{ kJ mol}^{-1}$
- E22.13(a)**  $-91 \text{ J K}^{-1} \text{ mol}^{-1}$
- E22.14(a)**  $-72 \text{ J K}^{-1} \text{ mol}^{-1}$
- E22.15(a)** (a)  $-46 \text{ J K}^{-1} \text{ mol}^{-1}$  (b)  $+5.0 \text{ kJ mol}^{-1}$   
(c)  $+18.7 \text{ kJ mol}^{-1}$
- E22.16(a)**  $7.1 \text{ dm}^6 \text{ mol}^{-2} \text{ min}^{-1}$
- E22.17(a)**  $1.9 \times 10^{-19} \text{ J}$ , 1.2 eV
- E22.18(a)**  $12.5 \text{ nm}^{-1}$
- E22.19(a)** 0.138 V
- E22.20(a)**  $2.82 \text{ mA cm}^{-2}$
- E22.21(a)** increases, factor of 50
- E22.22(a)** (a)  $1.7 \times 10^{-4} \text{ A cm}^{-2}$   
(b)  $1.7 \times 10^{-4} \text{ A cm}^{-2}$
- E22.23(a)** (a)  $0.31 \text{ mA cm}^{-2}$   
(b)  $5.44 \text{ mA cm}^{-2}$   
(c)  $-2 \times 10^{42} \text{ mA cm}^{-2}$

- E22.25(a)** (a)  $33 \text{ } \Omega$  (b)  $3.3 \times 10^{10} \text{ } \Omega$
- E22.26(a)** one can (barely) deposit zinc

## Chapter 23

- E23.1(a)**  $\frac{k_b K [\text{AH}]^2 [\text{B}]}{[\text{BH}^+]}$
- E23.2(a)**  $1.50 \text{ mmol dm}^{-3} \text{ s}^{-1}$
- E23.3(a)**  $k_{\text{cat}} = 1.18 \times 10^5 \text{ s}^{-1}$ ,  $\eta = 7.9 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$
- E23.4(a)**  $2.0 \times 10^{-5} \text{ mol dm}^{-3}$
- E23.5(a)** (a) (i)  $1.07 \times 10^{21} \text{ cm}^{-2} \text{ s}^{-1}$  (ii)  $1.4 \times 10^{14} \text{ cm}^{-2} \text{ s}^{-1}$   
(b) (i)  $2.30 \times 10^{20} \text{ cm}^{-2} \text{ s}^{-1}$  (ii)  $3.1 \times 10^{13} \text{ cm}^{-2} \text{ s}^{-1}$
- E23.6(a)** 0.13 bar
- E23.8(a)**  $12 \text{ m}^2$
- E23.9(a)**  $33.6 \text{ cm}^3$
- E23.10(a)** chemisorption, 50 s
- E23.11(a)**  $\theta_1 = 0.83$ ,  $\theta_2 = 0.36$
- E23.12(a)** (a) 0.24 kPa (b) 25 kPa
- E23.13(a)** 15 kPa
- E23.14(a)**  $-12.4 \text{ kJ mol}^{-1}$
- E23.15(a)**  $E_d = 65 \text{ kJ mol}^{-1}$ , (a)  $1.6 \times 10^{97} \text{ min}$  (b)  $2.8 \times 10^{-6} \text{ min}$
- E23.16(a)**  $61 \text{ kJ mol}^{-1}$
- E23.17(a)** (a)  $t_{1/2}(400 \text{ K}) = 9.1 \text{ ps}$ ,  $t_{1/2}(1000 \text{ K}) = 0.60 \text{ ps}$   
(b)  $t_{1/2}(400 \text{ K}) = 4.1 \times 10^6 \text{ s}$ ,  $t_{1/2}(1000 \text{ K}) = 6.6 \text{ } \mu\text{s}$
- E23.18(a)** (a) zeroth-order (b) first-order

# Solutions to odd-numbered problems

A horizontal bar over the last digit in some answers denotes an insignificant digit.

## Chapter 1

- P1.1**  $-233^{\circ}\text{N}$   
**P1.3**  $-272.95^{\circ}\text{C}$   
**P1.5** (a) 0.0245 kPa (b) 9.14 kPa (c) 0.0245 kPa  
**P1.7** (a)  $12.5\text{ dm}^3\text{ mol}^{-1}$  (b)  $12.3\text{ dm}^3\text{ mol}^{-1}$   
**P1.9** (a)  $0.941\text{ dm}^3\text{ mol}^{-1}$  (b)  $2.69\text{ dm}^3\text{ mol}^{-1}$ ,  $2.67\text{ dm}^3\text{ mol}^{-1}$  (c)  $5.11\text{ dm}^3\text{ mol}^{-1}$   
**P1.11** (a)  $0.1353\text{ dm}^3\text{ mol}^{-1}$  (b) 0.6957 (c) 0.7158  
**P1.13**  $a = 5.649\text{ dm}^6\text{ atm mol}^{-2}$ ,  $b = 59.4\text{ cm}^3\text{ mol}^{-1}$ ,  $p = 21\text{ atm}$   
**P1.15**  $1.26\text{ dm}^6\text{ atm mol}^{-2}$ ,  $34.6\text{ cm}^3\text{ mol}^{-1}$   
**P1.17**  $\frac{1}{3}$   
**P1.19**  $0.0866\text{ atm}^{-1}$ ,  $2.12\text{ dm}^3\text{ mol}^{-1}$   
**P1.23** 0.011  
**P1.25**  $3.4 \times 10^8\text{ dm}^3$   
**P1.27** (a)  $1.7 \times 10^{-5}$  (b) 0.72  
**P1.31** 0.0029 atm

## Chapter 2

**P2.1** Total cycle

| State | $p/\text{atm}$ | $V/\text{dm}^3$ | $T/\text{K}$ |
|-------|----------------|-----------------|--------------|
| 1     | 1.00           | 22.44           | 273          |
| 2     | 1.00           | 44.8            | 546          |
| 3     | 0.50           | 44.8            | 273          |

Thermodynamic quantities calculated for reversible steps.

| Step              | Process                        | $q/\text{kJ}$ | $w/\text{kJ}$ | $\Delta U/\text{kJ}$ | $\Delta H/\text{kJ}$ |

**P19.19**  $\frac{1}{d^2} = \left( \frac{h}{a} \right)^2 + \left( \frac{k}{b} \right)^2 + \left( \frac{l}{c} \right)^2$   
**P19.25** 0  
**P19.29** (a)  $\rho(E) = - \frac{(N+1)/2\pi\beta}{\left[ 1 - \left( \frac{E-\alpha}{2\beta} \right)^2 \right]^{1/2}}$   
**P19.35**  $1 - \left( \frac{1}{4(p/K) + 1} \right)^{1/2}$ , increases  
**P19.37**  $3.61 \times 10^5$  g mol<sup>-1</sup>

## Chapter 20

- P20.3** (b) 1.8894 m (c) 1.8897 m  
**P20.5** 7.3 mPa  
**P20.7**  $0.613$  mS m<sup>2</sup> mol<sup>-1</sup>

**P20.9**  $13.82 \mu\text{mol dm}^{-3}$

**P20.11**  $\frac{G_{\text{H}^+}}{\sum_{\text{all ions}} G_i} = 0.821, \frac{G_{\text{H}^+}}{\sum_{\text{all ions}} G_i} = 0.00279$

**P20.13** (b) four, one to two

**P20.15** (a) 0, (b)  $0.0630 \text{ mol dm}^{-3}$

**P20.17**  $\Lambda_{\text{m}}^{\circ}(\text{NaI}) = 60.7 \text{ S cm}^2 \text{ mol}^{-1}$ ,  $\Lambda_{\text{m}}^{\circ}(\text{KI}) = 58.9 \text{ S cm}^2 \text{ mol}^{-1}$ ,  
 $\lambda(\text{Na}^+) - \lambda(\text{K}^+) = 1.8 \text{ S cm}^2 \text{ mol}^{-1}$ ,  $\Lambda_{\text{m}}^{\circ}(\text{NaI}) = 127 \text{ S cm}^2 \text{ mol}^{-1}$ ,  
 $\Lambda_{\text{m}}^{\circ}(\text{KI}) = 150 \text{ S cm}^2 \text{ mol}^{-1}$ ,  $\lambda(\text{Na}^+) - \lambda(\text{K}^+) = -23 \text{ S cm}^2 \text{ mol}^{-1}$

**P20.19**  $0.83 \text{ nm}$

**P20.21**  $f(v) = \left(\frac{m}{kT}\right) v e^{-mv^2/2kT}, \left(\frac{\pi kT}{2m}\right)^{1/2}$  or  $\left(\frac{\pi RT}{2M}\right)^{1/2}$

**P20.23**  $P = 0.61$ , (a) 39 per cent (b) 61 per cent (c) 53 per cent, 47 per cent

**P20.25**  $p = p_0 e^{-t/\tau}$  where  $\tau = \left(\frac{2\pi M}{RT}\right)^{1/2} \frac{V}{A}$ ,  $t_{1/2} = \tau \ln(2) = \left(\frac{2\pi M}{RT}\right)^{1/2} \frac{V}{A} \ln(2)$

**P20.27**  $\langle x^4 \rangle^{1/4} / \langle x^2 \rangle^{1/2} = 3^{1/4}$

**P20.29**  $\frac{1}{\Lambda_{\text{m}}} = \frac{1}{\Lambda_{\text{m}, \alpha=1}} + \frac{(1-\alpha)\Lambda_{\text{m}}}{(\alpha\Lambda_{\text{m}, \alpha=1})^2}$ ,  $\Lambda_{\text{m}, \alpha=1} = \Lambda_{\text{m}}^{\circ} - \mathcal{K}(\alpha\alpha)^{1/2}$

**P20.31**  $D = 1.6 \times 10^{16} \text{ m}^2 \text{ s}^{-1}$ ,  $\kappa = 0.34 \text{ J K}^{-1} \text{ m}^{-1} \text{ s}^{-1}$

**P20.33** (a)  $5.4 \times 10^{-12} \text{ cm}^3$  (b)  $16 \text{ MK}$  (c)  $16 \text{ MK}$

**P20.35**  $1.7 \times 10^{-2} \text{ s}$

## Chapter 21

**P21.1** second-order,  $k_r = 0.0594 \text{ dm}^3 \text{ mol}^{-1} \text{ min}^{-1}$ ,  $2.94 \text{ g}$

**P21.3**  $7.0 \times 10^{-5} \text{ s}^{-1}$ ,  $7.3 \times 10^{-5} \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$

**P21.5**  $55.4\%$

**P21.7** first-order,  $1.7 \times 10^{-2} \text{ min}^{-1}$

**P21.9** first-order kinetics,  $7.2 \times 10^{-4} \text{ s}^{-1}$

**P21.11**  $k_r K_1 K_2 [\text{HCl}]^3 [\text{CH}_3\text{CH}=\text{CH}_2]$

**P21.13**  $16.7 \text{ kJ mol}^{-1}$

**P21.15** steady-state approximation

**P21.19**  $\frac{1}{I_f} = \frac{1}{I_{\text{abs}}} + \frac{k_0[\text{Q}]}{k_f I_{\text{abs}}}$ ,  $5.1 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$

**P21.21**  $3.5 \text{ nm}$

**P21.23** 
$$[\text{A}] = \frac{k'_r([\text{A}]_0 + [\text{B}]_0) + (k_r[\text{A}]_0 - k'_r[\text{B}]_0)e^{-(k_r+k'_r)t}}{k_r + k'_r}$$
  

$$[\text{A}]_{\infty} = \left(\frac{k'_r}{k_r + k'_r}\right) \times ([\text{A}]_0 + [\text{B}]_0)$$
,  $[\text{B}]_{\infty} = \left(\frac{k_r}{k_r + k'_r}\right) \times ([\text{A}]_0 + [\text{B}]_0)$ ,  

$$\frac{[\text{B}]_{\infty}}{[\text{A}]_{\infty}} = \frac{k_r}{k'_r}$$

**P21.25** (a)  $k_r t = \frac{2x(A_0 - x)}{A_0^2(A_0 - 2x)^2}$  (b)  $\left(\frac{2x}{A_0^2(A_0 - 2x)}\right) + \left(\frac{1}{A_0^2}\right) \ln\left(\frac{A_0 - 2x}{A_0 - x}\right)$

**P21.27** steady-state intermediate

**P21.29**  $\frac{k_1 k_2 k_3 [\text{A}]_0}{k'_1 k'_2 + k'_1 k_3 + k_2 k_3}$

**P21.31**  $\langle (M^2)_N - \langle M^2 \rangle_N^2 \rangle^{1/2} = \frac{p^{1/2} M_1}{1 - p}$ ,  $M_1 \{kt[\text{A}]_0(1 + kt[\text{A}]_0)\}^{1/2}$

**P21.33**  $k_t [\cdot\text{M}][\text{I}]^{-1/2}$

**P21.35**  $\left(\frac{I_a}{k_r}\right)^{1/2}$

**P21.37** first-order,  $k_r = 0.00765 \text{ min}^{-1} = 0.459 \text{ h}^{-1}$ ,

$t_{1/2} = 1.51 \text{ h} = 91 \text{ min}$

**P21.39**  $v_0 = 6 \times 10^{-14} \text{ mol dm}^{-3} \text{ s}^{-1}$ ,  $t_{1/2} = 4.4 \times 10^8 \text{ s} = 14 \text{ yr}$

**P21.41**  $5.9 \times 10^{-13} \text{ mol dm}^{-3} \text{ s}^{-1}$

## Chapter 22

**P22.1** (a)  $4.35 \times 10^{-20} \text{ m}^2$  (b)  $0.15$

**P22.3**  $1.64 \times 10^{11} \text{ mol}^{-1} \text{ dm}^3 \text{ s}^{-1}$ ,  $3.7 \text{ ns}$

**P22.9**  $0.78, 0.38$

**P22.13**  $0.50, 0.150 \text{ A m}^{-2}$ ,  $0.038 \text{ A m}^{-2}$

**P22.17**  $q_{\text{m}}^{\text{T}}/N_{\text{A}} = 1.4 = 10^7$ ,  $q_{\text{R}}(\text{nonlinear}) \approx 900$ ,  $q_{\text{R}}(\text{linear}) \approx 200$ ,  $q_{\text{R}} \approx q_{\text{E}} \approx 1$   
 $A = 6.3 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ,  $A = 3.3 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$   $P = 2 \times 10^{-7}$

**P22.19**  $\frac{v^3}{(v^{\ddagger})^2} e^{-\Delta E_0/RT}$ ,  $2.7 \times 10^{-15} \text{ m}^2 \text{ s}^{-1}$ ,  $1.1 \times 10^{-14} \text{ m}^2 \text{ s}^{-1}$

**P22.21** (a)  $1.37 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  (b)  $1.16 \times 10^6 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$

**P22.25** (a)  $6.23 \times 10^9 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  (b)  $4 \times 10^{-10} \text{ m}$

**P22.27**  $1.15 \text{ eV}$

**P22.29**  $9.5 \times 10^4 \text{ dm}^3 \text{ mol}^{-1} \text{ s}^{-1}$

## Chapter 23

**P23.1**  $v_{\text{max}} = 2.31 \mu\text{mol dm}^{-3} \text{ s}^{-1}$ ,  $k_{\text{b}} = 115 \text{ s}^{-1}$ ,  $k_{\text{cat}} = 115 \text{ s}^{-1}$ ,  
 $K_{\text{M}} = 1.11 \mu\text{mol dm}^{-3}$ ,  $\eta = 104 \text{ dm}^3 \mu\text{mol}^{-1} \text{ s}^{-1}$

**P23.3** (b)  $\text{pH} = 7.0$

**P23.5**  $V_{\text{total}} = -2.039 \times 10^{-18} \text{ J}$ ,  $V_{\text{total}} = -2.20 \times 10^{-19} \text{ J}$ ,  
 $V_{\text{total}} = -7.30 \times 10^{-19} \text{ J}$

**P23.7** (a)  $1.61 \times 10^{15} \text{ cm}^{-2}$  (b)  $1.14 \times 10^{15} \text{ cm}^{-2}$  (c)  $1.86 \times 10^{15} \text{ cm}^{-2}$

**P23.9** (a)  $c = 165$ ,  $V_{\text{mon}} = 13.1 \text{ cm}^3$  (b)  $c = 263$ ,  $V_{\text{mon}} = 12.5 \text{ cm}^3$

**P23.11**  $c_1 = 0.16 \text{ g}$ ,  $c_2 = 2.2$

**P23.13**  $K = 0.138 \text{ mg g}^{-1}$ ,  $n = 0.58$

**P23.15**  $n_{\infty} = 5.78 \text{ mol kg}^{-1}$ ,  $K = 7.02 \text{ MPa}^{-1}$

**P23.17** (a)  $\frac{[\text{P}]}{[\text{P}]_0} = (b+1) \frac{e^{at}}{1 + be^{at}}$  (c)  $-\frac{1}{a} \ln(b)$   
 (d)  $A_0(A_0 + P_0)kt = \left(\frac{y}{1-y}\right) + \left(\frac{1}{1-p}\right) \ln\left(\frac{p+y}{p(1-y)}\right)$ ,  
 $(A_0 + P_0)^2 kt_{\text{max}} = \frac{1}{2} - p - \ln 2p$   
 (e)  $A_0(A_0 + P_0)kt = \left(\frac{y}{p(p+y)}\right) + \left(\frac{1}{1+p}\right) \ln\left(\frac{p+y}{p(1-y)}\right)$ ,  
 $\frac{2-p}{2p} + (A_0 + P_0)^2 kt_{\text{max}} = \ln \frac{2}{p}$

**P23.19**  $v = \frac{v_{\text{max}}}{1 + \frac{1}{K[\text{S}]_0}}$ ,  $k'_a \gg k_b$

**P23.23** it is described by the BET isotherm,  $3.96, 75.8 \text{ cm}^3$

**P23.25** (a)  $R$  values in the range  $0.975$  to  $0.991$  (b)  $k_a = 3.68 \times 10^{-3}$ ,  
 $\Delta_{\text{ad}}H = -8.67 \text{ kJ mol}^{-1}$ ,  $k_b = 2.62 \times 10^{-5} \text{ ppm}^{-1}$ ,  
 $\Delta_{\text{b}}H = -15.7 \text{ kJ mol}^{-1}$

**P23.27** (b)  $K_{\text{F}} = 0.164 \text{ mg g}^{-1}$ ,  $n = 1.14$  (c)  $0.164 c_{\text{eq}}^{-0.46}$

## Mathematical relations

$\pi = 3.141\,592\,653\,59 \dots$

$e = 2.718\,281\,828\,46 \dots$

## Logarithms and exponentials

$\ln x + \ln y + \dots = \ln xy \dots$

$\ln x - \ln y = \ln(x/y)$

$a \ln x = \ln x^a$

$\ln x = (\ln 10) \log x = (2.302\,585 \dots) \log x$

$e^x e^y e^z \dots = e^{x+y+z+\dots}$

$e^x/e^y \dots = e^{x-y}$

$(e^x)^a = e^{ax}$

$e^{\pm ix} = \cos x \pm i \sin x$

## Taylor expansions

$$f(x) = \sum_{n=0}^{\infty} \frac{1}{n!} \left( \frac{d^n f}{dx^n} \right)_a (x-a)^n$$

$$e^x = 1 + x + \frac{1}{2}x^2 + \dots$$

$$\ln x = (x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \frac{1}{4}(x-1)^4 + \dots$$

$$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 \dots$$

$$\frac{1}{1+x} = 1 - x + x^2 \dots$$

## Derivatives

$$d(f+g) = df + dg$$

$$d(fg) = f dg + g df$$

$$d \frac{f}{g} = \frac{1}{g} df - \frac{f}{g^2} dg$$

$$\frac{df}{dt} = \frac{df}{dg} \frac{dg}{dt}$$

$$\left( \frac{\partial y}{\partial x} \right)_z \left( \frac{\partial x}{\partial z} \right)_y \left( \frac{\partial z}{\partial y} \right)_x = -1$$

$$(\partial y / \partial x)_z = 1 / (\partial x / \partial y)_z$$

$$\frac{dx^n}{dx} = nx^{n-1}$$

$$\frac{d}{dx} e^{ax} = ae^{ax}$$

$$\frac{d \ln x}{dx} = \frac{1}{x}$$

## Integrals

$$\int x^n dx = \frac{x^{n+1}}{n+1} + \text{constant}$$

$$\int \frac{1}{x} dx = \ln x + \text{constant}$$

$$\int_0^{\infty} x^n e^{-ax} dx = \frac{n!}{a^{n+1}}$$

$$\int \sin^2 ax dx = \frac{1}{2}x - \frac{1}{4a} \sin 2ax + \text{constant}$$

$$\int \sin ax \sin bx dx = \frac{\sin(a-b)x}{2(a-b)} - \frac{\sin(a+b)x}{2(a+b)} + \text{constant}$$

if  $a^2 \neq b^2$

$$\operatorname{erf} z = \frac{2}{\pi^{1/2}} \int_0^z e^{-y^2} dy$$

$$\operatorname{erfc} z = 1 - \operatorname{erf} z$$
